Similarly, NEPA requires that BPA request comments from federal agencies with special expertise in the resources that would be affected by the proposed development. 40 C.F.R. § 1503.1(a)(1). NEPA requires that the BPA seek comments from state agencies and tribal governments. 40 C.F.R. § 1503.1(a)(2). The NEPA regulations also requires that federal agencies respond to requests for comments: “Federal agencies with jurisdiction by law or special expertise with respect to any environmental impact involved and agencies which are authorized to develop and enforce environmental standards shall comment on statements within their jurisdiction, expertise, or authority.” 40 C.F.R. § 1503.2. NEPA regulations also require that BPA prepare the DEIS “concurrently with and integrated with” required consultations. 40 C.F.R. § 1502.25(a).

Despite these clear, abundantly sensible requirements, the DEIS fails to show consultation with agencies that have expertise in the resources that would be impacted by the proposal. In fact, comments from expert agencies conveying substantial concerns about significant adverse impacts from the proposal were summarily ignored. These agencies were not

even listed under the “Environmental Consultation” section of the DEIS, nor in the Distribution List for receiving copies of the DEIS after they commented. *See* DEIS at §§ 4.0, 5.0.

EFSEC and BPA are unambiguously required to seek comments from agencies with expertise in the resources that would be impacted. Federal agencies with special expertise have a nondiscretionary obligation to respond to those requests with comments. Agencies with expertise in the resources that would be affected include the USDA Forest Service, which administers portions of the Columbia River Gorge National Scenic Area and the Lower White Salmon Wild and Scenic River Area, and the National Park Service, which administers the Lewis & Clark National Historic Trail, the Oregon Pioneer National Historic Trail, and the newly designated Ice Age Floods National Geologic Trail. As administrators of these areas, both agencies have expertise in evaluating impacts to scenic resources and historically important viewsheds.

Both of these agencies submitted comments during the scoping process. Both comments pointed out that the project would cause significant adverse impacts to scenic resources and recommended mitigation measures, including removal of turbines from Scenic Area viewsheds as seen from designated key viewing areas. These comments have been summarily ignored. The DEIS demonstrates an utter failure of the agencies to follow through with the requirements of NEPA and SEPA, as well as the agencies’ duties to protect environmental values and surrounding communities, by responding to these expert agencies’ comments.

The scenic resources that would be affected by the proposal are of national significance. This warrants the utmost care in consulting with expert agencies to ensure that the decision-making agencies have impartial and objective analysis of the likely impacts to the environment.

The Forest Service has inventoried and ranked the viewshed that would be directly affected by this project, and has the expertise to measure the impacts of the proposal on this

landscape. Thus, the Forest Service's inventories and conclusions are directly relevant to the scenic resource impacts analysis for the project. Portions of the viewsheds that would be affected have been identified by the Forest Service as having the highest rankings for scenic values. This includes "outstanding" scenic diversity, "primary" landscape significance, and "critical" landscape sensitivity. The Forest Service staff has special expertise in evaluating how the development would impact these landscapes, and must be consulted.

It is of paramount importance that both EFSEC and the BPA address the Forest Service's scoping comments and seek further clarification from the Forest Service regarding the likely project impacts. Given the level of study already performed by the Forest Service with respect to the affected scenic resources, the DEIS does a disservice by not incorporating that information into the environmental review.

Swift v. Island County established the importance of taking expert agency comments into consideration during SEPA review. *Swift v. Island County*, 87 Wash. 2d 348, 552 P.2d 175 (1976) (en banc). In *Swift* the court ruled that an Island County determination of non-significance violated SEPA because the finding conflicted with the comments of other agencies and experts. The agencies and experts included "the United States Department of the Interior, Fish and Wildlife Service; State Parks and Recreation Commission; State Department of Game; State Department of Ecology; the Central Whidbey Island Historic Preservation Advisory Committee" and an authority on birds. 87 Wn. 2d at 355. Just as Island County ignored expert agency comments in *Swift*, EFSEC is completely ignoring expert agency comments in the present matter.

EFSEC and the BPA should also address whether expert agencies have altered or withheld comments due to pressure from elected officials. Documents obtained through public

records requests and submitted by Keith Brown and Teresa Robbins have uncovered e-mail chains evidencing political interference and muzzling of agency experts at the direct request of the applicant. This episode underscores EFSEC's and BPA's legal and moral obligations to ensure that thorough and complete expert agency consultation is obtained regardless of the political connections of the proponent.

The Applicant has asserted that the expert agencies are somehow attempting to improperly assert control over private land outside their jurisdictions. This is entirely inaccurate. Simply put, the agencies have expertise in the resources that would be affected by the proposed development, and therefore must be consulted pursuant to NEPA and SEPA. The consulting agencies simply help the action agencies understand and evaluate the harm to the environment that would result from this proposal. The Applicant apparently fundamentally misunderstands the role of consulting agencies under NEPA and SEPA.

The National Park Service's interest in the affected resources is evidenced by the Management Plan for the Lewis and Clark National Scenic Trail and recent mission statements that accompanied notices that the Park Service will be revising the Lewis and Clark Trail Management Plan: "Certain segments of the Lewis and Clark National Historic Trail *retain characteristics and a sense of place as seen and experienced by the original expedition and continue to provide opportunities for similar experiences today.*" Lewis and Clark Trail Master Planning Newsletter (July 27, 2010) (emphasis added). "Today the Missouri, Clearwater, and Columbia Rivers, their watersheds, and the overland routes across the Rocky Mountains have changed, however, *the natural resources and ecosystems that remain intact are fundamental to the experience of this Trail. These complex resources are critical to providing the context within which modern visitors experience the Trail and the story of Lewis and Clark.*" Lewis and Clark

Trail Master Planning Newsletter (July 27, 2010). The Park Service certainly has the mandate and the expertise to comment on the likely impacts of the project.

EFSEC and BPA should also actively solicit comments from the Oregon Department of Transportation and the Oregon Parks and Recreation Department. These agencies manage the Historic Columbia River Highway, which is listed on the National Register of Historic Places as a National Historic District. The proposal would adversely affect views from the Historic Highway, harming the scenic, recreational, and historical values of the resource. These agencies are also coordinating plans to restore abandoned sections of the Historic Highway as part of the “Milepost 2016 Reconnection Project,” which furthers the goals of the Historic Columbia River Highway Master Plan, portions of which are attached hereto. The impacts to these efforts, in terms of impacts to historical interpretation opportunities and scenic resources, must be acknowledged and consulted on.

EFSEC and the BPA must also consult with the Columbia River Gorge Commission, which manages the landscape and regulates land use and development in the immediate vicinity of the project. The DEIS mentions the Columbia River Gorge National Scenic Area Act in the “Environmental Consultation” section, but does not mention consulting with the Gorge Commission. DEIS at 4-9, § 4.11. This section should be revised to accurately reflect the regulatory framework for the National Scenic Area. This section states that the General Management Area of the Scenic Area includes a mixture of “farming, logging, residential, and cattle grazing” land uses. DEIS at 4-9. The section should be revised to state that the General Management Area also includes public recreation and commercial recreation uses along with some of the most sensitive open space areas. EFSEC and the BPA must also consult with the Gorge Commission regarding any regulatory review that would be required to ensure compliance

with Scenic Area Act standards for the portion of the project located within the National Scenic Area—namely, the proposed haul route.

The DEIS at 3-141 and 3-194 also quotes 16 USC § 544o(a)(10), which states that the Scenic Area Act does not, “of itself,” authorize the creation of any buffer or protective perimeter. This provision does not prohibit expert agencies from using the National Scenic Area’s resource inventories and regulatory standards as tools for measuring impacts to the environment.

Agencies with expertise regarding wildlife, including the U.S. Fish and Wildlife Service and Washington State Department of Fish and Wildlife, must be consulted. And the Washington Department of Natural Resources must be consulted regarding compliance with the Washington Forest Practices Act, which regulates the conversion of forested land to non-forestry uses. The Washington DNR must also be consulted regarding the feasibility of alternative siting locations on public land to the north of the current project area.

III. The DEIS Misquotes and Misrepresents the Language and Meaning of the Columbia River Gorge National Scenic Area Act.

The DEIS attempts to rewrite the Columbia River Gorge National Scenic Area Act to effect a dramatically different purpose than intended by Congress. This misrepresentation, if it goes uncorrected, would dramatically hinder EFSEC’s and the BPA’s ability to protect the public from adverse impacts to important local, state, and national resources. The DEIS includes the following passage that purports to quote the Columbia River Gorge National Scenic Area Act:

The Act states that “no protective perimeters or buffer zones shall be established around the scenic area or each special management area. Activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas” (16 U.S.C. § 544O(a)(10)).

DEIS at 3-194 (emphasis in original).

The above language, reprinted verbatim from the DEIS, seriously misquotes and misrepresents the Act. The actual language in the Act is as follows:

(a) *Nothing in this Act shall . . .*

(10) Establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas.

16 U.S.C. § 544o(a)(10) (emphasis added).

The first sentence of the misquoted Act in the DEIS completely changes the meaning of the statute. The intent to misrepresent is clear. The difference in the meaning of the true wording versus the quoted wording is significant.

The language in 16 U.S.C. § 544o(a)(10) provides that *nothing in the Scenic Area Act* shall establish protective perimeters or buffer zones. It does not, as the DEIS language states, outright prohibit protective buffers, for example under operation of some other local, state, or federal law. EFSEC and the BPA must apply numerous other laws in their decision-making, and must protect affected resources and communities. The misquoted language in the DEIS implies that Congress mandated that some other law or factor, independent of the Scenic Area Act, could not result in the protection of lands adjacent to the Scenic Area. This is absolutely incorrect. While the Scenic Area Act does not in and of itself impose buffers, neither does it prevent them under operation of other laws.

///

IV. The DEIS Prematurely and Erroneously Concludes That the Project Would Be Consistent With the Applicable Land Use Regulations.

A. The Land Use Consistency Determination in the DEIS is Premature.

The DEIS concludes that “the proposed project would be consistent with the applicable land use regulations.” DEIS 3-152. The DEIS further states that “the project would be consistent with the Comprehensive Plan vision and the Conservancy designation in that it would conserve and manage existing natural forest and wind resources to maintain a sustained yield and utilization of both.” *Id.* These and all other statements in the DEIS regarding consistency with applicable land use regulations are premature, because EFSEC has not yet concluded its land use consistency process nor issued a determination as to whether the proposed project is consistent and in conformance with the applicable land use plans and zoning ordinances through the process required by WAC 463-26-110 and RCW 80.50.090(2). The DEIS erroneously contains consistency determinations long before the issue of consistency will be adjudicated in the land use process before EFSEC. EFSEC has effectively prejudged the consistency results by including its premature conclusions in the DEIS.

The DEIS should be revised to remove all conclusions as to land use consistency. Instead, the DEIS should state what the potentially applicable regulations are, and then state that EFSEC will reach a conclusion on consistency as part of its adjudicative process, and that the BPA will decide whether it concurs with that determination. At most, the DEIS could summarize the different arguments that have been made to date regarding the applicable regulations. But prejudging consistency long before the consistency process is complete is inappropriate and a violation of Friends’ right to a fair and impartial adjudicative hearing.

Contrary to the conclusions in the DEIS, the project is *not* consistent with applicable land use requirements. Friends will continue to address, via EFSEC’s adjudicative process, the many

reasons why the project is not consistent with the applicable land use requirements. Rather than restate Friends' arguments at length in the instant comments, Friends relies on its previous submissions to EFSEC, as well as its briefing to the Skamania County Hearing Examiner in the prior administrative appeal involving Skamania County's proposed (now abandoned) energy zoning amendments (County File No. SEP-08-35),⁴ except as modified or supplemented below. Friends also adopts and reiterates all arguments of Save Our Scenic Area regarding land use consistency.

B. The Application and DEIS are Inconsistent and Incomplete Regarding the Proposed Haul Route through the National Scenic Area.

The Application and DEIS are internally inconsistent and incomplete regarding the proposed haul route through the National Scenic Area. The specialized trucks for hauling wind energy turbine components for this project are both massive and heavy; these trucks may have trouble navigating certain intersections and bridges. The application and DEIS do not clearly establish which route is proposed through the National Scenic Area, and whether that route would entail any road construction or ground-disturbing activities within the General Management Area of the National Scenic Area. The information that *has* been made available about the haul route is internally inconsistent and does not comply with EFSEC's rules for a complete application.

EFSEC rules require, among other items, the application to include information about traffic and transportation impacts:

- (1) Transportation systems. The application shall identify all permanent transportation facilities impacted by the construction and operation of the energy facilities, the nature of the impacts and the methods to mitigate impacts. Such impact identification, description, and mitigation shall, at least, take into account:

⁴ Copies of all the relevant documents from both proceedings are attached hereto as exhibits.

* * *

(b) Access routes for moving heavy loads, construction materials, or equipment;

* * *

(2) Vehicular traffic. The application shall describe existing roads, estimate volume, types, and routes of vehicular traffic which will arise from construction and operation of the facility. The applicant shall indicate the applicable standards to be utilized in improving existing roads and in constructing new permanent or temporary roads or access, and shall indicate the final disposition of new roads or access and identify who will maintain them.

* * *

WAC 463-60-372.

The original application proposed two alternative haul routes through the National Scenic Area, Routes 1 and 2. The amended application adds a third alternative haul route, Route 3. Amended Application at 2.19-3. The DEIS adopts Route 3 as the haul route for the project. DEIS at 1-12.

At page 1-16, the DEIS states that both Routes 1 and 2 have been “eliminated as . . . construction roadway access alternative[s].” However, at page 3-172, the DEIS states that Route 1 (the Ausplund Road Route) “would be used to access the [project site] for construction and maintenance.” The agencies need to address this inconsistency, and clarify the extent to which Routes 1 or 2 would be used, if at all, for this project.

Moreover, a number of unanswered questions remain regarding Route 3, and specifically whether this route would involve any road construction or ground-disturbing activities within the General Management Area of the National Scenic Area. This route includes an aging bridge on Cook-Underwood Road across the Little White Salmon River and within the GMA. In the attached November 6, 2009 letter submitted to the Gorge Commission, WRE freely admits that “[t]he County has not yet determined whether any modifications or repair of [this] bridge would

be required” to enable the bridge to be used for the haul route. Furthermore, there is no evidence in the application or in the record, such as engineering schematics or a discussion of the bridge’s load-bearing capacity, to establish whether construction work on the bridge will be necessary for this project.

In addition, an intersection of particular concern is the eastern intersection of Cook-Underwood Road and SR-14. WRE’s initial application states that road construction, including road widening, “would be required” at this intersection in order to provide a sufficient turning radius for oversized trucks hauling wind turbine components. Original Application at 4.3-13. WRE provided specific numbers for the necessary width of the inside turning radius. *Id.* According to WRE, “[w]idening would include removal of guardrail and an engineered fill section on the inside of the turn, and an engineered fill section and a possible embankment cut section.” *Id.* In addition, “[t]he engineered fill and embankment cut sections . . . would require an all-weather driving surface.” *Id.* Finally, “[r]ight of way ownership and easement determination would be required.” *Id.*

Then, after Appellants filed an appeal with the Gorge Commission of the County’s decision on the initial application, WRE abruptly made a 180-degree reversal on whether road construction is required at this intersection. Even though WRE still proposes to use this intersection as part of its preferred haul route, WRE in the amended application has deleted all language discussing the necessary road work and replaced it with language summarily concluding that no road construction will be necessary along the haul route. Amended Application at 4.3-14. When asked to explain the rationale behind these discrepancies, WRE merely stated in its November 6, 2009 letter that “[n]o roadway improvements *have been identified* as being needed at either the west or east intersection of SR-14 and Cook-Underwood

Road.” (emphasis added). This unhelpful statement completely ignores, and is in fact contradicted by, WRE’s previous statements that road improvements at the east intersection “*would be required.*” Original Application at 4.3-7 (emphasis added).

The western intersection of Cook-Underwood Road and State Route 14 is also important. The Applicant has proposed to use this intersection as part of the haul route, but has also not shown that road improvements at this intersection would not be necessary.

These distinctions are important, because if this project does in fact involve road construction or ground-disturbing activities within the GMA, such activities must be reviewed by Skamania County under the Scenic Area laws and rules for whether they are allowed and for the protection of resources. SCC § 22.06.010.

The agencies need to require better information about the proposed haul route, and resolve whether any road work would in fact be necessary. If so, Scenic Area review and a decision by Skamania County will be required.

V. The Environmental Impact Analysis in the DEIS is Seriously Deficient.

A. The DEIS Fails to Give Adequate Consideration to Cumulative Effects.

The consideration of cumulative effects in the DEIS is inadequate. A cumulative impact is the “impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions.” 40 C.F.R. § 1508.7. NEPA requires that an EIS assess cumulative impacts in sufficient detail to be “useful to a decision maker in deciding whether, or how, to alter the program to lessen cumulative impacts.” *City of Carmel-By-The-Sea v. U.S. Dep’t. of Transp.*, 123 F.3d 1142, 1160 (9th Cir. 1997). The cumulative impacts analysis for a proposed project must examine past, present, and proposed/reasonably foreseeable actions in the same area. 40 C.F.R. §§ 1508.7, 1508.25, 1508.27(b)(7); *Tomac v. Norton*, 433 F.3d 852, 864 (D.C. Cir. 2006).

Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. 40 C.F.R. § 1508.7. “To consider cumulative effects, some quantified or detailed information is required. Without such information, neither the courts nor the public, in reviewing [an action agency’s] decisions, can be assured that the [agency] provided the hard look that it is required to provide.” *Neighbors of Cuddy Mountain v. U.S. Forest Service*, 137 F.3d 1372, 1379 (9th Cir. 1998). The cumulative effects of the proposed action, combined with the cumulative effects of other proposed actions, must be described in detail. *Muckleshoot Indian Tribe v. U.S. Forest Service*, 177 F.3d 800, 810 (9th Cir. 1999). Broad and general statements “devoid of specific, reasoned conclusions” are not sufficient; neither are one-sided cumulative impact statements. *Id.* at 811.

As an initial matter, the geographic scope used in the DEIS to examine cumulative impacts is internally inconsistent and arbitrary and capricious. On the very same page (1-36), the DEIS contains two different geographic standards for measuring cumulative impacts. First, under Existing Development, the DEIS properly sets the geographic scope for wind power development as extending from Cascade Locks to the intersection of I-84 and I-82. Then, on the very same page, under Reasonably Foreseeable Future Development, the DEIS arbitrarily limits itself to projects within 20 miles from the Whistling Ridge project site. This internal inconsistency is arbitrary. Many of the existing wind projects more than 20 miles away contribute to adverse cumulative effects in conjunction with the proposed Whistling Ridge project. For instance, these existing wind projects can be seen in same viewshed as the Whistling Ridge site, as viewed from locations within the Gifford Pinchot National Forest such as Little Huckleberry Mountain. The arbitrary limit of 20 miles also means that certain pending projects such as Windy Flats West, which may have similar impacts on the National Scenic Area to those

of Whistling Ridge, but which is 26 miles away, are being improperly excluded from the impacts analysis.

The attempt in the DEIS at identifying and evaluating the cumulative impacts is sorely lacking. The DEIS fails to consider adequately the past, present, and reasonably foreseeable future impacts of other projects in the area. First, the DEIS does not adequately catalogue or discuss the impacts of past projects on the area, as it is required to do under NEPA. *City of Carmel*, 123 F.3d at 1160. Rather, it arbitrarily limits itself to considering only other wind projects, and even then relies on a rough and incomplete list of existing wind projects that discusses generalities, without providing the information necessary to complete the reasoned analysis that NEPA requires. Second, the DEIS fails to catalogue or analyze the impact of numerous planned or ongoing development projects, including wind projects and other types of projects.

For example, the DEIS fails to consider the cumulative impacts of the proposal in relation to the following planned and ongoing projects:

- The DEIS, at pages I-36 and 3-265–266, relies only on a wind power map and list found at <http://www.nwcouncil.org/maps/power/Default.asp>. The map relied on by the DEIS is severely incomplete, missing multiple wind energy projects within the project study area, including but not limited to Windy Flats West, Windy Flats, Windy Point II, Miller Ranch, Hactor Ridge, Imrie, Linden Ranch, Miller North, Windtricity, Harvest Wind, School Section, Golden Hills, Golden Hills Addition, Golden Hills 2, Golden Hills 3, Biglow Canyon 2, Biglow Canyon 3, Nook Wind, Star Point, Shepherds Flat, Shepherds Flats 2, Shepherds Flat 3, Shepherds Flat 4, Shepherds Flat 5, Pebble Springs, Willow Creek, Montague I,

Montague II, Condon Wind, Summit Ridge, Baseline, Saddle Butte, Echo Wind, and PáTu. The DEIS fails to consult multiple other maps and lists of wind projects in the region, let alone the documents pertaining to those projects such as environmental impact statements. As a result, the cumulative impacts of this project in conjunction with other wind projects in the region is grossly underestimated. Maps and lists of other wind projects can be found at <http://www.klickitatcounty.org/planning/FilesHtml/windprojects.pdf>, <http://www.oregon.gov/ENERGY/SITING/review.shtml>, and http://www.transmission.bpa.gov/PlanProj/Wind/documents/BPA_wind_map_2010.pdf and are being filed as Exhibits herewith.

- The applicant here, Whistling Ridge Energy, desires to construct an additional 35 turbines on DNR lands immediately adjacent to the north of this project. This project, known as “Saddleback” or “Whistling Ridge Phase II,” has been placed on hold by the DNR, but that hold could be removed at any time. The DEIS states that “use of these lands for project turbines was rejected from further consideration.” DEIS at 1-14. However, recent public records requests have uncovered new evidence that the use of DNR lands is still contemplated by WRE. Specifically, the attached April 9, 2010 email shows that WRE was evaluating whether a temporary FAA moratorium on certain wind projects would prohibit expansion onto the DNR lands. The DEIS fails to sufficiently address the likelihood of Phase II of this project going forward, and fails to address the cumulative impacts of expanding the scope of this project onto the adjacent land. All phases and portions of a project must be evaluated at the outset during

environmental review of the first phase. *See Merkel v. Port of Brownsville*, 8 Wn. App. 844, 850–51, 509 P. 2d 390, 395 (1973); *Indian Trail Property Owner's Ass'n v. City of Spokane*, 76 Wn. App. 430, 443, 886 P.2d 209 (Wn. App. 1994).

- The Broughton Lumber Company has proposed a 250-unit housing development and recreation resort at the site of its defunct lumber mill in Skamania County, Washington. The site is in the same viewshed as the proposed Whistling Ridge Project.
- A casino is proposed in Cascade Locks, Oregon. If built, it would induce unprecedented amounts of traffic through the National Scenic Area. The cumulative impacts of this project, including the high volumes of casino traffic in conjunction with the heavy and oversized load truck traffic potentially travelling along I-84 for the Whistling Ridge project, was not considered.
- Every year, multiple residential dwellings are approved in the same viewshed as the proposed Whistling Ridge Energy Project. This cumulative scenic impact is not even mentioned, let alone estimated, by the DEIS.
- The DEIS acknowledges that the footprint of the project is within working timber lands, but fails to discuss the cumulative impacts of clearcutting forest in conjunction with permanently converting forest land for industrial use. Washington DNR Forest Practice applications in the vicinity of the project include FPA 2702000, FPA 2702622, FPA 2702784, FPA 2702862, FPA 2703252, and FPA 2704427. The DEIS does not address the cumulative impacts of the massive clearcutting that has occurred or the impacts of those forest practices in conjunction with converting forest land to non-forest use.

- In addition to the forest practices in the immediate vicinity of the project, the DEIS must include evaluation of impacts of the project in conjunction with forest practices in the region. To date the northern spotted owl habitat conservation plan is not succeeding in recovering northern spotted owl populations. Since this project would permanently convert forest land within a Spotted Owl Special Emphasis Area (SOSEA) to non-forestry use, the DEIS must undertake additional analysis of how the industrialization of portions of the SOSEA will affect spotted owl populations within the entire SOSEA and the region.
- The Blue Bridge Pipeline has been proposed to be constructed in the vicinity of the project. This proposal is currently under review by the Federal Energy Regulatory Commission under Docket No. PF09-10-000. The project could involve permanent linear clearcuts in the vicinity of the project.
- Three towns in the Columbia River Gorge National Scenic Area have proposed expansions of their urban area boundaries into Scenic Area lands. These are Hood River, The Dalles, and Lyle. If approved, these urban expansions would result in population growth, more traffic, loss of farm land, forest land, open spaces, and likely adverse effects to scenic, natural, cultural and recreation resources.

These projects and others not analyzed in the DEIS will have cumulative impacts on environmental and socioeconomic factors. In order to adequately evaluate the impacts of the proposed project, the DEIS must consider these current projects. Failure to do so means that the DEIS lacks sufficient detail to allow a decision maker to meaningfully evaluate the full impacts of the proposed project or to decide how to alter the proposal to lessen cumulative effects.

Also, as explained in the attached expert analysis by Dr. Shawn Smallwood, the cumulative impacts analysis in section 3.14.3.5 of the DEIS is methodologically flawed and the conclusions are misleading. Similarly, the cumulative impacts analysis of visual resources in section 3.14.3.10 of the DEIS is methodologically flawed and the conclusions are in error. Landscape architect and expert in visual resource assessment methodologies Dean Apostol has analyzed the DEIS and found the visual analysis woefully lacking and not up to professional standards. For example, the scenic resources cumulative impacts analysis evaluates only impacts to travelers on Interstate 84. While it underestimated the impacts to these views, it completely ignores the impacts to travelers on the Historic Columbia River Highway, the Columbia River, and other recreational resources in the vicinity. The cumulative impacts portions of the EIS are woefully inadequate and do not meet NEPA's or SEPA's requirements to conduct a rigorous and thorough analysis of cumulative impacts.

B. The DEIS fails to consider the direct and cumulative impacts of the proposed development on the energy grid and its infrastructure, and resulting impacts to natural resources.

Under SEPA, the elements of the environment include the built environment, which in turn includes public services and utilities. WAC 197-11-444(2)(d). The energy grid is part of the built environment and impacts to the grid must be considered during the SEPA process. The DEIS failed to adequately analyze impacts to the grid.

The DEIS discusses the need for the project to interconnect to the BPA transmission system, but fails to analyze the indirect and cumulative effects of new wind energy development on the grid and the need for new transmission facilities. DEIS at 3-87—92, 3-278. The DEIS states that the “proposed project would not be expected to affect the operation of the BPA’s

transmission system.” DEIS at 3-92. The cumulative impacts section of the DEIS makes no mention of the grid or how the project would affect demand for new transmission facilities.

Wind energy production in the region will ultimately be limited by the capacity of the Bonneville Power Administration to integrate new wind energy resources into the BPA electricity grid. Recently, BPA expressed concern about how it will reliably integrate over 6,000 MW of wind energy by 2013. Northwest Power and Conservation Council, Sixth Power Plan, at 12-11 (available at <http://www.nwcouncil.org/energy/powerplan/6/default.htm>). By adding more energy to the grid, the project increases the need for more capacity and more transmission lines and other infrastructure.

In response to the rapid development of wind energy in the region in recent years the BPA has proposed several new transmission projects. These projects are necessary to integrate the intermittent nature of wind energy and to ensure sufficient transmission capacity to transmit energy to the region and markets in other regions. BPA’s own development plans demonstrate that the Whistling Ridge Energy Project would contribute to demand for transmission facilities and contribute to significant adverse impacts to the environment.

The BPA’s own documents, some of which are attached hereto as exhibits, explain that the McNary-John Day transmission project and the Big Eddy-Knight transmission project are needed to respond to the demands that new wind energy facilities place on the grid.

To respond to the increased demand for interconnections to the grid, the BPA conducts annual Network Open Seasons where prospective energy producers can submit Transmission Service Requests (TSRs) to BPA. From these requests the BPA offers eligible producers Preferred Transmission Service Agreements (PTSAs). Based on these agreements the BPA calculates the demand for transmission services and the need for any new transmission facilities.

As shown in the attached exhibits, in response to the 2008 Network Open Season, the BPA signed PTSAs securing 6,410 MW of transmission capacity. And in response to the 2009 Network Open Season the BPA signed PTSAs securing 1,553 MW of transmission capacity. In 2010 alone the BPA received TSRs for 4,456 MW of wind energy development that would be eligible to sign PTSAs. If all eligible PTSA are signed and completed, the total new services provided by BPA will total over 12,000 MW, generate the need for hundreds of miles of new transmission lines, and the expenditure of millions of dollars in public funds. The Whistling Ridge Energy Project Project would directly contribute to these impacts. The DEIS must acknowledge and evaluate these impacts and the further impacts that flow from them.

The BPA must include actual data on the grid's capacity to accommodate new sources of intermittent wind energy. As stated above, the BPA has previously expressed concern about how it will reliably integrate over 6,000 MW of wind energy by 2013. Northwest Power and Conservation Council, Sixth Power Plan, at 12-11. The DEIS must include some analysis of how much wind energy the grid can accommodate over the long-term and whether wind integration capacity will limit the amount of wind energy development that can occur in the region. If integration capacity will limit generation potential, then the DEIS must address why the Whistling Ridge Energy Project should take priority over potential development in other locations that would have reduced environmental impacts.

Importantly, the BPA has failed to undertake comprehensive review of the impacts of its transmission system. The BPA's last comprehensive review of the transmission system was in 1995. BPA Business Plan Final Environmental Impact Statement (DOE/EIS-0183) (hereinafter "BPA BP EIS"). That review noted that wind energy could cause adverse impacts to wildlife and scenic resources, but did not undertake any detailed review of how providing access to the

transmission system would lead to impacts from the explosion of wind energy development throughout the region. BPA BP EIS at 4-42, Section 4.3.1. The BPA BP EIS also does not address how much wind energy can be integrated into the grid.

In 2007, the BPA undertook a supplemental analysis of the Business Plan EIS, but declined to undertake further environmental review. Supplemental Analysis of the Business Plan EIS (DOE/EIS-0183) (April 6, 2007). The supplement stated that “continued consideration of a comprehensive policy for BPA’s transmission business is not in the best interests of the agency at this time.” The supplemental analysis was based on four wind projects totaling 750 MW of wind energy that had been connected to the BPA grid at that time. *Id.* at 42. The analysis did not discuss impacts to wildlife from this development. *Id.* at 46. The analysis did not include a section on scenic impacts, much less how wind energy development enabled by the BPA has transformed scenic landscapes. The supplemental review also failed to acknowledge the ongoing impacts to cultural resources from the development that has been enabled by BPA transmission project. *Id.* at 48—49.

Since the BPA’s last review of the environmental impacts associated with the transmission system and the energy production that system allows, an unprecedented level of new wind energy development was occurring throughout the region. Currently over 3,000 MW of wind energy has been interconnected to the grid. The BPA has signed PTSAs for as much as 12,000 additional MW of new generating capacity.

The impacts of this development have dramatically changed landscapes throughout thousands of acres of rural Washington and Oregon along with countless scenic vistas. This development is also killing or displacing an unknown number of birds and ongoing damage to cultural resources is occurring from the excessive ground disturbance and road building. Another

type of impact not anticipated or reviewed in the EIS is the potential overloading of the energy grid as a result of the dramatic increase in wind energy in the region, which can in turn affect fish populations by requiring an excess spilling of water over the region's hydroelectric dams in order to balance out unexpected surges in wind energy production.

This rapid expansion in wind energy has occurred without any programmatic review of the impacts of the generating sources, the existing transmission system, or the demands for new transmission lines. This has also occurred without an adequate understanding of how much wind energy development the grid can accommodate and how projects could be prioritized for grid access based on environmental impacts. These significant changes warrant preparation of a comprehensive cumulative impacts analysis. The DEIS must be substantially revised to reflect the project's contributions to the regional impacts of wind energy development.

C. The DEIS Fails to Adequately Evaluate and Address the Impacts of the Proposed Development on Scenic Resources.

SEPA requires that the environmental analysis include discussion of impacts to sensitive areas. The SEPA official "shall" consider whether a "proposal may to a significant degree . . . [a]dversely affect environmentally sensitive or special areas, such as loss or destruction of historic, scientific, and cultural resources, parks, prime farmlands, wetlands, wild and scenic rivers, or wilderness." WAC 197-11-330(3)(e)(I). SEPA also requires analysis of impacts to scenic resources. WAC 197-11-440(1)(e)(iv).

The current proposal is for a major industrial development towering over ridgelines on the perimeter of the Columbia River Gorge National Scenic Area, overlooking important segments of the Lewis and Clark National Historic Trail and the Historic Columbia River Highway, adjacent to the Gifford Pinchot National Forest, and adjacent to recreational trails on Washington Department of Natural Resources land. The proposed facility would overlook miles

of National Scenic Area viewsheds that have been inventoried as some of the highest quality scenic landscapes in the Gorge.

Unfortunately, the DEIS grossly mischaracterizes the likely impacts of the Whistling Ridge Energy Project on scenic resources. Instead of following SEPA's mandate to provide an unbiased and objective assessment of likely impacts, the DEIS blatantly misapplies established principles of landscape management to conceal the likely impacts of the proposed action. The analysis also violates NEPA's requirement that "[a]gencies shall insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements." 40 C.F.R. 1502.24. The DEIS does not list a single landscape architect, much less a landscape architect with training in scenic resource analysis methodologies, in the list of preparers. DEIS at Section 6.0. The lack of professional and scientific integrity is plainly evident through the scenic impacts analysis. The analysis is fundamentally flawed and violates both NEPA and SEPA.

As explained in the attached comments of Dean Apostol, the analysis completely misinterprets and misapplies the Federal Highway Administration's visual assessment system and the Forest Service's Scenery Management System. In addition, the analysis fails to consider impacts to several critical viewpoints and view corridors, reaches erroneous conclusions regarding the potential impacts on scenic resources, and fails to consider viable mitigation measures. Mr. Apostol concludes that the likely scenic impacts of the project would be significant because the project would highly contrast with an intact, high quality scenic landscape that is viewed by substantial number of viewers with high expectations for scenic quality. The project would break the skyline and/or be highly visible from multiple public vantage points and it is impossible to "blend in" wind turbines more than 400 feet tall into this

landscape. The DEIS also erroneously ties scenic sensitivity to distance zones. DEIS at 3-159. Low, moderate, and high impacts can occur in any distance zone depending on the impacts analysis.

The environmental review failed to sufficiently analyze the visual impact of the project as viewed from linear viewing areas such as Interstate 84, the Columbia River, the Historic Columbia River Highway, the Lewis and Clark National Historic Trail, and State Route 141. For some of these scenic corridors basic information such as the distance along linear viewing areas from which the project would be visible, an estimate of the amount of time the project would be visible when traveling along these view corridors, and a simulation of the most visible portion of the project as viewed from these viewing areas is missing from the analysis. Of particular concern is the complete absence of any analysis of views from the Columbia River and the Historic Columbia River Highway.

The DEIS also fails to supply sufficient information to understand and review potential impacts from lights on the proposed wind turbines—particularly nighttime impacts. DEIS at 3-161, 3-173, & 3-195. While FAA lighting standards may be required, compliance with federal regulations does not obviate the duty to comply with state law requiring full disclosure of all environmental impacts. The applicant must document how many lights would be visible from within the National Scenic Area viewshed. The applicant needs to provide additional information regarding what type of lighting would be installed, and which turbines would likely contain lighting. Without this information, it is impossible to accurately evaluate the scenic impacts of the project.

The DEIS also fails to include a detailed explanation of both the methodology used to create the visual simulations and the proper technique for viewing the simulations. To begin

with, all visual simulations should be accompanied by substantial disclaimers regarding their ability to depict real-world impacts. Two dimensional renderings can never accurately simulate the experience of real-world views. Nonetheless, visual simulations do have value in evaluating aesthetic impacts if best practices are used in preparing the simulations and proper qualifications are noted. Lens size, field of view, the format of the image in the simulations, and the viewer's distance from the image all play critical roles in presenting an accurate depiction of aesthetic impacts. For example, the wider the angle of view of a camera lens, the further away an object appears, and the narrower the angle of view, the nearer an object appears. If digital cameras were used, image distortions would need to be factored in when preparing the image. Similarly, the size of the simulation image and the viewer's distance from the image can dramatically alter the perceived impacts of development. EFSEC and the BPA must require clarification on these points to ensure that the inherent flaws in visual simulations are explained.

EFSEC and the BPA should also consider the National Academy of Sciences' recent document entitled, *Environmental Impacts of Wind-Energy Projects* (National Academies Press, 2007), which includes methodology for analyzing possible impacts from wind development on aesthetic resources. The DEIS should be revised to include discussion of the various standards described in this resource, which was cited and applied in other sections of the DEIS.

The DEIS argues that the visual impacts from roads and electric lines would be negligible. DEIS at 3-173–3-174. However, road and power lines have direct visual impacts and also contribute to the cumulative impacts of a project. As such, they must be included in the visual simulation and analysis. In particular, road and electric lines would likely be highly visible when viewed from recreational areas to the north of the project. These include recreational trails in the Gifford Pinchot National Forest and on land owned by the Washington Department of

National Resources. Particular recreational areas of concern include the Nestor Peak, Little Buck Creek Trail, Grassy Knoll, Little Huckleberry Mountain, and Cook Hill.

The conclusions regarding scenic impacts in the application are clearly in error. The project would have high scenic impacts, given viewer expectations, and the quality of the views that would be impacted. The proposed development would dominate the middleground and background views from multiple important viewpoints.

Not only did the DEIS fail to adequately review scenic impacts, it also failed to propose any mitigation or discuss any unmitigated adverse impacts that would occur. Measures and conditions that should have been, but were not, evaluated include alternate designs and siting to reduce visibility.

////

1. The DEIS Fails to Acknowledge Existing Scenic Resource Inventories and Visual Quality Objectives for the Affected Landscape.

The DEIS analysis of scenic impacts states that visual quality objectives (VQOs) have not been established for the landscape that would be affected by the proposed development. DEIS at 3-156. This assertion is demonstrably false. The Forest Service and Gorge Commission have established VQOs for the landscapes that would be affected by the proposed development. These VQOs are based on some of the most extensive and complete scenic resource inventories in the country. These VQOs must be used to measure the impact to viewsheds that would be altered by the proposed development.

In preparing the Management Plan for the National Scenic Area, the Gorge Commission and the Forest Service were required to inventory scenic resources of the National Scenic Area. *See* 16 USC 544d.(a)(1)(A). Pursuant to that mandate the Forest Service and Gorge Commission completed a scenic resource inventory using the Forest Service's Visual Management System

(“VMS”), which is the scenic resource management methodology provided in the Forest Service’s “National Forests Landscape Management Vol. 2” (Agriculture Handbook 462).⁵

All viewsheds visible from primary key viewing areas were inventoried. These inventories served as the basis for all scenic resource management policies and guidelines in the CRGNSA Management Plan. The original scenic resource inventory includes the following elements: Visual Attributes, Landscape Diversity, Landscape Significance, Seen Areas from Key Viewing Areas, Visual Absorption Capability, and Landscape Sensitivity. The 1991 CRGNSA Management Plan described the inventories:

Six maps were developed in the process of inventorying scenic resources. These maps are based on the Forest Service Visual Management System. They have been used to develop policies and guidelines that respond to the various levels of visual significance and sensitivity within the Gorge, and that highlight protection of landscapes seen by large numbers of people.

The first inventory map created, “Visual Attributes,” identifies 12 predominant landscape types found in the Gorge, ranging from rural townscapes to cliffs.

The “Landscape Diversity” map gauges the variety of visual features in the landscape. A basic premise of the visual management system is that visual diversity is a key element of those landscapes people find most visually appealing and interesting. Much of the Gorge, with its steep landforms, forested slopes, waterfalls, pastoral areas, and rural townscapes, has outstanding visual diversity.

A “Seen Areas” map shows which areas are visible from key viewing areas. The key viewing areas are important public vantage points from which Gorge landscapes are viewed. Scenic protection of lands seen from these vantage points has been emphasized since the inception of the Scenic Area planning process. The Management Plan continues this direction.

The “Landscape Significance” map combines the “Seen Areas” and “Landscape Diversity” maps, based on the concept that the most significant landscapes are those that are both visually diverse and seen from important viewpoints. The “Visual Absorption Capability” map displays the relative ability of different Gorge landscapes to absorb change (through new development) without

⁵ The Visual Management System has since been superseded by a revised methodology, the Scenery Management System (“SMS”). The methodology for the SMS is described in “Landscape Aesthetics: A Handbook for Scenery Management.” (Agriculture Handbook 701).

diminishing their scenic qualities. It is based primarily on the degree of slope and amount of vegetative cover.

“Landscape Sensitivity,” the last of the six inventory maps, combines “Landscape Significance” with “Visual Absorption Capability,” based on the assumption that the most visually sensitive lands are those that are both highly significant and most vulnerable to visual impacts from new development.

CRGNSA Management Plan 1991, at I-1—2. Copies of the inventory maps of the affected landscape are attached to these comments. The CRGNSA Management Plan policies and guidelines that were based on these inventories include the land use designations and landscape setting designations that serve as VQOs.

This background is critical to evaluating the impacts of the proposed development on scenic resources. As seen from the Columbia River, Interstate 84, and the Historic Columbia River Highway the project would break the skyline within viewsheds composed of both SMA Open Space and GMA Open Space land use designations that are also assigned the landscape setting of Gorge Walls, Canyon Lands, and Wildlands. For the SMA viewsheds the applicable VQO is retention, the highest level of scenic protection afforded any landscape in the Gorge. For the GMA viewsheds the applicable VQO is partial retention, with the added protection essentially creating a VQO of retention.

The view from Interstate 84, the Columbia River, and the Historic Columbia River Highway between Starvation Creek State Park and Viento State Park looking north and northeast is dominated by the Dog Mountain SMA and the Underwood Bluff Open Space.⁶ The proposed facility would be visible just to the east of the Dog Mountain SMA and north of the Underwood Bluff Open Space area. The attention of visitors traveling along these three scenic corridors would be drawn to the spinning blades and/or blinking lights of numerous wind turbines

⁶ Both Starvation Creek State Park and Viento State Park are also designated under the Lewis and Clark National Historic Trail Management Plan.

protruding above the skyline to the northeast. This would obviously detract from the integrity of the viewshed and completely frustrate the purpose of the extensive inventories and protections for this viewshed.

Stationary viewers at Mitchell Point would also be confronted with a dramatic change to the landscape. The view from the Mitchell Point area looks directly north at the Underwood Bluff Open Space area. The original scenic resource inventories assigned Underwood Bluff as “outstanding” landscape diversity, “primary” landscape significance, and “critical” landscape sensitivity. These are some of the highest valued lands inventoried in the Columbia River Gorge and justified a VQO that is essentially retention, the highest standard for protection. The ridgeline of Underwood Bluff forms the skyline from this viewpoint. The contours of Chemawa Hill undulate immediately behind the skyline and are nearly indistinguishable from the Underwood Bluff skyline. Underwood Bluff and its highest rated scenic resources, with Chemawa Hill immediately behind it, dominate the middleground views from this location. The southernmost turbines of the proposed facility would be sited at the top of Chemawa Hill and would break the skyline of views from the Columbia River, Interstate 84, and the Historic Columbia River Highway at this location. Once again, viewers’ attention would be drawn to giant spinning blades and/or flashing lights in middleground views of some of the most scenically sensitive views in the Columbia River Gorge.

The DEIS completely failed to acknowledge the robust and complete inventory of the scenic landscapes that would be affected by the proposed development. The existing resource inventories and established VQOs must be used to measure the impacts that would be caused by the proposed development. Based on this information, it is undeniable that the proposed development would cause significant adverse impacts to critically important scenic landscapes.

In addition, the DEIS failed to state whether the project would impact views from the Gifford Pinchot National Forest that have established VQOs.

2. The Scenic Impacts Analysis Deviates from BPA's Past Practices in Evaluating Scenic Impacts.

The application and environmental review diverges from the BPA's analyses of scenic impact for other energy projects in the region. The BPA's Draft EIS for the Central Ferry-Lower Monumental 500-kilovolt Transmission Line Project concluded that construction of a 200-foot-tall transmission line within viewsheds as viewed from the Lewis and Clark National Scenic Trail and the Lewis and Clark Scenic Byway would have "high" impacts to scenic resources. Central Ferry-Lower Monumental 500-kilovolt Transmission Line Project DEIS (July 2010) Section 3.7, p 3-91 to 3-104 (hereinafter Central Ferry DEIS). The Central Ferry transmission lines would be 104 to 189 feet tall and would have no moving parts and no lights. Central Ferry DEIS at 2-5. The BPA acknowledged that the transmission line would be visible from the Lewis and Clark National Historic Trail and scenic byways.

The Central Ferry DEIS described the affected landscape as "Typical view[s] of rolling hills and rural landscape adjacent to scenic by way." Table 3-22. The analysis explained that the transmission line would be 1.6 miles (middleground view) from the Lewis and Clark National Historic Trail at its closest point. Central Ferry DEIS at 3-98. The analysis also acknowledged that the transmission lines would create a skyline effect and break up the continuity of the skyline and open terrain, and that the project would introduce structures into a natural landscape. Central Ferry DEIS at 3-98. "The proposed towers and conductors would be a conspicuous change to the relatively natural and rural landscape and would disrupt the continuity of visual resources in the landscape." Central Ferry DEIS at 3-98. The project would be visible from "popular recreation areas and a frequently traveled roadway." Central Ferry DEIS at 3-98.

In comparison to the Central Ferry to Monument Transmission Project, the Whistling Ridge proposal would be located in a higher quality scenic landscape, with more state and federal designations for scenic, recreational, and historic importance. The project would be viewed by vastly more people with higher expectations for scenic quality. Whistling Ridge would be of comparable distance from important viewpoints, but would be over twice as large (over 430 feet tall compared to 104 to 198 feet tall), have more visible mass, include giant moving parts, include flashing lights, and would be painted white. The Whistling Ridge project would obviously contrast more with the landscape than the Central Ferry project. While the Central Ferry DEIS concluded that impacts would be high, the Whistling Ridge DEIS concludes that impacts to scenic resources would be moderate at worst.

It is abundantly clear that this project has not been reviewed under the same standard as previous projects under BPA review. This evidences an obvious attempt to thwart the purposes of SEPA and NEPA with environmental review that seeks to conceal impacts rather than objectively analyze impacts.

The adverse impacts of energy development, transmission lines in particular, were also acknowledged in the BPA's Business Plan EIS. BPA Business Plan Final Environmental Impact Statement (DOE/EIS-0183) (hereinafter BPA BP EIS). The Whistling Ridge would include transmission lines and analysis of impacts from transmission lines is equally applicable to scenic impacts analysis for industrial wind energy development. The Business Plan EIS stated:

In areas used for recreation, particularly in undeveloped places, studies show that many users find transmission lines to be an unwelcome visual intrusion. Also, many citizens feel strongly that transmission lines near their homes are visually intrusive, and that some property values may be reduced. Adverse visual effects may be perceived up to several kilometers from the line. Transmission lines may be more compatible with industrial areas. The effectiveness of potential mitigation measures depends on the site, and some measures may substantially increase the cost of the project. Possible measures include darkened towers in

forested areas; different tower designs more compatible with a particular environment; non-specular (nonshiny) conductor; and locations that avoid visually sensitive areas.

BPA BP EIS at 4-52, Section 4.3.2.6. The Business Plan EIS also explained that one of the main environmental risks of wind energy development is visual impacts. BPA Business Plan EIS at 4-42, Section 4.3.1. The BPA has previously relied on this environmental review when approving interconnections to the grid. How the BPA can acknowledge adverse impacts from transmission lines, but ignore adverse impacts from wind energy facilities, is inexplicable.

3. Views from the Lewis and Clark National Historic Trail would be adversely affected.

The Lewis and Clark National Scenic Trail was created to “stimulate Federal, State, and local agencies and individuals to identify, mark, and preserve for public inspiration and enjoyment the routes traveled by the Lewis and Clark Expedition.” Lewis and Clark Trail Management Plan at 1. The Management Plan for the trail recognizes that many of the historic and cultural resources have been altered or lost and the Expedition left scant traces of their passing. However, “In a very real sense, many of the historic resources are the *landmarks, vistas, flora, and fauna* that make up the Trail’s natural resources. It is virtually impossible to find either historic or natural resources along the Expedition route, which have not been altered in some way by man or nature.” Lewis and Clark Trail Management Plan at 4 & 13. Thus, the scenic vistas and natural resources of the Expedition route are critical to appreciating the trail. Locations where those vistas and natural resources are intact are exceedingly rare, and warrant the greatest attention during SEPA and NEPA review.

The Columbia River segment, which includes the portions of the Trail that would be affected by the Whistling Ridge project, was designated for three types of trail development: a water trail, a land trail, and a motor route. The Columbia River, Interstate 84 and Washington

State Route 14 are designated routes. The Management Plan notes that there was a “nearly continuous string of recreation sites along this segment.” Lewis and Clark Trail Management Plan at 70. Individual sites within sight of the Whistling Ridge Energy Project include Viento State Park, which is directly across the Columbia River from where the Lewis and Clark Expedition camped on October 29, 1805 and April 13, 1806, and Starvation Creek State Park. L & C Management Plan at 74.

The DEIS fails to acknowledge adverse scenic impacts to the Lewis and Clark National Scenic Trail. Locations along the route with intact scenic vistas that retain some of the same views that the Lewis and Clark Expedition experienced are critical important resources for the trail system. The views from I-84, the Columbia River, Viento State Park, and Starvation Creek State Park are largely intact as evidenced by the Forest Service’s resource inventories. The project would dramatically alter these views causing significant adverse impacts to the trail. This conclusion was clearly expressed by the National Park Service in at least two separate letters to the BPA and EFSEC. This conclusion is also supported by the BPA’s previous environmental analysis of other projects that would have similar, although less severe, impacts on the Lewis and Clark National Historic Trail. The egregious failure to acknowledge significant adverse impacts to the Lewis and Clark National Historic Trail must be corrected.

D. The DEIS Fails to Adequately Review the Likely Impacts of the Proposed Development on Natural Resources.

The Whistling Ridge project is likely to cause significant adverse impacts to natural resources, including the direct impacts of mortality to wildlife, as well as indirect effects from habitat destruction, displacement, and species avoidance of the project area after construction. Avian species often collide with wind turbines, and bats often die from internal hemorrhaging caused by the massive changes in air pressure near the spinning blades of a wind turbine, a

process known as “barotrauma.” Also, components of the industrial development, including collector lines, transfer stations, and access roads, can displace wildlife and fragment habitat. The DEIS failed to adequately analyze the likely impacts to wildlife and other natural resources.

In addition, as demonstrated in the written testimony of Dr. K. Shawn Smallwood (attached herein), the underlying data and environmental analysis relied upon in the DEIS is severely flawed. For example, without any scientific support the DEIS states that the clearcut project area is poor habitat for wildlife. However, Dr. Smallwood points out that “[b]ird species diversity is much greater at Whistling Ridge than at the Altamont Pass, where bird fatalities caused by wind turbines are notoriously high.” Whistling Ridge surveys found more than 1 species per hour of searching, whereas surveys at Altamont found 0.036 species per hour. The proponents’ ploy to clearcut the land and present a devastated ecosystem immediately before applying for an industrial energy facility is misleading and results in biased conclusions in the DEIS. As Dr. Smallwood concluded, based on independent analysis of the proponent’s own surveys, “Whistling Ridge exhibits a very high level of ecological integrity.” This is likely a result of the projects location within a largely intact ecoregion where species diversity remains high. This is also why the Klickitat County Energy Overlay Zone excluded forested areas.

Dr. Smallwood also points out contradictions between foundational statements and the conclusions in the DEIS. For both Keen’s myotis and Townsend’s big-eared bat, the DEIS states that the analysts had insufficient knowledge of the species, but nonetheless concluded that it was unlikely that they would occur at the site. DEIS at 3-59–60. It is plainly inappropriate to base conclusions on insufficient information. At best, the DEIS should say that impacts to bat species are unknown and then analyze the worst case scenario given that uncertainty..

The DEIS seriously underestimates the potential impacts of this project, both on an individual basis and when considered cumulatively with other wind energy projects. Dr. Smallwood has determined that the baseline studies to assess impacts were cursory and inadequate, the likely impacts to raptors are significant, the cumulative impacts analysis was biased and unrealistic, and the mitigation measures are inadequate.

The DEIS also failed to ensure the protection of wildlife and has failed to adequately review impacts to natural resources in a number of other ways, as described below.

1. The DEIS Fails to Include Best Available Science in the Analysis.

The avian impacts analysis is inadequate and not based on the Best Available Science. The baseline surveys were too cursory to support a scientifically credible baseline assessment. Failings include an inadequate sample and an inadequate amount of time dedicated to surveys. Avian utilization of a site can vary greatly from year to year, so the limited time span of these baseline surveys introduces large uncertainty into the resulting utilization rates. The sample sizes were grossly inadequate for what is needed for comparing bird utilization among project sites or for guiding wind turbine locations to minimize collision rates. Numerous other methodological errors in the analysis introduce additional biases that undermine the SEPA and NEPA review.

Wildlife surveys should be conducted using current state-of-the-art field and analysis protocol. At the least, surveys must take into account survey bias including, but not limited to, searcher efficiency, carcass “life expectancy” or persistence, and scavenger removal. The entire site should be surveyed before and after construction. Both pre-development survey and post-development monitoring should take into account the episodic nature of some bird migrations and nocturnal bird migrations. For example, long or inappropriately timed intervals between searches may miss a significant avian presence. The DEIS fails to account for these factors.

2. The DEIS Fails to Adequately Consider Displacement Effects on Avian Populations.

The DEIS failed to adequately consider displacement effects on avian populations. Impacts of wind projects on birds are not limited to collisions. When a landscape is industrialized by strings of giant machines, birds and other animals may be driven away rather than killed. And when multiple such strings are concentrated in one area, the impacts on species populations can be substantial. The environmental analysis is incomplete and must be supplemented with specific assessments of cumulative displacement impacts.

3. The DEIS Fails to Ensure Compliance with the Federal Endangered Species Act of 1973 (“ESA”), 16 U.S.C. §§ 1531–1544.

Under the ESA, “take” is defined as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct.” 16 U.S.C. § 1532(19). Section 9 of the ESA prohibits both acts that would “take” a species, as well as acts that would cause an act that constitutes a “taking.” The Ninth Circuit has held that “a habitat modification which significantly impairs the breeding and sheltering of a protected species amounts to ‘harm’ under the ESA.” *Marbled Murrelet v. Babbitt*, 83 F.3d 1060, 1067 (9th Cir. 1996). The DEIS failed to demonstrate that the project will be in compliance with Section 9 of the ESA.

The DEIS does state that there has been ongoing consultation with U.S. Fish and Wildlife Service. DEIS at 1-20. Pursuant to NEPA regulations the BPA is supposed to perform this consultation requirement “concurrently with and integrated with” preparation of the Draft EIS, not after the Draft EIS is complete. 40 C.F.R. § 1502.25. The results of this consultation process should have been included in the DEIS.

In Section 2.20.2.2 of the Amended Application, the Applicant states that a Biological Assessment will be prepared. The DEIS fails to make good on this promise. BPA and EFSEC

must ensure that a biological assessment is prepared, to better inform the agencies about potential adverse impacts to threatened and endangered species.

4. The DEIS Fails to Ensure Compliance with the Bald Eagle Protection Act, RCW Chapter 77.12, and Regulations Promulgated Pursuant Thereto, Located at WAC 232-12-292.

The DEIS fails to ensure compliance with the state Bald Eagle Protection Act, despite the presence of bald eagles and their habitat within and near the project site. There is no evidence that the Washington Department of Fish and Wildlife has been consulted pursuant to the Bald Eagle Protection regulations.

5. The DEIS Fails to Ensure Compliance with the Federal Bald and Golden Eagle Protection Act, 16 USC § 668–668d.

The DEIS fails to ensure compliance with the federal Bald and Golden Eagle Protection Act (“BGEPA”), again despite the presence of bald eagles and their habitat within and near the project site. The BGEPA prohibits any person, association, partnership or corporation from taking a bald or golden eagle at any time or by any manner without a permit. 16 USC § 668(a). A permit may be issued only if the taking would be compatible with the preservation of the species. *Id.* § 668a.

6. The DEIS Fails to Ensure Compliance with the Federal Migratory Bird Treaty Act, 16 U.S.C. §§ 703–712.

The Migratory Bird Treaty Act (“MBTA”) requires that the U.S. Fish and Wildlife Service (USFWS) enforce the MBTA against “any person, association, partnership, or corporation” that “by any means or in any manner,” pursues, hunts, takes, captures, kills or attempts to take, capture or kill a migratory bird or any part, nest or eggs of any migratory bird. 16 U.S.C. §§ 703, 707. Under the MBTA, a person may take or kill migratory birds only as permitted under USFWS regulations and based on the USFWS’s determination that the take or

kill is compatible with the migratory bird treaties. *Id.* §§ 703, 704. The USFWS’s determination must take into account scientific factors such as species abundance and distribution, migratory patterns, and breeding habits, as well as the economic value of birds. *Id.* § 704. The killing of a single migratory bird is sufficient to create criminal liability. *United States v. Corbin Farm Service*, 444 F.Supp. 510 (E.D. Cal), *aff’d*, 578 F.2d 259 (9th Cir. 1978). The killing of a migratory bird does not need to be intentional and the killing can occur “by any means or in any manner.” *United States v. Moon Lake Electric Ass’n, Inc.*, 45 F.Supp. 2d 1070, 1075–79 (D. Col. 1999) (upholding the prosecution of a utility for unintentionally electrocuting and killing seventeen birds). The DEIS fails to ensure compliance with the MBTA.

7. Inadequate review of impacts to northern spotted owl populations.

The DEIS states that construction of the proposed facility will not directly impact spotted owl habitat. However, the DEIS fails to address whether the project will adversely affect dispersal habitat and migration corridors that are essential to sustaining genetic diversity of owl populations. For example, the Columbia River Gorge is a likely crossing location for owls moving north and south between Oregon and Washington. The project could also affect the east-west movement of spotted owls between valleys. The DEIS fails to adequately address whether a major industrial energy facility sited within spotted owl territory will adversely affect the species.

The DEIS also fails to address the permanent loss of forested lands within the White Salmon Spotted Owl Special Emphasis Area (SOSEA). The DEIS claims that the project would meet Washington state standards for the retention of sufficient habitat within the SOSEA, but it does not adequately review the impacts of *permanently* converting forest land to an industrial

use, and how that permanent conversion would affect the longterm viability of spotted owl habitat within the SOSEA.

8. Failure to demonstrate sufficient protections for non-avian wildlife and insects.

The application and threshold determination fail to demonstrate sufficient protections for sensitive and rare wildlife species, including a number of sensitive and rare species that the application notes have been observed within the project site. The DEIS also fails to evaluate potential impacts on insects such as butterflies. Here, the impacts are typically not from direct turbine strikes, but rather from habitat disruption or destruction. There are several species of butterflies of particular concern in this area, particularly the rare Western Oak Dusky Wing (*Propertius duskywing*).

9. The DEIS fails to include adequate mitigation measures.

The decisions fail to include adequate mitigation measures to protect wildlife. For example, the DEIS include discussion relating to future surveying for wildlife impacts, but fail to include any conditions that would require any concrete actions in response to actual wildlife impacts.

10. The DEIS misrepresents the climate change and air quality impacts of the project and of the no-action alternative.

The DEIS repeatedly asserts that if the Whistling Ridge Energy Project is not built, then adverse impacts to climate change and air quality would necessarily result. For example, the DEIS states that “[i]f the No Action Alternative is selected, the growing electricity needs of the region would continue to be met through a combination of other renewable development and a combination of additional fossil fuels.” DEIS at 3-21–3-22. This completely false dilemma, in various forms, is repeated throughout the DEIS without any factual support.

In fact, the regional energy system will reduce greenhouse gas emissions and air pollutants regardless of whether this individual project is built, and primarily through conservation measures. The Northwest Power Planning Council's Sixth Power Plan, which will dictate the portfolio of energy production sources for the foreseeable future, has planned to meet 85% of new demand with conservation and efficiency measures over the next 20 years. Sixth Northwest Power Plan Overview at 1. The remaining 15% of new demand would be met with renewables. Notably, this would be achieved even while the Boardman coal-fired power plant is taken offline by 2020.

The Bright Future Report also provides some broader context for the supply and demand aspects of the regional energy grid. Bright Future Report, NW Energy Coalitions, Original Edition, March 2009 – Update 1, July 2009. The Bright Future Report analyzes how the region will meet its energy needs through 2050, factoring in the loss of the Boardman coal-fired power plant, the removal or reduced use of hydropower projects on the lower Snake River, and picking up that lost energy supply through conservation, efficiency, and clean new sources of energy. The Report's bottom line conclusions are that "[t]he region has enough renewable potential to more than meet all current and future power needs" and that the potential for affordable clean energy "[d]warfs" the need. Bright Future Update at 14, 15. Thus, foregoing the 21 average MW of production capacity that would result if the Whistling Ridge project is not constructed would be essentially irrelevant to the overall supply of alternative energy. Furthermore, there is absolutely no evidence in the record showing that the alternative to this particular wind project is continued use of fossil-fuel generation sources or new fossil-fuel generation sources. The real choice is between this particular wind facility and siting other wind facilities in alternative locations with fewer environmental impacts.

Thus, it is inappropriate for the DEIS to compare the likely impacts of a wind energy development to the impacts of fossil-fuel generation sources. The region's climate change goals and air quality goals will be achieved regardless of whether the Whistling Ridge project is constructed. Every statement asserting the false dichotomy between constructing the project and a future with higher carbon emissions and air quality problems must be removed from the DEIS.

E. The DEIS Fails to Adequately Review the Likely Impacts of the Proposed Development on Cultural Resources.

1. The DEIS Fails to Analyze Impacts to Cultural Resources and Fails to Integrate Adequate Consultation with Tribal governments.

The DEIS acknowledges that the BPA has an obligation under Section 106 of the National Historic Preservation Act (“NHPA”), 16 USC 470 et seq., to consult with Tribal governments about the likely impacts of the proposal. DEIS at 4-6. The BPA also explains that the “BPA’s 1996 government-to-government agreement with the 13 federally-recognized Native American Tribes of the Columbia basin provides the guidance for the Section 106 consultation process with the Tribes.” DEIS at 4-6. The Draft EIS explains that the BPA will conduct formal government-to-government consultation. DEIS at 3-204. The DEIS fails to acknowledge that NEPA regulations also require that the BPA must prepare the Draft EIS “concurrently with and integrated with” the required consultation under the NHPA. 40 C.F.R. § 1502.25(a).

SEPA requires EFSEC to consult with the Yakama Nation as well. Under SEPA, EFSEC is required to consider the likely impacts to cultural resources. “Cultural preservation” is an element of the environment that must be addressed through the SEPA process. WAC 197-11-444. In addition, the environmental checklist, which must be prepared for proposed actions, requires consideration of impacts to cultural resources. WAC 197-11-315; WAC 197-11-960. SEPA also requires that EFSEC consult with agencies with expertise in the impacted

environment. RCW 43.21C.030(2)(d); WAC 197-11-408(2)(a). EFSEC's SEPA regulations also require that EFSEC works with interested agencies throughout the preparation of the DEIS. WAC 463-47-140(5). The Yakama Nation's Cultural Resources Program is an agency with expertise in Yakama Nation cultural resources. Finally, the 1989 Centennial Accord between the State of Washington and federally recognized tribes mandates that EFSEC undertake government-to-government consultation with representatives of the Yakama Nation regarding the measures necessary for adequate environmental review and appropriate mitigation measures.

Based on the above-referenced sources of law, both EFSEC and BPA must engage in direct government-to-government consultation with the Yakama Nation. The BPA has already failed to comply with the NEPA requirements to integrate this consultation into preparation of the DEIS. *See* 40 C.F.R. § 1502.25(a). This consultation should have occurred months ago. Both EFSEC and the BPA have heard testimony from the Yakama Nation explaining that a cultural resources report was submitted in December 2009. There is no legitimate explanation for why this information was not included in the DEIS, which was issued in May 2010, or why government-to-government consultation was not undertaken concurrently with the environmental review process.

Industrial wind energy development in Klickitat County that has proceeded without adequate consultation and review for impacts to cultural resources has led to irreparable harm to cultural resources. This harm is evidenced by a media report in the *Yakima Herald-Republic* on the destruction of cultural resources during the construction of the Windy Point Wind Energy Facility in neighboring Klickitat County, a copy of which is attached hereto. EFSEC and the BPA must not allow this type of mistake to repeat itself. The agencies must perform adequate

consultation, analyze likely impacts, and ensure that Yakama Nation cultural resources would not be adversely impacted by the proposal.

2. The DEIS Fails to Demonstrate Compliance With the National Historic Preservation Act.

The project would be highly visible from the Historic Columbia River Highway (“HCRH” or “Historic Highway”). This invaluable historic treasure, built between 1913 and 1922, was the first road planned as a scenic highway in the United States. Today, the Historic Highway is listed on the National Register of Historic Places, as a Historic District, as a Scenic Byway, and as a National Historic Civil Engineering Landmark by the American Society of Civil Engineers. Even more significantly, the Historic Highway has been designated by the Secretary of the Interior as a National Historic Landmark for its “exceptional value as commemorating or illustrating the history of the United States.” More than other historic places on the National Register, National Historic Landmarks are granted special protection against impacts caused by federal action. Indeed, section 110(f) of the National Historic Preservation Act (“NHPA”) requires federal agencies to undertake, “to the maximum extent possible,” such planning and actions as may be necessary to minimize harm to these properties.

Portions of the Historic Highway are being restored by the Oregon Parks and Recreation Department (“OPRD”) and the Oregon Department of Transportation (“ODOT”) as part of the Historic Columbia River Highway State Trail. Acting on a 1987 directive by the Oregon Legislature to preserve and restore the Historic Highway, ODOT and OPRD are creating a series of long, narrow parks in the Columbia River Gorge that will be open to pedestrians, bicyclists, children, and people in wheelchairs, and closed to all motor vehicle traffic. More detailed information on the HCRH can be found in the “Historic Columbia River Highway Master Plan: HCRH Segments,” a copy of which is attached to these comments.

It is important to note that the BPA is under special obligations with regard to protecting this National Historic Landmark. Section 110(f) of the NHPA provides as follows:

Prior to the approval of any Federal undertaking which may directly and adversely affect any National Historic Landmark, the head of the responsible Federal agency shall, to the maximum extent possible, undertake such planning and actions as may be necessary to minimize harm to such landmark, and shall afford the Advisory Council on Historic Preservation a reasonable opportunity to comment on the undertaking.

16 U.S.C. § 470h-2(F).

Section 106 of the NHPA and its implementing regulations adopted by the Advisory Council on Historic Preservation entitled “Protection of Historic Properties” (36 C.F.R. Part 800), describe agency responsibilities when an undertaking will affect properties listed in the National Register of Historic Places, including National Historic Landmarks.

The Whistling Ridge project would adversely affect views from the Historic Columbia River Highway. The HCRH was built as a scenic highway. Its historic features include design elements that accentuate views of the remarkable scenic landscapes of the Columbia River Gorge. Curves and pullouts in the HCRH were designed to focus the traveling public’s attention on scenic landscapes. The highway includes substantial tunneling in numerous places, with tunnels designed to optimize views. The Mitchell Point Tunnel,

known as the “Tunnel of Many Vistas,” included multiple windows that presented views of the Columbia River, Underwood Bluff, Dog Mountain, the mouth of the Little White Salmon River,

and the diverse array of vegetative and geologic textures on these landforms. East of Mitchell Point, the HCRH traversed parallel to Underwood Bluff and crosses Ruthton Point, where the curve of the road presents spectacular views of the Columbia River, Underwood Bluff, and Dog Mountain, along with rural pastoral land above Underwood Bluff.

Other important segments of the HCRH include the segment between Starvation Creek and Viento State Park, which have the added importance of being part of the Lewis and Clark National Historic Trail. The HCRH segments from Hood River heading east include the Hood River Loops and the Mark O. Hatfield West Trailhead. This segment also includes spectacular views of the Gorge, particularly Underwood Bluff, Chemewa Hill, and Underwood Mountain to the north and northwest. To the east of the Mark O. Hatfield West Trailhead is the fully restored Hood River to Mosier segment of the HCRH. Several tunnels along this stretch have been reopened, fulfilling the plans of the HCRH Master Plan and setting an example for the ultimate

goal of restoring the entire Highway for recreation and historical interpretation. While the views from the West Trailhead to Mosier become more distant from the project the views are nonetheless highly important to the HCRH. Impacts from these locations are also likely to be high.

While the “Tunnel of Many Vistas” was destroyed during the construction of Interstate 84, segments of the original HCRH are present through this area. The sections that were lost are currently being restored and recreated through ongoing efforts of ODOT, the Oregon State Parks and Recreation Department, and Friends of the Historic Columbia River Highway. The “Tunnel of Many Vistas” will likely be re-created within the next ten years. If the Whistling Ridge Energy Project is constructed, the view from the “Many Vistas” would not include a historically intact landscape. Rather, the vistas would be transformed to include an industrialized skyline with moving parts and flashing lights less than 3 miles away.

The impacts to opportunities for historic interpretation and impacts to this National Historic Landmark were not analyzed in the DEIS. The proposed development would directly impact these views and undermine opportunities for historic interpretation. This constitutes a major adverse impact to the environment that needs to be reviewed and addressed.

////

F. The DEIS Fails to Adequately Review the Likely Impacts of the Proposed Development on Recreational Resources.

The DEIS fails to adequately review the likely impacts to recreational resources. The project site is centered within a wide array of significant recreational resources, ranging from internationally recognized landmarks to local hikes with epic views. The DEIS fails to inventory all of the recreation resources in the vicinity and fails to adequately analyze the likely impacts to those resources.

The recreation resources in the vicinity include numerous locations to the south including the Columbia River Gorge National Scenic Area, The Lewis and Clark National Historic Trail, the Oregon Pioneer National Historic Trail, the Ice Age Floods National Historic Trail, the Historic Columbia River Highway Trail, Starvation Creek State Park, Viento State Park, Spring Creek Hatchery State Park, the Columbia River, the Mitchell Point Trail, Indian Head, and hiking along the Lower White Salmon River near the confluence with the Columbia. Locations to the north include the Lower White Salmon Wild and Scenic River, the Little White Salmon River, Nestor Peak, the Little Buck Creek Trail, the Grassy Knoll Trail, Cook Hill, Little Huckleberry Mountain, and numerous other hiking trails and drive-up viewpoints in and near the Gifford Pinchot National Forest. The DEIS fails to adequately inventory these resources.

*View from Little Huckleberry Mountain. Whistling Ridge and Chemawa Hill in center of photo.
Photo by Jozsef Urmos.*

As explained above, the Lewis and Clark National Scenic Trail includes the Columbia River, State Route 14, Interstate 84, Starvation Creek State Park, and Viento State Park. The DEIS fails to acknowledge these components of the National Historic Trail. The DEIS fails to acknowledge that Starvation Creek State Park and Viento State Park also provide river access for wind surfing, kite boarding, motor boating, canoeing and other water activities. The DEIS also fails to acknowledge that the City of Hood River is an international hub for windsurfing and that the project would be visible from multiple windsurfing locations. The DEIS also fails to

recognize that the Little White Salmon River and the White Salmon River are internationally known in whitewater kayaking communities.

The DEIS states that “[o]n the Oregon side of the Columbia River, land use within the Scenic Area is predominately commercial timber production and residential.” DEIS at 3-265. This is one of the more absurd errors in the DEIS. The Forest Service owns thousands of acres of public land within the Scenic Area on the Oregon side of the Columbia that is managed to protect natural resources and provide recreation opportunities, not for timber production. The leading land uses on the Oregon side of the Gorge, excluding urban areas, are conservation and recreation.

The DEIS states that “no parks or recreation facilities are planned within a 5-mile radius of the site, either as part of the Skamania County Parks and Recreation Master Plan or the Columbia River Gorge National Scenic Area Management Plan.” DEIS at 3-139. This statement is patently wrong and ignores plans to restore and develop facilities at Mitchell Point as part of the Historic Columbia River Highway. While Mitchell Point is already owned by Oregon State Parks, the development proposals are certainly new and warrant acknowledgement.

The DEIS failed to give proper consideration to impacts to recreational resources, including a failure to analyze whether the project would be consistent with the Management Plan for the Lewis and Clark National Historic Trail and the Historic Columbia River Highway Master Plan, or the recreation resource provisions of the CRGNSA Management Plan. While these plans do not have direct regulatory authority over the project (assuming no ground disturbance would occur in the National Scenic Area), the goals and policies could be frustrated by the project. There needs to be at least a discussion of the potential impacts.

Project construction activities would generate traffic delays that would adversely affect recreational users. Countless residents hike, windsurf, or kayak every day of the week and use the roads that would be used as a haul route for this project to access these recreational spots. Industrial traffic and associated delays would have an adverse impact on these resources. For example, use of the east access for Cook-Underwood Road for this project would block access to a recreational trail along the White Salmon River. Similarly, the west access for Cook-Underwood Road is regularly used by whitewater kayakers to access the lower three miles of Little White Salmon River, which has achieved legendary status due to the challenging rapids and consistent water flows. By failing to fully acknowledge such impacts and prepare a traffic mitigation plan for public review, EFSEC and the BPA have foreclosed the opportunity to evaluate the project's true impacts and inform the public of these impacts.

Project operation would also affect recreation. The DEIS section that addresses direct impacts of project development fails to mention recreation resources. DEIS at 3-153. Similarly, the cumulative effects section of the DEIS does not identify a single impact to recreational resources. DEIS at 3-279–3-280. The DEIS does acknowledge low to moderate impacts to views, but fails to acknowledge that scenery is typically a central part of outdoor recreation. As stated above, the scenic resource analysis was grossly inadequate.

Recreation resources that were not acknowledged through the scenic resource assessment include Little Huckleberry Mountain, Nestor Peak, and Cook Hill. These hiking areas provide dramatic panoramic views of Mount Hood and Washington's southern Cascades. Impacts to these resources were completely ignored.

The proposed development would be located in the heart of one of the greatest recreational destinations in the world. Windsurfers, kiteboarders, kayakers, and hikers come

from around the world to this area, and the Gorge itself is recognized as a national recreational treasure. Beyond the international and national fame, the area surrounding the project is home to people who hike, boat, bird, view wildflowers, and explore mountains and forests as a primary recreational pursuit. The project would be located in the middle of many of these activities. The recreational impacts analysis warrants substantial revision to reflect the actual impacts to recreational resources.

G. The DEIS Fails to Adequately Analyze the Likely Impacts to Agricultural Tourism.

The DEIS's analysis of potential impacts to agritourism is limited to a superficial comparison to wind energy development that has occurred in area between Walla Walla and Kennewick. DEIS at 3-151. The DEIS merely states that “[w]ind power and winery tourism already co-exist in the Columbia River Area. For example, four wind power facilities are located between Walla Walla and Kennewick (Canyon, Stateline, Vansycle, Combine Hills). This area is home to a thriving wind industry with over 60 wineries.” DEIS at 3-151.

The DEIS provides no analysis of whether industrial wind development has caused any adverse impacts to wineries in that area, or whether the landscape and proximity of the two uses is even remotely comparable to the proposed Whistling Ridge project and existing agritourism activities in the area.

For example, the DEIS does not explain how close any of the wind facilities are to the 60 referenced wineries. For Whistling Ridge, the project would be within a mile of existing wineries, would dominate views, and may also be heard. Importantly, the DEIS does not even attempt to quantify the number of agritourism businesses in the Underwood community, nor how close they might be to the proposed Whistling Ridge project.

The DEIS fails to explain how many of the 60 wineries are open to the public, and thus how many support agritourism. Wineries in the Underwood area have tasting rooms and host commercial events.

The DEIS fails to provide any economic data evidencing business trends and property values for the 60 wineries before and after wind energy facilities were constructed in that region. Even if 60 wineries coexist with the wind industry in that region, that does not mean the agritourism industry in that region has not been affected by the wind industry.

In sum, the analysis of potential impacts to agritourism fails to provide any meaningful substantive analysis that can inform decision makers on the likely impacts of the proposed development.

H. The Transportation Impacts Analysis is Inadequate and Must be Revised to Include Alternatives that Avoid and/or Mitigate Impacts to the Underwood Community.

The DEIS must adequately review the likely impacts to the local and regional transportation system. The proposed development would generate thousands of vehicle trips through areas that are predominately used for recreation, agriculture, rural residential, and forest uses. Industrial development and land uses are prohibited in the areas that the proposed haul route would travel through. The transportation impacts would likely be substantial. Impacts would include significant delays due to increased traffic and the size of vehicles associated with the use. The vehicles associated with the proposal would also be incompatible with local uses.

Whistling Ridge would make thousands of vehicular trips across the proposed haul route, including the hauling of heavy construction materials and equipment exceeding the Washington State Department of Transportation's legal load limit of 52.75 tons. *See* RCW 46.44.041. There would be more than 1,700 trips using specialized over-sized trucks designed specifically for the

industrial purpose of hauling the enormous turbine components. These specialized trucks are up to 150 feet long, 17.5 feet high, and 14.5 feet wide. Since October 11, 2007, trucks longer than 125 feet in length have been prohibited on Washington SR-14 along the haul route.

In addition to the specialized trucks, other large and oversized trucks would be needed to haul construction equipment, plus three pilot vehicles for each truck wider than 10 feet, and construction worker vehicles. Although WRE has not yet proposed a total number for all vehicular trips along the haul route, the total number would likely exceed 10,000 trips. The specialized trucks and their frequent, heavy loads are expected to damage the roads along the haul route. Thus, WRE proposes to repair road damage resulting from the industrial hauling.

This massive intrusion of industrial construction equipment would run through rural residential, agricultural, and recreational areas. Given the impact to the community, EFSEC and the BPA should study alternative routes that would preclude or minimize the use of Cook-Underwood Road as it runs through the National Scenic Area.

In addition, the DEIS provides internally inconsistent information about the true extent of the traffic impact. At pages 1-29 and 3-233, the DEIS states that traffic flow could be restricted for up to 20 minutes during the construction phase. But at page 3-228, the DEIS states that traffic delays would increase by only six seconds as a result of this project. The agencies should explain the inconsistency.

I. The DEIS Fails to Adequately Analyze and Address the Potential Health Impacts from Wind Energy Facility Operation.

The nearest residence would be within one-half mile of the proposed facility. Numerous other residences would be in similarly close proximity. EFSEC and BPA must ensure that the DEIS includes adequate review of the likely impacts on neighboring properties.

Recent studies have shown a potential for wind energy facilities to cause adverse impacts to human health. Adverse health impacts could occur from low-frequency noise that interferes with inner ear functions resulting in dizziness, nausea, and loss of sleep. While the research is not conclusive, the uncertainty regarding health impacts of wind development warrant a precautionary approach to siting wind facilities near residential structures. The DEIS should include analysis of a variety of sources on the health impacts of wind energy development. EFSEC and the BPA should require that the facility be set back at least 1 mile from the nearest residence.

Friends also incorporates the comments of Keith Brown and Teresa Robbins regarding the potential noise and human health impacts of the proposed project.

CONCLUSION

The Draft Environmental Impact Statement for the Whistling Ridge Energy Project is grossly inadequate and fails to comply with the requirements of SEPA, NEPA, and other applicable laws. The DEIS has been heavily influenced by the preferences and biases of the Applicant to rationalize a predetermined outcome, not to provide an impartial and informed analysis of environmental impacts. The flawed document cannot be used as a basis for decision making and must be substantially revised before any conclusions on environmental impacts can be drawn.

The Whistling Ridge Energy Project is easily the most controversial and problematic wind energy facility proposed to date in Washington State. The project would cause significant adverse impacts to unique resources in both Washington and Oregon, including scenic, natural, cultural, and recreational resources. The affected resources include the Columbia River Gorge National Scenic Area, the Historic Columbia River Highway, the Lewis and Clark National

Historic Trail, the Oregon Pioneer National Historic Trail, sensitive wildlife species such as the federally listed northern spotted owl, sensitive Native American cultural resources, and multiple hiking trails and other recreational resources.

Because of these unique factors, the environmental review must be of the highest integrity. Unfortunately, this DEIS fails to take the hard look required by NEPA and SEPA. The DEIS is improperly designed so that the applicant's private economic interests unlawfully dictate the purpose, need, alternatives, and eventual outcome for the proposed action. The DEIS does not demonstrate that EFSEC and BPA consulted with agencies with expertise in the resources that would be affected by the project. The DEIS also misquotes and misrepresents the language and meaning of the Columbia River Gorge National Scenic Area Act, and prematurely and erroneously concludes that the project would be consistent with the applicable land use regulations. Finally, the DEIS fails to adequately evaluate the direct, indirect, and cumulative impacts of the proposed project.

The DEIS is so deficient that it cannot be used as the basis for a decision on the project. The proposed project should be denied outright, but if it is to be given further consideration, a supplemental or revised DEIS is required.

Subject: Whistling Ridge DEIS Comments
Attachments: Comments of Friends of the Columbia Gorge on the Whistling Ridge DEIS.pdf

Dear Messrs. Montaño and Posner:

Please find attached the comments of Friends of the Columbia Gorge on the DEIS for the Whistling Ridge Energy Project. If possible, we request that the BPA post our comments on its web site.

We also have multiple exhibits. I will send as many of these as I can by email, and will also mail all exhibits (including the large ones) on CDs to each of you. I recently checked with Maryam Ashgharian at the BPA and she said this method would be acceptable, given the limitations of the BPA electronic comment form in accepting large files.

Thank you very much for your consideration. If you have any questions or comments, please do not hesitate to contact me.

INTRODUCTION

These comments regarding the Draft Environmental Impact Statement for the Whistling Ridge Energy Project are submitted by Friends of the Columbia Gorge.¹ Friends is a nonprofit organization with approximately 4,700 members dedicated to protecting and enhancing the resources of the Columbia River Gorge.

Of all the wind energy projects that EFSEC and BPA have reviewed to date, the Whistling Ridge Energy Project is easily the most controversial and problematic, as well as the project most likely to cause significant environmental impacts. This is the only project proposed to be located within forested habitat. This is the only project proposed within a designated Special Emphasis Area for the federally listed Northern Spotted Owl. This is the only project proposed within three miles of the Lewis and Clark National Historic Trail, the Oregon Pioneer National Historic Trail, the Historic Columbia River Highway (designated as a National Historic District on the National Register of Historic Places, as well as a National Historic Landmark), and the Ice Age Floods National Geological Trail. This is the only project for which multiple other agencies, including the United States Forest Service and the National Park Service, have recommended substantial modifications to the project. This is the only project proposed adjacent to a National Forest. This is the only project that would cause significant adverse impacts in two states (not just Washington). This is the only proposed project surrounded by recreational and cultural resources. And last but certainly not least, this is the only proposed project that would cause significant adverse impacts to a National Scenic Area.

¹ Friends hereby incorporates by reference all of its previous written and oral comments to the agencies, as well as its submissions to EFSEC through that agency's adjudicative proceeding and land use consistency process. The DEIS does not adequately address many of Friends' previous comments. Friends also incorporates all comments of Save Our Scenic Area.

Because of these unique factors, the agencies must take a special, close look at the impacts. Unfortunately, this Draft Environmental Impact Statement fails to take the hard look required by NEPA and SEPA. The DEIS is fundamentally flawed because it improperly narrows the scope of study, ignores and trivializes the impacts of the project, ignores or summarily dismisses detailed comments from the public and expert agencies, and was largely drafted and/or influenced by the applicant and the applicant's consultants behind closed doors and is therefore extremely biased in favor of the project. The DEIS is so deficient that it cannot be used as the basis for a decision on the project. The proposed project should be denied outright, but if it is to be given further consideration, a supplemental or revised DEIS is required.

BACKGROUND

I. The Columbia River Gorge and the Affected Communities

The Whistling Ridge project would be sited in the heart of the Columbia River Gorge. Many of the proposed turbines would be sited immediately adjacent to and/or highly visible from the Columbia River Gorge National Scenic Area. In addition, portions of the proposed "haul route," along which construction materials and turbine components would be transported, are located within the National Scenic Area.

Established by Congress in 1986, the National Scenic Area is an extraordinary national treasure, an area protected under federal law for its aesthetic, biological, ecological, historic, and recreational values. *See* Columbia River Gorge National Scenic Area Act ("Scenic Area Act"), 16 U.S.C. §§ 544–544p.

The Gorge, under the protection of the Scenic Area Act, offers unfettered scenic and historic views along the Columbia River, site of the final portion of Lewis and Clark's journey across the West. Additionally, the Gorge offers unique recreational opportunities with its many

side-river canyons, ridgetops, and the Columbia River itself. Hiking, bicycling, river rafting, kayaking, skiing, boating, fishing, camping, kiteboarding, windsurfing, birdwatching, and wildflower viewing are all pursued actively by the public throughout the Gorge. The overall character of the surrounding region highly scenic, ranging from wilderness to rural areas with quaint towns and spectacular vistas, rather than industrial or commercial.

In its November/December 2009 issue, *National Geographic Traveler* ranked the Columbia Gorge region #6 internationally, and second in the nation, among “iconic destinations.” The Gorge was ranked higher than all of the county’s national parks that were surveyed, and higher than Tuscany, Italy; the Serengeti Plains; and Mount Kilimanjaro. A primary reason given by *National Geographic* for the Gorge’s high ranking was the Gorge’s international reputation for “an incredible job of protecting the views.” Another stated reason was the Gorge’s “[g]reat potential for ‘agritourism and geotourism.’”

The Gorge has long been considered a special area. In 1915, the U.S. Forest Service (“USFS” or “Forest Service”) established Eagle Creek as the first Forest Service Recreation Area in the nation. The following year, the Gorge was proposed as a National Park. Continuing development pressures led to the establishment of the National Scenic Area in 1986. Today the Gorge contains hundreds of miles of hiking and bike trails through locales as diverse as misty river canyons and arid grassland plateaus. The Gorge also contains dozens of lakes, parks, campgrounds, and other recreational areas.

The proposed energy project would be highly visible from several urban areas and unincorporated communities in or near the National Scenic Area. These include Underwood, Hood River, Mosier, Mill A, Willard, and White Salmon. Hundreds of residents of these and

other communities are strongly opposed to the project and have expressed their opposition and concerns in comments to the reviewing agencies and to Skamania County.

II. The National Environmental Policy Act

A major purpose of the National Environmental Policy Act (“NEPA”) is to ensure that federal agencies conduct fully informed environmental decision-making. NEPA promotes its sweeping commitment to “prevent or eliminate damage to the environment and biosphere” by focusing the attention of federal decision makers and the public on the environmental and other impacts of proposed agency action. 42 U.S.C. § 4321. By focusing agency attention on the environmental and socioeconomic impacts of a proposed action, NEPA ensures that the agency will not act on incomplete information, only to regret its decision once finalized. *See Robertson v. Methow Valley Citizens Council*, 490 U.S. 332, 349 (1989).

To that end, “[t]he sweep of NEPA is extraordinarily broad, compelling consideration of any and all types of environmental impacts of federal action.” *Calvert Cliffs’ Coordinating Comm. v. U.S. Atomic Energy Comm’n*, 449 F.2d 1109, 1122 (D.C. Cir. 1971). An agency must “take the initiative of considering environmental values at every distinctive and comprehensive stage of the process.” *Id.* at 1111.

III. The State Environmental Policy Act

The Washington State Environmental Policy Act (“SEPA”) applies to state and local governmental actions and decisions. SEPA’s general purpose is to require consideration of environmental factors at the earliest possible stage in order to allow decisions to be based on a complete disclosure of environmental consequences. *See Stempel v. Dept. of Water Resources v. City of Kirkland*, 82 Wn. 2d. 109, 118 (1973). Agencies are required to engage in an open and public study of environmental impacts at the earliest possible time. RCW § 43.21C.030(b); *see*

also WAC § 197-11-300.

Agencies must assess the likely cumulative, direct, indirect, short-term, and long-term impacts to the environment. WAC 197-11-030(2)(b), (2)(g); *see also* State Environmental Policy Act Handbook (SEPA Handbook) at 2 (2003). Agencies must also evaluate alternatives and mitigation measures. WAC 197-11-055(2)(c); *see also* SEPA Handbook at 2. Agencies “shall not limit” consideration only to impacts within the boundaries of the agencies’ jurisdiction. WAC 197-11-060(4).

For projects with likely significant impacts, environmental impact statements are required to ensure that government agencies and interested citizens have an opportunity to thoroughly review environmental impacts of proposed actions at the earliest possible stage; the agency must use the EIS in planning actions and making decisions. WAC 197-11-400(4). “The primary purpose of an environmental impact statement is to ensure that SEPA’s policies are an integral part of the ongoing programs and actions of state and local government.” WAC 197-11-400(1).

The EIS must be *impartial* and must inform decision makers of alternatives and mitigation measures that avoid or minimize impacts of a proposed action. WAC 197-11-400(2). The EIS must not merely rationalize a predetermined outcome. WAC 197-11-402(10). (“EISs shall serve as the means of assessing the environmental impact of proposed agency action, rather than justifying decisions already made.”) Rather, the EIS must include sufficient objective analysis to actually inform the agency’s decision making process.

The EIS must be completed early enough to serve as a practical contribution to the decision making process. WAC 197-11-406 (“The statement shall be prepared early enough so it can serve practically as an important contribution to the decision making process and will not be used to rationalize or justify decisions already made.”); *see also King County v. Boundary*

Review Board, 122 Wn.2d 648, 666, 860 P.2d 1024 (1993); *Barrie v. Kitsap County*, 93 Wn.2d 843, 854, 613 P.2d 1148 (1980); *Mentor v. Kitsap County*, 22 Wn.App. 285, 291, 588 P.2d 1226 (1978).

For projects with potentially significant or serious impacts, SEPA requires the same hard look that NEPA does. “The level of detail shall be commensurate with the importance of the impact,” and in the face of any scientific uncertainty, the EIS must disclose the uncertainty and analyze the worst case scenario and the likelihood of its occurrence. WAC 197-11-402(2) and 197-11-080(2), (3).

DISCUSSION

I. The DEIS is Improperly Designed so that the Applicant’s Private Economic Interests Unlawfully Dictate the Purpose, Need, Alternatives, and Eventual Outcome for the Proposed Action.

A. The Purpose and Need Statement in the DEIS is Being Improperly Driven by the Applicant’s Private Economic Interests.

NEPA requires federal agencies to “rigorously explore and objectively evaluate all reasonable alternatives” to a proposed action. 40 C.F.R. § 1502.14(a). In order to do so, the agency must first reasonably and objectively define the purpose and need of a proposed action. *See Simmons v. United States Army Corps of Eng’rs*, 120 F.3d 664, 666 (7th Cir. 1997) (citing *Citizens Against Burlington, Inc. v. Busey*, 938 F.2d 190, 195–96 (D.C. Cir. 1991)). The chosen statement of purpose and need effectively dictates the range of alternatives evaluate in an EIS.

Id.

“[A]n agency cannot define its objectives in unreasonably narrow terms.” *City of Carmel-By-The-Sea v. United States Dep’t of Transp.*, 123 F. 3d 1142, 155 (9th Cir. 1997). “An agency may not define the objectives of its action in terms so unreasonably narrow that only one alternative . . . would accomplish the goals of the agency’s action, and the EIS would become a

foreordained formality. *Nat'l Parks & Conservation Ass'n v. Bureau of Land Mgmt.*, 606 F.3d 1058, 1070 (9th Cir. 2010). Moreover, an agency may not allow the economic needs and goals of a private applicant to define the purpose and need, and hence the inevitable outcome, of an EIS. *Id.*

Unfortunately, that is exactly what is happening with this EIS. The DEIS lists the applicant's "needs," including the "business needs of the applicant" (such as "diversifying the holdings" of the Applicant) as stated needs for the project, and lists no agency-defined objectives or needs other than complying with applicable laws. The DEIS fails to even acknowledge that the agencies have no obligation or responsibility whatsoever to meet the applicant's needs or desires. As a result, the Applicant-identified needs are defining and driving the characteristics of this project and the alternatives thereto. This approach is inappropriate and unlawful.

Interestingly, some of the Applicant-identified needs are suspect. For instance, the Applicant identifies a need for utilities in Washington State to provide more alternative energy to their customers. DEIS at 1-4-1-6. But nowhere has the Applicant specified or publicly committed to sell the electricity from this project within Washington State. As it stands, well over half of all the wind energy produced in Washington and Oregon is currently being sent to California. If a similar fate occurs with the electricity from the Whistling Ridge project, then the Washington state requirements for alternative energy are wholly irrelevant to the project. The applicant cannot have it both ways. It cannot assert that meeting Washington state renewable portfolio standards is a need for the project, and yet refuse to commit energy from this project to remain in Washington state.

The DEIS repeatedly states or implies that the project would reliably produce between 70 MW and 75 MW of energy. *See, e.g.*, DEIS at I-9, 3-90, 3-271. The DEIS significantly

overvalues the generating potential of the project. Wind energy facilities cannot continually generate energy at their rated capacity. Generally, wind energy facilities generate energy at 30% of capacity. So for this project, the actual energy output would be only 21 MW. Every assertion or implication in the DEIS that the Whistling Ridge project would produce 70 or 75 MW of energy must be corrected to reflect the likely actual production of the facility. This correction must also be reflected in the purported need to produce at least 70 MW of energy for the project to be marketable. In any event, the facility would likely deliver 21 MW of energy to the grid.

Further, the Applicant's purpose and need statement appears to be defined only in terms of conveying power from a wind energy generation facility. This purpose and need is too narrowly limited, and avoids the question of whether there truly is a need for a wind energy project. As a result, the purpose and need statement improperly limits the alternatives considered by the agencies.

As in the *National Parks & Conservation Association* case, the private economic interests of the Applicant are the driving force behind the purpose and need statement, and thus behind the entire DEIS. The narrowly drawn statement unreasonably constrains the possible range of alternatives, because it excludes alternatives that fail to meet the Applicant's specific private objectives, which are to build a wind energy project. The result of such a narrowly driven statement led to only two alternatives to be considered: the proposed action (authorizing construction and operation of the proposed Whistling Ridge Energy Project and associated components) and the No Action Alternative (not authorizing construction and operation of the proposed project). This extremely narrow range of alternatives is unreasonable, and thus, violates NEPA.

////

B. The Stated Purposes Fail to Acknowledge EFSEC’s Duty to Protect State or Local Governmental or Community Interests.

One of EFSEC’s mandates is to “protect state or local governmental or community interests affected by the construction or operation of the energy facility.” WAC 463-64-020. Any site certification agreement must contain conditions to meet this mandate. *Id.*

The DEIS fails to even mention this mandate, let alone apply it. This mandate should be expressly included in the stated purpose and need for action on page 1-3 of the EIS, and should be applied and reflected throughout the DEIS.

C. The Range of Alternatives Considered is Inadequate.

The DEIS discusses only the Proposed Action Alternative (the proposed project) and the No Action Alternative. Such a truncated alternatives analysis violates the agencies’ duties under NEPA and SEPA to fully review all reasonable alternatives.

“The purpose of NEPA is to require disclosure of relevant environmental considerations that were given a ‘hard look’ by the agency, and thereby to permit informed public comment on proposed action and any choices or alternatives that might be pursued with less environmental harm.” *Te-Moak Tribe of Western Shoshone of Nevada v. United States Dep’t of the Interior*, --- F.3d ---, 2010 WL 2431001 (9th Cir. 2010) (quoting *Lands Council v. Powell*, 395 F.3d 1019, 1027 (9th Cir.2005)); *see also* 42 U.S.C. § 4332(E) (requiring agencies to “study, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources”). Agencies are required to consider alternatives in an EIS and must give full and meaningful consideration to all reasonable alternatives. *Id.*; *see also* 40 C.F.R. § 1508.9(b). “The existence of a viable but unexamined alternative renders an environmental impact statement inadequate.” *Id.* (citing *Idaho Conservation League v. Mumma*, 956 F.2d 1508, 1519 (9th Cir.1992) (quoting *Citizens for*

a *Better Henderson v. Hodel*, 768 F.2d 1051, 1057 (9th Cir.1985)).

SEPA also requires an EIS to evaluate alternatives. RCW 43.21C.030(2)(c)(i). The applicable guidelines are found at WAC 197-11-440(5). An alternative considered for purposes of an EIS need not be certain or uncontested, it must only be reasonable. *King County v. Central Puget Sound Growth Management Hearings Bd.* 138 Wn.2d 161, 184-85, 979 P.2d 374, 385 (1999). A reasonable alternative is one that could feasibly attain or approximate a proposal's objectives at a lower cost to the environment. *Id.*; see also WAC 197-11-440(5)(b).

According to the applicable federal regulations, an EIS "shall inform decision-makers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment." 40 C.F.R. § 1502.1. CEQ clarified the meaning of this requirement in its "Forty Most Asked Questions" policy guidance by defining "reasonable alternatives" as including "those that are *practical or feasible* from the technical and economic standpoint and using common sense, rather than simply *desirable* from the standpoint of the applicant." Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, 46 Fed. Reg. 18,026 (Mar. 23, 1981) (emphasis in original).

When selecting alternatives, an agency may *consider* an applicant's desires, but is not by any means bound or limited by them. It is not appropriate for an agency to rely on the "self-serving statements of the project applicants." *Southern Utah Wilderness Alliance v. Norton*, 237 F. Supp. 2d 48, 53 (D.D.C. 2002). Instead, the action agency must "to the fullest extent possible . . . study, develop and describe appropriate alternatives to recommended courses of action in any proposal which includes unresolved conflicts concerning alternative uses of available resources." *Id.* at 54 (citing 42 U.S.C. § 4332(2)(E)). Moreover, "[o]ther factors [other than the applicant's desires] to be developed during the scoping process—comments received from the public, other

government agencies and institutions, and development of the agency's own environmental data—should certainly be incorporated into the decision of which alternatives to seriously evaluate in the EIS.” CEQ, Guidance Regarding NEPA Regulations, 48 Fed. Reg. 34,263, 34,267 (July 28, 1983).

Again, the DEIS analyzes the impacts of only two alternatives: 1) the proposed project, and 2) the no action alternative. These options advance the Applicant's goals, rather than the agencies' goals, to the exclusion of other reasonable alternatives. The DEIS is fatally flawed in its failure to consider an adequate range of reasonable alternatives. *See Muckleshoot Indian Tribe v. USFS*, 177 F.3d 800, 913 (9th Cir. 1999) (agency failed to consider an adequate range of alternatives when an EIS considered only a no action alternative along with two “virtually identical” action alternatives).

Various other alternatives should have been considered. First, at page 1-13 of the DEIS, the BPA did not consider any alternate locations for the wind turbine project other than those owned by the Applicant. Likewise, alternatives for interconnecting the wind project with transmission lines off of the project site were eliminated.

Indeed, under NEPA, the EIS may even have to look at alternatives over which the applicant has no control. *NRDC v. Morton*, 458 F.2d 827, 835 (D.C. Cir. 1972); *NWF v. NMFS*, 235 F. Supp.2d 1143 (W.D. Wash. 2002). Further, it is irrelevant whether an applicant already owns alternative sites for the purposes of NEPA review: “The fact that this applicant does not now own an alternative site is only marginally relevant (if it is relevant at all) to whether feasible alternatives exist to the applicant's proposal.” *Van Abbema v. Fornell*, 807 F.2d 633, 638 (7th Cir. 1986).

As stated in the *Van Abbema* case, other alternatives for a project cannot be eliminated as non-feasible simply because the Applicant does not now own the site where an alternative location may exist. Here, SDS and Broughton Lumber own tens of thousands of acres of land in Oregon and Washington that could potentially be available for energy production purposes. The EIS fails to consider those lands, and fails to consider the possibility of applicant purchasing lands in other locations, such as east of the National Scenic Area, for an energy facility.

Similarly, SEPA also requires a discussion of alternate development sites for a proposed project in order to have an adequate discussion of reasonable alternatives. *See Barrie v. Kitsap County*, 93 Wn.2d 843, 855, 613 P.2d 11481155 (1980) (EIS was inadequate because it looked only at the use of the applicant's private property for siting a shopping center, and failed to discuss alternative development sites).

Here, alternate locations could provide comparable energy output. This approach would be consistent with the BPA stated goals of acting consistently with its environmental and social responsibilities and providing for cost and administrative efficiency. Surely other sites with far less impacts could easily be located. Not far to the east of this project site, thousands of wind turbines have been constructed recently, the vast majority of which pose far less resource impacts than the Whistling Ridge site.

Another potential site is immediately north of the proposed project site, on DNR lands. In fact, this property has been designated by WRE as "Phase 2" of the Whistling Ridge project. Although DNR has indefinitely placed on hold consideration of WRE's request for a wind power lease of this property, that does not mean use of the property is forever out of the question. In fact, recent emails by WRE representatives, obtained by Skamania County residents Keith Brown and Teresa Robbins in response to a public records request, indicate that WRE still

wishes to use the DNR property for wind energy. The DEIS fails to analyze the possibility of siting wind turbines on this property rather than on the SDS and Broughton Lumber land.

Second, the BPA did not consider alternate configurations (with fewer wind turbines and/or in different locations) for the project. On page 1-14, the DEIS states that “the project must be capable of producing a minimum of 70 MW” and that the project size “was selected to *optimize* . . . economic feasibility” (emphasis added). There are no financial data or projections provided to support this claim. Moreover, the agencies eliminated any alternatives that would have considered a smaller generation facility, for instance in order to address potential environmental impacts, solely in an effort to “optimize”² the applicant’s economic wishes. Nor did the agency consider alternative locations for individual turbines that would reduce their impacts. This approach is unlawful and violates the agencies’ legal mandates.

Third, the BPA did not consider other potential renewable energy sources in the DEIS. A dismissal of renewable energy sources other than wind energy, such as distributed generation, does not comport with the agencies’ stated goal of acting consistently with their environmental and social responsibilities.

Fourth, no conservation alternatives were considered to eliminate the stated “need” for this 70 MW of installed capacity. Conservation alternatives, such as demand response technologies, also should have been included in order to meet the agencies’ goals of promoting their environmental and social responsibilities.

Fifth, another reasonable alternative is one that analyzes and considers the future development of the proposal. WAC 197-11-440(5)(c) states that the EIS shall:

(vii) Discuss the benefits and disadvantages of reserving for some future time the implementation of the proposal, as compared with possible approval at this time. The

² The *Webster’s Dictionary* definition of “optimize” is “to make as effective, perfect, or useful as possible.”

agency perspective should be that each generation is, in effect, a trustee of the environment for succeeding generations. Particular attention should be given to the possibility of foreclosing future options by implementing the proposal.

The DEIS fails to comply with this requirement, because it fails to consider the possibility of delaying the development of wind energy until a later date, perhaps at a time when the energy grid will be more equipped to handle the addition of new wind energy sources.

The above alternatives were either eliminated from the study, or not considered at all, because the Applicant's economic needs, rather than the stated goals of the agencies, dictated the results of this DEIS. In effect, the agencies are violating their duties to consider all reasonable alternatives.

D. The Applicant and its Consultants Appear to Have Played an Improper Role in the Drafting of the DEIS, Leading to a Biased and Result-Oriented Document.

The agencies' ability to prepare an EIS that would provide a balanced and objective analysis, leading to a decision that addresses the interests of the general community and not just the Applicant, have become further compromised by an apparent decision to allow the same consultants who prepared the application on behalf of the Applicant to also prepare analytical content in the DEIS.³

Originally, the agencies stated that the Applicant and its consultants would be preparing the EIS. However, because the public objected to this arrangement and pointed out that it would violate NEPA, the agencies made the following announcement in the DEIS May 21, 2010 cover letter:

While EFSEC and BPA are the entities that have prepared the Draft EIS, these agencies have worked collaboratively with Whistling Ridge Energy LLC to

³ These consultants include employees of URS Corporation, West Inc., and others. Although several consultants who prepared the application also are listed in section 6 of the DEIS as "preparers" of the DEIS, none of them noted their role in preparing the application on their disclosure statements in Appendix F.

obtain necessary information about the project and its potential impacts for the EIS. Initially, EFSEC had intended to allow Whistling Ridge Energy LLC to prepare the EIS, as allowed by SEPA; however, after public concern was raised, EFSEC and BPA decided that the lead agencies would be directly responsible for preparing the EIS. Accordingly, we have used environmental information provided by Whistling Ridge Energy LLC and its consultants in the EIS as appropriate. All such information has been independently evaluated and reviewed for accuracy by the lead agencies, as well as by an independent, third party consultant retained by EFSEC.

This statement invites more questions than it answers. What was the exact nature and extent of the involvement of WRE and its consultants in the preparation the DEIS? Did they simply supply environmental “information,” as stated in the cover letter, or did they supply analysis, findings, and/or conclusions for the DEIS? Why does the DEIS adopt lengthy passages from the application verbatim or practically verbatim? If WRE and/or its consultants were allowed to write portions of the DEIS, will the agencies identify which portions? Were the applicant and/or its consultant allowed to review any portions of the EIS before it was made final, and if so, did they make any changes to it?

There is a major difference between the applicant’s consultants supplying the agencies with information and data (such as species survey data, photographs, coordinates for turbine locations, etc.) and the applicant’s consultants drafting analysis and conclusions to be inserted into the DEIS document. Unfortunately, the DEIS cover letter does not satisfactorily explain which scenario occurred, but the extremely biased nature of the DEIS in favor of the project strongly implies an active role by the Applicant’s consultants in its preparation.

An attached May 28, 2010 email string further calls into question whether EFSEC and BPA staff actually wrote the content of the EIS, or allowed the applicant’s consultants to write it. The emails show that a landscape architect with the U.S. Forest Service telephoned the EFSEC Site Manager “express[ing] concerns about the quality of the [visual resource] analysis.” The

Forest Service employee asked EFSEC “who did the analysis,” “what their qualifications were,” and “whether or not a Landscape Architect was consulted during development of this section.” Apparently not knowing the answer to these questions, the EFSEC Site Manager appears to have referred the questions to the Project Manager with URS Corporation, the Applicant’s lead consultants.

As with the agencies’ DEIS cover letter, this email string poses a number of questions. If EFSEC and BPA prepared the DEIS, why does it appear that EFSEC had to ask the Applicant’s consultants who wrote it? If the agencies were directly responsible for the content of the EIS, why did they not know whether a landscape architect participated in its drafting? And as the Forest Service asked, who in fact “did the analysis,” and what were their qualifications?

On the face of the email and the DEIS itself, it certainly appears as if the same people who wrote the application (*i.e.*, the Applicant’s consultants) were also allowed to prepare the analysis reviewing the application. In fact, it appears that the entire scenic resources analysis section of the application, including all analysis, findings, and conclusions, was simply lifted from the application and inserted verbatim into the DEIS. Although the agencies claim to have “prepared” the content of the DEIS and independently reviewed and verified any information from the applicant, by all outward appearances this did not occur—at least with major sections of the DEIS. Rather, it appears that the Applicant’s consultants were allowed to write major portions of the DEIS. If so, then the Applicant has been allowed to exert undue influence over the content of the DEIS. The predictable outcome is a DEIS that, in effect, serves as an extremely biased and result-oriented prospectus for the proposed project exactly as proposed by the Applicant, instead of the searching and balanced decision-making document required by NEPA and SEPA.

NEPA case law and guidance are clear that an applicant, such as Whistling Ridge Energy, should not be allowed to influence the analytical content of an EIS. *See, e.g., Sierra Club v. Sigler*, 695 F.2d 957, 962 n.3 (5th Cir. 1983) (expressing serious concern over role of private firm in preparation of EIS). An EIS must be an entirely objective analysis intended to aid the decision maker and the public in understanding the consequences of an agency decision. Thus, it is standard practice for action agencies to ensure that applicants for federal action are insulated from all aspects of EIS preparation other than providing information.

Any arrangement that allows the very same consultants who drafted the application to also draft analytical content for the DEIS is improper and cannot be allowed to continue. If in fact the agencies have been relying on the Applicant's consultants (rather than agency employees) to draft analytical content for the DEIS, then the agencies should immediately withdraw the DEIS, and should either retain new consultants unaffiliated with the applicants to prepare a revised DEIS or should ensure that a revised DEIS is drafted by disinterested agency employees. The Applicant and its consultants must not be allowed to continue to play a direct and significant role in the preparation of factual and legal conclusions in the EIS. Such a role is improper and invalidates the DEIS as the basis for further decision-making.

The agencies also state that they have hired a third-party consultant who has been charged with independently verifying the content of the DEIS. However, it is ultimately the agencies' responsibility, and not that of any consultants, to independently verify the DEIS's content. The agencies are "responsible for the independent verification and use of the data, evaluation of the environmental issues, and . . . the scope and content of the environmental assessment." *Save Our Wetlands v. Sands*, 711 F.2d 634, 642 (5th Cir. 1983). Given the

extremely biased nature of this document, Friends questions whether the agencies are meeting this responsibility.

II. The DEIS Does not Demonstrate that EFSEC and BPA Consulted with Agencies with Expertise in the Resources that Would be Affected by the Whistling Ridge Energy Project.

EFSEC must consult with agencies with expertise in the resources that may be impacted by the proposed development. RCW 43.21C.030(2)(d); WAC 197-11-408(2)(a). SEPA requires that the agency “utilize a systematic, interdisciplinary approach” to environmental review. RCW 43.21C030(2)(A). EFSEC’s SEPA regulations also require that EFSEC works with interested agencies throughout the preparation of the DEIS. WAC 463-47-140(5).

Similarly, NEPA requires that BPA request comments from federal agencies with special expertise in the resources that would be affected by the proposed development. 40 C.F.R. § 1503.1(a)(1). NEPA requires that the BPA seek comments from state agencies and tribal governments. 40 C.F.R. §1503.1(a)(2). The NEPA regulations also requires that federal agencies respond to requests for comments: “Federal agencies with jurisdiction by law or special expertise with respect to any environmental impact involved and agencies which are authorized to develop and enforce environmental standards shall comment on statements within their jurisdiction, expertise, or authority.” 40 C.F.R. § 1503.2. NEPA regulations also require that BPA prepare the DEIS “concurrently with and integrated with” required consultations. 40 C.F.R. § 1502.25(a).

Despite these clear, abundantly sensible requirements, the DEIS fails to show consultation with agencies that have expertise in the resources that would be impacted by the proposal. In fact, comments from expert agencies conveying substantial concerns about significant adverse impacts from the proposal were summarily ignored. These agencies were not

even listed under the “Environmental Consultation” section of the DEIS, nor in the Distribution List for receiving copies of the DEIS after they commented. *See* DEIS at §§ 4.0, 5.0.

EFSEC and BPA are unambiguously required to seek comments from agencies with expertise in the resources that would be impacted. Federal agencies with special expertise have a nondiscretionary obligation to respond to those requests with comments. Agencies with expertise in the resources that would be affected include the USDA Forest Service, which administers portions of the Columbia River Gorge National Scenic Area and the Lower White Salmon Wild and Scenic River Area, and the National Park Service, which administers the Lewis & Clark National Historic Trail, the Oregon Pioneer National Historic Trail, and the newly designated Ice Age Floods National Geologic Trail. As administrators of these areas, both agencies have expertise in evaluating impacts to scenic resources and historically important viewsheds.

Both of these agencies submitted comments during the scoping process. Both comments pointed out that the project would cause significant adverse impacts to scenic resources and recommended mitigation measures, including removal of turbines from Scenic Area viewsheds as seen from designated key viewing areas. These comments have been summarily ignored. The DEIS demonstrates an utter failure of the agencies to follow through with the requirements of NEPA and SEPA, as well as the agencies’ duties to protect environmental values and surrounding communities, by responding to these expert agencies’ comments.

The scenic resources that would be affected by the proposal are of national significance. This warrants the utmost care in consulting with expert agencies to ensure that the decision-making agencies have impartial and objective analysis of the likely impacts to the environment.

The Forest Service has inventoried and ranked the viewshed that would be directly affected by this project, and has the expertise to measure the impacts of the proposal on this

landscape. Thus, the Forest Service's inventories and conclusions are directly relevant to the scenic resource impacts analysis for the project. Portions of the viewsheds that would be affected have been identified by the Forest Service as having the highest rankings for scenic values. This includes "outstanding" scenic diversity, "primary" landscape significance, and "critical" landscape sensitivity. The Forest Service staff has special expertise in evaluating how the development would impact these landscapes, and must be consulted.

It is of paramount importance that both EFSEC and the BPA address the Forest Service's scoping comments and seek further clarification from the Forest Service regarding the likely project impacts. Given the level of study already performed by the Forest Service with respect to the affected scenic resources, the DEIS does a disservice by not incorporating that information into the environmental review.

Swift v. Island County established the importance of taking expert agency comments into consideration during SEPA review. *Swift v. Island County*, 87 Wash. 2d 348, 552 P.2d 175 (1976) (en banc). In *Swift* the court ruled that an Island County determination of non-significance violated SEPA because the finding conflicted with the comments of other agencies and experts. The agencies and experts included "the United States Department of the Interior, Fish and Wildlife Service; State Parks and Recreation Commission; State Department of Game; State Department of Ecology; the Central Whidbey Island Historic Preservation Advisory Committee" and an authority on birds. 87 Wn. 2d at 355. Just as Island County ignored expert agency comments in *Swift*, EFSEC is completely ignoring expert agency comments in the present matter.

EFSEC and the BPA should also address whether expert agencies have altered or withheld comments due to pressure from elected officials. Documents obtained through public

records requests and submitted by Keith Brown and Teresa Robbins have uncovered e-mail chains evidencing political interference and muzzling of agency experts at the direct request of the applicant. This episode underscores EFSEC's and BPA's legal and moral obligations to ensure that thorough and complete expert agency consultation is obtained regardless of the political connections of the proponent.

The Applicant has asserted that the expert agencies are somehow attempting to improperly assert control over private land outside their jurisdictions. This is entirely inaccurate. Simply put, the agencies have expertise in the resources that would be affected by the proposed development, and therefore must be consulted pursuant to NEPA and SEPA. The consulting agencies simply help the action agencies understand and evaluate the harm to the environment that would result from this proposal. The Applicant apparently fundamentally misunderstands the role of consulting agencies under NEPA and SEPA.

The National Park Service's interest in the affected resources is evidenced by the Management Plan for the Lewis and Clark National Scenic Trail and recent mission statements that accompanied notices that the Park Service will be revising the Lewis and Clark Trail Management Plan: "Certain segments of the Lewis and Clark National Historic Trail *retain characteristics and a sense of place as seen and experienced by the original expedition and continue to provide opportunities for similar experiences today.*" Lewis and Clark Trail Master Planning Newsletter (July 27, 2010) (emphasis added). "Today the Missouri, Clearwater, and Columbia Rivers, their watersheds, and the overland routes across the Rocky Mountains have changed, however, *the natural resources and ecosystems that remain intact are fundamental to the experience of this Trail. These complex resources are critical to providing the context within which modern visitors experience the Trail and the story of Lewis and Clark.*" Lewis and Clark

Trail Master Planning Newsletter (July 27, 2010). The Park Service certainly has the mandate and the expertise to comment on the likely impacts of the project.

EFSEC and BPA should also actively solicit comments from the Oregon Department of Transportation and the Oregon Parks and Recreation Department. These agencies manage the Historic Columbia River Highway, which is listed on the National Register of Historic Places as a National Historic District. The proposal would adversely affect views from the Historic Highway, harming the scenic, recreational, and historical values of the resource. These agencies are also coordinating plans to restore abandoned sections of the Historic Highway as part of the “Milepost 2016 Reconnection Project,” which furthers the goals of the Historic Columbia River Highway Master Plan, portions of which are attached hereto. The impacts to these efforts, in terms of impacts to historical interpretation opportunities and scenic resources, must be acknowledged and consulted on.

EFSEC and the BPA must also consult with the Columbia River Gorge Commission, which manages the landscape and regulates land use and development in the immediate vicinity of the project. The DEIS mentions the Columbia River Gorge National Scenic Area Act in the “Environmental Consultation” section, but does not mention consulting with the Gorge Commission. DEIS at 4-9, § 4.11. This section should be revised to accurately reflect the regulatory framework for the National Scenic Area. This section states that the General Management Area of the Scenic Area includes a mixture of “farming, logging, residential, and cattle grazing” land uses. DEIS at 4-9. The section should be revised to state that the General Management Area also includes public recreation and commercial recreation uses along with some of the most sensitive open space areas. EFSEC and the BPA must also consult with the Gorge Commission regarding any regulatory review that would be required to ensure compliance

with Scenic Area Act standards for the portion of the project located within the National Scenic Area—namely, the proposed haul route.

The DEIS at 3-141 and 3-194 also quotes 16 USC § 544o(a)(10), which states that the Scenic Area Act does not, “of itself,” authorize the creation of any buffer or protective perimeter. This provision does not prohibit expert agencies from using the National Scenic Area’s resource inventories and regulatory standards as tools for measuring impacts to the environment.

Agencies with expertise regarding wildlife, including the U.S. Fish and Wildlife Service and Washington State Department of Fish and Wildlife, must be consulted. And the Washington Department of Natural Resources must be consulted regarding compliance with the Washington Forest Practices Act, which regulates the conversion of forested land to non-forestry uses. The Washington DNR must also be consulted regarding the feasibility of alternative siting locations on public land to the north of the current project area.

III. The DEIS Misquotes and Misrepresents the Language and Meaning of the Columbia River Gorge National Scenic Area Act.

The DEIS attempts to rewrite the Columbia River Gorge National Scenic Area Act to effect a dramatically different purpose than intended by Congress. This misrepresentation, if it goes uncorrected, would dramatically hinder EFSEC’s and the BPA’s ability to protect the public from adverse impacts to important local, state, and national resources. The DEIS includes the following passage that purports to quote the Columbia River Gorge National Scenic Area Act:

The Act states that “no protective perimeters or buffer zones shall be established around the scenic area or each special management area. Activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas” (16 U.S.C. § 544O(a)(10)).

DEIS at 3-194 (emphasis in original).

The above language, reprinted verbatim from the DEIS, seriously misquotes and misrepresents the Act. The actual language in the Act is as follows:

(a) *Nothing in this Act shall . . .*

(10) Establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas.

16 U.S.C. § 544o(a)(10) (emphasis added).

The first sentence of the misquoted Act in the DEIS completely changes the meaning of the statute. The intent to misrepresent is clear. The difference in the meaning of the true wording versus the quoted wording is significant.

The language in 16 U.S.C. § 544o(a)(10) provides that *nothing in the Scenic Area Act* shall establish protective perimeters or buffer zones. It does not, as the DEIS language states, outright prohibit protective buffers, for example under operation of some other local, state, or federal law. EFSEC and the BPA must apply numerous other laws in their decision-making, and must protect affected resources and communities. The misquoted language in the DEIS implies that Congress mandated that some other law or factor, independent of the Scenic Area Act, could not result in the protection of lands adjacent to the Scenic Area. This is absolutely incorrect. While the Scenic Area Act does not in and of itself impose buffers, neither does it prevent them under operation of other laws.

///

IV. The DEIS Prematurely and Erroneously Concludes That the Project Would Be Consistent With the Applicable Land Use Regulations.

A. The Land Use Consistency Determination in the DEIS is Premature.

The DEIS concludes that “the proposed project would be consistent with the applicable land use regulations.” DEIS 3-152. The DEIS further states that “the project would be consistent with the Comprehensive Plan vision and the Conservancy designation in that it would conserve and manage existing natural forest and wind resources to maintain a sustained yield and utilization of both.” *Id.* These and all other statements in the DEIS regarding consistency with applicable land use regulations are premature, because EFSEC has not yet concluded its land use consistency process nor issued a determination as to whether the proposed project is consistent and in conformance with the applicable land use plans and zoning ordinances through the process required by WAC 463-26-110 and RCW 80.50.090(2). The DEIS erroneously contains consistency determinations long before the issue of consistency will be adjudicated in the land use process before EFSEC. EFSEC has effectively prejudged the consistency results by including its premature conclusions in the DEIS.

The DEIS should be revised to remove all conclusions as to land use consistency. Instead, the DEIS should state what the potentially applicable regulations are, and then state that EFSEC will reach a conclusion on consistency as part of its adjudicative process, and that the BPA will decide whether it concurs with that determination. At most, the DEIS could summarize the different arguments that have been made to date regarding the applicable regulations. But prejudging consistency long before the consistency process is complete is inappropriate and a violation of Friends’ right to a fair and impartial adjudicative hearing.

Contrary to the conclusions in the DEIS, the project is *not* consistent with applicable land use requirements. Friends will continue to address, via EFSEC’s adjudicative process, the many

reasons why the project is not consistent with the applicable land use requirements. Rather than restate Friends' arguments at length in the instant comments, Friends relies on its previous submissions to EFSEC, as well as its briefing to the Skamania County Hearing Examiner in the prior administrative appeal involving Skamania County's proposed (now abandoned) energy zoning amendments (County File No. SEP-08-35),⁴ except as modified or supplemented below. Friends also adopts and reiterates all arguments of Save Our Scenic Area regarding land use consistency.

B. The Application and DEIS are Inconsistent and Incomplete Regarding the Proposed Haul Route through the National Scenic Area.

The Application and DEIS are internally inconsistent and incomplete regarding the proposed haul route through the National Scenic Area. The specialized trucks for hauling wind energy turbine components for this project are both massive and heavy; these trucks may have trouble navigating certain intersections and bridges. The application and DEIS do not clearly establish which route is proposed through the National Scenic Area, and whether that route would entail any road construction or ground-disturbing activities within the General Management Area of the National Scenic Area. The information that *has* been made available about the haul route is internally inconsistent and does not comply with EFSEC's rules for a complete application.

EFSEC rules require, among other items, the application to include information about traffic and transportation impacts:

- (1) Transportation systems. The application shall identify all permanent transportation facilities impacted by the construction and operation of the energy facilities, the nature of the impacts and the methods to mitigate impacts. Such impact identification, description, and mitigation shall, at least, take into account:

⁴ Copies of all the relevant documents from both proceedings are attached hereto as exhibits.

* * *

(b) Access routes for moving heavy loads, construction materials, or equipment;

* * *

(2) Vehicular traffic. The application shall describe existing roads, estimate volume, types, and routes of vehicular traffic which will arise from construction and operation of the facility. The applicant shall indicate the applicable standards to be utilized in improving existing roads and in constructing new permanent or temporary roads or access, and shall indicate the final disposition of new roads or access and identify who will maintain them.

* * *

WAC 463-60-372.

The original application proposed two alternative haul routes through the National Scenic Area, Routes 1 and 2. The amended application adds a third alternative haul route, Route 3. Amended Application at 2.19-3. The DEIS adopts Route 3 as the haul route for the project. DEIS at 1-12.

At page 1-16, the DEIS states that both Routes 1 and 2 have been “eliminated as . . . construction roadway access alternative[s].” However, at page 3-172, the DEIS states that Route 1 (the Ausplund Road Route) “would be used to access the [project site] for construction and maintenance.” The agencies need to address this inconsistency, and clarify the extent to which Routes 1 or 2 would be used, if at all, for this project.

Moreover, a number of unanswered questions remain regarding Route 3, and specifically whether this route would involve any road construction or ground-disturbing activities within the General Management Area of the National Scenic Area. This route includes an aging bridge on Cook-Underwood Road across the Little White Salmon River and within the GMA. In the attached November 6, 2009 letter submitted to the Gorge Commission, WRE freely admits that “[t]he County has not yet determined whether any modifications or repair of [this] bridge would

be required” to enable the bridge to be used for the haul route. Furthermore, there is no evidence in the application or in the record, such as engineering schematics or a discussion of the bridge’s load-bearing capacity, to establish whether construction work on the bridge will be necessary for this project.

In addition, an intersection of particular concern is the eastern intersection of Cook-Underwood Road and SR-14. WRE’s initial application states that road construction, including road widening, “would be required” at this intersection in order to provide a sufficient turning radius for oversized trucks hauling wind turbine components. Original Application at 4.3-13. WRE provided specific numbers for the necessary width of the inside turning radius. *Id.* According to WRE, “[w]idening would include removal of guardrail and an engineered fill section on the inside of the turn, and an engineered fill section and a possible embankment cut section.” *Id.* In addition, “[t]he engineered fill and embankment cut sections . . . would require an all-weather driving surface.” *Id.* Finally, “[r]ight of way ownership and easement determination would be required.” *Id.*

Then, after Appellants filed an appeal with the Gorge Commission of the County’s decision on the initial application, WRE abruptly made a 180-degree reversal on whether road construction is required at this intersection. Even though WRE still proposes to use this intersection as part of its preferred haul route, WRE in the amended application has deleted all language discussing the necessary road work and replaced it with language summarily concluding that no road construction will be necessary along the haul route. Amended Application at 4.3-14. When asked to explain the rationale behind these discrepancies, WRE merely stated in its November 6, 2009 letter that “[n]o roadway improvements *have been identified* as being needed at either the west or east intersection of SR-14 and Cook-Underwood

Road.” (emphasis added). This unhelpful statement completely ignores, and is in fact contradicted by, WRE’s previous statements that road improvements at the east intersection “*would be required.*” Original Application at 4.3-7 (emphasis added).

The western intersection of Cook-Underwood Road and State Route 14 is also important. The Applicant has proposed to use this intersection as part of the haul route, but has also not shown that road improvements at this intersection would not be necessary.

These distinctions are important, because if this project does in fact involve road construction or ground-disturbing activities within the GMA, such activities must be reviewed by Skamania County under the Scenic Area laws and rules for whether they are allowed and for the protection of resources. SCC § 22.06.010.

The agencies need to require better information about the proposed haul route, and resolve whether any road work would in fact be necessary. If so, Scenic Area review and a decision by Skamania County will be required.

V. The Environmental Impact Analysis in the DEIS is Seriously Deficient.

A. The DEIS Fails to Give Adequate Consideration to Cumulative Effects.

The consideration of cumulative effects in the DEIS is inadequate. A cumulative impact is the “impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions.” 40 C.F.R. § 1508.7. NEPA requires that an EIS assess cumulative impacts in sufficient detail to be “useful to a decision maker in deciding whether, or how, to alter the program to lessen cumulative impacts.” *City of Carmel-By-The-Sea v. U.S. Dep’t. of Transp.*, 123 F.3d 1142, 1160 (9th Cir. 1997). The cumulative impacts analysis for a proposed project must examine past, present, and proposed/reasonably foreseeable actions in the same area. 40 C.F.R. §§ 1508.7, 1508.25, 1508.27(b)(7); *Tomac v. Norton*, 433 F.3d 852, 864 (D.C. Cir. 2006).

Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. 40 C.F.R. § 1508.7. “To consider cumulative effects, some quantified or detailed information is required. Without such information, neither the courts nor the public, in reviewing [an action agency’s] decisions, can be assured that the [agency] provided the hard look that it is required to provide.” *Neighbors of Cuddy Mountain v. U.S. Forest Service*, 137 F.3d 1372, 1379 (9th Cir. 1998). The cumulative effects of the proposed action, combined with the cumulative effects of other proposed actions, must be described in detail. *Muckleshoot Indian Tribe v. U.S. Forest Service*, 177 F.3d 800, 810 (9th Cir. 1999). Broad and general statements “devoid of specific, reasoned conclusions” are not sufficient; neither are one-sided cumulative impact statements. *Id.* at 811.

As an initial matter, the geographic scope used in the DEIS to examine cumulative impacts is internally inconsistent and arbitrary and capricious. On the very same page (1-36), the DEIS contains two different geographic standards for measuring cumulative impacts. First, under Existing Development, the DEIS properly sets the geographic scope for wind power development as extending from Cascade Locks to the intersection of I-84 and I-82. Then, on the very same page, under Reasonably Foreseeable Future Development, the DEIS arbitrarily limits itself to projects within 20 miles from the Whistling Ridge project site. This internal inconsistency is arbitrary. Many of the existing wind projects more than 20 miles away contribute to adverse cumulative effects in conjunction with the proposed Whistling Ridge project. For instance, these existing wind projects can be seen in same viewshed as the Whistling Ridge site, as viewed from locations within the Gifford Pinchot National Forest such as Little Huckleberry Mountain. The arbitrary limit of 20 miles also means that certain pending projects such as Windy Flats West, which may have similar impacts on the National Scenic Area to those

of Whistling Ridge, but which is 26 miles away, are being improperly excluded from the impacts analysis.

The attempt in the DEIS at identifying and evaluating the cumulative impacts is sorely lacking. The DEIS fails to consider adequately the past, present, and reasonably foreseeable future impacts of other projects in the area. First, the DEIS does not adequately catalogue or discuss the impacts of past projects on the area, as it is required to do under NEPA. *City of Carmel*, 123 F.3d at 1160. Rather, it arbitrarily limits itself to considering only other wind projects, and even then relies on a rough and incomplete list of existing wind projects that discusses generalities, without providing the information necessary to complete the reasoned analysis that NEPA requires. Second, the DEIS fails to catalogue or analyze the impact of numerous planned or ongoing development projects, including wind projects and other types of projects.

For example, the DEIS fails to consider the cumulative impacts of the proposal in relation to the following planned and ongoing projects:

- The DEIS, at pages I-36 and 3-265–266, relies only on a wind power map and list found at <http://www.nwcouncil.org/maps/power/Default.asp>. The map relied on by the DEIS is severely incomplete, missing multiple wind energy projects within the project study area, including but not limited to Windy Flats West, Windy Flats, Windy Point II, Miller Ranch, Hactor Ridge, Imrie, Linden Ranch, Miller North, Windtricity, Harvest Wind, School Section, Golden Hills, Golden Hills Addition, Golden Hills 2, Golden Hills 3, Biglow Canyon 2, Biglow Canyon 3, Nook Wind, Star Point, Shepherds Flat, Shepherds Flats 2, Shepherds Flat 3, Shepherds Flat 4, Shepherds Flat 5, Pebble Springs, Willow Creek, Montague I,

Montague II, Condon Wind, Summit Ridge, Baseline, Saddle Butte, Echo Wind, and PáTu. The DEIS fails to consult multiple other maps and lists of wind projects in the region, let alone the documents pertaining to those projects such as environmental impact statements. As a result, the cumulative impacts of this project in conjunction with other wind projects in the region is grossly underestimated. Maps and lists of other wind projects can be found at <http://www.klickitatcounty.org/planning/FilesHtml/windprojects.pdf>, <http://www.oregon.gov/ENERGY/SITING/review.shtml>, and http://www.transmission.bpa.gov/PlanProj/Wind/documents/BPA_wind_map_2010.pdf and are being filed as Exhibits herewith.

- The applicant here, Whistling Ridge Energy, desires to construct an additional 35 turbines on DNR lands immediately adjacent to the north of this project. This project, known as “Saddleback” or “Whistling Ridge Phase II,” has been placed on hold by the DNR, but that hold could be removed at any time. The DEIS states that “use of these lands for project turbines was rejected from further consideration.” DEIS at 1-14. However, recent public records requests have uncovered new evidence that the use of DNR lands is still contemplated by WRE. Specifically, the attached April 9, 2010 email shows that WRE was evaluating whether a temporary FAA moratorium on certain wind projects would prohibit expansion onto the DNR lands. The DEIS fails to sufficiently address the likelihood of Phase II of this project going forward, and fails to address the cumulative impacts of expanding the scope of this project onto the adjacent land. All phases and portions of a project must be evaluated at the outset during

environmental review of the first phase. *See Merkel v. Port of Brownsville*, 8 Wn. App. 844, 850–51, 509 P. 2d 390, 395 (1973); *Indian Trail Property Owner's Ass'n v. City of Spokane*, 76 Wn. App. 430, 443, 886 P.2d 209 (Wn. App. 1994).

- The Broughton Lumber Company has proposed a 250-unit housing development and recreation resort at the site of its defunct lumber mill in Skamania County, Washington. The site is in the same viewshed as the proposed Whistling Ridge Project.
- A casino is proposed in Cascade Locks, Oregon. If built, it would induce unprecedented amounts of traffic through the National Scenic Area. The cumulative impacts of this project, including the high volumes of casino traffic in conjunction with the heavy and oversized load truck traffic potentially travelling along I-84 for the Whistling Ridge project, was not considered.
- Every year, multiple residential dwellings are approved in the same viewshed as the proposed Whistling Ridge Energy Project. This cumulative scenic impact is not even mentioned, let alone estimated, by the DEIS.
- The DEIS acknowledges that the footprint of the project is within working timber lands, but fails to discuss the cumulative impacts of clearcutting forest in conjunction with permanently converting forest land for industrial use.

Washington DNR Forest Practice applications in the vicinity of the project include FPA 2702000, FPA 2702622, FPA 2702784, FPA 2702862, FPA 2703252, and FPA 2704427. The DEIS does not address the cumulative impacts of the massive clearcutting that has occurred or the impacts of those forest practices in conjunction with converting forest land to non-forest use.

- In addition to the forest practices in the immediate vicinity of the project, the DEIS must include evaluation of impacts of the project in conjunction with forest practices in the region. To date the northern spotted owl habitat conservation plan is not succeeding in recovering northern spotted owl populations. Since this project would permanently convert forest land within a Spotted Owl Special Emphasis Area (SOSEA) to non-forestry use, the DEIS must undertake additional analysis of how the industrialization of portions of the SOSEA will affect spotted owl populations within the entire SOSEA and the region.
- The Blue Bridge Pipeline has been proposed to be constructed in the vicinity of the project. This proposal is currently under review by the Federal Energy Regulatory Commission under Docket No. PF09-10-000. The project could involve permanent linear clearcuts in the vicinity of the project.
- Three towns in the Columbia River Gorge National Scenic Area have proposed expansions of their urban area boundaries into Scenic Area lands. These are Hood River, The Dalles, and Lyle. If approved, these urban expansions would result in population growth, more traffic, loss of farm land, forest land, open spaces, and likely adverse effects to scenic, natural, cultural and recreation resources.

These projects and others not analyzed in the DEIS will have cumulative impacts on environmental and socioeconomic factors. In order to adequately evaluate the impacts of the proposed project, the DEIS must consider these current projects. Failure to do so means that the DEIS lacks sufficient detail to allow a decision maker to meaningfully evaluate the full impacts of the proposed project or to decide how to alter the proposal to lessen cumulative effects.

Also, as explained in the attached expert analysis by Dr. Shawn Smallwood, the cumulative impacts analysis in section 3.14.3.5 of the DEIS is methodologically flawed and the conclusions are misleading. Similarly, the cumulative impacts analysis of visual resources in section 3.14.3.10 of the DEIS is methodologically flawed and the conclusions are in error. Landscape architect and expert in visual resource assessment methodologies Dean Apostol has analyzed the DEIS and found the visual analysis woefully lacking and not up to professional standards. For example, the scenic resources cumulative impacts analysis evaluates only impacts to travelers on Interstate 84. While it underestimated the impacts to these views, it completely ignores the impacts to travelers on the Historic Columbia River Highway, the Columbia River, and other recreational resources in the vicinity. The cumulative impacts portions of the EIS are woefully inadequate and do not meet NEPA's or SEPA's requirements to conduct a rigorous and thorough analysis of cumulative impacts.

B. The DEIS fails to consider the direct and cumulative impacts of the proposed development on the energy grid and its infrastructure, and resulting impacts to natural resources.

Under SEPA, the elements of the environment include the built environment, which in turn includes public services and utilities. WAC 197-11-444(2)(d). The energy grid is part of the built environment and impacts to the grid must be considered during the SEPA process. The DEIS failed to adequately analyze impacts to the grid.

The DEIS discusses the need for the project to interconnect to the BPA transmission system, but fails to analyze the indirect and cumulative effects of new wind energy development on the grid and the need for new transmission facilities. DEIS at 3-87—92, 3-278. The DEIS states that the “proposed project would not be expected to affect the operation of the BPA’s

transmission system.” DEIS at 3-92. The cumulative impacts section of the DEIS makes no mention of the grid or how the project would affect demand for new transmission facilities.

Wind energy production in the region will ultimately be limited by the capacity of the Bonneville Power Administration to integrate new wind energy resources into the BPA electricity grid. Recently, BPA expressed concern about how it will reliably integrate over 6,000 MW of wind energy by 2013. Northwest Power and Conservation Council, Sixth Power Plan, at 12-11 (available at <http://www.nwcouncil.org/energy/powerplan/6/default.htm>). By adding more energy to the grid, the project increases the need for more capacity and more transmission lines and other infrastructure.

In response to the rapid development of wind energy in the region in recent years the BPA has proposed several new transmission projects. These projects are necessary to integrate the intermittent nature of wind energy and to ensure sufficient transmission capacity to transmit energy to the region and markets in other regions. BPA’s own development plans demonstrate that the Whistling Ridge Energy Project would contribute to demand for transmission facilities and contribute to significant adverse impacts to the environment.

The BPA’s own documents, some of which are attached hereto as exhibits, explain that the McNary-John Day transmission project and the Big Eddy-Knight transmission project are needed to respond to the demands that new wind energy facilities place on the grid.

To respond to the increased demand for interconnections to the grid, the BPA conducts annual Network Open Seasons where prospective energy producers can submit Transmission Service Requests (TSRs) to BPA. From these requests the BPA offers eligible producers Preferred Transmission Service Agreements (PTSAs). Based on these agreements the BPA calculates the demand for transmission services and the need for any new transmission facilities.

As shown in the attached exhibits, in response to the 2008 Network Open Season, the BPA signed PTSAs securing 6,410 MW of transmission capacity. And in response to the 2009 Network Open Season the BPA signed PTSAs securing 1,553 MW of transmission capacity. In 2010 alone the BPA received TSRs for 4,456 MW of wind energy development that would be eligible to sign PTSAs. If all eligible PTSA are signed and completed, the total new services provided by BPA will total over 12,000 MW, generate the need for hundreds of miles of new transmission lines, and the expenditure of millions of dollars in public funds. The Whistling Ridge Energy Project Project would directly contribute to these impacts. The DEIS must acknowledge and evaluate these impacts and the further impacts that flow from them.

The BPA must include actual data on the grid's capacity to accommodate new sources of intermittent wind energy. As stated above, the BPA has previously expressed concern about how it will reliably integrate over 6,000 MW of wind energy by 2013. Northwest Power and Conservation Council, Sixth Power Plan, at 12-11. The DEIS must include some analysis of how much wind energy the grid can accommodate over the long-term and whether wind integration capacity will limit the amount of wind energy development that can occur in the region. If integration capacity will limit generation potential, then the DEIS must address why the Whistling Ridge Energy Project should take priority over potential development in other locations that would have reduced environmental impacts.

Importantly, the BPA has failed to undertake comprehensive review of the impacts of its transmission system. The BPA's last comprehensive review of the transmission system was in 1995. BPA Business Plan Final Environmental Impact Statement (DOE/EIS-0183) (hereinafter "BPA BP EIS"). That review noted that wind energy could cause adverse impacts to wildlife and scenic resources, but did not undertake any detailed review of how providing access to the

transmission system would lead to impacts from the explosion of wind energy development throughout the region. BPA BP EIS at 4-42, Section 4.3.1. The BPA BP EIS also does not address how much wind energy can be integrated into the grid.

In 2007, the BPA undertook a supplemental analysis of the Business Plan EIS, but declined to undertake further environmental review. Supplemental Analysis of the Business Plan EIS (DOE/EIS-0183) (April 6, 2007). The supplement stated that “continued consideration of a comprehensive policy for BPA’s transmission business is not in the best interests of the agency at this time.” The supplemental analysis was based on four wind projects totaling 750 MW of wind energy that had been connected to the BPA grid at that time. *Id.* at 42. The analysis did not discuss impacts to wildlife from this development. *Id.* at 46. The analysis did not include a section on scenic impacts, much less how wind energy development enabled by the BPA has transformed scenic landscapes. The supplemental review also failed to acknowledge the ongoing impacts to cultural resources from the development that has been enabled by BPA transmission project. *Id.* at 48—49.

Since the BPA’s last review of the environmental impacts associated with the transmission system and the energy production that system allows, an unprecedented level of new wind energy development was occurring throughout the region. Currently over 3,000 MW of wind energy has been interconnected to the grid. The BPA has signed PTSAs for as much as 12,000 additional MW of new generating capacity.

The impacts of this development have dramatically changed landscapes throughout thousands of acres of rural Washington and Oregon along with countless scenic vistas. This development is also killing or displacing an unknown number of birds and ongoing damage to cultural resources is occurring from the excessive ground disturbance and road building. Another

type of impact not anticipated or reviewed in the EIS is the potential overloading of the energy grid as a result of the dramatic increase in wind energy in the region, which can in turn affect fish populations by requiring an excess spilling of water over the region's hydroelectric dams in order to balance out unexpected surges in wind energy production.

This rapid expansion in wind energy has occurred without any programmatic review of the impacts of the generating sources, the existing transmission system, or the demands for new transmission lines. This has also occurred without an adequate understanding of how much wind energy development the grid can accommodate and how projects could be prioritized for grid access based on environmental impacts. These significant changes warrant preparation of a comprehensive cumulative impacts analysis. The DEIS must be substantially revised to reflect the project's contributions to the regional impacts of wind energy development.

C. The DEIS Fails to Adequately Evaluate and Address the Impacts of the Proposed Development on Scenic Resources.

SEPA requires that the environmental analysis include discussion of impacts to sensitive areas. The SEPA official "shall" consider whether a "proposal may to a significant degree . . . [a]dversely affect environmentally sensitive or special areas, such as loss or destruction of historic, scientific, and cultural resources, parks, prime farmlands, wetlands, wild and scenic rivers, or wilderness." WAC 197-11-330(3)(e)(I). SEPA also requires analysis of impacts to scenic resources. WAC 197-11-440(1)(e)(iv).

The current proposal is for a major industrial development towering over ridgelines on the perimeter of the Columbia River Gorge National Scenic Area, overlooking important segments of the Lewis and Clark National Historic Trail and the Historic Columbia River Highway, adjacent to the Gifford Pinchot National Forest, and adjacent to recreational trails on Washington Department of Natural Resources land. The proposed facility would overlook miles

of National Scenic Area viewsheds that have been inventoried as some of the highest quality scenic landscapes in the Gorge.

Unfortunately, the DEIS grossly mischaracterizes the likely impacts of the Whistling Ridge Energy Project on scenic resources. Instead of following SEPA's mandate to provide an unbiased and objective assessment of likely impacts, the DEIS blatantly misapplies established principles of landscape management to conceal the likely impacts of the proposed action. The analysis also violates NEPA's requirement that "[a]gencies shall insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements." 40 C.F.R. 1502.24. The DEIS does not list a single landscape architect, much less a landscape architect with training in scenic resource analysis methodologies, in the list of preparers. DEIS at Section 6.0. The lack of professional and scientific integrity is plainly evident through the scenic impacts analysis. The analysis is fundamentally flawed and violates both NEPA and SEPA.

As explained in the attached comments of Dean Apostol, the analysis completely misinterprets and misapplies the Federal Highway Administration's visual assessment system and the Forest Service's Scenery Management System. In addition, the analysis fails to consider impacts to several critical viewpoints and view corridors, reaches erroneous conclusions regarding the potential impacts on scenic resources, and fails to consider viable mitigation measures. Mr. Apostol concludes that the likely scenic impacts of the project would be significant because the project would highly contrast with an intact, high quality scenic landscape that is viewed by substantial number of viewers with high expectations for scenic quality. The project would break the skyline and/or be highly visible from multiple public vantage points and it is impossible to "blend in" wind turbines more than 400 feet tall into this

landscape. The DEIS also erroneously ties scenic sensitivity to distance zones. DEIS at 3-159. Low, moderate, and high impacts can occur in any distance zone depending on the impacts analysis.

The environmental review failed to sufficiently analyze the visual impact of the project as viewed from linear viewing areas such as Interstate 84, the Columbia River, the Historic Columbia River Highway, the Lewis and Clark National Historic Trail, and State Route 141. For some of these scenic corridors basic information such as the distance along linear viewing areas from which the project would be visible, an estimate of the amount of time the project would be visible when traveling along these view corridors, and a simulation of the most visible portion of the project as viewed from these viewing areas is missing from the analysis. Of particular concern is the complete absence of any analysis of views from the Columbia River and the Historic Columbia River Highway.

The DEIS also fails to supply sufficient information to understand and review potential impacts from lights on the proposed wind turbines—particularly nighttime impacts. DEIS at 3-161, 3-173, & 3-195. While FAA lighting standards may be required, compliance with federal regulations does not obviate the duty to comply with state law requiring full disclosure of all environmental impacts. The applicant must document how many lights would be visible from within the National Scenic Area viewshed. The applicant needs to provide additional information regarding what type of lighting would be installed, and which turbines would likely contain lighting. Without this information, it is impossible to accurately evaluate the scenic impacts of the project.

The DEIS also fails to include a detailed explanation of both the methodology used to create the visual simulations and the proper technique for viewing the simulations. To begin

with, all visual simulations should be accompanied by substantial disclaimers regarding their ability to depict real-world impacts. Two dimensional renderings can never accurately simulate the experience of real-world views. Nonetheless, visual simulations do have value in evaluating aesthetic impacts if best practices are used in preparing the simulations and proper qualifications are noted. Lens size, field of view, the format of the image in the simulations, and the viewer's distance from the image all play critical roles in presenting an accurate depiction of aesthetic impacts. For example, the wider the angle of view of a camera lens, the further away an object appears, and the narrower the angle of view, the nearer an object appears. If digital cameras were used, image distortions would need to be factored in when preparing the image. Similarly, the size of the simulation image and the viewer's distance from the image can dramatically alter the perceived impacts of development. EFSEC and the BPA must require clarification on these points to ensure that the inherent flaws in visual simulations are explained.

EFSEC and the BPA should also consider the National Academy of Sciences' recent document entitled, *Environmental Impacts of Wind-Energy Projects* (National Academies Press, 2007), which includes methodology for analyzing possible impacts from wind development on aesthetic resources. The DEIS should be revised to include discussion of the various standards described in this resource, which was cited and applied in other sections of the DEIS.

The DEIS argues that the visual impacts from roads and electric lines would be negligible. DEIS at 3-173–3-174. However, road and power lines have direct visual impacts and also contribute to the cumulative impacts of a project. As such, they must be included in the visual simulation and analysis. In particular, road and electric lines would likely be highly visible when viewed from recreational areas to the north of the project. These include recreational trails in the Gifford Pinchot National Forest and on land owned by the Washington Department of

National Resources. Particular recreational areas of concern include the Nestor Peak, Little Buck Creek Trail, Grassy Knoll, Little Huckleberry Mountain, and Cook Hill.

The conclusions regarding scenic impacts in the application are clearly in error. The project would have high scenic impacts, given viewer expectations, and the quality of the views that would be impacted. The proposed development would dominate the middleground and background views from multiple important viewpoints.

Not only did the DEIS fail to adequately review scenic impacts, it also failed to propose any mitigation or discuss any unmitigated adverse impacts that would occur. Measures and conditions that should have been, but were not, evaluated include alternate designs and siting to reduce visibility.

////

1. The DEIS Fails to Acknowledge Existing Scenic Resource Inventories and Visual Quality Objectives for the Affected Landscape.

The DEIS analysis of scenic impacts states that visual quality objectives (VQOs) have not been established for the landscape that would be affected by the proposed development. DEIS at 3-156. This assertion is demonstrably false. The Forest Service and Gorge Commission have established VQOs for the landscapes that would be affected by the proposed development. These VQOs are based on some of the most extensive and complete scenic resource inventories in the country. These VQOs must be used to measure the impact to viewsheds that would be altered by the proposed development.

In preparing the Management Plan for the National Scenic Area, the Gorge Commission and the Forest Service were required to inventory scenic resources of the National Scenic Area. *See* 16 USC 544d.(a)(1)(A). Pursuant to that mandate the Forest Service and Gorge Commission completed a scenic resource inventory using the Forest Service's Visual Management System

("VMS"), which is the scenic resource management methodology provided in the Forest Service's "National Forests Landscape Management Vol. 2" (Agriculture Handbook 462).⁵

All viewsheds visible from primary key viewing areas were inventoried. These inventories served as the basis for all scenic resource management policies and guidelines in the CRGNSA Management Plan. The original scenic resource inventory includes the following elements: Visual Attributes, Landscape Diversity, Landscape Significance, Seen Areas from Key Viewing Areas, Visual Absorption Capability, and Landscape Sensitivity. The 1991 CRGNSA Management Plan described the inventories:

Six maps were developed in the process of inventorying scenic resources. These maps are based on the Forest Service Visual Management System. They have been used to develop policies and guidelines that respond to the various levels of visual significance and sensitivity within the Gorge, and that highlight protection of landscapes seen by large numbers of people.

The first inventory map created, "Visual Attributes," identifies 12 predominant landscape types found in the Gorge, ranging from rural townscapes to cliffs.

The "Landscape Diversity" map gauges the variety of visual features in the landscape. A basic premise of the visual management system is that visual diversity is a key element of those landscapes people find most visually appealing and interesting. Much of the Gorge, with its steep landforms, forested slopes, waterfalls, pastoral areas, and rural townscapes, has outstanding visual diversity.

A "Seen Areas" map shows which areas are visible from key viewing areas. The key viewing areas are important public vantage points from which Gorge landscapes are viewed. Scenic protection of lands seen from these vantage points has been emphasized since the inception of the Scenic Area planning process. The Management Plan continues this direction.

The "Landscape Significance" map combines the "Seen Areas" and "Landscape Diversity" maps, based on the concept that the most significant landscapes are those that are both visually diverse and seen from important viewpoints. The "Visual Absorption Capability" map displays the relative ability of different Gorge landscapes to absorb change (through new development) without

⁵ The Visual Management System has since been superseded by a revised methodology, the Scenery Management System ("SMS"). The methodology for the SMS is described in "Landscape Aesthetics: A Handbook for Scenery Management." (Agriculture Handbook 701).

diminishing their scenic qualities. It is based primarily on the degree of slope and amount of vegetative cover.

“Landscape Sensitivity,” the last of the six inventory maps, combines “Landscape Significance” with “Visual Absorption Capability,” based on the assumption that the most visually sensitive lands are those that are both highly significant and most vulnerable to visual impacts from new development.

CRGNSA Management Plan 1991, at I-1—2. Copies of the inventory maps of the affected landscape are attached to these comments. The CRGNSA Management Plan policies and guidelines that were based on these inventories include the land use designations and landscape setting designations that serve as VQOs.

This background is critical to evaluating the impacts of the proposed development on scenic resources. As seen from the Columbia River, Interstate 84, and the Historic Columbia River Highway the project would break the skyline within viewsheds composed of both SMA Open Space and GMA Open Space land use designations that are also assigned the landscape setting of Gorge Walls, Canyon Lands, and Wildlands. For the SMA viewsheds the applicable VQO is retention, the highest level of scenic protection afforded any landscape in the Gorge. For the GMA viewsheds the applicable VQO is partial retention, with the added protection essentially creating a VQO of retention.

The view from Interstate 84, the Columbia River, and the Historic Columbia River Highway between Starvation Creek State Park and Viento State Park looking north and northeast is dominated by the Dog Mountain SMA and the Underwood Bluff Open Space.⁶ The proposed facility would be visible just to the east of the Dog Mountain SMA and north of the Underwood Bluff Open Space area. The attention of visitors traveling along these three scenic corridors would be drawn to the spinning blades and/or blinking lights of numerous wind turbines

⁶ Both Starvation Creek State Park and Viento State Park are also designated under the Lewis and Clark National Historic Trail Management Plan.

protruding above the skyline to the northeast. This would obviously detract from the integrity of the viewshed and completely frustrate the purpose of the extensive inventories and protections for this viewshed.

Stationary viewers at Mitchell Point would also be confronted with a dramatic change to the landscape. The view from the Mitchell Point area looks directly north at the Underwood Bluff Open Space area. The original scenic resource inventories assigned Underwood Bluff as “outstanding” landscape diversity, “primary” landscape significance, and “critical” landscape sensitivity. These are some of the highest valued lands inventoried in the Columbia River Gorge and justified a VQO that is essentially retention, the highest standard for protection. The ridgeline of Underwood Bluff forms the skyline from this viewpoint. The contours of Chemawa Hill undulate immediately behind the skyline and are nearly indistinguishable from the Underwood Bluff skyline. Underwood Bluff and its highest rated scenic resources, with Chemawa Hill immediately behind it, dominate the middleground views from this location. The southernmost turbines of the proposed facility would be sited at the top of Chemawa Hill and would break the skyline of views from the Columbia River, Interstate 84, and the Historic Columbia River Highway at this location. Once again, viewers’ attention would be drawn to giant spinning blades and/or flashing lights in middleground views of some of the most scenically sensitive views in the Columbia River Gorge.

The DEIS completely failed to acknowledge the robust and complete inventory of the scenic landscapes that would be affected by the proposed development. The existing resource inventories and established VQOs must be used to measure the impacts that would be caused by the proposed development. Based on this information, it is undeniable that the proposed development would cause significant adverse impacts to critically important scenic landscapes.

In addition, the DEIS failed to state whether the project would impact views from the Gifford Pinchot National Forest that have established VQOs.

2. The Scenic Impacts Analysis Deviates from BPA's Past Practices in Evaluating Scenic Impacts.

The application and environmental review diverges from the BPA's analyses of scenic impact for other energy projects in the region. The BPA's Draft EIS for the Central Ferry-Lower Monumental 500-kilovolt Transmission Line Project concluded that construction of a 200-foot-tall transmission line within viewsheds as viewed from the Lewis and Clark National Scenic Trail and the Lewis and Clark Scenic Byway would have "high" impacts to scenic resources. Central Ferry-Lower Monumental 500-kilovolt Transmission Line Project DEIS (July 2010) Section 3.7, p 3-91 to 3-104 (hereinafter Central Ferry DEIS). The Central Ferry transmission lines would be 104 to 189 feet tall and would have no moving parts and no lights. Central Ferry DEIS at 2-5. The BPA acknowledged that the transmission line would be visible from the Lewis and Clark National Historic Trail and scenic byways.

The Central Ferry DEIS described the affected landscape as "Typical view[s] of rolling hills and rural landscape adjacent to scenic by way." Table 3-22. The analysis explained that the transmission line would be 1.6 miles (middleground view) from the Lewis and Clark National Historic Trail at its closest point. Central Ferry DEIS at 3-98. The analysis also acknowledged that the transmission lines would create a skyline effect and break up the continuity of the skyline and open terrain, and that the project would introduce structures into a natural landscape. Central Ferry DEIS at 3-98. "The proposed towers and conductors would be a conspicuous change to the relatively natural and rural landscape and would disrupt the continuity of visual resources in the landscape." Central Ferry DEIS at 3-98. The project would be visible from "popular recreation areas and a frequently traveled roadway." Central Ferry DEIS at 3-98.

In comparison to the Central Ferry to Monument Transmission Project, the Whistling Ridge proposal would be located in a higher quality scenic landscape, with more state and federal designations for scenic, recreational, and historic importance. The project would be viewed by vastly more people with higher expectations for scenic quality. Whistling Ridge would be of comparable distance from important viewpoints, but would be over twice as large (over 430 feet tall compared to 104 to 198 feet tall), have more visible mass, include giant moving parts, include flashing lights, and would be painted white. The Whistling Ridge project would obviously contrast more with the landscape than the Central Ferry project. While the Central Ferry DEIS concluded that impacts would be high, the Whistling Ridge DEIS concludes that impacts to scenic resources would be moderate at worst.

It is abundantly clear that this project has not been reviewed under the same standard as previous projects under BPA review. This evidences an obvious attempt to thwart the purposes of SEPA and NEPA with environmental review that seeks to conceal impacts rather than objectively analyze impacts.

The adverse impacts of energy development, transmission lines in particular, were also acknowledged in the BPA's Business Plan EIS. BPA Business Plan Final Environmental Impact Statement (DOE/EIS-0183) (hereinafter BPA BP EIS). The Whistling Ridge would include transmission lines and analysis of impacts from transmission lines is equally applicable to scenic impacts analysis for industrial wind energy development. The Business Plan EIS stated:

In areas used for recreation, particularly in undeveloped places, studies show that many users find transmission lines to be an unwelcome visual intrusion. Also, many citizens feel strongly that transmission lines near their homes are visually intrusive, and that some property values may be reduced. Adverse visual effects may be perceived up to several kilometers from the line. Transmission lines may be more compatible with industrial areas. The effectiveness of potential mitigation measures depends on the site, and some measures may substantially increase the cost of the project. Possible measures include darkened towers in

forested areas; different tower designs more compatible with a particular environment; non-specular (nonshiny) conductor; and locations that avoid visually sensitive areas.

BPA BP EIS at 4-52, Section 4.3.2.6. The Business Plan EIS also explained that one of the main environmental risks of wind energy development is visual impacts. BPA Business Plan EIS at 4-42, Section 4.3.1. The BPA has previously relied on this environmental review when approving interconnections to the grid. How the BPA can acknowledge adverse impacts from transmission lines, but ignore adverse impacts from wind energy facilities, is inexplicable.

3. Views from the Lewis and Clark National Historic Trail would be adversely affected.

The Lewis and Clark National Scenic Trail was created to “stimulate Federal, State, and local agencies and individuals to identify, mark, and preserve for public inspiration and enjoyment the routes traveled by the Lewis and Clark Expedition.” Lewis and Clark Trail Management Plan at 1. The Management Plan for the trail recognizes that many of the historic and cultural resources have been altered or lost and the Expedition left scant traces of their passing. However, “In a very real sense, many of the historic resources are the *landmarks, vistas, flora, and fauna* that make up the Trail’s natural resources. It is virtually impossible to find either historic or natural resources along the Expedition route, which have not been altered in some way by man or nature.” Lewis and Clark Trail Management Plan at 4 & 13. Thus, the scenic vistas and natural resources of the Expedition route are critical to appreciating the trail. Locations where those vistas and natural resources are intact are exceedingly rare, and warrant the greatest attention during SEPA and NEPA review.

The Columbia River segment, which includes the portions of the Trail that would be affected by the Whistling Ridge project, was designated for three types of trail development: a water trail, a land trail, and a motor route. The Columbia River, Interstate 84 and Washington

State Route 14 are designated routes. The Management Plan notes that there was a “nearly continuous string of recreation sites along this segment.” Lewis and Clark Trail Management Plan at 70. Individual sites within sight of the Whistling Ridge Energy Project include Viento State Park, which is directly across the Columbia River from where the Lewis and Clark Expedition camped on October 29, 1805 and April 13, 1806, and Starvation Creek State Park. L & C Management Plan at 74.

The DEIS fails to acknowledge adverse scenic impacts to the Lewis and Clark National Scenic Trail. Locations along the route with intact scenic vistas that retain some of the same views that the Lewis and Clark Expedition experienced are critical important resources for the trail system. The views from I-84, the Columbia River, Viento State Park, and Starvation Creek State Park are largely intact as evidenced by the Forest Service’s resource inventories. The project would dramatically alter these views causing significant adverse impacts to the trail. This conclusion was clearly expressed by the National Park Service in at least two separate letters to the BPA and EFSEC. This conclusion is also supported by the BPA’s previous environmental analysis of other projects that would have similar, although less severe, impacts on the Lewis and Clark National Historic Trail. The egregious failure to acknowledge significant adverse impacts to the Lewis and Clark National Historic Trail must be corrected.

D. The DEIS Fails to Adequately Review the Likely Impacts of the Proposed Development on Natural Resources.

The Whistling Ridge project is likely to cause significant adverse impacts to natural resources, including the direct impacts of mortality to wildlife, as well as indirect effects from habitat destruction, displacement, and species avoidance of the project area after construction. Avian species often collide with wind turbines, and bats often die from internal hemorrhaging caused by the massive changes in air pressure near the spinning blades of a wind turbine, a

process known as “barotrauma.” Also, components of the industrial development, including collector lines, transfer stations, and access roads, can displace wildlife and fragment habitat. The DEIS failed to adequately analyze the likely impacts to wildlife and other natural resources.

In addition, as demonstrated in the written testimony of Dr. K. Shawn Smallwood (attached herein), the underlying data and environmental analysis relied upon in the DEIS is severely flawed. For example, without any scientific support the DEIS states that the clearcut project area is poor habitat for wildlife. However, Dr. Smallwood points out that “[b]ird species diversity is much greater at Whistling Ridge than at the Altamont Pass, where bird fatalities caused by wind turbines are notoriously high.” Whistling Ridge surveys found more than 1 species per hour of searching, whereas surveys at Altamont found 0.036 species per hour. The proponents’ ploy to clearcut the land and present a devastated ecosystem immediately before applying for an industrial energy facility is misleading and results in biased conclusions in the DEIS. As Dr. Smallwood concluded, based on independent analysis of the proponent’s own surveys, “Whistling Ridge exhibits a very high level of ecological integrity.” This is likely a result of the projects location within a largely intact ecoregion where species diversity remains high. This is also why the Klickitat County Energy Overlay Zone excluded forested areas.

Dr. Smallwood also points out contradictions between foundational statements and the conclusions in the DEIS. For both Keen’s myotis and Townsend’s big-eared bat, the DEIS states that the analysts had insufficient knowledge of the species, but nonetheless concluded that it was unlikely that they would occur at the site. DEIS at 3-59–60. It is plainly inappropriate to base conclusions on insufficient information. At best, the DEIS should say that impacts to bat species are unknown and then analyze the worst case scenario given that uncertainty..

The DEIS seriously underestimates the potential impacts of this project, both on an individual basis and when considered cumulatively with other wind energy projects. Dr. Smallwood has determined that the baseline studies to assess impacts were cursory and inadequate, the likely impacts to raptors are significant, the cumulative impacts analysis was biased and unrealistic, and the mitigation measures are inadequate.

The DEIS also failed to ensure the protection of wildlife and has failed to adequately review impacts to natural resources in a number of other ways, as described below.

1. The DEIS Fails to Include Best Available Science in the Analysis.

The avian impacts analysis is inadequate and not based on the Best Available Science. The baseline surveys were too cursory to support a scientifically credible baseline assessment. Failings include an inadequate sample and an inadequate amount of time dedicated to surveys. Avian utilization of a site can vary greatly from year to year, so the limited time span of these baseline surveys introduces large uncertainty into the resulting utilization rates. The sample sizes were grossly inadequate for what is needed for comparing bird utilization among project sites or for guiding wind turbine locations to minimize collision rates. Numerous other methodological errors in the analysis introduce additional biases that undermine the SEPA and NEPA review.

Wildlife surveys should be conducted using current state-of-the-art field and analysis protocol. At the least, surveys must take into account survey bias including, but not limited to, searcher efficiency, carcass “life expectancy” or persistence, and scavenger removal. The entire site should be surveyed before and after construction. Both pre-development survey and post-development monitoring should take into account the episodic nature of some bird migrations and nocturnal bird migrations. For example, long or inappropriately timed intervals between searches may miss a significant avian presence. The DEIS fails to account for these factors.

2. The DEIS Fails to Adequately Consider Displacement Effects on Avian Populations.

The DEIS failed to adequately consider displacement effects on avian populations.

Impacts of wind projects on birds are not limited to collisions. When a landscape is industrialized by strings of giant machines, birds and other animals may be driven away rather than killed. And when multiple such strings are concentrated in one area, the impacts on species populations can be substantial. The environmental analysis is incomplete and must be supplemented with specific assessments of cumulative displacement impacts.

3. The DEIS Fails to Ensure Compliance with the Federal Endangered Species Act of 1973 (“ESA”), 16 U.S.C. §§ 1531–1544.

Under the ESA, “take” is defined as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct.” 16 U.S.C. § 1532(19).

Section 9 of the ESA prohibits both acts that would “take” a species, as well as acts that would cause an act that constitutes a “taking.” The Ninth Circuit has held that “a habitat modification which significantly impairs the breeding and sheltering of a protected species amounts to ‘harm’ under the ESA.” *Marbled Murrelet v. Babbitt*, 83 F.3d 1060, 1067 (9th Cir. 1996). The DEIS failed to demonstrate that the project will be in compliance with Section 9 of the ESA.

The DEIS does state that there has been ongoing consultation with U.S. Fish and Wildlife Service. DEIS at 1-20. Pursuant to NEPA regulations the BPA is supposed to perform this consultation requirement “concurrently with and integrated with” preparation of the Draft EIS, not after the Draft EIS is complete. 40 C.F.R. § 1502.25. The results of this consultation process should have been included in the DEIS.

In Section 2.20.2.2 of the Amended Application, the Applicant states that a Biological Assessment will be prepared. The DEIS fails to make good on this promise. BPA and EFSEC

must ensure that a biological assessment is prepared, to better inform the agencies about potential adverse impacts to threatened and endangered species.

4. The DEIS Fails to Ensure Compliance with the Bald Eagle Protection Act, RCW Chapter 77.12, and Regulations Promulgated Pursuant Thereto, Located at WAC 232-12-292.

The DEIS fails to ensure compliance with the state Bald Eagle Protection Act, despite the presence of bald eagles and their habitat within and near the project site. There is no evidence that the Washington Department of Fish and Wildlife has been consulted pursuant to the Bald Eagle Protection regulations.

5. The DEIS Fails to Ensure Compliance with the Federal Bald and Golden Eagle Protection Act, 16 USC § 668–668d.

The DEIS fails to ensure compliance with the federal Bald and Golden Eagle Protection Act (“BGEPA”), again despite the presence of bald eagles and their habitat within and near the project site. The BGEPA prohibits any person, association, partnership or corporation from taking a bald or golden eagle at any time or by any manner without a permit. 16 USC § 668(a). A permit may be issued only if the taking would be compatible with the preservation of the species. *Id.* § 668a.

6. The DEIS Fails to Ensure Compliance with the Federal Migratory Bird Treaty Act, 16 U.S.C. §§ 703–712.

The Migratory Bird Treaty Act (“MBTA”) requires that the U.S. Fish and Wildlife Service (USFWS) enforce the MBTA against “any person, association, partnership, or corporation” that “by any means or in any manner,” pursues, hunts, takes, captures, kills or attempts to take, capture or kill a migratory bird or any part, nest or eggs of any migratory bird. 16 U.S.C. §§ 703, 707. Under the MBTA, a person may take or kill migratory birds only as permitted under USFWS regulations and based on the USFWS’s determination that the take or

kill is compatible with the migratory bird treaties. *Id.* §§ 703, 704. The USFWS's determination must take into account scientific factors such as species abundance and distribution, migratory patterns, and breeding habits, as well as the economic value of birds. *Id.* § 704. The killing of a single migratory bird is sufficient to create criminal liability. *United States v. Corbin Farm Service*, 444 F.Supp. 510 (E.D. Cal), *aff'd*, 578 F.2d 259 (9th Cir. 1978). The killing of a migratory bird does not need to be intentional and the killing can occur "by any means or in any manner." *United States v. Moon Lake Electric Ass'n, Inc.*, 45 F.Supp. 2d 1070, 1075–79 (D. Col. 1999) (upholding the prosecution of a utility for unintentionally electrocuting and killing seventeen birds). The DEIS fails to ensure compliance with the MBTA.

7. Inadequate review of impacts to northern spotted owl populations.

The DEIS states that construction of the proposed facility will not directly impact spotted owl habitat. However, the DEIS fails to address whether the project will adversely affect dispersal habitat and migration corridors that are essential to sustaining genetic diversity of owl populations. For example, the Columbia River Gorge is a likely crossing location for owls moving north and south between Oregon and Washington. The project could also affect the east-west movement of spotted owls between valleys. The DEIS fails to adequately address whether a major industrial energy facility sited within spotted owl territory will adversely affect the species.

The DEIS also fails to address the permanent loss of forested lands within the White Salmon Spotted Owl Special Emphasis Area (SOSEA). The DEIS claims that the project would meet Washington state standards for the retention of sufficient habitat within the SOSEA, but it does not adequately review the impacts of *permanently* converting forest land to an industrial

use, and how that permanent conversion would affect the longterm viability of spotted owl habitat within the SOSEA.

8. Failure to demonstrate sufficient protections for non-avian wildlife and insects.

The application and threshold determination fail to demonstrate sufficient protections for sensitive and rare wildlife species, including a number of sensitive and rare species that the application notes have been observed within the project site. The DEIS also fails to evaluate potential impacts on insects such as butterflies. Here, the impacts are typically not from direct turbine strikes, but rather from habitat disruption or destruction. There are several species of butterflies of particular concern in this area, particularly the rare Western Oak Dusky Wing (*Propertius duskywing*).

9. The DEIS fails to include adequate mitigation measures.

The decisions fail to include adequate mitigation measures to protect wildlife. For example, the DEIS include discussion relating to future surveying for wildlife impacts, but fail to include any conditions that would require any concrete actions in response to actual wildlife impacts.

10. The DEIS misrepresents the climate change and air quality impacts of the project and of the no-action alternative.

The DEIS repeatedly asserts that if the Whistling Ridge Energy Project is not built, then adverse impacts to climate change and air quality would necessarily result. For example, the DEIS states that “[i]f the No Action Alternative is selected, the growing electricity needs of the region would continue to be met through a combination of other renewable development and a combination of additional fossil fuels.” DEIS at 3-21–3-22. This completely false dilemma, in various forms, is repeated throughout the DEIS without any factual support.

In fact, the regional energy system will reduce greenhouse gas emissions and air pollutants regardless of whether this individual project is built, and primarily through conservation measures. The Northwest Power Planning Council's Sixth Power Plan, which will dictate the portfolio of energy production sources for the foreseeable future, has planned to meet 85% of new demand with conservation and efficiency measures over the next 20 years. Sixth Northwest Power Plan Overview at 1. The remaining 15% of new demand would be met with renewables. Notably, this would be achieved even while the Boardman coal-fired power plant is taken offline by 2020.

The Bright Future Report also provides some broader context for the supply and demand aspects of the regional energy grid. Bright Future Report, NW Energy Coalitions, Original Edition, March 2009 – Update 1, July 2009. The Bright Future Report analyzes how the region will meet its energy needs through 2050, factoring in the loss of the Boardman coal-fired power plant, the removal or reduced use of hydropower projects on the lower Snake River, and picking up that lost energy supply through conservation, efficiency, and clean new sources of energy. The Report's bottom line conclusions are that "[t]he region has enough renewable potential to more than meet all current and future power needs" and that the potential for affordable clean energy "[d]warfs" the need. Bright Future Update at 14, 15. Thus, foregoing the 21 average MW of production capacity that would result if the Whistling Ridge project is not constructed would be essentially irrelevant to the overall supply of alternative energy. Furthermore, there is absolutely no evidence in the record showing that the alternative to this particular wind project is continued use of fossil-fuel generation sources or new fossil-fuel generation sources. The real choice is between this particular wind facility and siting other wind facilities in alternative locations with fewer environmental impacts.

Thus, it is inappropriate for the DEIS to compare the likely impacts of a wind energy development to the impacts of fossil-fuel generation sources. The region's climate change goals and air quality goals will be achieved regardless of whether the Whistling Ridge project is constructed. Every statement asserting the false dichotomy between constructing the project and a future with higher carbon emissions and air quality problems must be removed from the DEIS.

E. The DEIS Fails to Adequately Review the Likely Impacts of the Proposed Development on Cultural Resources.

1. The DEIS Fails to Analyze Impacts to Cultural Resources and Fails to Integrate Adequate Consultation with Tribal governments.

The DEIS acknowledges that the BPA has an obligation under Section 106 of the National Historic Preservation Act ("NHPA"), 16 USC 470 et seq., to consult with Tribal governments about the likely impacts of the proposal. DEIS at 4-6. The BPA also explains that the "BPA's 1996 government-to-government agreement with the 13 federally-recognized Native American Tribes of the Columbia basin provides the guidance for the Section 106 consultation process with the Tribes." DEIS at 4-6. The Draft EIS explains that the BPA will conduct formal government-to-government consultation. DEIS at 3-204. The DEIS fails to acknowledge that NEPA regulations also require that the BPA must prepare the Draft EIS "concurrently with and integrated with" the required consultation under the NHPA. 40 C.F.R. § 1502.25(a).

SEPA requires EFSEC to consult with the Yakama Nation as well. Under SEPA, EFSEC is required to consider the likely impacts to cultural resources. "Cultural preservation" is an element of the environment that must be addressed through the SEPA process. WAC 197-11-444. In addition, the environmental checklist, which must be prepared for proposed actions, requires consideration of impacts to cultural resources. WAC 197-11-315; WAC 197-11-960. SEPA also requires that EFSEC consult with agencies with expertise in the impacted

environment. RCW 43.21C.030(2)(d); WAC 197-11-408(2)(a). EFSEC's SEPA regulations also require that EFSEC works with interested agencies throughout the preparation of the DEIS. WAC 463-47-140(5). The Yakama Nation's Cultural Resources Program is an agency with expertise in Yakama Nation cultural resources. Finally, the 1989 Centennial Accord between the State of Washington and federally recognized tribes mandates that EFSEC undertake government-to-government consultation with representatives of the Yakama Nation regarding the measures necessary for adequate environmental review and appropriate mitigation measures.

Based on the above-referenced sources of law, both EFSEC and BPA must engage in direct government-to-government consultation with the Yakama Nation. The BPA has already failed to comply with the NEPA requirements to integrate this consultation into preparation of the DEIS. *See* 40 C.F.R. § 1502.25(a). This consultation should have occurred months ago. Both EFSEC and the BPA have heard testimony from the Yakama Nation explaining that a cultural resources report was submitted in December 2009. There is no legitimate explanation for why this information was not included in the DEIS, which was issued in May 2010, or why government-to-government consultation was not undertaken concurrently with the environmental review process.

Industrial wind energy development in Klickitat County that has proceeded without adequate consultation and review for impacts to cultural resources has led to irreparable harm to cultural resources. This harm is evidenced by a media report in the *Yakima Herald-Republic* on the destruction of cultural resources during the construction of the Windy Point Wind Energy Facility in neighboring Klickitat County, a copy of which is attached hereto. EFSEC and the BPA must not allow this type of mistake to repeat itself. The agencies must perform adequate

consultation, analyze likely impacts, and ensure that Yakama Nation cultural resources would not be adversely impacted by the proposal.

2. The DEIS Fails to Demonstrate Compliance With the National Historic Preservation Act.

The project would be highly visible from the Historic Columbia River Highway (“HCRH” or “Historic Highway”). This invaluable historic treasure, built between 1913 and 1922, was the first road planned as a scenic highway in the United States. Today, the Historic Highway is listed on the National Register of Historic Places, as a Historic District, as a Scenic Byway, and as a National Historic Civil Engineering Landmark by the American Society of Civil Engineers. Even more significantly, the Historic Highway has been designated by the Secretary of the Interior as a National Historic Landmark for its “exceptional value as commemorating or illustrating the history of the United States.” More than other historic places on the National Register, National Historic Landmarks are granted special protection against impacts caused by federal action. Indeed, section 110(f) of the National Historic Preservation Act (“NHPA”) requires federal agencies to undertake, “to the maximum extent possible,” such planning and actions as may be necessary to minimize harm to these properties.

Portions of the Historic Highway are being restored by the Oregon Parks and Recreation Department (“OPRD”) and the Oregon Department of Transportation (“ODOT”) as part of the Historic Columbia River Highway State Trail. Acting on a 1987 directive by the Oregon Legislature to preserve and restore the Historic Highway, ODOT and OPRD are creating a series of long, narrow parks in the Columbia River Gorge that will be open to pedestrians, bicyclists, children, and people in wheelchairs, and closed to all motor vehicle traffic. More detailed information on the HCRH can be found in the “Historic Columbia River Highway Master Plan: HCRH Segments,” a copy of which is attached to these comments.

It is important to note that the BPA is under special obligations with regard to protecting this National Historic Landmark. Section 110(f) of the NHPA provides as follows:

Prior to the approval of any Federal undertaking which may directly and adversely affect any National Historic Landmark, the head of the responsible Federal agency shall, to the maximum extent possible, undertake such planning and actions as may be necessary to minimize harm to such landmark, and shall afford the Advisory Council on Historic Preservation a reasonable opportunity to comment on the undertaking.

16 U.S.C. § 470h-2(F).

Section 106 of the NHPA and its implementing regulations adopted by the Advisory Council on Historic Preservation entitled "Protection of Historic Properties" (36 C.F.R. Part 800), describe agency responsibilities when an undertaking will affect properties listed in the National Register of Historic Places, including National Historic Landmarks.

The Whistling Ridge project would adversely affect views from the Historic Columbia River Highway. The HCRH was built as a scenic highway. Its historic features include design elements that accentuate views of the remarkable scenic landscapes of the Columbia River Gorge. Curves and pullouts in the HCRH were designed to focus the traveling public's attention on scenic landscapes. The highway includes substantial tunneling in numerous places, with tunnels designed to optimize views. The Mitchell Point Tunnel, known as the "Tunnel of Many Vistas," included multiple windows that presented views of the Columbia River, Underwood Bluff, Dog Mountain, the mouth of the Little White Salmon River,

and the diverse array of vegetative and geologic textures on these landforms. East of Mitchell Point, the HCRH traversed parallel to Underwood Bluff and crosses Ruthton Point, where the curve of the road presents spectacular views of the Columbia River, Underwood Bluff, and Dog Mountain, along with rural pastoral land above Underwood Bluff.

Other important segments of the HCRH include the segment between Starvation Creek and Viento State Park, which have the added importance of being part of the Lewis and Clark National Historic Trail. The HCRH segments from Hood River heading east include the Hood River Loops and the Mark O. Hatfield West Trailhead. This segment also includes spectacular views of the Gorge, particularly Underwood Bluff, Chemewa Hill, and Underwood Mountain to the north and northwest. To the east of the Mark O. Hatfield West Trailhead is the fully restored Hood River to Mosier segment of the HCRH. Several tunnels along this stretch have been reopened, fulfilling the plans of the HCRH Master Plan and setting an example for the ultimate

goal of restoring the entire Highway for recreation and historical interpretation. While the views from the West Trailhead to Mosier become more distant from the project the views are nonetheless highly important to the HCRH. Impacts from these locations are also likely to be high.

While the “Tunnel of Many Vistas” was destroyed during the construction of Interstate 84, segments of the original HCRH are present through this area. The sections that were lost are currently being restored and recreated through ongoing efforts of ODOT, the Oregon State Parks and Recreation Department, and Friends of the Historic Columbia River Highway. The “Tunnel of Many Vistas” will likely be re-created within the next ten years. If the Whistling Ridge Energy Project is constructed, the view from the “Many Vistas” would not include a historically intact landscape. Rather, the vistas would be transformed to include an industrialized skyline with moving parts and flashing lights less than 3 miles away.

The impacts to opportunities for historic interpretation and impacts to this National Historic Landmark were not analyzed in the DEIS. The proposed development would directly impact these views and undermine opportunities for historic interpretation. This constitutes a major adverse impact to the environment that needs to be reviewed and addressed.

////

F. The DEIS Fails to Adequately Review the Likely Impacts of the Proposed Development on Recreational Resources.

The DEIS fails to adequately review the likely impacts to recreational resources. The project site is centered within a wide array of significant recreational resources, ranging from internationally recognized landmarks to local hikes with epic views. The DEIS fails to inventory all of the recreation resources in the vicinity and fails to adequately analyze the likely impacts to those resources.

The recreation resources in the vicinity include numerous locations to the south including the Columbia River Gorge National Scenic Area, The Lewis and Clark National Historic Trail, the Oregon Pioneer National Historic Trail, the Ice Age Floods National Historic Trail, the Historic Columbia River Highway Trail, Starvation Creek State Park, Viento State Park, Spring Creek Hatchery State Park, the Columbia River, the Mitchell Point Trail, Indian Head, and hiking along the Lower White Salmon River near the confluence with the Columbia. Locations to the north include the Lower White Salmon Wild and Scenic River, the Little White Salmon River, Nestor Peak, the Little Buck Creek Trail, the Grassy Knoll Trail, Cook Hill, Little Huckleberry Mountain, and numerous other hiking trails and drive-up viewpoints in and near the Gifford Pinchot National Forest. The DEIS fails to adequately inventory these resources.

*View from Little Huckleberry Mountain. Whistling Ridge and Chemawa Hill in center of photo.
Photo by Jozsef Urmos.*

As explained above, the Lewis and Clark National Scenic Trail includes the Columbia River, State Route 14, Interstate 84, Starvation Creek State Park, and Viento State Park. The DEIS fails to acknowledge these components of the National Historic Trail. The DEIS fails to acknowledge that Starvation Creek State Park and Viento State Park also provide river access for wind surfing, kite boarding, motor boating, canoeing and other water activities. The DEIS also fails to acknowledge that the City of Hood River is an international hub for windsurfing and that the project would be visible from multiple windsurfing locations. The DEIS also fails to

recognize that the Little White Salmon River and the White Salmon River are internationally known in whitewater kayaking communities.

The DEIS states that “[o]n the Oregon side of the Columbia River, land use within the Scenic Area is predominately commercial timber production and residential.” DEIS at 3-265. This is one of the more absurd errors in the DEIS. The Forest Service owns thousands of acres of public land within the Scenic Area on the Oregon side of the Columbia that is managed to protect natural resources and provide recreation opportunities, not for timber production. The leading land uses on the Oregon side of the Gorge, excluding urban areas, are conservation and recreation.

The DEIS states that “no parks or recreation facilities are planned within a 5-mile radius of the site, either as part of the Skamania County Parks and Recreation Master Plan or the Columbia River Gorge National Scenic Area Management Plan.” DEIS at 3-139. This statement is patently wrong and ignores plans to restore and develop facilities at Mitchell Point as part of the Historic Columbia River Highway. While Mitchell Point is already owned by Oregon State Parks, the development proposals are certainly new and warrant acknowledgement.

The DEIS failed to give proper consideration to impacts to recreational resources, including a failure to analyze whether the project would be consistent with the Management Plan for the Lewis and Clark National Historic Trail and the Historic Columbia River Highway Master Plan, or the recreation resource provisions of the CRGNSA Management Plan. While these plans do not have direct regulatory authority over the project (assuming no ground disturbance would occur in the National Scenic Area), the goals and policies could be frustrated by the project. There needs to be at least a discussion of the potential impacts.

Project construction activities would generate traffic delays that would adversely affect recreational users. Countless residents in the gorge hike, windsurf, or kayak every day of the week and use the roads that would be used as a haul route for this project to access these recreational spots. Industrial traffic and associated delays would have an adverse impact on these resources. For example, use of the east access for Cook-Underwood Road for this project would block access to a recreational trail along the White Salmon River. Similarly, the west access for Cook-Underwood Road is regularly used by whitewater kayakers to access the lower three miles of Little White Salmon River, which has achieved legendary status due to the challenging rapids and consistent water flows. By failing to fully acknowledge such impacts and prepare a traffic mitigation plan for public review, EFSEC and the BPA have foreclosed the opportunity to evaluate the project's true impacts and inform the public of these impacts.

Project operation would also affect recreation. The DEIS section that addresses direct impacts of project development fails to mention recreation resources. DEIS at 3-153. Similarly, the cumulative effects section of the DEIS does not identify a single impact to recreational resources. DEIS at 3-279-3-280. The DEIS does acknowledge low to moderate impacts to views, but fails to acknowledge that scenery is typically a central part of outdoor recreation. As stated above, the scenic resource analysis was grossly inadequate.

Recreation resources that were not acknowledged through the scenic resource assessment include Little Huckleberry Mountain, Nestor Peak, and Cook Hill. These hiking areas provide dramatic panoramic views of Mount Hood and Washington's southern Cascades. Impacts to these resources were completely ignored.

The proposed development would be located in the heart of one of the greatest recreational destinations in the world. Windsurfers, kiteboarders, kayakers, and hikers come

from around the world to this area, and the Gorge itself is recognized as a national recreational treasure. Beyond the international and national fame, the area surrounding the project is home to people who hike, boat, bird, view wildflowers, and explore mountains and forests as a primary recreational pursuit. The project would be located in the middle of many of these activities. The recreational impacts analysis warrants substantial revision to reflect the actual impacts to recreational resources.

G. The DEIS Fails to Adequately Analyze the Likely Impacts to Agricultural Tourism.

The DEIS's analysis of potential impacts to agritourism is limited to a superficial comparison to wind energy development that has occurred in area between Walla Walla and Kennewick. DEIS at 3-151. The DEIS merely states that “[w]ind power and winery tourism already co-exist in the Columbia River Area. For example, four wind power facilities are located between Walla Walla and Kennewick (Canyon, Stateline, Vansycle, Combine Hills). This area is home to a thriving wind industry with over 60 wineries.” DEIS at 3-151.

The DEIS provides no analysis of whether industrial wind development has caused any adverse impacts to wineries in that area, or whether the landscape and proximity of the two uses is even remotely comparable to the proposed Whistling Ridge project and existing agritourism activities in the area.

For example, the DEIS does not explain how close any of the wind facilities are to the 60 referenced wineries. For Whistling Ridge, the project would be within a mile of existing wineries, would dominate views, and may also be heard. Importantly, the DEIS does not even attempt to quantify the number of agritourism businesses in the Underwood community, nor how close they might be to the proposed Whistling Ridge project.

The DEIS fails to explain how many of the 60 wineries are open to the public, and thus how many support agritourism. Wineries in the Underwood area have tasting rooms and host commercial events.

The DEIS fails to provide any economic data evidencing business trends and property values for the 60 wineries before and after wind energy facilities were constructed in that region. Even if 60 wineries coexist with the wind industry in that region, that does not mean the agritourism industry in that region has not been affected by the wind industry.

In sum, the analysis of potential impacts to agritourism fails to provide any meaningful substantive analysis that can inform decision makers on the likely impacts of the proposed development.

H. The Transportation Impacts Analysis is Inadequate and Must be Revised to Include Alternatives that Avoid and/or Mitigate Impacts to the Underwood Community.

The DEIS must adequately review the likely impacts to the local and regional transportation system. The proposed development would generate thousands of vehicle trips through areas that are predominately used for recreation, agriculture, rural residential, and forest uses. Industrial development and land uses are prohibited in the areas that the proposed haul route would travel through. The transportation impacts would likely be substantial. Impacts would include significant delays due to increased traffic and the size of vehicles associated with the use. The vehicles associated with the proposal would also be incompatible with local uses.

Whistling Ridge would make thousands of vehicular trips across the proposed haul route, including the hauling of heavy construction materials and equipment exceeding the Washington State Department of Transportation's legal load limit of 52.75 tons. *See* RCW 46.44.041. There would be more than 1,700 trips using specialized over-sized trucks designed specifically for the

industrial purpose of hauling the enormous turbine components. These specialized trucks are up to 150 feet long, 17.5 feet high, and 14.5 feet wide. Since October 11, 2007, trucks longer than 125 feet in length have been prohibited on Washington SR-14 along the haul route.

In addition to the specialized trucks, other large and oversized trucks would be needed to haul construction equipment, plus three pilot vehicles for each truck wider than 10 feet, and construction worker vehicles. Although WRE has not yet proposed a total number for all vehicular trips along the haul route, the total number would likely exceed 10,000 trips. The specialized trucks and their frequent, heavy loads are expected to damage the roads along the haul route. Thus, WRE proposes to repair road damage resulting from the industrial hauling.

This massive intrusion of industrial construction equipment would run through rural residential, agricultural, and recreational areas. Given the impact to the community, EFSEC and the BPA should study alternative routes that would preclude or minimize the use of Cook-Underwood Road as it runs through the National Scenic Area.

In addition, the DEIS provides internally inconsistent information about the true extent of the traffic impact. At pages 1-29 and 3-233, the DEIS states that traffic flow could be restricted for up to 20 minutes during the construction phase. But at page 3-228, the DEIS states that traffic delays would increase by only six seconds as a result of this project. The agencies should explain the inconsistency.

I. The DEIS Fails to Adequately Analyze and Address the Potential Health Impacts from Wind Energy Facility Operation.

The nearest residence would be within one-half mile of the proposed facility. Numerous other residences would be in similarly close proximity. EFSEC and BPA must ensure that the DEIS includes adequate review of the likely impacts on neighboring properties.

Recent studies have shown a potential for wind energy facilities to cause adverse impacts to human health. Adverse health impacts could occur from low-frequency noise that interferes with inner ear functions resulting in dizziness, nausea, and loss of sleep. While the research is not conclusive, the uncertainty regarding health impacts of wind development warrant a precautionary approach to siting wind facilities near residential structures. The DEIS should include analysis of a variety of sources on the health impacts of wind energy development. EFSEC and the BPA should require that the facility be set back at least 1 mile from the nearest residence.

Friends also incorporates the comments of Keith Brown and Teresa Robbins regarding the potential noise and human health impacts of the proposed project.

CONCLUSION

The Draft Environmental Impact Statement for the Whistling Ridge Energy Project is grossly inadequate and fails to comply with the requirements of SEPA, NEPA, and other applicable laws. The DEIS has been heavily influenced by the preferences and biases of the Applicant to rationalize a predetermined outcome, not to provide an impartial and informed analysis of environmental impacts. The flawed document cannot be used as a basis for decision making and must be substantially revised before any conclusions on environmental impacts can be drawn.

The Whistling Ridge Energy Project is easily the most controversial and problematic wind energy facility proposed to date in Washington State. The project would cause significant adverse impacts to unique resources in both Washington and Oregon, including scenic, natural, cultural, and recreational resources. The affected resources include the Columbia River Gorge National Scenic Area, the Historic Columbia River Highway, the Lewis and Clark National

Historic Trail, the Oregon Pioneer National Historic Trail, sensitive wildlife species such as the federally listed northern spotted owl, sensitive Native American cultural resources, and multiple hiking trails and other recreational resources.

Because of these unique factors, the environmental review must be of the highest integrity. Unfortunately, this DEIS fails to take the hard look required by NEPA and SEPA. The DEIS is improperly designed so that the applicant's private economic interests unlawfully dictate the purpose, need, alternatives, and eventual outcome for the proposed action. The DEIS does not demonstrate that EFSEC and BPA consulted with agencies with expertise in the resources that would be affected by the project. The DEIS also misquotes and misrepresents the language and meaning of the Columbia River Gorge National Scenic Area Act, and prematurely and erroneously concludes that the project would be consistent with the applicable land use regulations. Finally, the DEIS fails to adequately evaluate the direct, indirect, and cumulative impacts of the proposed project.

The DEIS is so deficient that it cannot be used as the basis for a decision on the project. The proposed project should be denied outright, but if it is to be given further consideration, a supplemental or revised DEIS is required.

To: Bonneville Power Administration and Washington State Energy Facility Site Evaluation Council
Re: Draft Environmental Impact Statement for the Whistling Ridge Energy Project (DOE/EIS - 0419)
Date: August 19, 2010

This memo is intended to provide an independent professional evaluation of the Draft Environmental Impact Statement for the Whistling Ridge Energy Project, proposed to be located in the central part of the Columbia River Gorge near White Salmon, Washington. The memo is provided at the request of Friends of the Columbia Gorge.

Background

I am a professional landscape architect with over 31 years experience. I am currently employed as a Senior Landscape Architect by MIG Inc., a multi-disciplinary planning and design firm with over 100 staff in California and Oregon. My areas of professional emphasis include scenic resource assessment, natural resource planning, landscape ecology and ecological restoration. My clients have included the Oregon Department of Transportation, the U.S. Forest Service, the National Park Service, the Washington Forest Law Center, the Forest Stewardship Council, Metro, Friends of the Columbia Gorge, Western Resource Advocates and several private landowners located within the Columbia River Gorge National Scenic Area. Prior to entering private practice, I was chief landscape architect at the Mt. Hood National Forest. My work included having the lead role for management of scenic resources, and design of several projects within the Columbia River Gorge. I have included a more complete resume as an attachment.

I have reviewed the sections of the Draft Environmental Impact Statement (DEIS) that address scenic impacts, including maps, drawings, photos and simulations, and will focus my comments on scenic impacts. I am familiar with the general area from previous work in the Gorge.

Project Description

The proposal is to construct a wind energy project in the southeast portion of Skamania County, Washington, north and west of Underwood Mountain. Up to 50 commercial-scale wind turbines are proposed on forested land owned by SDS and Broughton Lumber Companies. According to the DEIS, the total land area involved is 1,152 acres, of which about 384 acres would be developed with turbines and associated facilities and roads. The proposed towers would each be over 400 feet tall, including three blades each up to 150 feet long. Analysis by the proponent demonstrates that most of the proposed turbines would be visible from multiple key viewing areas (KVAs) within the Columbia River Gorge National Scenic Area, as well as from other public and private viewpoints.

The project site lies within the Cascade Range, and is at the western edge of the Columbia Plateau. The landscape topography includes a series of ridges west of White Salmon that orient generally northwest to southeast and overlook the Columbia River and Hood River, Oregon. Current land use is commercial timber. The surrounding landscape is a patchwork of forest, brushfields, and meadows in varying stages of regeneration from timber harvest, as well as dramatic mountain vistas, steep rocky cliffs, pastoral lands, and the Columbia River. Landforms in the vicinity are steep, complex and dissected by deep ravines.

Wind Facilities and Aesthetic Impacts

Wind energy is still a relatively new type of land development, both in the Pacific Northwest and nationally. The first large-scale commercial wind energy project in the United States appeared at San Geronio Pass near Palm Springs, California in the early 1980s. This project and others in California (Altamont and Tehachapi passes) were and still are controversial, with aesthetic impacts often noted as a serious issue. The past few years have seen a significant number of proposals for wind energy development. Parts of the region, most notably the Columbia Basin, have already been visually transformed by the sheer number of turbines installed. Wind energy projects are land extensive, with single turbines needing 50 or more acres of free space around them. If present trends continue, hundreds of thousands of acres in Oregon and Washington will be developed with wind turbines within the next decade.

The fundamental aesthetic problem of commercial wind energy development is that it introduces very large-scale, modern, industrial structures into rural, semi-natural, or even wild landscapes. Due to their large scale and unique appearance, *modern wind turbines by their very nature result in high visual contrast to most landscapes*. High contrast normally results in high impacts to scenery. Wind turbines challenge conventional approaches to scenic resource conservation, which rely on eliminating or reducing the contrast of built facilities or landscape alterations. In most cases modern wind turbines cannot reasonably be “visually blended” into natural or cultural landscapes. They are inherently visually dominant due to their huge scale, unique appearance, high color contrast, moving parts and the need for continuous lighting for air safety.

Key factors in assessing the visual impact of wind turbines include:

- The number of visible turbines and the extent to which they dominate vertically and horizontally.
- The visual coherence or sense of order they present. Because they tend to be so prominent, turbines have to “make sense” within the view.
- Wind turbines look best in simple, open, low relief landscapes like farm, prairie or rangeland. They fit uncomfortably in highly complex landscapes with lots of vertical relief and diverse vegetation patterns, like the Columbia Gorge.
- Roads and power lines serving turbines can add substantially to visual impacts of wind energy developments.
- Turbine placement may include other landscape disruptions, particularly land clearing and ground disturbance.

There is little question that the vertical and horizontal scale of modern wind turbines has the power to transform entire landscapes. The huge size of individual towers and the horizontal scale of large projects can create substantial impacts even when viewed from distances of 10 miles or more.

Page 3-172 of the DEIS states: “wind turbines are relatively large.” Commercial wind turbines are *very* large, out of scale with anything in the landscape around Underwood. They are nearly as tall as the tallest buildings in downtown Portland, and they do not look like any rural building or structure in existence. Modern wind towers and blades are nothing like the historic, small-scale, vernacular windmills of the Netherlands, Crete and Portugal. They feature sleek, industrial designs. They are large enough, different enough, and high contrast enough, to transform the surrounding landscape from predominantly natural or rural into an industrial scene.

Wind turbines are not designed to be place-sensitive. Energy companies are focused on maximizing productivity and minimizing costs. Thus, a one size fits all approach is used, and custom design is almost never considered. Wind facilities are context-free, meaning they look the same anywhere. And while they may be perfectly appropriate as an expression of their own function, they do not aesthetically fit in many landscapes.

Every landscape includes the basic elements of form, line, color and texture that provide visual identity. Forms result from large and small scale elements interacting to create spaces. They can be regular or irregular, curvilinear or geometric. Lines are linear features, like roads or the edge of a clearing. Natural colors tend to include greens, browns, tans and blues. Textures can be rough, smooth, fine or coarse grained. To the extent that landscape changes or new objects repeat these elements, contrast is reduced between the proposed development and natural landscape character. This in turn results in less of a visual impact. Large arrays of modern wind turbines easily dominate over the form, line, color and texture of scenic natural and cultural landscapes. It is extremely difficult to relate them to existing landforms, vegetation patterns, and natural lines in ways that reinforce or harmonize. They introduce strong vertical lines and have a color and texture unlike anything that is found in most natural landscapes.

Ridgelines are places where the land meets the sky, and where the viewer's eye is easily drawn. Wind turbines, including those proposed for the Whistling Ridge Energy Project, are often located on high, visually prominent topographic points, causing them to extend far above the horizon and create "skyline" impacts that accentuate their visibility. This detracts from surrounding landforms. One reason wind turbines look more at home on flat or gently rolling topography is the absence of conflict with prominent land forms, such as those found around the project area. The rotating blades of wind turbines are another unique feature that attracts additional attention. Lighting (including both nighttime and daytime lighting) accentuates visual impacts and extends them to all hours.

Flawed Methodologies

On 3-155 of the DEIS: "It assesses the potential for visual impacts using accepted methods of evaluating landscape quality and predicts the type and degree of effects the project likely would have on those attributes." Two methods were used: The U.S. Forest Service Landscape Aesthetics Handbook and the Federal Highway Administration (FHWA) process for visual impact assessment.

In my opinion, the FHWA method is not a suitable method for evaluating the visual impacts of wind energy projects in general, and this project in particular. This system was designed to be used only for assessing impacts from highway related development. It contains no process or method for assessing the visual contrast presented by wind turbines or related energy facilities (such as power lines). This is stated in the very title of the FHWA manual: *Visual Impact Assessment for Highway Projects*, and is explicitly noted in the opening sentence on page one: "This field guide is intended to help those who prepare or review the coverage of visual impacts in environmental assessments *for highway projects*" (emphasis added). Unlike the Forest Service and BLM methods, the FHWA process is not a flexible method that can easily be adapted to different project types. The mere fact that other wind projects have used it in the past does not justify its continued misuse.

Like all visual impact assessment methods, the FHWA contains terminology, approaches and ideas that can be borrowed or used elsewhere, but the proponent seems to have gone beyond mere borrowing and has assumed this method is more adaptable than it is. The decision to use this method seems based on a single factor, that it is used in lands that do not have assigned visual quality objectives. The flaws and

limitations of the FHWA method have been overlooked. Moreover, visual quality objectives for viewpoints within the Scenic Area exist. Although the Scenic Area Act does not apply these VQOs outside the Scenic Area, they are a useful way of measuring the scenic impacts of the project on the affected landscape pursuant to NEPA and SEPA.

Both the Forest Service and BLM visual assessment methods were designed and have been gradually adapted and refined to address numerous impact types. Though neither method anticipated giant commercial wind turbines, both have been used to review utilities, dams, mining and other energy related infrastructure. The BLM visual contrast method in particular has proven to be very useful and adaptable to assessing wind turbine development.

Yet on page 3-156 of the DEIS the project proponents dismiss the BLM visual contrast method due to the absence of pre-existing “visual resource objectives” (even though as stated earlier, these exist for the affected key viewing areas). The assumption appears to be that visual contrast cannot be determined unless one first establishes resource objectives. But visual contrast is a useful way of measuring impacts regardless of whether a resource management objective has been established, because it relies on simple and time tested analytical standards, summarized below from BLM Manual 8431, Visual Contrast Rating:

Degree of Contrast	Criteria
None	The element (wind turbines) contrast is not visible or perceived
Weak	The element contrast can be seen but does not attract attention
Moderate	The element contrast begins to attract attention and begins to dominate
Strong	The element contrast demands attention, will not be overlooked, and is dominant

In the BLM method, an objective measurement of contrast is combined with viewer sensitivity to determine the level of impact. A number of factors are considered, including distance, view angle, view duration, project size, atmospheric conditions and motion (i.e. spinning blades). The Forest Service method (Landscape Aesthetics, A Handbook for Scenery Management) has similar applicability, but substitutes the terms Retention (no contrast), Partial Retention (weak contrast), Modification (moderate contrast) and Unacceptable modification (strong contrast). Either of these methods would be appropriate for use on the Whistling Ridge project.

A second flaw in methodology is the failure of the DEIS to analyze the landscape character of the project site and its vicinity. Only a general description of the regional landscape and local surroundings is presented on pages 3-161 to 3-163. The DEIS fails to recognize the visual prominence of the series of landforms and water bodies that comprise the surrounding landscape, including Whistling Ridge, Saddleback Mountain, Underwood Mountain, Underwood Bluff, Chemawa Hill, Dog Mountain, and the mouth of the Little White Salmon River. These are prominent and important focal features. The visual integrity of some of these landforms has already been somewhat compromised due to timber harvest and utility line construction, but that does not make these visually complex landforms any less important or less visible. On the contrary, it argues for being careful to not introduce additional impacts that increase cumulative effects.

The DEIS’s failure to analyze the impacted area’s landscape character is an important omission, because landscape character is the baseline from which changes or contrasts are determined. Natural and cultural landscapes have identifiable form, line, color and texture characteristics that can be documented and

described. The extent to which a development either blends or contrasts with these characteristics is a key basis for understanding impacts.

Scenic Quality Ratings and Viewer Sensitivity

Page 3-157 of the DEIS states that “Scenic quality ratings were based on observations in the field, photographs of the affected area, methods for assessing visual quality, *and research on public perceptions of the environment...*” (emphasis added). It needs to be noted that wind project proposals in scenic landscapes tend to generate a lot of public concern and opposition, while proposals in less scenic areas (i.e. the prairie and plains states) generate very little opposition. For example, Cape Wind (off Cape Cod) several wind projects in New England and upstate New York, previous projects along the Columbia River Gorge National Scenic Area, including the abandoned Cascade Wind proposal not far from this site in Wasco County, projects proposed near the Willamette and Steens Mountains in Oregon, and those in coastal areas have raised significant public opposition.

In contrast, multiple projects proposed and built in the open range and farm land of the Columbia Basin have generated very little opposition based on aesthetic impact. This experience suggests that much if not most of the public is uncomfortable with the scenic impacts of commercial-scale wind energy projects in landscapes valued for their scenic qualities.

The Columbia River Gorge is clearly valued for its scenic qualities, both natural and cultural. It is a federally protected national scenic area. It has a unique bi-state commission that plans, regulates, and monitors to protect scenic quality. The American Society of Landscape Architects included the Columbia River Gorge as one of the 100 most outstanding landscapes in the United States, ranking it along with Yosemite, Yellowstone and other national icons. Clearly, the public has already weighed in on the issue of whether the Gorge is scenic and merits conservation, and the answer is “yes.”

Another flaw in the DEIS is the way the scenic quality ratings were created. Page 3-158 includes a table (3.9-1) that describes scenic quality ratings 1 (low) through 6 (outstanding). It states that “each viewpoint is assigned a final rating based on this scale.” A landscape is either scenic or it isn’t based on its intrinsic qualities. Every landscape region has places that are more inherently scenic than other places. In the Washington Cascade Mountains, steep, rugged, complex and diverse landscapes, especially those with water features rank higher on scenic quality scales than do areas with gentle terrain, bland vegetation cover and no visible water. This is true regardless of where the observer happens to be standing. Both the BLM and Forest Service methods are useful in assessing the intrinsic scenic quality of landscapes. These sources and materials should be used, so that scenic impacts can be properly evaluated.

Pages 3-159 contains questionable statements and assumptions on viewer sensitivity. Given that the project borders on a federally protected national scenic area and that key viewing areas and visual quality objectives have already been established for this landscape, there seems little need to create new assumptions about sensitivity from these viewpoints. *All KVAs are by definition high sensitivity.* Viewer sensitivity from KVAs is high based on the very definition the proponent uses on page 3-159:

“**High.** Residential, recreational and viewers congregating in public viewing areas (churches, schools, *designated scenic viewpoints*, etc) are considered to have comparatively high visual sensitivity.” (emphasis added).

Additionally, contrary to the statements on page 3-159, sensitivity is not related to distance. A KVA, by definition, is a high sensitivity viewpoint, regardless of the distance to the object viewed. What changes is the degree of contrast experienced. At greater distances contrast is reduced and thus visual impacts normally decrease. Sensitivity, which is related to the observer, does not diminish with distance.

On page 3-163, the DEIS states: “The local landscape visual appearance is of moderate visual quality *with a moderate level of sensitivity*.” (emphasis added). For reasons stated above, there is no analytical basis for making this determination. The landscape surrounding the proposed turbines may be of low, moderate or high quality scenically. But *viewer sensitivity* is inherently high from designated scenic viewpoints such as key viewing areas.

For viewpoints outside of the Scenic Area (i.e. Husum) some analysis on sensitivity may be useful.

The selection and analysis of viewpoints in the DEIS is flawed. On page 3-164, the DEIS states: “Each viewpoint was assessed for its scenic quality and viewer sensitivity, and a rating was applied to provide an overall average for the area.” This sentence makes no sense. The scenic quality of the viewpoints is not an issue. The scenic quality of the project site and how this would change under the proposal is the issue. Viewer sensitivity, as previously stated, should be presumed to be high from any KVA. That is exactly why they were designated KVAs in the first place. There is no such thing as an “overall average” with respect to scenic quality. One cannot average the scenic quality or impacts among differing viewpoints. Each must be assessed on its own merits.

Viewshed and Viewpoint Analysis

Figures 3.9-1 and 3.9-2 are useful in assessing the potential visibility of proposed turbines from within the National Scenic area and elsewhere. But they fail to note the full extent to which the turbines would be exposed to key viewing areas. The analysis treats the scenic impact problem as a *viewpoint impact* as opposed to a *view corridor* impact, but several of the affected KVAs are corridors, not points. These corridors include designated scenic roads and the Columbia River. The DEIS should be revised to analyze the distance along the entire length of these KVAs from which the project would be visible and to simulate views from multiple points along these KVAs in order to identify where the greatest impacts are likely to occur.

As it stands, the viewpoints chosen for analysis may not be truly representative: I-84, the Columbia River and the Historic Columbia River Highway all have multiple possible view locations that may experience greater impacts than the single locations chosen by the applicant. Each of these view corridors come within 3 miles of the project, yet all sample viewpoints are more than 4 miles from the project. Additional views along these three KVAs should be analyzed. For example, a simulation from the Historic Columbia River Highway at Mitchell Point, directly across the Columbia River from the project, is critical.

The visibility maps (Figures 3.91 and 3.92) illustrate that a huge area covering thousands of acres is potentially within line of site of one or more turbines. Given the high visibility of the project, additional viewpoints need to be selected to help analyze visual impacts. For example, the analysis failed to consider the impact from certain KVAs, including Tom McCall Point

Finally, there is a need to identify which turbines are visible from which viewpoints. This will aid the applicant, reviewing agencies, and the public in understanding both the extent of impact and in identifying potential mitigation measures.

Photomontages

The applicant is relying heavily on the small number of selected viewpoints and photomontages to determine the level of impact. Regulatory reviewers of this proposal, as well as concerned members of the public, need to understand the inherent limits of what these photomontages can represent.

First, the choice of viewpoints is critical. Are the viewpoints chosen truly representative of the views available in the area? For reasons mentioned, I do not believe this has been shown to be the case. Given the scale of this project and the number of viewpoints potentially affected, additional viewpoints should be analyzed.

Second, photomontages are not, and cannot, be true to life representations and should not be viewed as such. The inherent limitations of photomontages should be discussed in the DEIS. Two-dimensional photo images can never replicate a three-dimensional world because people see stereoscopically, and will view real life turbines from within three-dimensional space, not as if they were painted upon a flat plane. Real world resolution is also much greater than what can be portrayed on a photo. *Brightness ratio* is a measure of contrast between the lightest and darkest elements in any given view. On a clear day, a viewer might experience a 1,000 to 1 brightness ratio. The same image on a computer monitor provides a 100 to 1, or at best 400 to 1 brightness ratio. If this image is printed, the brightness ratio is cut in half or less. What this means is that a photographic image is inherently much lower contrast than what one would see in the real light of day.

Additionally, the size of the image one looks at and the distance from which one views that image are crucial. Page 3-160 of the DEIS states that "Visual simulations were developed using photographs taken with a 35 mm digital SLR camera. Various focal lengths from 40-70mm were used with the intent to capture the maximum pixels and resolution for the simulation." A 50mm focal length approximates what the human eye sees. A 40mm length shows a wider angle, and pushes an image farther away, while a 70mm length brings it closer to the viewer. Most people will view the photomontages either on a computer monitor or on a printed page. Research indicates that to get a realistic sense of scale and distance, the original photo should be taken with a 70mm focal length and the image should be printed or viewed at a full page size, either 8 x 11 or 11 x 17 depending on the extent of the area being shown. This is because most people need to hold an image 15-20 inches away from their eyes in order to be focused. Viewing a photo of an object several miles distant, and moving that photo a few inches away adds miles to the effective visual distance. Also, by clipping images together to create panoramas, the photomontages effectively make the turbines recede farther into the background than they would appear in reality.

It is nearly impossible for people to judge the true scale of wind turbines when looking at photos of them taken from a distance of several miles. The problem is there is usually no clear frame of reference within the photo to measure the size of a turbine against. Unless there is something of known size near the turbines, a house or barn for example, one cannot tell if the turbines are 100 or several hundred feet tall.

In short, the images provided are too few and otherwise limited to be able to accurately assess the potential visual impacts of the proposal.

The images included in the DEIS vary greatly in scale. For example, the turbines appear much larger in the simulation for viewpoint 3, a distance of 7.6 kilometers, than they do for viewpoint 1, a distance of 6.4 kilometers. How can this be? The turbines should appear larger in the closer view. The answer must be that the reproduced image provided, no matter what focal length was used, does not reflect the

distance. This is also evident in comparing viewpoints 11 and 12, which are similar view angles. The turbines in the simulation for viewpoint 12 appear smaller and farther away than those for viewpoint 11, even though the former is 3 kilometers nearer according to the data provided on the image.

Lastly, even if the photo images were perfect representations of the wind turbines, they would fail to capture the added impacts due to the motion of spinning blades. Blade motion would attract the eye and add to visibility. Simulations that include motion (animations) should be provided by the applicant to properly assess impacts.

Specific viewpoints

I have selected a few viewpoints to illustrate the magnitude of impacts that may result from this project as designed.

Viewpoint 11: I-84 Westbound

As viewed from this viewpoint, the 25 turbines with visible hubs clearly are visually dominant over the natural form, line, color, and texture of the existing landscape. They are high contrast, even with the inherent brightness ratio limitations of the photomontages. They have a strong skyline presence that draws attention to them. Spinning blades would only increase their obvious visual dominance. A key problem from this viewpoint is the chaotic, jumbled appearance of the turbines. They are bunched up and overlap each other, creating too much visual density, with too little space between individual turbines and clusters. The turbines viewed from this vantage point present a *very high contrast*. Given the huge number of viewers, long view duration, and high sensitivity, the visual impact from the I-84 KVA and the adjacent Columbia River KVA in this area is very high.

Viewpoint 12: Koberg Beach State Park

Impacts from viewpoint 12 are high, but not as high as from viewpoint 11. The angle of view is similar to the previous one, but because the distance is shorter, some of the turbines have ducked behind the horizon. The result is a bit better visual composition and thus somewhat less impact. The turbines are still visually dominant, but their horizontal scale is less, and the array is more coherent. Taking these two images together, one can conclude that the impacts might be even greater when viewed from further east. This is supported by the viewpoint map, which indicates that more turbines are visible from further east.

Viewpoint 13: I-84 Eastbound

The photomontage included in the DEIS is suspiciously low contrast. Given the much shorter view distance as compared with the previous two viewpoints, and taking the wireframe into account, the 12 turbines seen from here would be visually dominant. The skyline effect is strong, but the horizontal scale is modest. The biggest impact is from the dense cluster of turbines at the high point in the center of the image, best viewed on the wireline (Figure 3.9-10). Again, in looking at the viewpoint map, it appears that the turbines would be visible from along I-84 stretching 2 miles to the west and several miles to the east. This means a long duration view, and possibly more visible turbines. The composition of the turbines from this viewpoint is problematic. There are two areas of overlapping rotors, which create some visual incoherence. Impacts from this viewpoint are high.

Viewpoint 14: Viento State Park

This is a very misleading photomontage. The image is very faint, and the size does not correspond to the relatively short view distance of 6.4 kilometers (4 miles). The wireframe view indicates that the 18 turbines seen from this viewpoint would be very high contrast and would have high impacts, similar to

those discussed under Viewpoint 11. All 18 turbines break the skyline, there are overlapping rotors and a jumbled, chaotic composition. The turbines located at the high point in the center of the image are particularly strong impact. The turbines would be framed by Dog Mountain, seen on the left side of the photo, and a portion of Underwood Bluff, seen on the right side of the photo (Figure 3.9-11). These are very natural, highly intact landforms, exacerbating the contrast that the turbines would introduce. Existing development prohibitions on these landforms, which lie within the National Scenic Area, are at the highest protection level, allowing no visual contrast. This illustrates the high sensitivity of the viewshed.

Viewpoint 19: Historic Columbia River Highway

This is also a visually misleading photomontage that most likely vastly understates the visibility and contrast of the 11 turbines in view. The image is much too hazy, and the white clouds behind the turbines provide a convenient low contrast backdrop for white turbines. By viewing the wireframe, I conclude that the turbines would be moderate to high contrast, and would be co-dominant to dominant. Impacts would be at least moderate, and possibly high. One visual advantage is that from this angle the turbine composition is reasonably coherent and the horizontal scale (along the horizon) is not great. The location of the turbines at a low point along the ridge presents lower impacts than noted in the previous photos. My concern is that the Historic Columbia River Highway runs within 3 miles of the project boundary west of this site. Selecting a single viewpoint over 7 miles from the project probably does not fully reflect the actual impacts to this Key Viewing Area.

Unknowns

The analysis in the DEIS leaves some unanswered questions in addition to the ones already raised. First, what will be the extent of short-term and permanent forest clearings around the turbines? Typically wind turbines need a lot of free space around them to reduce turbulence and blade interference. How far will this clearing extend from each turbine? Has this forest clearing been incorporated into the photomontages? It does not appear to have been..

Second, the DEIS mentions new and improved roads, but no roads are shown in the photomontages. Has the proponent determined that these roads will not be visible, or have they simply been left out of the picture? Since the turbines are along prominent, narrow ridges, it is possible that roads will have to be cut into the sideslopes in order to be at an appropriate grade. If this is the case, the road cuts could be visible from some viewpoints.

Third, what turbines will be used and how large will they be? The scale of commercial turbines continues to increase year by year. Taller turbines than the ones depicted would be even more visible and higher contrast.

Fourth, the analysis does not include an evaluation of impacts from lighting (both daytime and nighttime). Lighting can cause a high contrast with surrounding landforms, dramatically increasing the impacts of development, both during the day and at night. The DEIS does not even attempt to estimate the extent of lighting, instead merely providing general guidance regarding the placement of lights and stating that the FAA will require lighting later. The DEIS needs to be revised to estimate the extent of lighting for this project and its impacts within the affected landscapes.

Findings

The visual impact analysis provided in the DEIS is faulty and incomplete. In addition, the DEIS's conclusions that visual sensitivity is only low to moderate and that impacts would be low to moderate

from most viewpoints (Table 3.9-2) are not supported by the facts. The project as presented would have substantial adverse impacts to scenic resources.

- Given the project location adjacent to the National Scenic Area, and its high visibility, the potential scenic impacts of the Whistling Ridge Energy Project are clearly high.
- The proposed project is located on visually prominent, complex topographic features. Research and experience shows that it is difficult to successfully “blend” large-scale industrial commercial wind turbines with complex, forested landforms like those that make up the proposed site.
- It may be technically difficult or impractical to rearrange the turbines in arrays that appear orderly and coherent. The proponent has made no attempt to do so in any event.
- Visual impacts from key viewing areas within the Columbia River Gorge National Scenic Area are moderate to very high from several of the viewpoints selected by the proponent for analysis.
- Additional affected viewpoints and key viewing areas have not been, but need to be, analyzed to get a better sense of the extent of impacts.
- Duration of view, particularly along KVA corridors, needs to be fully analyzed. Indications are that the view duration will be long from I-84, the Columbia River, and the Historic Columbia River Highway, further exacerbating impacts.
- The proposed turbines contribute to adverse cumulative impacts when added to existing clearcuts and transmission line corridors on the project site.
- Given that there are additional wind energy facilities currently proposed along the National Scenic Area boundary east of this project, there is a real potential for increased cumulative impacts from multiple key viewing areas. By approving projects one at a time, we could someday in the not-distant-future reach a point where wind turbines are in view from Hood River all the way to the eastern boundary of the National Scenic Area.
- The photomontage images in the DEIS are flawed. The scale and distance appear to be inconsistent. Atmospheric conditions on some photos are hazy. Use of a white cloud background reduces apparent color contrast of turbines skylined on visually prominent ridges.
- From several viewpoints, the array of turbines in view is chaotic and incoherent. Rotors frequently overlap. Research is clear that, because modern commercial turbines are so large and inherently contrasting, good design that is visually coherent is crucial to mitigating visual impacts.
- The photomontages provided do not appear to take account of additional visual impacts from tree removal and roads associated with the turbines.
- The analysis fails to account for nighttime lighting visual impacts. Turbine lighting will be required by the FAA.
- The analysis fails to account for the additional visual impacts due to blade motion.
- The proponent has not offered any meaningful mitigation for visual impacts that will result from this project. The visual impacts are treated as “unavoidable,” even though no effort has been made to avoid them.

Recommendations

Provision of renewable energy is an important goal, but that does not mean areas immediately adjacent to and highly visible from the Columbia River Gorge National Scenic Area are suitable locations for commercial-scale wind energy. If this project moves forward, the following steps should be required:

- The proponent should go back to the drawing board and test different turbine locations and sizes to reduce visual impacts. Turbines that are visible from key viewing areas within the national

scenic area should be moved or removed. It may be possible to build a smaller number of turbines, carefully located, in such a way as to avoid adverse impacts.

- The analysis should expand the number of viewpoints and should include view duration. Specific turbines that are most visible from the most viewpoints should be identified.
- Photomontages should be re-done to include likely impacts from permanent forest clearing and road construction.
- Photomontages should be redone to reflect the clear sky atmospheric conditions under which the turbines would be most visible.
- Photomontages should be created from initial images shot with a 70mm focal length and reproduced at a full single sheet size that correctly depicts the scale as one would see it in reality.
- Photomontages should include a note describing the ideal distance the viewer should be from the image to best approximate the actual scale.
- Reviewers should note that the images provided, no matter how good, are not reality. The real-world experience of viewing large turbines in three dimensions and much higher brightness will be different, and likely stronger, than can be depicted.
- The proposed development should be required to use newly available radar-activated lights to reduce the scenic impacts of the turbines at night.
- Alternative turbine colors should be considered that may reduce visual contrast. For example, in Scotland light gray turbines have less visual contrast than white ones seen against the sky.

KEY PERSONNEL - MIG

Dean Apostol

Scenic Resource Specialist/Landscape Architect

Education

Bachelor of Science, Landscape Architecture, Iowa State Univ.

Graduate coursework, Geography, Portland State University

License

Landscape Architect: Oregon, #173

Qualifications

Dean Apostol has over 30 years of experience in scenic impact analysis, landscape design and ecological restoration. He is a regional and national expert on scenic resource analysis and conservation, and has served as an expert witness on several projects.

Prior to joining MIG, Mr. Apostol managed a sole-proprietary practice. Some of Mr. Apostol's previous projects include the evaluation of scenic impacts from forest practices in Washington, wind energy proposals in the Columbia Gore National Scenic Area, scenic character analysis for new communities, and mitigation of scenic impacts from highway development. He was also a landscape architect for Mount Hood National Forest for 11 years, where he developed management plans for scenic byways, historic trails, and wild and scenic rivers. In addition, Mr. Apostol helped develop a Natural Resource Management Plan for the Quinalt Nation in Washington State and worked with the Warm Springs Nation on various projects.

While at the Forest Service Mr. Apostol published *Forest Landscape Analysis and Design*, a book that describes a method for integrating planning and ecology over large forested areas. He managed multiple scenic resource conservation projects, from wild and scenic rivers to ski areas. Mr. Apostol has also published *Restoring the Pacific Northwest: The Art and Science of Ecological Restoration* in Cascadia in 2006, the leading text on the practice of ecological restoration in the Northwest region. He co-authored chapters on landscape scale and riparian restoration, and co-authored *Designing Sustainable Forest Landscapes* (Taylor and Francis Press, 2008). This text integrates conservation of forest scenery with forest ecology for temperate regions. Mr. Apostol continues to write, lecture and teach at the University of Oregon and Portland State University on natural resource management and ecological restoration topics.

**Comments on the Whistling Ridge Wind Energy Power Project DEIS
Skamania County, Washington**

K. Shawn Smallwood, Ph.D.

27 August 2010

Friends of the Columbia Gorge asked me to prepare an expert comment letter on the Whistling Ridge Wind Energy Project DEIS.¹ I reviewed this document and its appendices. My comments will mostly address the baseline data used to assess impacts and proposed mitigation measures. A summary of my comments appears on page 24.

I am an ecologist with 25 years of research and consulting experience on issues related to wildlife management and conservation problems. My qualifications for preparing this declaration are summarized in my curriculum vitae, which is attached. I received a Ph.D. degree in ecology from the University of California at Davis in 1990. Following four years of post-graduate research in the Agronomy and Range Science Department at UCD, I have worked for citizen groups, businesses, attorneys, and government agencies, largely on solving problems affecting wildlife, especially on special-status species.

I have eleven years of experience with the biological impacts caused by wind turbines. I performed multiple monitoring and research programs in the Altamont Pass Wind Resources Area (APWRA), and I senior authored many reports that followed, most of which were peer-reviewed. I consulted for the California Energy Commission on matters related to wind farm development. I also consulted to wind power companies, and helped project applicants obtain permits to repower a portion of the APWRA. My contribution to wind energy development has been to produce research-based solutions to avoiding, minimizing, and reducing bird collisions with wind turbines.²

ESTIMATES OF PROJECT IMPACTS – WIND TURBINE COLLISIONS

WEST, Inc. appeared to have relied on several types of empirical evidence to predict wind turbine-caused impacts at the proposed 75 MW Whistling Ridge wind energy project. These lines of evidence included a model based on fatality rates regressed on utilization rates, comparisons of exposure index values among species seen at the site, and a comparison of raptor nest density to nesting densities at other wind project sites. However, these approaches have consistently led to inaccurate predictions of project impacts at other locations (see below), and therefore should be examined carefully before relying on them yet again.

Predicted Collision Rates

Not only have most predictions of raptor fatality rates at wind projects been proven wrong after the project was developed and monitored for fatalities, but some of the wrong predictions have been very wrong (Table 1). Following construction and monitoring, raptor fatalities were estimated to be twice as high as predicted at Stateline, nearly 5 times higher than predicted at

Hopkins Ridge, 3 times higher than predicted at Wild Horse, 6.9 times higher than predicted at Shiloh I, at least 11 times higher than predicted at Klondike II, and about 14 times higher than predicted at Big Horn. Even in the scientific field of wildlife biology, prediction errors of these magnitudes would be considered gross failures. Prediction failures are caused by fundamental shortfalls in the assumptions and methodology used to make the predictions.³ The repeat failures to predict wind project impacts should prompt the States of Washington and Oregon to demand a review of the methods used, and to require new standards, including consequences for wind projects exceeding predicted fatality levels by more than 50%.

Table 1. *Predictions of raptor fatality rates at proposed wind projects, and compared to estimated fatality rates following project development. Reported estimates were those appearing in fatality monitoring reports provided by consultants, and the Smallwood estimates were those made by me, using a common set of methods and assumptions, including search detection and scavenger removal rates reported in Smallwood (2007).*

Project	Raptor fatalities / MW / Year			How fatality rates compared to predicted rates
	Predicted	Reported estimate	Smallwood estimate	
Klondike I	0.029 - 0.044	0.000	0.000	Lower
Combine Hills	0.00-0.02	0.000	0.000	Accurate
Buena Vista ^a	0.331-0.581	0.605	0.544	Accurate
Klondike II	~0	0.11	0.062	≥11 times higher
Stateline	0.061	0.091	0.130	1.5 to 2.1 × higher
Big Horn	0.015 – 0.020	0.150	0.243	8.6 to 13.9 × higher
Shiloh I	0.109	0.820	0.756	6.9 to 7.5 × higher
Wild Horse	0.007-0.074	0.090	0.251	2.2 to 3.1 × higher
Hopkins Ridge	0.020-0.040	0.139	0.172	4.6 to 5.7 × higher

^a I co-authored the report that presented the predicted fatality rates for Buena Vista.

Fatality rates regressed on utilization rates

WEST, Inc. relied on a regression relationship (*Figure 8* in App. C-4) that regularly appears in their environmental documentation in support of wind energy projects, and which I have commented on before (see *Figure 1*, below). Affirming its reliance on the WEST, Inc. approach to assessing potential project impacts, the DEIS (page 3-63) stated, “*Mean overall bird use in the study area was low compared to these other wind resource areas studied: ranking 19th compared to 24 other wind resource areas...*” and, “*Mean annual raptor use was 0.28 raptors per plot per 20-minute survey, which is a standardized way to measure use in order to compare results to avian use at other sites.*” However, this approach was inappropriate for use as a predictive tool due to multiple fundamental flaws, which are addressed in the following paragraphs.

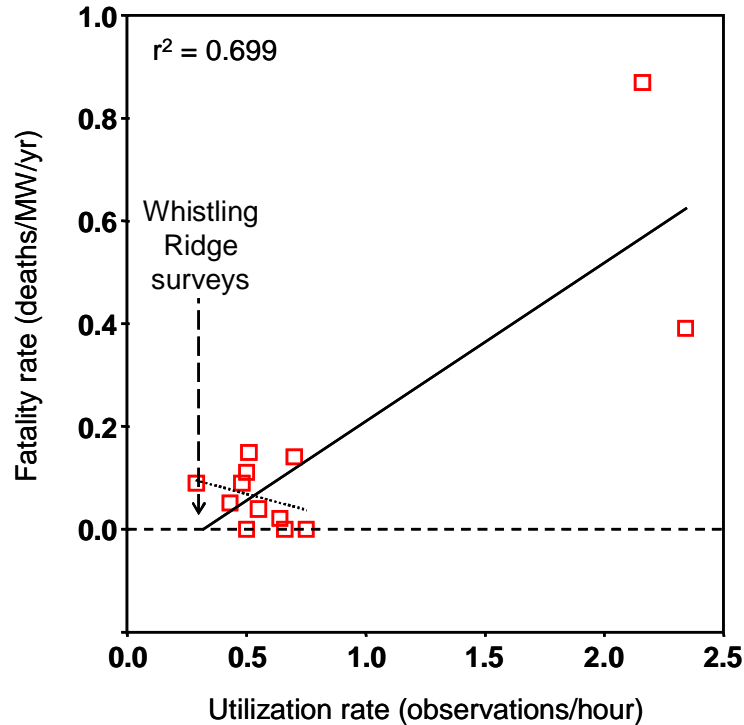

Figure 1. Fatality rate as a function of utilization rate, according to WEST, Inc., Figure 8 in Appendix C-4. The dotted line fitting the clump of data points at the lower left represents an alternative regression relationship if data from the two California WRAs in the upper right aspect of the graph were omitted. The regression relationship was pseudoreplicated.

Sufficiency of survey effort.—The vertical dashed arrow in Figure 1 represents the utilization rate that WEST, Inc. estimated for raptors at the Whistling Ridge project site. Although a non-biologist might be impressed with the number of bird surveys performed at the Whistling Ridge project site, totaling 261 surveys, biologists familiar with utilization surveys at wind project sites have cause for concern regarding conclusions drawn from the level of effort devoted to Whistling Ridge. The 261 surveys lasted 20 minutes each, so totaled 87 hours. Eighty-seven hours was insufficient time to detect multiple raptor species and many other bird species, especially considering the high levels of visual occlusion due to forest cover surrounding observation stations at Whistling Ridge, along with the large volumes of airspace that would have been occluded due to mountainous terrain and cloudiness.

Even the large amount of survey time invested in the Altamont Pass WRA -- where no forest occluded views -- failed to detect multiple species that are killed by APWRA wind turbines, including threatened and endangered species such as brown pelican and peregrine falcon, and many hours were needed to detect only one individual of many species. For example, 774 hours of survey at Vasco Caves Regional Preserve in the Altamont Pass WRA⁴ failed to detect peregrine falcon even though this species was twice documented as killed by Altamont Pass wind turbines. At Vasco Caves, it took 387 hours per merlin observation, even though this species is killed by Altamont Pass wind turbines. It took all 774 hours to detect one red-shouldered hawk, and it took 70 hours per Cooper's hawk observation and 55 hours per Swainson's hawk observation, even though members of these species have been killed in the

Altamont Pass. Just because a species goes undetected in the minimal survey efforts that have been directed to birds at wind project sites does not mean that that species will avoid collisions with wind turbines.

An earlier study in a different part of the Altamont Pass WRA involved 980 hours of bird surveys.⁵ In that study the number of hours required per observation was 490 for Cooper's hawk, 980 for white-tailed kite, 163 for rough-legged hawk, 7 for loggerhead shrike (a commonly killed species), 43 for cliff swallow (another commonly killed species), and 2 for golden eagle. Even though in the Altamont Pass we invested more than 11 times the hours committed to Whistling Ridge, we were unable to detect any significant relationships between fatality rates and utilization rates among rows or larger plots of wind turbines.⁶ My colleagues and I concluded that not only were relatively small sample sizes an impediment to detecting a relationship between fatality rates and utilization rates, but there was the interference of a substantial bias caused by declining survey detection rates with increasing distance from the observer, especially for smaller-bodied bird species. The survey effort at Whistling Ridge was grossly insufficient for informing decision-makers about the impacts of the project that will be caused by wind turbine collisions with birds.

The surveys were diurnal.—The utilization surveys at Whistling Ridge did not record any birds flying at dawn, dusk, or at night, so they inadequately characterized the suite of bird species that uses the project area. (Utilization surveys are different from protocol-level call-back surveys used to detect northern spotted owls, and the data are recorded differently and used differently, including for wind turbine siting.) No nocturnal owl species would have been detected unless an owl flushed in daylight hours for some reason, and multiple other species would have been missed if they flew at night. This shortfall can be applied to most survey efforts that have been performed at wind project sites throughout the USA, so it was not unique to Whistling Ridge. This shortfall should be acknowledged and the level of uncertainty attributed to conclusions of impacts should be increased.

Variation in visibility of surveyed airspace.—Survey observation stations are typically located on prominent aspects of the study area so that the observers can scan for birds in as much of the airspace as possible. The surveyed airspace is that airspace between the observer and the maximum survey radius (a maximum distance from the observer), and between the ground and to whatever elevation above the ground (ceiling) the surveyor is scanning for birds. WEST, Inc. routinely uses an 800-m maximum survey radius. However, at least some of the airspace between the observer and the maximum survey radius is usually hidden from the observer, due to hills, the slope of the hill upon which the observer stands, trees, and the prevalence of fog or clouds. In hilly or mountainous terrain, observers stationed on prominent locations might be able to see a smaller proportion of the available airspace between 40 and 100 m away due to the slope dropping away from the observer. These observers might be able to survey a larger volume of airspace between 100 and 250 m away because those distances overlap canyon bottoms into which the observer might be able to see and over which there is more airspace due to a larger elevation range extending from below the observer (canyon bottom) to whatever elevation ceiling the observations might extend (assuming there is a ceiling). In other words, prominent locations tend to provide surveyors with variable volumes and proportions of volumes of

airspace as functions of distance from the observer, due to the manner in which the ground surface slopes away from the observation station.

The ground surface area of a flat circle within 800 m of the observer at a single station equals 2.01 km². Assuming the WEST, Inc. survey team can see birds as high as they seem to think they can see them in distance, the volume of airspace surveyed on perfectly flat and unobstructed landscapes would be 1.61 km³, which in my opinion is a huge volume of airspace in which to expect to see more than a small fraction of the available birds. In the Altamont Pass my colleagues and I did not believe we could reliably detect most birds flying as high as 800 m, so we selected a ceiling of 140 m above the elevation of the observer, excluding birds above that ceiling from utilization rate estimates. This 140-m ceiling above flat terrain would have the surveyors searching 0.28 km³, which is still a volume I consider unmanageable, but which is much smaller than within an 800-m ceiling.

However, flat ground is rarely where bird surveys are performed in WRAs, especially in the Pacific Northwest. From station to station, and from project site to project site across the US, the visible volume of airspace surveyed will vary greatly due to variability in topography and forest cover surrounding each station. To illustrate the influence of this variability, Lee Neher and I constructed a digital elevation model (DEM) of the Vasco Caves Regional Preserve in the Altamont Pass and we calculated the volume of airspace visible from each of 15 observation stations (Figure 2). Our results demonstrated that bird observations need to be related to visible volumes of airspace to avoid confounding any comparison that would be made of utilization rates among observation stations or wind project sites.

Figure 2. Change in mean (left graph) and station-specific (right graph) percentage of visible volume of airspace within 140-m ceiling and within specific radial bands from the observer (x-axis) among 15 observation stations at Vasco Caves Regional Preserve in the Altamont Pass.

Note that our maximum survey radius was 2009 feet, or 600 m, whereas WEST, Inc. uses a maximum survey radius of 800 m, including at Whistling Ridge. Projecting the trends in this Figure to 800 m, we might expect a mean of 60% of the airspace to be visible, ranging about 20% to 94% among the stations, and this variation did not include airspace hidden by forest surrounding observation stations at Whistling Ridge. Without accounting for this source of variation in utilization rates, comparing utilization among sites within a project area could be misleading, and comparing utilization rates among wind project sites across the US might qualify as very misleading.

800 m maximum survey radius was too far.--Lee Neher and I quantified the effect of variable distances of birds from the observer, using our DEM of a project area in the Altamont Pass (Figures 3 and 4). We calculated detection functions from the patterns depicted in Figures 3 and 4 (see Table 2), enabling me to project our detection rates to visible volumes of airspace within the maximum survey radii used by other investigators. Raptor utilization rates within an 800 m maximum survey radius would be reported at about 81% of the rate within a 600 m maximum survey radius, at 60% of the rate within a 400 m survey radius, and 22% of the rate within a 100 m survey radius. Without accounting for the effect of distance from the observer, utilization rates cannot be compared among wind projects, nor can utilization rates be compared appropriately among species.

Table 2. First detections/hr/km³ of visible airspace regressed on distance from observer within radial boundary increased from 30 m to 600 m at Vasco Caves Regional Preserve, California.

Species/Group	Model	Model parameters				
		a	b	r ²	SE	P
Golden eagle	Power	12.6915	-0.7430	0.97	0.10	0.001
Red-tailed hawk	Power	90.0736	-0.6041	0.96	0.10	0.001
Turkey vulture	Power	66.4367	-0.7159	0.97	0.11	0.001
Northern harrier	Logarithmic	11.0526	-3.2695	0.95	0.63	0.001
Prairie falcon	Power	21.8581	-1.1817	0.98	0.14	0.001
American kestrel	Power	75.5038	-1.0143	0.94	0.21	0.001
Raptors	Power	281.1493	-0.7349	0.97	0.10	0.001
Common raven	Power	306.0222	-0.7777	0.97	0.12	0.001

Pseudoreplication.--The regression relationship in Figure 8 of App. C-4 likely exemplifies pseudoreplication in correlation analysis, which is a fundamental experimental design flaw that is routinely warned against in statistics textbooks.⁷ The regression is based on two clusters of data, one from wind projects located mostly in the Pacific Northwest and the other from two projects located nearby each other in California. If the variation in the graph was more representative of the two regions -- Washington/Oregon versus Central California -- than of the individual project sites, then the sampling units were really the regions and not the project sites. In presenting their graph, Johnson and Erickson (2008, 2010) presented a value for the coefficient of determination, r^2 , but they neglected to present an error term. Furthermore, they presented the relationship as significant, and the DEIS repeated that conclusion along with the prediction, based on the regression, that 0 raptors would be killed by Whistling Ridge wind turbines (page 3-79).

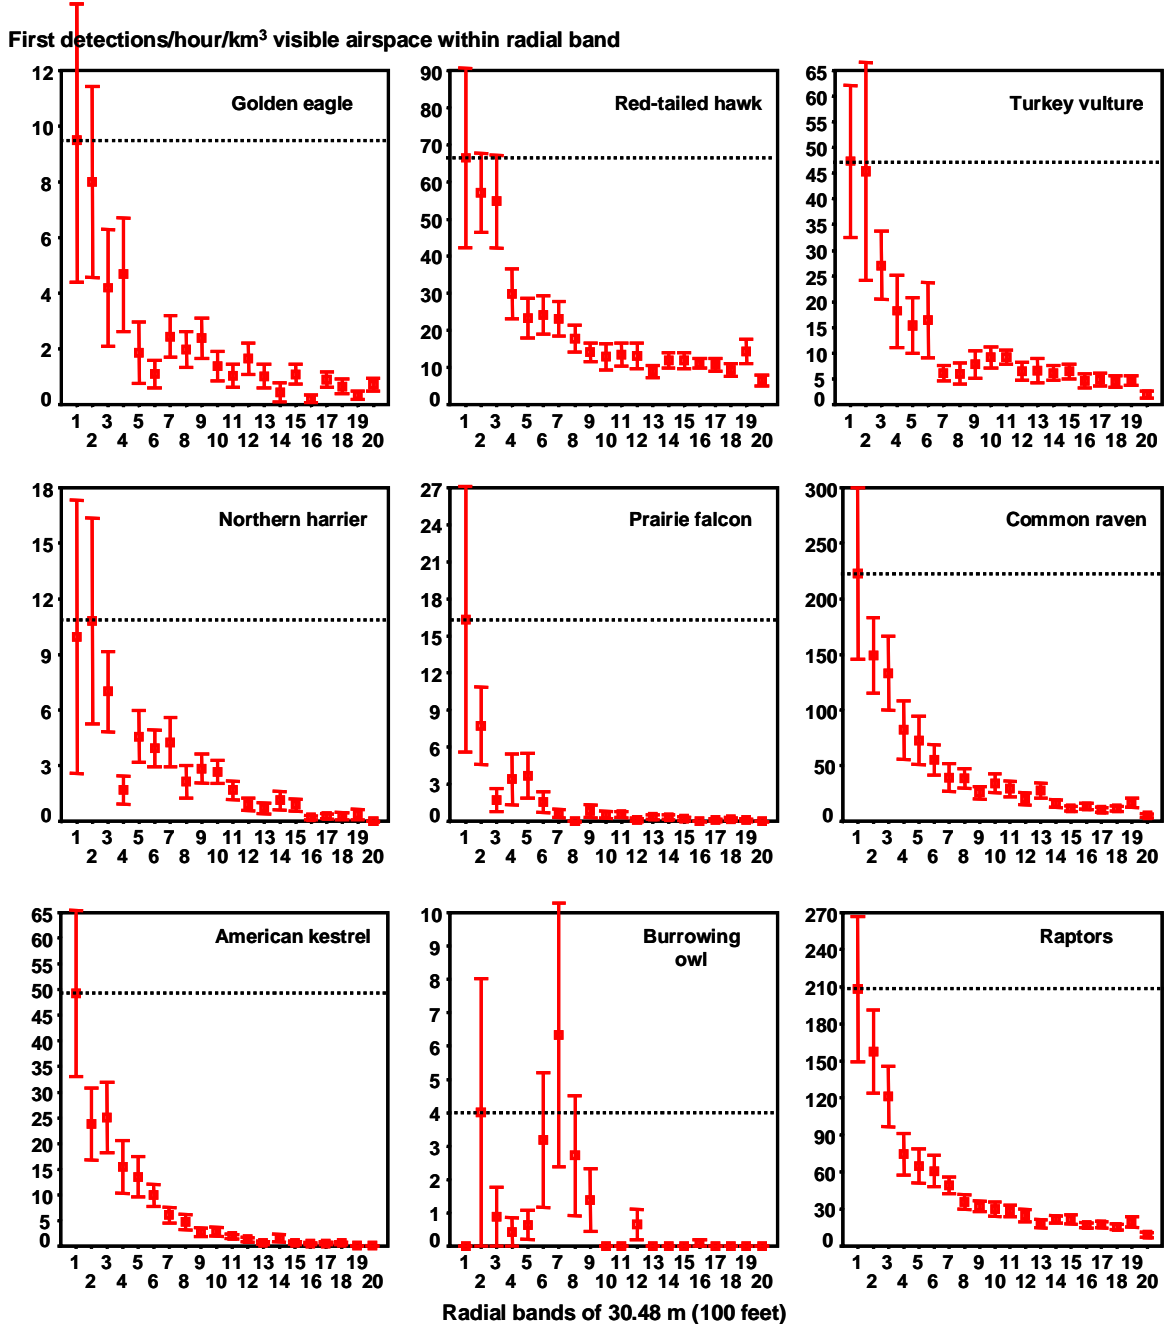

Figure 3. Within specific 100-foot radial bands, mean first detections/hour/km³ of visible airspace decreased with increasing distance from the observer for golden eagle, red-tailed hawk, turkey vulture, northern harrier, prairie falcon, common raven, American kestrel, burrowing owl, and all raptors as a group in Vasco Caves Regional Preserve, 2006-2007. Horizontal dashed lines represented detection rates expected of each species assuming spatial distributions were most accurate within the closest 100 or 200 feet to the observer.

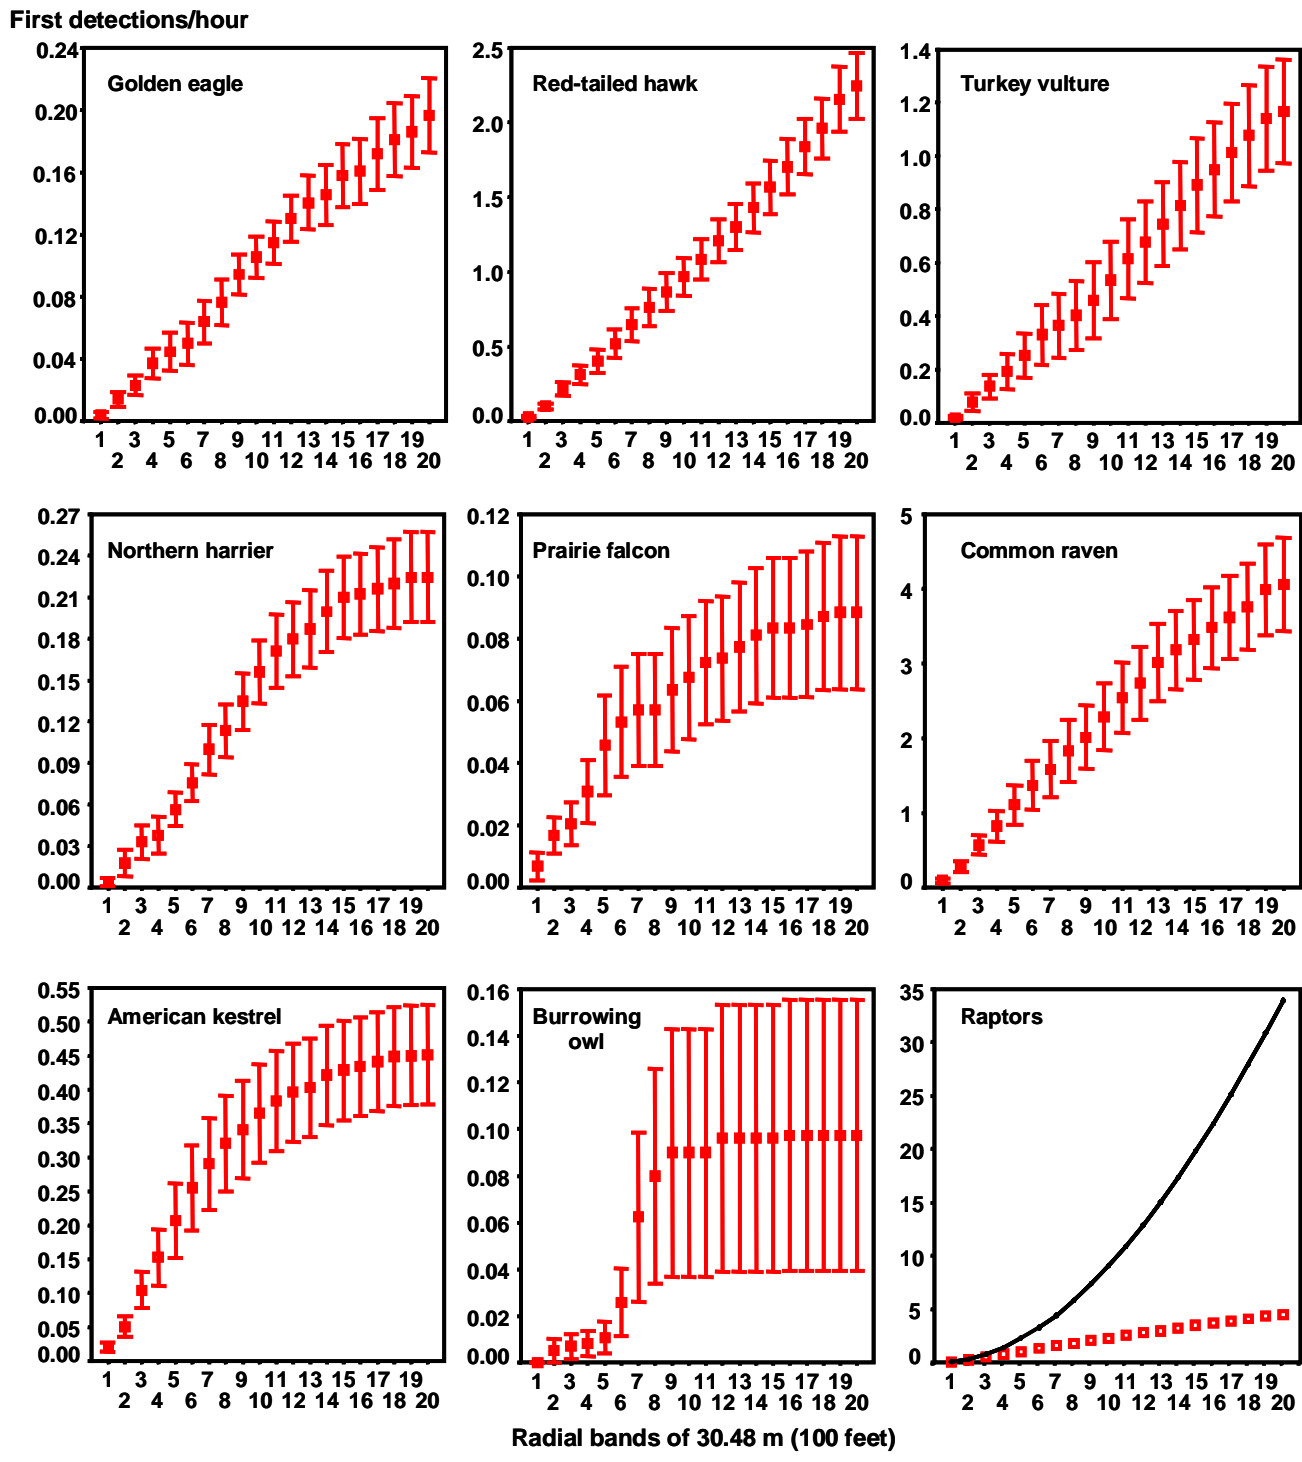

Figure 4. Cumulative mean first detections/hour increased with increasing distance from the observer for golden eagle, red-tailed hawk, turkey vulture, northern harrier, prairie falcon, common raven, American kestrel, burrowing owl, and all raptors as a group in Vasco Caves Regional Preserve, 2006-2007. The solid line in the lower right graph depicts the exponential increase in cumulative detections of raptors, assuming the spatial distribution of raptors was unaffected by the locations of observation stations and detection rate was most accurate within the closest 100 feet.

The coefficient of determination is an index of both response and precision, but the reader must be familiar with regression analysis to visually assess the degrees to which variability or precision contributed to r^2 . A more direct measure of precision is the root mean square error (RMSE) of the regression, otherwise known as standard error. In my experience, RMSE can serve as a diagnostic tool for deciding whether r^2 was influenced more by leveraging from outliers or from pseudoreplication. Another diagnostic test is to omit data from one of the clusters to learn whether the regression slope would change significantly. In fact, omitting the two data points from Central California project sites converted a strongly positive slope to a negative slope (see dotted line in Figure 1), and the revised regression line was a better fit to the data, based on RMSE (RMSE = 0.0567, which was a third of the value for the pseudoreplicated regression slope). In cases like this, when two data points determine whether an estimated regression slope is strongly positive or negative, the analyst should not use the regression equation to make predictions. It was inappropriate for the DEIS to predict that 0 raptors would be killed by Whistling Ridge.

Accuracy of fatality rates.—Where able, and in the time I had before preparing this comment letter, I used data available in reports to independently estimate fatality rates at project sites across the western USA. My estimates averaged 2.44 times higher than reported for all birds as a group (N = 23 reports), 1.34 times higher for all raptors as a group (N = 23), and 2 times higher for all bats (N = 20). Probably the principal reason for my higher estimates was the difference in fatality estimator. Most of the monitoring reports I reviewed had utilized the following estimator of fatalities per MW per year, F_A :

$$F_A = \frac{F_U}{\left(\frac{\bar{t} \times p}{I}\right) \cdot \left(\frac{e^{1/\bar{t}} - 1}{e^{1/\bar{t}} - 1 + p}\right)}, \quad \text{eqn. 1}$$

where F_U is unadjusted average number of carcasses observed per MW per year, \bar{t} is mean number of days until carcass removal, and is estimated by scavenger removal trials, p is proportion of carcasses found by fatality searchers during searcher detection trials, and I is average search interval in days. The other estimator in use, and the one I use, is derived from the Horvitz and Thompson (1952)⁸ estimator:

$$F_A = \frac{F_U}{R_C \times p}, \quad \text{eqn. 2}$$

where R_C is the average proportion of carcasses remaining since the last fatality search and is estimated by scavenger removal trials. I assume carcasses are deposited at a steady rate from wind turbines, so I take the average proportion of carcasses remaining each sequential day between searches:

$$R_C = \frac{\sum_{i=1}^I R_i}{I}, \quad \text{eqn. 3}$$

where R_i is proportion of carcasses remaining by the i th day following the initiation of a scavenger removal trial. Thus, the expected proportion of carcasses remaining by the next fatality search should be R_C corresponding with the fatality search interval, I .

A key difference between the two estimators is the use of \bar{t} in eqn. 1 and the use of R_C in eqn. 2. The sample size of placed carcasses contributing to R_C never changes from start to finish of a removal trial, as none of the carcasses need to be censored. On the other hand, the sample size contributing to \bar{t} starts small and increases quickly as the trial grows longer (Figure 5, left graph). If 10 carcasses were placed to obtain R_C , then 10 carcasses will contribute to R_C after 1 day, 10 days, or 30 days. If 10 carcasses are placed to obtain \bar{t} , then it may be that none of them will contribute to \bar{t} after a day because none had been removed by then, and so all had to be censored from the calculation. If 4 carcasses were removed after 10 days, then only these 4 would contribute to the calculation of \bar{t} . If 7 carcasses were removed after 30 days, then only these 7 would contribute to the calculation of \bar{t} . Thus, \bar{t} increases exponentially with the sample size used to calculate \bar{t} because the increasingly large sample is also composed of carcasses that have persisted longer into the trial (Figure 5, right graph). Furthermore, \bar{t} increases nonlinearly with number of days into a trial (Figure 6), indicating a bias. Perhaps the main bias, however, is the use of \bar{t} , which is derived from a time period that is necessarily much longer than the average search interval of the fatality monitoring (see text that follows).

Figure 5. Sample sizes used to calculate mean days to carcass removal decline with shorter trial duration (left graph), and mean days to removal increases exponentially with sample size (right graph) at Vasco Caves Regional Preserve, Altamont Pass, California.

Figure 6. Mean days to carcass removal increases with longer duration of the carcass removal trial at Vasco Caves Regional Preserve, Altamont Pass, California.

When censoring remaining carcasses, \bar{t} cannot be calculated unless at least one carcass has been removed. If no carcasses are removed during a trial, then \bar{t} will be undefined, whereas R_C would equal 1 and the fatality rate could still be estimated. To prevent a trial result in which no carcasses are removed, and hence \bar{t} cannot be calculated, investigators can place larger numbers of carcasses or they can perform longer trials. Placing larger numbers of carcasses can potentially swamp the vertebrate scavengers, thereby increasing mean days to removal. The option to perform longer trials might help explain why many of the trials intended to obtain \bar{t} have been conducted for 40 to 64 days, or from nearly twice as long to more than four times longer than the average search interval used in the corresponding fatality monitoring. Values of \bar{t} derived from such long trials will be larger than those derived from trials lasting no longer than the fatality search interval (Figure 5), and the fatality rates will be underestimated.

I must also point out that my estimates, relying on eqn. 1, remain conservative because I have yet to account for declining searcher detection rates as the search interval increases (searcher detection trials are based on a search interval of less or equal to one day). I also have not accounted for crippling bias – the non-detection of mortally wounded birds that leave the search area on their own volition before perishing – because there is no means to account for this bias. Underestimates of fatality rates in the Pacific Northwest might be partly caused by reliance on mean days to carcass removal as an adjustment for scavenger removal rates (Smallwood 2007), but some of the scavenger removal trials were sufficiently flawed that I had to replace their results with national averages in Smallwood (2007). Under-estimated fatality rates have been used to predict fatality rates of planned projects, which may be one reason why predicted fatality rates have so often been wrong (Table 1). The regression analysis appearing in Figure 8 of App. C-4 was based on inaccurate fatality rate estimates.

Accounting for inter-annual variation.—The data presented in *Figure 8* of App. C-4 were derived mostly from one-year monitoring programs. However, inter-annual variation in fatality rates and utilization rates can be very high at a given project site. For example, fatality rates varied 5.7-fold from low to high over 8 years within a 10-year period in the Altamont Pass WRA (*Figure 7*). They varied nearly 2-fold over a 3-year period at Foote Creek Rim⁹ and nearly 3-fold over a 4-year period at Buffalo Ridge.¹⁰ Given this range of variation, single-year estimates are mere snapshots of fatality rates and unlikely to reveal meaningful relationships between fatality rates and utilization rates among wind projects.

Figure 7. Inter-annual estimates of raptor fatality rates in the Altamont Pass WRA.

Regression relationship based on selective inclusion of data.—*Figure 8* of App. C-4 was based on only some of the wind projects for which there exists fatality rate and utilization rate estimates. Including more of the estimates available, the regression slope reported by Johnson et al. in the Whistling Ridge DEIS no longer applies (*Figure 8*).

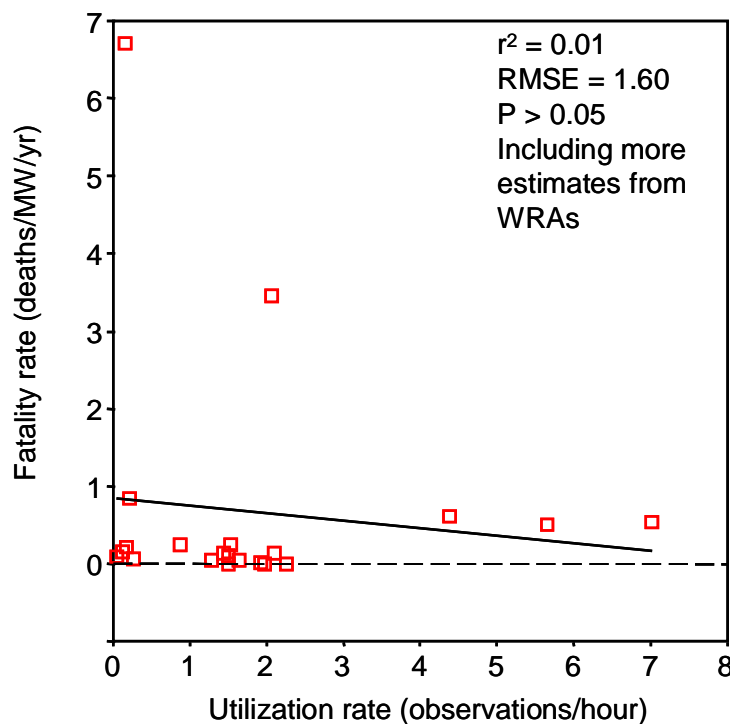

Figure 8. Fatality rate estimates regressed on utilization rate estimates after including data from additional WRAs to those used by WEST, Inc.

Consistency of regression relationship.—WEST, Inc. has been inconsistent in its utilization rates and fatality rates used to construct the regression model in *Figure 8* of App. C-4. For example, in the environmental review documents prepared for Windy Point, Windy Flats, and Hatchet Ridge, data representing the two extreme California wind projects (Diablo Winds and High Winds) indicated 30% higher utilization rates than depicted in the Whistling Ridge DEIS. Also, the fatality rate representing Diablo Winds was half as great in the Windy point, Windy Flats, and Hatchet Ridge documents compared to the Whistling Ridge DEIS. Compared to the regression model presented in the environmental review documents for Windy Point, Windy Flats, and Hatchet Ridge, the regression slope was more than twice as steep in the model presented for Whistling Ridge. These inconsistencies should be explained.

Fitted regression line intercepts 0 fatalities before it intercepts Y-axis.—The DEIS (page 3-79) predicted that Whistling Ridge will cause 0 raptor fatalities because its estimated utilization rate appeared to the left of the Y-axis 0-intercept in *Figure 8* of App. C-4. This prediction was unrealistic and inconsistent with the very data that contributed to the estimated regression line. In fact, one of the wind projects that contributed to Johnson et al.'s regression model also appeared to the left of the Y-axis 0-intercept, but it was represented as having killed 0.09 raptors/MW/year (my estimate of the fatality rate of this project was twice as high, however). In addition to this inconsistency in the use of the regression, omitting the two Central California wind projects from the analysis flips the regression slope from positive to negative, potentially leading to an opposite conclusion – that Whistling Ridge will kill more raptors than any other wind project in Washington or Oregon. However, for multiple reasons discussed below, I advise against using my revised regression line or the Johnson et al.'s regression line for predicting fatality rates.

Calculation of utilization rates.—Utilization rates contributing to the regression model were often calculated as means among seasonal totals, rather than annual total observations per year or weighted averages. Weighted averages should be used if surveys were performed regularly across all seasons, where the weightings are based on duration of each season. Without weighting, simple averaging among seasonal total utilization rates likely under-represents the contributions of longer seasons with higher bird use.

Summary of fatality rates regressed on utilization rates

The consultants who prepared the supporting documents for the DEIS have been unable to accurately predict raptor fatality rates, as demonstrated above. In fact, their predictions have been much too low, and the same problem can be demonstrated for bats and other bird species. Upon examination, the methods used to predict fatality rates appear to be ineffective, as raptor fatality rates failed to correlate with nesting densities, utilization rates, and exposure index values. The methods used by the consultants simply do not work. The predictions of fatality rates in the Whistling Ridge DEIS cannot be relied upon.

Exposure index values

On page 3-77, the DEIS summarizes the calculation of the exposure index (also see App. C-4), which it said was used to assess the risk of collision of each bird species. In fact, on the same page and on subsequent pages the DEIS did just that – it offered conclusions about the likelihoods of collision-caused fatalities based on values of the exposure index. However, I have never seen a test of the relationship between fatality rates and exposure index. Based on my own experience attempting to relate fatality rates to variables similar to the exposure index, I am skeptical that WEST, Inc. has actually generated a hypothesis test result that would support the use of the exposure index as a predictive tool. Therefore, I tested for a relationship using data from the Big Horn and Wild Horse Wind Projects (Figure 7).

I found no hint that fatality rates could be predicted by the exposure index. Furthermore, between the two projects 27 species (23%) were not detected during utilization surveys at one or both project sites but were killed by wind turbines at the same project site. Of the 22 species that were detected during utilization surveys at one or both project sites and that were also killed by wind turbines, only 4 of them (18%) were given exposure index values >0 . In other words, there was no correspondence between the exposure index and fatality rates. The exposure index appears to be completely ineffective as a predictor of fatality rates caused by wind projects.

Nesting densities

I collected reports of raptor nesting densities and raptor fatality rates from wind projects throughout the western states. I found no trend in the relationship between fatality rates and nesting density that would suggest that nesting density explains some of the variation in raptor fatality rates (Figure 8).

Figure 7. Relationship between fatality rates and exposure index values for each bird species documented in utilization surveys and fatality searches at the Big Horn and Wild Horse Wind Energy projects. I omitted bats and unidentified birds such as sparrow, falcon, or passerine. I included only estimates for individual, named species, totaling 115 estimates between the project sites (some species appear twice, once for each project site).

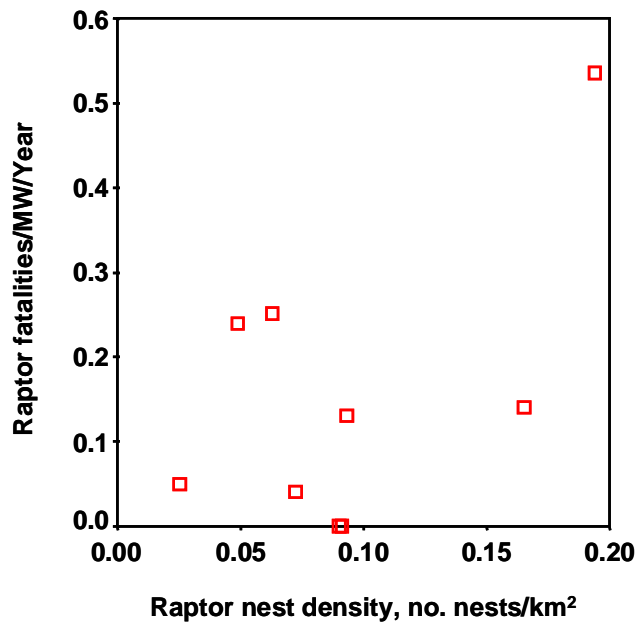

Figure 8. Raptor fatality rates did not correlate significantly with raptor nest densities recorded on project sites and usually within a 2 mile buffer of the project boundaries. Raptor nesting density did not appear to predict raptor fatality rates at wind projects.

ESTIMATES OF PROJECT IMPACTS – COLLISIONS

The DEIS predicted 0 raptors would be killed by the Whistling Ridge wind turbines, but this conclusion did not comport with the record of fatalities documented at existing wind energy projects (Table 3). There have been only two wind projects that documented 0 raptor fatalities, but those estimates were based on one year of monitoring, which was insufficient. Based on reports of fatality monitoring at 23 wind projects in Washington, Oregon and California, the average fatality rates projected to 75 MW of rated capacity would predict 33 raptor fatalities per year, 422 bird (including raptor) fatalities per year, and 86 bat fatalities per year (Table 3). However, the Whistling Ridge project site differs from all the others because it would be in a mountainous and forested environment that is also often enveloped by clouds. Given the absence of existing wind farms in these conditions in the Pacific Northwest, I cannot provide reliable estimates of collision rates at Whistling Ridge, but I caution that fatality rates could be much higher than listed in Table 3.

Furthermore, the fatality rate projections in Table 3 are interim rates before I update Smallwood (2007) to improve the adjustment factors for searcher detection error and scavenger removal rate. My 2007 paper was based on available searcher detection and scavenger removal trials available at the time, but hundreds of trials have been performed since then. I have integrated the data from these hundreds of trials, and I have observed much faster removal rates for most taxonomic groups, especially for bats, as well as lower searcher detection rates. I have not had time yet to finalize my analysis of these data from newer trials. I anticipate that my fatality rate estimates will be higher once I have updated Smallwood (2007).

Table 3. *Predicted wind turbine-caused annual fatalities based on projections of my independent estimates of collision deaths/MW/year among 23 modern wind farms in Washington, Oregon, and California. Note that these projections did not account for the unique environmental setting of Whistling Ridge, as none of the available fatality rate data were from forested landscapes. Fatality rates could be considerably higher at Whistling Ridge due to forest cover and due to occlusion of turbines caused by the area being frequently enveloped by clouds.*

Group	Collision deaths/MW/yr		Annual deaths
	Predicted in Whistling Ridge DEIS	Mean among 23 modern wind projects in western US	Projected to Whistling Ridge
All raptors	0	0.438	33
All birds	No prediction	5.623	422
All bats	“Some”	1.143	86

ESTIMATES OF PROJECT IMPACTS -- HABITAT

According to the DEIS (page 3-35), “the project area includes no native habitat and is permanently committed to use by commercial forestry operations...” and, due to frequent and repeated disturbances, “the quality and value of the forest is generally considered low.” These statements reveal a lack of understanding in the habitat concept, and are therefore inappropriate in a document intended to inform the public and decision-makers. Habitat is defined by the

species' use of the environment,¹¹ so there is no such thing as "native habitat." The fact that many terrestrial vertebrate species continue to reside and use the project area, as documented by the utilization surveys,¹² is proof that the project site continues to serve as habitat for many species. Over 87 hours of surveys from fixed observation stations, WEST, Inc. detected 90 species of bird, which equals >1 species per hour detected. For comparison, 979 hours of survey at Altamont Pass detected 35 bird species, or 0.036 species per hour.¹³ Bird species diversity is much greater at Whistling Ridge than at the Altamont Pass, where bird fatalities caused by wind turbines are notoriously high.

Ecological integrity is the degree to which the species assemblage is composed of native species that are supposed to occur in a particular environment. The degree to which a species list is composed of exotic species is a measure of site invisibility, which tends to increase with reduced ecological integrity.¹⁴ Of the 90 bird species detected at Whistling Ridge, only wild turkey was exotic, and this species is quasi-exotic as it only spread its range from east of the Mississippi River. In my experience, Whistling Ridge exhibits a very high level of ecological integrity and a very low level of site invisibility for terrestrial vertebrates. The characterization of poor habitat and low value on Page 3-35 was misleading.

According to the DEIS (page 3-50), "*northern spotted owls will not be "taken" by the proposed project.*" I disagree with the foundation for this conclusion. The argument was made that a US Fish and Wildlife Service protocol can be interpreted to conclude that northern spotted owls no longer occupy historical nest sites because owls were not detected at the sites in 6 to 8 years. Government protocols do not dictate biological reality. It has been well established that animal populations tend to be spatially dynamic, meaning that centers of activity shift periodically.¹⁵ In most cases, the shifting of activity centers tend to shift locations every generation or so, and I would consider 6 to 8 years to be short of a northern spotted owl generation. Hypotheses for the spatial shifts have included: (1) escaping parasite or predator loads; (2) exhaustion of resources; (3) dispersal of progeny as the natal population senesces; and, (4) some combination of these hypothesized factors. Just because a species has not been detected for a while does not mean the species will never return, and I state this without implying that I believe northern spotted owls no longer occur at the site.

Some conclusions in the DEIS were inconsistent with earlier foundation statements. For example, on page 3-59, the DEIS stated, "*little is known about this species [Keen's myotis],*" and then a few sentences later it stated, "*the likelihood of occurrence on the site is considered low.*" Similarly, on page 3-60, the DEIS stated, "*Based on lack of detailed information on this species (Townsend's big-eared bat) distribution and nature of the bat surveys conducted on the site, it is difficult to conclude with certainty the likelihood of Townsend's big-eared bats occurring on the project site. ... the likelihood of occurrence on the site is considered to be low.*" In both these cases, the conclusions of low likelihood of occurrence came immediately following admissions that the analysts knew very little about these species. These types of conclusions are inconsistent with the precautionary principle in risk assessment, which should be a principle applied to any DEIS.

CUMULATIVE IMPACTS ANALYSIS

On page 3-83, the DEIS stated, “*The proposed project would cause mortality to birds and bats through turbine collisions. However, the level of mortality is not anticipated to be sufficient to negatively affect the population viability of any single species.*” This conclusion was offered in the absence of any population viability analyses (PVAs) or any other defensible risk assessments. There is no scientific basis for this conclusion. In the discussion that follows, I address the cumulative impacts analyses performed by WEST, Inc. and included in the DEIS as Appendices C-11 and C-12.

In Apps. C-11 and C-12, Johnson and Erickson (2008)¹⁶ and Young and Poulton (2007)¹⁷ performed what they termed cumulative effects analysis. In the case of Johnson and Erickson (2008), the cumulative effects analysis was of the wind industry’s desired build-out of about 6,700 MW of wind energy capacity on the Columbia Plateau spanning eastern Washington and eastern Oregon. They averaged fatality rates from existing wind farms in the region and multiplied the average rate against the desired build-out capacity of 6,700 MW. They then compared their predicted annual fatalities to their estimates of regional population size, relying on a population estimator based on breeding bird survey (BBS) results from the 1990s and provided by the Partners in Flight North American Landbird Conservation Plan. However, these estimates were unsuitable for the use that Johnson and Erickson (2010) and Young and Poulton (2007) made of them, and I found several other problems with the analysis, discussed below.

Regional Population Estimates.--Johnson and Erickson (2010) neglected to mention that there exist relatively large standard errors associated with the mean detections per BBS route. I used the standard errors to calculate 95% confidence intervals, which yielded very large ranges of population size for each species addressed in Johnson and Erickson (2008). For example, the lower bound estimate for ferruginous hawk was less than 0, and the differences between one side of the confidence interval and the mean population estimate ranged 29% (American kestrel) to 65% (ferruginous hawk) of the magnitude of the mean. Without addressing the large error terms in the data, Johnson and Erickson (2008) inadequately informed the reader about the suitability of their population estimates for assessing biological significance of “cumulative impacts.”

More importantly, Johnson and Erickson (2008) dismissed strong criticism of a review of the Partners in Flight approach. Thogmartin et al. (2006)¹⁸ reviewed the population estimation approach of Partners in Flight, and found the approach to be an inappropriate use of BBS data. The BBS was designed for detecting long-term population trends, but not for estimating population size. Thogmartin et al. (2006) also pointed out several potential biases in the Partners in Flight use of BBS data. The most likely and most substantial bias is the extrapolation of detection rates from roadways across large expanses of potential habitat lacking roads. Having performed many years of bird surveys both along roadways and far from roads, I cannot agree more with Thogmartin et al.’s conclusion that this was a serious bias, and one that likely inflated population estimates of the species addressed in Johnson and Erickson (2008). American kestrels, red-tailed hawks, and ferruginous hawks congregate along roadways because utility poles occur along roadways and are used for perching, especially on agricultural and shrub-steppe landscapes lacking natural tall perch structures. Furthermore, on agricultural landscapes, foraging habitat often occurs as strips between roads and disked fields. Extrapolating densities

from roadways will produce absurdly inflated numerical estimates of numerous bird species, especially for American kestrels because their densities were estimates only within 200 m of BBS routes (the usual radius used by Partners in Flight was 400 m). A later version of Johnson and Erickson's cumulative impacts analysis (Johnson and Erickson 2010), which was mysteriously not the analysis used in App. C11, dismissed Thogmartin et al.'s review because no other regional population estimates exist for the Columbia Plateau. This rationale was unscientific.¹⁹

Johnson and Erickson (2008) did not provide a Partners in Flight estimate of the population size for golden eagles on the Columbia Plateau Ecoregion within Washington and Oregon because golden eagle fatalities had yet to be documented among wind turbines on the Columbia Plateau. However, golden eagle fatalities were subsequently documented, so the 2010 version of Johnson and Erickson's cumulative impacts analysis included a golden eagle population estimate, which was 1,700. For this number of golden eagles to occur on the Columbia Plateau within Washington and Oregon, the population density would have to be nearly as high as recorded in the Altamont Pass, or nearly one nesting pair per 19 km².²⁰ The Altamont Pass golden eagle density was characterized by Hunt et al. as one of the highest ever recorded. Therefore, for the Johnson and Erickson estimate to be true, the Columbia Basin would require an Altamont-level density to extend across the entirety of the Plateau, which is highly unlikely based on my understanding of animal density and distribution. Furthermore, the baseline studies performed by Johnson and Erickson and their WEST, Inc. colleagues have universally reported much lower golden eagle observations per hour among project sites in the Columbia Plateau Ecoregion as compared to the utilization rates documented in the Altamont Pass. As examples, WEST, Inc. reported 0 golden eagle observations during baseline surveys at Big Horn, 0.07/hour after 90 hours at Wild Horse, 0.033/hour after 270 hours at Golden Hills, 0.024/hour after 126 hours at Hopkins Ridge. For comparison, representative observation rates from the Altamont Pass have been 0.278/hour and 0.314/hour. The golden eagle population on the Columbia Plateau cannot be just as dense as in the Altamont Pass while at the same time trained observers count them at rates that are 0%, 8%, and 24% of the rates observed in the Altamont Pass.

As for Swainson's hawk, Johnson and Erickson (2008) estimated 10,000 breeding Swainson's hawks reside on the Columbia Plateau within Washington and Oregon. My model of nesting density projected only 579 pairs, or 1,158 adults.²¹ My projection was extended beyond all the population density estimates that were available to contribute to the model, so to be conservative I can rationalize doubling my estimate to 2,315, which is still a much smaller population size than estimated by Johnson and Erickson.

Johnson and Erickson estimated the breeding American kestrel population to be 170,000 on the Columbia Plateau within Washington and Oregon. This number would amount to 7% of the entire North American breeding population that was estimated 28 years ago, and it would be a much larger percentage of today's North American breeding population.²² It would have me believe that at least 7% of North America's American kestrel population resides on 0.55% of North America's land mass, or nearly 13 times more densely other than expected in the Columbia Plateau Ecoregion. This regional population estimate also would have me believe there resides 1 breeding American kestrel for every 0.79 km², or one pair per 1.58 km². This density across such a large area would be highly unlikely. Furthermore, Johnson and Erickson

(2008) claimed that the level of mortality likely to be caused by wind turbines following desired build-out in the Columbia Plateau would be sustainable and therefore of no significant population impact. This conclusion was not supported by a scientifically acceptable analysis, and it was inconsistent with the overall declining trend of American kestrels across North American and within Washington, specifically.²³

Fatality Rates.--Johnson and Erickson (2008, 2010) compared fatality rates among Oregon and Washington wind farms, and then extrapolated the mean fatality rates to the projected build-out of 6,700 MW of wind power capacity in the Columbia Plateau Ecoregion. The fatality rates in their Table 2 (Table 1 in the 2010 analysis) were too low (Table 4). For example, using the same data, I found their estimates to be low for Big Horn, Wild Horse, and Stateline. The raptor fatality rate reported for Big Horn was 0.15 deaths/MW/year, whereas I estimated the rate to be 60% higher.²⁴ The raptor fatality rate at Wild Horse was reported to be 0.09 deaths/MW/year, but I estimate the rate to be 178% higher. The raptor fatality rate at Stateline was reported to be 0.091 deaths/MW/year, but I estimated the rate to be 43% higher. Extrapolating my Wild Horse fatality rate estimates to 6,700 MW of cumulative capacity yielded 1,688 raptors per year and 27,230 total birds per year. Extrapolating my Big Horn fatality rate estimates to 6,700 MW of cumulative capacity yielded 1,625 raptors per year and 23,568 total birds per year. The average of the extrapolations from these two projects yielded 1,656 raptors per year and 25,399 total birds per year. These extrapolations are 3.2 times greater for all raptors and 1.4 times greater for all birds than forecast by Johnson and Erickson (2008, 2010), and I have yet to consider the confidence intervals around the fatality rate estimates, which are very large. As for American kestrel, Johnson and Erickson (2008, 2010) forecast 162 deaths/MW/year, but my average estimates between Wild Horse and Big Horn, extrapolated to 6,700 MW, indicates the cumulative toll will be 1,381 deaths/MW/year, or 8.5 times greater than forecast by Johnson and Erickson (2008, 2010).

I also compared cumulative annual fatalities predicted by WEST, Inc. (and included in the DEIS) to my predictions based on my independent estimates of fatality rates using data in the same reports (Table 4). Compared to the predictions made by WEST, Inc., my predicted cumulative annual fatalities caused by the projected build-out of wind energy facilities in the Columbia Basin Ecoregion were 6.3 times greater for raptors, 2.6 times greater for all birds as a group, and about the same for bats (Table 4). Most of the difference in predictions between those made by me and WEST, Inc. can be explained by the estimators used, and specifically whether scavenger removal rates of carcasses were characterized by mean days to removal or by proportion of carcasses remaining at the *i*th day into a removal trial (see earlier discussion).

Table 4. Differences in predicted fatality rates across neighboring Klickitat County and across the Columbia Basin Ecoregion, where the predictions were made by WEST, Inc. and by my use of the same data in available reports. Note that Whistling Ridge is not part of the Columbia Basin Ecoregion, but the DEIS nevertheless relied on a cumulative impacts analysis directed toward wind projects in the Columbia Basin Ecoregion. In either case, the WEST, Inc. estimates of fatality rates were much lower than my estimates, based on the same data.

Group	Annual deaths in 1,000 MW Klickitat County		Annual deaths in 6,700 MW Columbia Basin Ecoregion		My estimate as multiple of WEST, Inc. estimates	
	Predicted by WEST (2004) ²⁵	Projected by my mean estimate (N = 23)	Predicted by Johnson and Erickson (2008)	Projected by my mean estimate (N = 23)	Klickitat County	Columbia Basin Ecoregion
All raptors	33	438	469	2,935	13.3	6.3
All birds	1461	5,623	14,539	37,674	3.8	2.6
All bats	467-600	1,143	7,906	7,658	1.9-2.4	1.0

Avian Use Rates.--It was inappropriate to compare avian use rates among wind farms without accounting for differences in maximum survey distances from the observer and in volumes of visible airspace from observation stations. Topography varies from place to place, and so does the proportion of the survey area that is visible from the observation stations. Also, detection rates of birds decline rapidly with distance from the observer, more so for smaller-bodied birds, so comparing use rates between wind farms will be substantially biased when the maximum survey distance was 800 meters in one wind farm and only 400 meters in another, or when few birds of one species will be detected beyond 300 m whereas most birds of another species will be detectable to 800 m. Without accounting for species-specific detection functions and variation in visible airspace due to topographic occlusion, comparisons of use rates cannot be reliable.²⁶

ADDITIONAL COMMENTS ON THE DEIS

Cumulative impacts analysis in App. C-12 (page 1) identified dryland agriculture, CRP, and rangeland to be more suitable for wind power development on the Columbia Plateau than the surrounding mountainous areas that are more forested. I agree with this assessment. While developing a screening tool for siting wind energy facilities in California, I discovered that forested sites pose greater hazards to more bird species, including special-status species.²⁷ It appeared that overall impacts of wind power projects on wildlife would likely be greater in forested environments.

According to the DEIS (page 3-46), “*Although [golden eagles] soar at high altitudes, they drop down to the ground to capture prey.*” This characterization can be misleading. Golden eagles typically hunt while flying low to the ground, using a flight behavior termed ‘contour flying.’ In fact, the summary of the two golden eagles seen flying on the project site (same page, 3-46) indicated the eagles were at heights above ground typical of the heights used during contour flights. This contour flying appears to be a behavior that predisposes golden eagles to wind turbine collisions, and it is not a behavior that this species will change.

MITIGATION MEASURES

The DEIS listed several wind turbine design features as mitigation measures, including:

- Use of tubular tower to minimize perching;
- Minimize use of turbines lighting to minimize the chance of disorienting birds and bats; and,
- Install newer generation up-wind turbines.

However, all three of these design features are pursued for economic reasons having nothing to do with mitigating wildlife impacts, and there is no empirical evidence that any of these features have anything to do with bird and bat fatalities. These design features do not in any way mitigate for the impacts of bird and bat collisions.

Conducting a raptor nest survey prior to construction would unlikely mitigate project impacts. How could it, other than influencing the timing of installation to minimize disturbance caused by construction activities? There is no established relationship between raptor nest density and wind turbine collision rates.

I concur with the need for post-construction fatality monitoring, but I would set the minimum to three years instead of two years, and I would require that all the turbines are searched for fatalities over the first three years and that a subset of the turbines be searched through the life of the project.

I agree that a Technical Advisory Committee (TAC) should be established, but EFSEC and BPA should impose minimum standards for TAC membership, including scientific credentials and experience with issues relevant to avian and bat impacts caused by wind projects. The TAC should be clearly authorized to select the fatality monitor, to require additional mitigation, and to change the monitoring. However, this measure should refrain from giving the impression that additional mitigation measures are readily available. In truth, there is little if anything that can be done to reduce bird and bat fatalities once the wind turbines are installed. There is no evidence that any measures have been implemented to reduce bird fatalities at modern wind energy projects, and so no evidence that any measures were effective.³¹

Unless the TAC is formed long before project construction, I do not believe mention should be made of adaptive management. To be true adaptive management, the measures would need to be formulated ahead of time, along with thresholds of success and alternative prescriptions. The TAC should work together with stakeholder groups to formulate an adaptive management plan, and the plan should be informed by adequate, directed pre-construction surveys. The currently available surveys are not adequate for informing adaptive management.

Recommended Mitigation Measures

Once the wind turbines are installed, there is little, if anything, that can be done to reduce fatality rates. Therefore, it is very important to carefully plan the installation of wind turbines, including tower height and wind turbine siting. Lee Neher and I have developed spatial models to predict hazard zones for specific species of raptor in the Altamont Pass, relying heavily on behavior and utilization surveys. Sufficient sample sizes of birds displaying specific flight behaviors, e.g., hovering, contouring, fly-catching, are needed to inform the models, which also rely on a resolute digital elevation model of the project area so that slope and wind conditions can be measured and related to bird flight patterns. Our models are being implemented in two repowering projects. Our approach or a similar approach should be utilized at Whistling Ridge, if the project is developed.

Once wind turbines are carefully sited, tower heights are decided upon to minimize encounters with birds, and the electrical distribution system is designed to minimize impacts, the wind turbine-caused fatalities should be low enough to establish a reasonable nexus between the project's impacts and the benefits gained through compensatory, offset mitigation.

Fatality monitoring and post-construction utilization monitoring should be performed for at least three years following project installation. The monitoring is needed to learn of successes and failures of the project planning so that the lessons can be applied to future wind energy projects. It is also needed to inform compensatory mitigation. All wind turbines should be included in the fatality monitoring to ensure adequate sample sizes are obtained. Fatality searches should be performed no less frequently than every two weeks, and two teams should perform searches independently of each other so that detection rates can be estimated without performing independent searcher detection and scavenger removal trials, which are fraught with biases and sources of uncertainty.³²

SUMMARY

Collision Impacts

- The analysis of direct impacts caused by bird and bat collisions with wind turbines was incorrect and misleading. It relied on the same methodology that has most often resulted in predicted fatality rates being proven by post-construction monitoring to have been much too low. Measured raptor fatality rates have been up to 14 times higher than predicted fatalities.
- The impacts assessment relied on raptor fatality rates regressed on utilization rates, but this regression was fundamentally flawed in multiple ways.
 - The regression between fatality rates and utilization rates was pseudoreplicated, meaning the effective study units were not the study units implied in the graph – they were regions instead of wind projects. The positive regression slope was strongly leveraged by two California wind projects, the omission of which reverses the direction of the regression slope.

- The effort directed toward avian utilization surveys totaled 87 hours, which was grossly insufficient for characterizing utilization rates of many species, especially golden eagle and other raptors.
- The utilization surveys were diurnal, so were not designed to detect species active in the early morning, evening, or at night.
- The utilization surveys were extended to 800 m from the observer, which ensured that most flying birds would be undetected during each survey session, and no attempt was made to account for the proportion of the sky over the survey area that was occluded by terrain and forest. For these reasons, the utilization survey results were not comparable to other wind farms or among plots within the Whistling Ridge project site.
- The regression slope between fatality rates and utilization rates relied on fatality rates that were biased low in most of the available monitoring reports. Most of the fatality rates in the Pacific Northwest were derived from an estimator that relies on mean days to removal of placed carcasses in carcass removal trials, but carcasses in these trials must be censored from the calculation of the mean if the carcasses have not been removed by the end of the trial. This means the trials must extend for much longer periods than the average search interval of the fatality monitoring, and that mean days to removal is biased high and the resulting fatality estimates biased low.
- The regression between fatality rates and utilization rates was based mostly on monitoring that lasted only one year, but the inter-annual variation measured at other wind projects revealed up to nearly 6-fold differences in low to high fatality rates between years. This high inter-annual variation warrants a much larger sample size before any validity can be given to the regression used in this DEIS.
- The prediction of zero raptor fatalities at Whistling Ridge was fallacious because the prediction was based on the regression slope intercept being to the right of Whistling Ridge on the continuum of utilization rates among wind farms. In the very same graph, the slope intercept was also to the right of other wind farms where fatality rates were greater than zero.
- The DEIS also appeared to rely on an exposure index value to assess collision impacts of individual species. However, I tested the relationship between fatality rates and this exposure index at other wind farms, and found no relationship whatsoever.
- The DEIS appeared to rely on a comparison of raptor nesting densities among wind project sites, but I was unable to find a significant relationship between fatality rates and raptor nesting densities.

- Based on mean fatality rates estimated at other wind projects throughout Washington, Oregon and California, the minimum numbers of annual fatalities at Whistling Ridge would likely be 33 raptors, 422 birds (including raptors), and 86 bats, but actual rates would likely be much higher because unlike the other wind projects used to calculate the means, Whistling Ridge is located in a forested environment that is also frequently enveloped by clouds.

Other Impacts

- The impacts assessment directed to habitat fragmentation was also fallacious because the DEIS characterized the site as biologically impoverished, whereas the mere 87 hours of avian surveys there revealed a much higher avian species diversity than occurs in the Altamont Pass – the site of the most notoriously dangerous wind energy project on Earth to birds. Furthermore, all but one of 90 bird species were endemics, indicating a high level of ecological integrity at the site.
- Impacts to northern spotted owl were inappropriately dismissed, because this conclusion relied too much on interpreting US Fish and Wildlife Service protocols and not enough on wildlife biology and common sense.

Cumulative Impacts

- The cumulative impacts analysis in the DEIS was fundamentally flawed in several ways. First, the DEIS relied on a cumulative impacts analysis of the Columbia Basin Ecoregion, but Whistling Ridge occurs in a forested environment outside this Ecoregion. Second, the analysis relied on a Partners in Flight web site to estimate regional population sizes of bird species, but the Partners in Flight estimator did not pass scientific scrutiny in the scientific literature and the population estimates used in the DEIS were absurdly large. Third, reported avian fatality rates have been underestimated, so low fatality rates were compared to absurdly large population sizes to arrive at erroneous conclusions of no significant cumulative impacts. The cumulative impacts analysis cannot be taken seriously.
- Based on means from available reports of fatality monitoring at wind projects in the western US, build-out of 6,700 MW in the neighboring Columbia Basin Ecoregion could be expected to annually kill at least 2,935 raptors, 37,674 birds, and 7,658 bats, far exceeding the annual death toll at the notorious Altamont Pass.
- A new cumulative impacts analysis is needed for this project, and it needs to include the potentially unique impacts of siting wind turbines in the forested environment of Skamania County.

Mitigation Measures

- The DEIS listed several design features of the proposed wind turbines as preventive mitigation measures, but these features have not affected fatality rates and so are misleading.

- Post-construction monitoring should last at least 3 years for all turbines, and throughout the life of the project for a subset of turbines. Fatality searches should be no less frequent than twice per month.
- Minimum standards are needed for Technical Advisory Committee membership, and the TAC should be given authority to select the monitor, make changes to the monitoring program, and to require additional mitigation measures.
- Wind turbines should be carefully sited, and the siting should be based on adequate bird surveys, the results of which are related quantitatively to a resolute digital elevation model of the project site.
- Tower heights and the low and high reaches of the rotor plane should be based on an analysis of adequate avian survey data.

I recommend that the DEIS for Whistling Ridge be withdrawn, and that a new one be prepared. Much more effort should be directed toward pre-construction bird and bat surveys, and adequate analysis of the data should be performed. The methods used to predict impacts need to be replaced by scientifically defensible methods. The cumulative impacts analysis needs to be replaced, and the new one should include the impacts of siting wind turbines in the forested environments of Skamania County. The section on mitigation needs to be revised to avoid misleading readers about the effectiveness of turbine design features and adaptive management. The TAC needs to consist of qualified scientists, and the post-construction monitoring needs to be strengthened.

TESTIMONY OF GARY K. KAHN
FRIENDS OF THE COLUMBIA GORGE
MAY 7, 2009

My name is Gary Kahn and I am an attorney representing Friends of the Columbia Gorge. Friends is a non-profit organization with approximately 5,000 members dedicated to protecting and enhancing the resources of the Columbia River Gorge. Friends' membership includes hundreds of citizens who reside within the Columbia River Gorge National Scenic Area. Friends supports renewable energy development, so long as projects are responsibly sited and comply with all applicable laws.

Friends of the Columbia Gorge opposes the Whistling Ridge Energy project as it is currently proposed. S.D.S. Co., LLC must modify its application to better address the applicable review criteria, to remove all portions of the project from the National Scenic Area, and to substantially reduce the impacts of the project on scenic, natural, and recreational resources.

As for consistency with land use laws, the application contains a fatal flaw: part of the project would be located within the National Scenic Area. The entire project is classified as an industrial use under the Scenic Area rules because it would be primarily involved in the production of electric power for commercial purposes.¹ Industrial uses are prohibited within the General Management Area of the Scenic Area.² Despite this prohibition, SDS proposes to construct and use more than two miles of roads within the General Management Area for industrial purposes.³

¹ SCC § 22.04.010(88)(d) (definition of "industrial use.")

² SCC § 22.10.020(A); 16 U.S.C. § 544d(d)(6).

³ Application at Fig. 2.3-1.

In both the National Scenic Area and in Skamania County generally, both the construction and uses of roads must be reviewed. Attached as Exhibit A is a 2002 letter from the Columbia River Gorge Commission discussing the requirement to review roads in the National Scenic Area for their intended uses. A recent federal court decision, *Friends of the Columbia Gorge v. United States Forest Service*,⁴ discusses the same requirement.⁵ A copy of that decision is attached as Exhibit B.

Similar to the Scenic Area requirement, Skamania County requires its private roads to be classified “based on their primary functions.”⁶ The County road system has several different classification categories, ranging from private driveways to commercial development to recreational use.⁷ Proposals to change roads from one category to another, such as residential to commercial use, trigger review.⁸

In the instant matter, the roads proposed within the Scenic Area are proposed specifically for industrial purposes. The applicant proposes to construct new roads and to widen and improve existing public and private roads, converting them to new uses.⁹ These roads would be used to haul wind energy turbine components and construction materials—industrial loads that would exceed the WSDOT legal load limit of 52.75 tons.¹⁰ This is an industrial activity.

In summary, the proposed road construction and use within the General Management Area are part of the proposed industrial project and are prohibited. SDS must modify the proposal to remove all project components from the GMA.

⁴ 546 F. Supp. 2d 1088 (2008).

⁵ *Id.* at 1113 (“Because the road had not been used in at least one year *for log hauling*, the use of the road *for logging purposes* is a ‘discontinued use.’”) (emphasis added).

⁶ SCC § 12.03.030

⁷ *Id.*

⁸ SCC § 12.03.070.

⁹ Application at §§ 2.20.4.8, 2.20.4.9.

¹⁰ Application at 4.3-37.

SUBJECT: Whistling Ridge Energy Project Draft Environmental Impact Statement: EFSEC Application 2009-01

Dear Mr. Posner,

The Washington Department of Fish and Wildlife (WDFW) has reviewed the above-referenced documents and offers the following comments at this time. Other comments may be offered as the project progresses.

WDFW is continuing to carefully considered the potential impacts to natural resources on the site. A statement from the *Bat Acoustic Studies for the Whistling Ridge Wind Resource Area Skamania County, Washington June 4th – October 25th, 2009* (WEST, Inc., 2009) captures our approach to evaluating the entire project:

“However, no data on bat mortality levels associated with wind energy developments in western coniferous forests are available to help predict risk to bats at the WRWRA. Bat fatality patterns may differ from those in open habitats as well as in eastern deciduous forests...”

We feel that this statement can be extended to address the potential impacts to avian species as well, since, and reiterating from our May 14, 2009 response to the project, ...

“...other new wind projects in the Pacific Northwest are in shrub-steppe and agricultural habitats; not coniferous forest...”

Additionally, the data illustrated in figures 7 and 8 on pages 57 and 58 in Appendix C, Final Wildlife Report are confusing in that the coniferous-forested Whistling Ridge site is compared to other U.S. wind energy facilities regardless of habitat types. This same type of comparison is also shown for All Birds in figure 9 on page 59. Again, regardless of habitat type.

Raptor migration routes along the east Cascades are documented at the Bonney Butte, Oregon, *Hawk Watch* raptor banding and counting stations. The *Final Report* compared the Whistling Ridge project to other wind energy project through such statements as:

“The annual rate was low relative to raptor use at 36 other wind-energy facilities that implemented similar protocols to the present study and had data for three or four different seasons.”

“A 90% prediction interval around this estimate is zero to 0.25 fatalities per megawatt per year.”

WDFW would like to emphasize that fluctuations in raptor populations, as well as other avian species, may result in greater mortality than what is predicted in the *Final Report*. As a result, operational controls may be necessary to address avian mortality that exceeds predicted mortality.

Specifically, WDFW recommends that operational controls be a condition of the site certification, if issued, so that individual turbines or strings of turbines can be shutdown as a result of individual species and cumulative avian and bat fatalities in excess of the predicted mortality.

In closing, WDFW would like to acknowledge that the applicant has submitted a preliminary mitigation plan that we are currently reviewing. The preliminary mitigation plan encompasses approximately 100 acres in Klickitat County 12 miles due east of the project site. The mitigation site is forested with Oregon White Oak with some Douglas fir and Ponderosa pine and shares a portion of its northern boundary with 40 acres of WDNR land and. This mitigation site provides habitat for several PHS entries including Western gray squirrels. Additionally, the site includes the fish-bearing Silva Creek, a tributary to the Klickitat River.

We look forward to working with all interested parties as this project moves forward.

Sincerely,

A handwritten signature in black ink that reads "Michael Ritter". The signature is written in a cursive style and is positioned to the left of a vertical line.

To: Montano,Andrew M - KEC-4; Stephen Posner
Subject: Whistling Ridge: Communications concerning DEIS

Dear Mr. Montano and Mr. Posner:

As you know, this office represents Save Our Scenic Area (SOSA) with regard to the application of Whistling Ridge Energy to construction several wind turbines near Underwood Mountain in Skamania County. As part of the environmental review for this project, a DEIS has been prepared with comments due on August 27, 2010. SOSA intends to comment on the DEIS.

While we understand that the DEIS is being prepared by EFSEC and BPA, we have concerns as to the degree of input into the document that has been received from the applicant WRE. In the recent submission from WRE they indicate that they have participated in meetings with staff and Council consultants regarding the DEIS. Accordingly, we request that you provide us with any and all correspondence, emails, notes, memoranda or other communications concerning the DEIS between EFSEC, BPA or their DEIS consultants and any persons affiliated with the applicant WRE or WRE's attorneys.

We will be happy to review these documents at Council offices in Olympia. We would like to conduct this review as soon as possible to be able to use the information gathered in making SOSA's comment on the DEIS.

Thank you for your assistance in this matter.

SUBJECT: Whistling Ridge Energy Project

Dear Mr. Posner and Mr. Montaño:

As a resident of Clark County and as one who has been involved in the decisions regarding the Columbia River Gorge since before and after the Columbia River Gorge National Scenic Areas was established, I have a deep appreciation for the Gorge and a deep awareness of what it takes to operate a successful business in the Scenic Area and in the Pacific Northwest. My family and I enjoy visiting the Gorge frequently from our Vancouver home, and we are not interested in seeing the character of the Gorge destroyed or significantly altered.

Currently, I am president of the Association of Washington Business (AWB), but I am commenting on behalf of myself. AWB is Washington's state chamber of commerce and manufacturing and technology association. Our 7,000 members employ more than 650,000 workers in our state's private sector.

Prior to joining AWB in 1986, I was Washington public affairs manager for Crown Zellerbach Corp. (CZ). At the time, CZ owned and operated the Camas pulp and paper operation just to the west of the Scenic Area boundary and owned thousands of acres of commercial timberlands inside and adjacent to the Scenic Area on both sides of the Columbia River.

I was involved in the negotiations with the state of Washington to exchange our Gorge lands with the state of Washington for state timber sale contract relief in 1982, 1983 and 1984. In that process, I learned a great deal about the forest land potential, the forest practices and view corridor considerations and alterations, the productivity of the timberlands, and the people and companies inside and adjacent to the Scenic area who are dependent upon the industry and businesses. I also came to learn that some of our forested sites along the ridge lines had higher potential for other uses such as a wind farm, although generating electricity from the wind was in its development stages.

While CZ believed that we could manage those lands and our Camas operations so as to protect the unique features of the Gorge inside and around the Scenic Area, we also worked with those who wrote the legislation establishing the Scenic Area to protect the commercial activities within and around the Gorge. We recognized this would be an ongoing challenge, but we also realized that many of our employees and their families lived in and around the Scenic Area, had jobs and livelihood which depended upon commercial activity. Therefore, it was important to maintain and preserve the

commercial viability of private and public lands and the industries and businesses within and adjacent to the Scenic Area.

I sincerely hope that the Council appreciates the unique challenges that the private sector confronts in operating within the Columbia River Gorge National Scenic Area. We fully understand the concerns of those who provide private sector jobs and generate the tax revenues for local governments and schools with and around the Scenic Area should be paramount. So, that is why I agree that SDS Lumber, a long-held family-owned business, should be allowed to move forward with its Whistling Ridge Energy Project. Further, it seems to me that it makes sense for the State of Washington to lease the adjacent ridgeline so as to extent the wind farm and allow our state, which is severely financially strapped, to earn income from the public lands for schools, colleges and universities and rural counties such as Skamania.

Those of us in Clark County are aware of the onerous requirements imposed by the Act. While much of Clark and Multnomah counties only have a peripheral stake in the Gorge, 6% of Skamania's land mass is privately held, and much of that falls within the Scenic Area. The point is when opportunities arise to enhance the economy in Skamania County, add much needed renewable electricity to the grid, and provide new family-wage jobs; we should not pass that opportunity up.

We are also keenly aware that the last monthly adjusted unemployment figure released for the Portland-Vancouver metro area was 13.3%. Rural counties are also feeling the bite of high unemployment and the Whistling Ridge Energy Project not only brings construction jobs in these recessionary times but ongoing employment maintaining the turbines and transmission system.

Council members should, if they are not already, be aware of the history behind the Act and what is becoming a remarkable and implicit disregard for the takings of property rights that the Act seems to have spawned. The bitterness which has developed since passage of the Act is troubling especially for the communities in the Scenic Area. That bitterness is regrettable and is growing. It remains because advocacy groups campaign constantly for expansion of restrictions within and extensions beyond the defined CRGNSA boundary.

The Energy Facility Site Evaluation Council has already heard considerable testimony along these lines; testimony that bears no repeating here. My point is simply that none of what has been entered into the record is supported by the legislative intent of the Act's authors, or in the language of the Act as written. The proposition that whatever can be seen from within the Scenic Area should be treated as if it were within its boundary is ludicrous. It is also outrageous. I can tell you personally that when the law was written that was never the intent.

This is outrageous because a reduction in the capacity of SDS' wind farm will render the entire project untenable. Outrageous because prohibiting SDS from pursuing the highest and best use of its lands in ways fully compatible with timber production, is a blatant property rights taking. Outrageous because Whistling Ridge, with the jobs and tax revenue and local purchases it will engender, is a private economic stimulus for a community that urgently needs one. And finally, asserting a de facto expansion of the Scenic Area boundary is outrageous because it pours salt on the wound of decades of local residents' bitterness toward the original Act despite its clearly limited mandate; there never was, nor should be, a buffer around or extension of the CRGNSA boundary.

Finally, reflecting as I do as a citizen of Washington State, I'm hopeful that the Council will, in its deliberations, take cognizance of existing state policies which promote renewable energy development.

8.14.2010

Don Brunell Comments
Whistling Ridge Energy Project

In other words, I trust that you will reflect in your decision, the policy priorities that the Governor and Legislature not to mention the electorate through I-937 have made law.

The Stevenson family and SDS as a company are good people who work hard and provide jobs and tax revenues. They are the kind of citizens and employers that our state and region needs. They are doing the right thing with Whistling Ridge project putting the land to its highest and best use while provided needed power to our business, hospitals, schools, factories and families.

It is inconceivable to me that a few people, with their own interests in mind, will succeed in stopping a well-designed wind farm project from being built on private land that is located outside the CRGNSA on the grounds that the project defiles the Gorge. Give me a break! It most surely does not, and their claims fail to approach any standard of common sense.

I strongly urge the Council to separate what is true from what is not, from what is self-service from what is in the best interests of the working families in south central Washington and north central Oregon, and that you recommend approval for the Whistling Ridge Energy Project to the governor. We also add that we hope that approval can be expedited.

Thank you for your consideration.

Don C. Brunell

WHISTLING RIDGE WIND TURBINE DEVELOPMENT
WRITTEN DEIS COMMENTS
AUGUST 26, 2010

Written Comments of the Board of Directors
Skamania County Agri-Tourism Association,
a Washington Non-Profit Corporation

INTRODUCTION

The Skamania County Agri-Tourism Association is a Washington non-profit corporation dedicated to the promotion and improvement of sustainable agri-tourism in Skamania County. Our mission is to create and maintain favorable business conditions for association members. All members own and operate agricultural businesses in Underwood, Washington which is located in eastern Skamania County. Our unincorporated community sits directly across the Columbia from Hood River, Oregon. Members of the Skamania County Agri-Tourism Association include:

<u>Member</u>	<u>Business</u>
Acadia Vineyards	75 acre vineyard & orchard
Crooked Acres Vineyard	20 acre vineyard
The Davis Family Farm	50 acre farm & orchard
Energeia Vineyards	64 acre vineyard
Gorge Crest Vineyards & Winery	41 acre vineyard, winery & commercial event site
Gorge Estate Vineyards	95 acre vineyard & winery
Lamonti Vineyards	32 acre vineyard
Pearblossom Vineyards	18 acre vineyard & orchard
Sanctuary Herb Farm	18 acre herb farm and vineyard
Soluna Vineyards	34 acre vineyard
Underwood Gardens	6 acre lavender farm
Wine Spring	40 acre vineyard

As a group, these farms, vineyards and wineries currently give thousands of people each year a reason to visit our community and share in the awe inspiring beauty and bucolic charm. Some bring the entire family and 50 of their closest friends to say “I do”; some come to taste wine and touch grapes on the vine; some come to buy an organic free-range pig for a celebration; and others simply come because the views of the river, the Gorge, and the Hood River Valley

are unsurpassed. But more importantly for the purposes of this hearing, each of these people brings with them a domino effect of economic activity that benefits our entire region.

The Agri-Tourism Association hereby provides the Council and BPA (collectively referred to as "Council" herein) with our comments on the Whistling Ridge DEIS and the potential impact on our members and on agri-tourism in Underwood as a whole if the deficiencies in the DEIS are not corrected. We respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS:

1. Resiting of the seven most southerly "A Towers" (A1-A7) to a location within the proposed site that mitigates negative impacts;
2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW;
3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts;
4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and
5. Elimination of towers A1-A7 to mitigate negative impacts.

Such alternatives should be considered in the DEIS and the Final EIS to mitigate negative impacts based on the following five facts:

1. That tourism is the life blood of Skamania County and all communities throughout the Columbia River Gorge;
2. That Agri-Tourism is the present day driver of tourism in the famous Hood River Valley and that Underwood is well on its way to duplicating that economic success in Eastern Skamania County;
3. That Underwood's historic transformation from pear orchards to Agri-Tourism and to one of the premier wine producing regions in the world has enormous present-day socio-economic value;

4. That the very real present-day economic value of Underwood Agri-Tourism, as well as its future potential, would be severely impacted by the seven “A Towers” as currently sited; and finally
5. That this Council has the authority and responsibility to put the reins on this project by requiring the responsible re-siting or elimination of the seven “A Towers”; towers that will otherwise dominate the skyline and become Underwood’s new “calling card.”

As we detail in our written comments, failure to re-site the seven “A Towers” would improperly force the blossoming Underwood Agri-Tourism industry to bear a disproportionate share of the negative environmental and socioeconomic impacts of this project in violation of WAC 463-60-085. Such a result is prohibited by WAC 463-47-110 which states that “[t]he overriding policy of the council is to avoid or mitigate adverse environmental impacts which may result from the council's decisions.”

TOURISM IS THE LIFE BLOOD OF THE GORGE

Facts

Skamania County is more dependent on tourism than any county in the State of Washington. (See Appendix 1). In 2007:

- 47% of all retail and lodging tax collections in the county came from visitors.
 - The highest percentage in the state.
- Almost 11% of all spending in Skamania County was travel related. Over 58 million dollars.
 - The highest percentage in the state.

Where do these figures come from? In December of 2008, the State of Washington, through the Department of Community Trade and Economic Development, which also employs the staff of this Council, released these findings in a report on the importance of Travel Impacts to the economy of this state.

The state concluded that the travel industry:

- Generates tax benefits for Washington residents.
- Generates job opportunities for Washington residents.
- And benefits all regions of the state.

This study found in particular that rural counties, including Skamania County, have a greater number of travel-generated jobs in relation to total employment. And that we are more dependent on the travel industry. They determined that over 10% of Skamania County's jobs are generated by tourism. Maybe this is no great surprise since we live in one of the most beautiful places on earth.

The State of Washington also released a report in 2002 titled "Travel Industry Employment." (See Appendix 1 to our DEIS Scoping Comments. All other references to appendices in these comments refer to the appendices attached to our Scoping Comments.). It was released by the Washington Department of Business & Tourism Development. They reached the same conclusions and found specifically that "[t]his is because some rural areas are recreation destinations and/or have little employment in manufacturing or other industries...." Once again topping the list are counties in the Columbia River Gorge.

Two key conclusions of this study:

- The travel industry develops and thrives "to the extent [it] has comparative advantages in the Northwest relative to other locations in the U.S.
- "[H]igh-quality, natural, and outdoor recreation resources" are an example of such an advantage.

Why does this all matter in the DEIS? Because any development proposal that has the potential to cut off the life blood of our economy needs to be closely monitored, carefully studied, and mitigated in a manner that eliminates damaging impacts.

AGRI-TOURISM DRIVES HOOD RIVER AND EASTERN SKAMANIA COUNTY

Facts

Hood River is a tourist mecca just like Skamania County. The Hood River Valley is famous worldwide for the breathtaking beauty of its farms, orchards and vineyards. In fact, Hood River is a case study in the economic power and sustainability of agri-tourism. You need look no further than the front page of the Hood River County Chamber of Commerce website. (See Appendix 2). The image of Hood River **IS** agri-tourism. It is plastered everywhere: pictures, events, festivals and links to other sites dedicated to agri-tourism in its many forms.

The other marketing push in Hood River? Recreation and scenery, of course. Just as the State of Washington has concluded in its studies, “high-quality, natural, and outdoor recreation resources” are our primary asset and must be leveraged. They must also be carefully guarded to assure our economic health and well being.

Why is Hood River important to consider? Because Underwood, which is in Eastern Skamania County, and which is the site of this proposal, sits directly across the Columbia from Hood River and is inextricably tied to Hood River: topographically, economically, and evolutionarily. Although our county seat is 30 miles away in Stevenson, we have a uniquely different set of issues and opportunities. Issues and opportunities that county government has failed to understand. This is evident in light of the county’s decision to publically endorse this project without consideration of the impacts to Underwood agri-tourism. Agri-tourism that holds the key to Underwood’s economic future... if it is responsibly cared for.

UNDERWOOD AGRITOURISM IS GROWING QUICKLY

Facts

The primary driver of agri-tourism in Underwood is its far reaching reputation as one of the premier wine producing regions in the world. (See Appendix 3). Amazing as it may sound, the new Columbia Gorge Wine Appellation was recently recognized as one of the best emerging regions in the world along with Paso Robles, California and the Maule Valley in Chile. The same accolades were earned in Seattle Magazine.

In fact the Washington wine industry is now ranked as the second largest premium wine producer in the U.S. Washington Winery of the Year in 2009 was Maryhill Winery, located here

in the Gorge. Winery of the Year in 2007 was Cathedral Ridge Winery in Hood River, also located directly across the river from Underwood, and often touting Underwood wines. (See Appendix 3).

Even more to the point, Celilo Vineyards in Underwood, is consistently ranked as one of the Top 10 vineyards in Washington, which as mentioned, is ranked second nationally in the production of premium wines. The entire south slope of Underwood Mountain is considered the cream of the crop. If any question remains regarding the value of the wine industry in Underwood, we need look no further than the seal of approval of SDS Lumber who recently informed the community that it has purchased potential vineyard land in Underwood.

The DEIS naively accepts the proponents claim that "Wine and Wind" projects are de facto compatible because the uses co-exist in Walla Walla. The problem with this claim is that it ignores the fact that the wind projects in Walla Walla (like State-Line) are many miles from the vineyard and winery sites. The proposed A Towers, on the other hand, directly border the heart of Skamania County agri-tourism. No one argues that they will not dominate the landscape from upper Underwood. Resiting or elimination of Towers A1-7 eliminates all such impacts.

SOCIO-ECONOMIC VALUE OF UNDERWOOD AGRI-TOURISM

Facts

Agri-Tourism is a reality in Underwood as we sit here today. There are over 30 large scale agricultural operations within the community. Some of these enterprises were started generations ago, and others have broken ground within the last year. In many ways, the Skamania County Agri-Tourism Association owes its new found status to the proposal before you. We have formally come together for the first time out of necessity. A necessity borne from the threat that this project poses to our very existence.

Although our members have each made extraordinary commitments of time and capital to the common vision of making Underwood the premier agri-tourism destination in the Gorge, until recently, we were working in parallel, rather than in concert. The threat that this project poses to that vision, however, immediately galvanized farm, winery, and vineyard owners across the community. We now stand here with a consensus of opinion, not just on this project, but on future lobbying goals, marketing strategies, and product offerings.

The Association has two primary marketing strategies:

- Promote the “Underwood Agri-Tourism Loop” in a manner similar to the Hood River Fruit Loop.
 - The Hood River Fruit Loop is considered a national model for successful agri-tourism
 - See Appendix 2 (Fruit Loop) and Appendix 4 (Underwood Agri-Tourism Loop)
- Establish the Underwood Vineyard Trek as a “can’t be missed” one-of-a-kind opportunity to hike through 12 of the country’s premier vineyards while sampling world class wines and views.
 - Nowhere else in the U.S. have 12 contiguous vineyards collectively developed a private trek situated in the heart of a National Scenic Area.
 - See Appendix 4 (Underwood Vineyard Trek)

Underwood Agri-Tourism is not just about wine. Other members offer produce, free-range organic livestock, lavender viewing, and organic herbs. One of the original visionaries in Underwood is Hank Patton, who founded World Steward which is located in the Upper Underwood Agri-Tourism Loop, and is committed to environmental stewardship, sustainable farming, research and education. (See Appendix 4).

In addition, three wineries are already in operation in Underwood. One of those wineries is now considered by many to be the premier commercial events site in the Columbia Gorge. A number of other vineyards located in the Upper Loop have future winery plans which have been put on hold as a result of the potential negative impacts of this proposal.

As set forth in Appendix 4 to our comments, the economic and socioeconomic value of the existing Underwood Agri-Tourism industry is significant and quantifiable. It is diverse and sustainable and benefits citizens and governments throughout the region. The tremendous future potential is also quantifiable and dwarfs the tax benefits of the seven A Towers as projected by SDS Lumber. (See Appendix 1, 2, 3 & 4-Economics of Wine in Underwood).

AGRI-TOURISM & 40 STORY TURBINES DON’T MIX

Facts

SDS once told the Underwood community that wind turbines are “beautiful.” We are all welcome to our personal opinions, but in these proceedings facts should rule. And the fact is

that tourists, and especially tourists in the Gorge, don't want to see industrial development. This fact is set forth clearly in studies conducted by the U.S. Government, and the State of Oregon which are attached to our comments as Appendix 5 and Appendix 6. These facts are undisputed and need no further discussion.

As set forth above, the DEIS naively accepts the proponents claim that "Wine and Wind" projects are de facto compatible because the uses co-exist in Walla Walla. The problem with this claim is that it ignores the fact that the wind projects in Walla Walla (like State-Line) are many miles from the vineyard and winery sites. The proposed A Towers, on the other hand, directly border the heart of Skamania County agri-tourism. No one argues that they will not dominate the landscape from upper Underwood. Resiting or elimination of Towers A1-7 eliminates all such impacts.

MOVING THE "A TOWERS" MITIGATES TOURISM IMPACTS

Facts

The seven "A Towers" sit alone on a clear-cut ridge at the very most southern portion of the proposed project. If installed they would dominate views, day and night, from far more locations than are depicted in the application submitted to Council. To remove any uncertainty about the visual impacts of the seven A Towers, the Agri-Tourism Association hired a pilot to fly a photographer along the ridge where these towers are proposed. In Appendix 7 to our comments, you will find the results. Take note of the photograph that was taken directly over the ridge at an elevation of 300 feet above the ridge. This photograph tells the story of who will see the seven A Towers. Also note that the photograph was taken 120 feet below the top of the proposed towers.

Then take note of the next photograph that shows the locations of existing businesses along the Underwood Agri-Tourism Loop. The impacts are clear. The solution is also clear. The re-siting of the seven A Towers eliminates all visual impacts to the Underwood Agri-Tourism industry, as well as the visual impacts to a vast area throughout the Gorge.

CONCLUSION

We are very thankful that the Council brings to this process a broad perspective of the benefits and impacts of wind development. A perspective that is understandably missing from a county government in financial crisis.

We are also confident that this council will use its broad mitigation powers, its depth of experience and basic common sense to draw a line in the sand. A line that will make it clear to people throughout the country that in the Northwest, turbines don't have a right to dominate every ridgeline just because the wind blows.

We feel fortunate. Fortunate that each of you has visited the Gorge, and fortunate that during your site visit, you were able to experience the extraordinary beauty of our agricultural community and understand why it is a priceless resource in and of itself...not just to those of us who live Underwood, but to people throughout the Gorge who benefit economically from its snowballing reputation as one of the premier wine producing destinations in the United States.

For the reasons set forth above, we respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS:

1. Resiting of the seven most southerly "A Towers" (A1-A7) to a location within the proposed site that mitigates negative impacts;
2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW;
3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts;
4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and
5. Elimination of towers A1-A7 to mitigate negative impacts.

We also direct Council to our comments on the land use consistency issues which are attached hereto and incorporated herein by this reference.

WHISTLING RIDGE WIND TURBINE DEVELOPMENT
LAND USE CONSISTENCY HEARING
May 7, 2009

Written Comments of the Board of Directors
Skamania County Agri-Tourism Association,
a Washington Non-Profit Corporation

INTRODUCTION

My name is John Crumpacker; I live in Underwood, Washington. I am a member of the Board of Directors of the Skamania County Agri-Tourism Association. The Skamania County Agri-Tourism Association is a Washington non-profit corporation dedicated to the promotion and improvement of sustainable agri-tourism in Skamania County. Our mission is to create and maintain favorable business conditions for association members. All members own and operate agricultural businesses in Underwood, Washington which is located in eastern Skamania County. Members of the Skamania County Agri-Tourism Association include:

<u>Member</u>	<u>Business</u>
Acadia Vineyards	75 acre vineyard & orchard
Crooked Acres Vineyard	20 acre vineyard
The Davis Family Farm	50 acre farm & orchard
Energeia Vineyards	64 acre vineyard
Gorge Crest Vineyards & Winery	41 acre vineyard, winery & commercial event site
Gorge Estate Vineyards	95 acre vineyard & winery
Lamonti Vineyards	32 acre vineyard
Pearblossom Vineyards	18 acre vineyard & orchard
Sanctuary Herb Farm	18 acre herb farm and vineyard
Soluna Vineyards	34 acre vineyard
Underwood Gardens	6 acre lavender farm
Wine Spring	40 acre vineyard

The Agri-Tourism Association is here today to provide the Council with our comments on the Land Use Consistency issues posed by the proposed Whistling Ridge project and the potential impact on our members. Today we will again confine our comments to the seven “A Towers.” We will address two issues: (1) Why the proposed “A Towers” are inconsistent with the county land use policy; and (2) Why simply moving them prevents these violations.

THE SEVEN “A TOWERS” ARE INCONSISTENT WITH CURRENT ZONING AND EXISTING USES

In the land use portion of its application, SDS suggests that this project will diversify the use of its land and, in turn, the county’s economy. Next they state that this “natural resource-based land use would better insulate the Applicant from economic cycles that have undermined similar timber operations...” What they don’t mention is that the “A Towers” would sit on land that is specifically set aside for just the opposite purpose: to protect and insulate existing uses such as the agricultural operations of the members of the Skamania County Agri-Tourism Association. Operations which continue to diversify the county’s tourism based economy, and barring the “A Towers,” are not at risk of economic failure.

We will discuss applicant’s claims in the order they are presented in Part 4.2 of the application which addresses whether the “A Towers” would comply with the controlling conditional use requirements.

The first requirement is that the seven “A Towers”

Be either compatible with other uses in the surrounding area or is no more incompatible than are other outright permitted uses in the applicable zoning district.

The applicant, and for that matter, the county, never took the time to study the socio-economic value of agri-tourism and why the A Towers are incompatible with such outright permitted uses. Our appendix of data establishes complete incompatibility and is based on research conducted by the U.S. government, the State of Washington, and the State of Oregon. This is not a wheat field surrounded by nothing. The A Towers would loom over one of the country’s premier winemaking regions and the most valuable agri-tourism land in Skamania County.

To claim that these towers are “no more incompatible with the surrounding area than other uses permitted in the County’s zoning code,” is uninformed. To say that this “project would in no way impair the use of any of the surrounding lands” conveniently ignores the years of work and the capital invested by members of the Agri-Tourism Association, not to mention the high regulatory hurdles we have so painstakingly cleared. The fact is that nowhere in this state have 420 foot turbines been approved as permanent fixtures on a ridge with such profound compatibility concerns.

The next requirement is that the project

Not materially endanger the health, safety, and welfare of the surrounding community to an extent greater than that associated with other permitted uses in the applicable zoning district.

The seven “A Towers” are the single greatest threat to the economic welfare of the Agri-Tourism community in Underwood. Our comments yesterday address this issue and no more needs to be said today.

Next, the project may

Not hinder or discourage the development of permitted uses on neighboring properties in the applicable zoning district as a result of the location, size or height of the buildings, structures, walls, or required fences or screening vegetation to a greater extent than other permitted uses in the applicable zoning district;

The application states that the “turbines in the corridor proposed in the For/Ag-20 zones would be approximately 426 feet tall” and that “the proposed turbines would be taller than other structures permitted outright in the For/Ag-20 zone.” The application claims that their height and visibility would not hinder or discourage the development of any of the uses identified in Table 4.2-2. Just the opposite is true. Commercial agriculture, a permitted use in Table 4.2-2 is the very basis of agri-tourism, which as proven in Hood River, can drive the economy of an entire county. And as established in the data we submitted yesterday, the seven “A Towers” are incompatible with agri-tourism and have therefore caused a number of wineries to table development plans.

This council deserves better than applicant’s bare claim that “the project would in no way hinder the use or development of surrounding properties.”

MOVING THE “A TOWERS” ELIMINATES THE VIOLATION OF THE COUNTY’S ZONING POLICY

The last of the conditional use requirements for the “A Towers” leads us to the policies behind our county’s land use law. It requires that this project:

Not be in conflict with the goals and policies expressed in the current version of the County's comprehensive plan.

The policies behind the For/Ag-20 zone more clearly explains why the "A Towers" don't belong. The county policy for the Resource Production Zone is:

To provide land for present and future commercial farm and forest operations in areas that have been and are currently suitable for such operations, and to prevent conflicts between forestry and farm practices and nonresource production uses by not allowing inappropriate development of land within this zone classification" (SCC 21.56.010[A]).

(Emphasis added.) This is a clear statement that the conflict the "A Towers" create should not be allowed.

This same conclusion must be reached by applying the County's own vision statement for our community which states that:

Skamania County is strongly committed to protecting our rural character and natural resource based industries while allowing for planned future development that is balanced with the protection of critical resources and ecologically sensitive areas, while preserving the community's high quality of life.

(Emphasis added.)

CONCLUDING REMARKS

As the Council may have gathered, the "A Towers" are very different than the rest of this project. And they deserve to be treated differently.

These comments, and the supporting data, will be submitted to Council and posted on the "News" page of the Skamania County Agri-Tourism Association web site which is located at www.scaassn.org Thank you.

WHISTLING RIDGE WIND TURBINE DEVELOPMENT
WRITTEN DEIS COMMENTS
AUGUST 26, 2010

Written Comments of the Board of Directors
Skamania County Agri-Tourism Association,
a Washington Non-Profit Corporation

INTRODUCTION

The Skamania County Agri-Tourism Association is a Washington non-profit corporation dedicated to the promotion and improvement of sustainable agri-tourism in Skamania County. Our mission is to create and maintain favorable business conditions for association members. All members own and operate agricultural businesses in Underwood, Washington which is located in eastern Skamania County. Our unincorporated community sits directly across the Columbia from Hood River, Oregon. Members of the Skamania County Agri-Tourism Association include:

<u>Member</u>	<u>Business</u>
Acadia Vineyards	75 acre vineyard & orchard
Crooked Acres Vineyard	20 acre vineyard
The Davis Family Farm	50 acre farm & orchard
Energeia Vineyards	64 acre vineyard
Gorge Crest Vineyards & Winery	41 acre vineyard, winery & commercial event site
Gorge Estate Vineyards	95 acre vineyard & winery
Lamonti Vineyards	32 acre vineyard
Pearblossom Vineyards	18 acre vineyard & orchard
Sanctuary Herb Farm	18 acre herb farm and vineyard
Soluna Vineyards	34 acre vineyard
Underwood Gardens	6 acre lavender farm
Wine Spring	40 acre vineyard

As a group, these farms, vineyards and wineries currently give thousands of people each year a reason to visit our community and share in the awe inspiring beauty and bucolic charm. Some bring the entire family and 50 of their closest friends to say "I do"; some come to taste wine and touch grapes on the vine; some come to buy an organic free-range pig for a celebration; and others simply come because the views of the river, the Gorge, and the Hood River Valley

are unsurpassed. But more importantly for the purposes of this hearing, each of these people brings with them a domino effect of economic activity that benefits our entire region.

The Agri-Tourism Association hereby provides the Council and BPA (collectively referred to as "Council" herein) with our comments on the Whistling Ridge DEIS and the potential impact on our members and on agri-tourism in Underwood as a whole if the deficiencies in the DEIS are not corrected. We respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS:

1. Resiting of the seven most southerly "A Towers" (A1-A7) to a location within the proposed site that mitigates negative impacts;
2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW;
3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts;
4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and
5. Elimination of towers A1-A7 to mitigate negative impacts.

Such alternatives should be considered in the DEIS and the Final EIS to mitigate negative impacts based on the following five facts:

1. That tourism is the life blood of Skamania County and all communities throughout the Columbia River Gorge;
2. That Agri-Tourism is the present day driver of tourism in the famous Hood River Valley and that Underwood is well on its way to duplicating that economic success in Eastern Skamania County;
3. That Underwood's historic transformation from pear orchards to Agri-Tourism and to one of the premier wine producing regions in the world has enormous present-day socio-economic value;

4. That the very real present-day economic value of Underwood Agri-Tourism, as well as its future potential, would be severely impacted by the seven "A Towers" as currently sited; and finally
5. That this Council has the authority and responsibility to put the reins on this project by requiring the responsible re-siting or elimination of the seven "A Towers"; towers that will otherwise dominate the skyline and become Underwood's new "calling card."

As we detail in our written comments, failure to re-site the seven "A Towers" would improperly force the blossoming Underwood Agri-Tourism industry to bear a disproportionate share of the negative environmental and socioeconomic impacts of this project in violation of WAC 463-60-085. Such a result is prohibited by WAC 463-47-110 which states that "[t]he overriding policy of the council is to avoid or mitigate adverse environmental impacts which may result from the council's decisions."

TOURISM IS THE LIFE BLOOD OF THE GORGE

Facts

Skamania County is more dependent on tourism than any county in the State of Washington. (See Appendix 1). In 2007:

- 47% of all retail and lodging tax collections in the county came from visitors.
 - The highest percentage in the state.
- Almost 11% of all spending in Skamania County was travel related. Over 58 million dollars.
 - The highest percentage in the state.

Where do these figures come from? In December of 2008, the State of Washington, through the Department of Community Trade and Economic Development, which also employs the staff of this Council, released these findings in a report on the importance of Travel Impacts to the economy of this state.

The state concluded that the travel industry:

- Generates tax benefits for Washington residents.
- Generates job opportunities for Washington residents.
- And benefits all regions of the state.

This study found in particular that rural counties, including Skamania County, have a greater number of travel-generated jobs in relation to total employment. And that we are more dependent on the travel industry. They determined that over 10% of Skamania County's jobs are generated by tourism. Maybe this is no great surprise since we live in one of the most beautiful places on earth.

The State of Washington also released a report in 2002 titled "Travel Industry Employment." (See Appendix 1 to our DEIS Scoping Comments. All other references to appendices in these comments refer to the appendices attached to our Scoping Comments.) It was released by the Washington Department of Business & Tourism Development. They reached the same conclusions and found specifically that "[t]his is because some rural areas are recreation destinations and/or have little employment in manufacturing or other industries...." Once again topping the list are counties in the Columbia River Gorge.

Two key conclusions of this study:

- The travel industry develops and thrives "to the extent [it] has comparative advantages in the Northwest relative to other locations in the U.S.
- "[H]igh-quality, natural, and outdoor recreation resources" are an example of such an advantage.

Why does this all matter in the DEIS? Because any development proposal that has the potential to cut off the life blood of our economy needs to be closely monitored, carefully studied, and mitigated in a manner that eliminates damaging impacts.

AGRI-TOURISM DRIVES HOOD RIVER AND EASTERN SKAMANIA COUNTY

Facts

Hood River is a tourist mecca just like Skamania County. The Hood River Valley is famous worldwide for the breathtaking beauty of its farms, orchards and vineyards. In fact, Hood River is a case study in the economic power and sustainability of agri-tourism. You need look no further than the front page of the Hood River County Chamber of Commerce website. (See Appendix 2). The image of Hood River IS agri-tourism. It is plastered everywhere: pictures, events, festivals and links to other sites dedicated to agri-tourism in its many forms.

The other marketing push in Hood River? Recreation and scenery, of course. Just as the State of Washington has concluded in its studies, "high-quality, natural, and outdoor recreation resources" are our primary asset and must be leveraged. They must also be carefully guarded to assure our economic health and well being.

Why is Hood River important to consider? Because Underwood, which is in Eastern Skamania County, and which is the site of this proposal, sits directly across the Columbia from Hood River and is inextricably tied to Hood River: topographically, economically, and evolutionarily. Although our county seat is 30 miles away in Stevenson, we have a uniquely different set of issues and opportunities. Issues and opportunities that county government has failed to understand. This is evident in light of the county's decision to publically endorse this project without consideration of the impacts to Underwood agri-tourism. Agri-tourism that holds the key to Underwood's economic future... if it is responsibly cared for.

UNDERWOOD AGRITOURISM IS GROWING QUICKLY

Facts

The primary driver of agri-tourism in Underwood is its far reaching reputation as one of the premier wine producing regions in the world. (See Appendix 3). Amazing as it may sound, the new Columbia Gorge Wine Appellation was recently recognized as one of the best emerging regions in the world along with Paso Robles, California and the Maule Valley in Chile. The same accolades were earned in Seattle Magazine.

In fact the Washington wine industry is now ranked as the second largest premium wine producer in the U.S. Washington Winery of the Year in 2009 was Maryhill Winery, located here

in the Gorge. Winery of the Year in 2007 was Cathedral Ridge Winery in Hood River, also located directly across the river from Underwood, and often touting Underwood wines. (See Appendix 3).

Even more to the point, Celilo Vineyards in Underwood, is consistently ranked as one of the Top 10 vineyards in Washington, which as mentioned, is ranked second nationally in the production of premium wines. The entire south slope of Underwood Mountain is considered the cream of the crop. If any question remains regarding the value of the wine industry in Underwood, we need look no further than the seal of approval of SDS Lumber who recently informed the community that it has purchased potential vineyard land in Underwood.

The DEIS naively accepts the proponents claim that "Wine and Wind" projects are de facto compatible because the uses co-exist in Walla Walla. The problem with this claim is that it ignores the fact that the wind projects in Walla Walla (like State-Line) are many miles from the vineyard and winery sites. The proposed A Towers, on the other hand, directly border the heart of Skamania County agri-tourism. No one argues that they will not dominate the landscape from upper Underwood. Resiting or elimination of Towers A1-7 eliminates all such impacts.

SOCIO-ECONOMIC VALUE OF UNDERWOOD AGRITOURISM

Facts

Agri-Tourism is a reality in Underwood as we sit here today. There are over 30 large scale agricultural operations within the community. Some of these enterprises were started generations ago, and others have broken ground within the last year. In many ways, the Skamania County Agri-Tourism Association owes its new found status to the proposal before you. We have formally come together for the first time out of necessity. A necessity borne from the threat that this project poses to our very existence.

Although our members have each made extraordinary commitments of time and capital to the common vision of making Underwood the premier agri-tourism destination in the Gorge, until recently, we were working in parallel, rather than in concert. The threat that this project poses to that vision, however, immediately galvanized farm, winery, and vineyard owners across the community. We now stand here with a consensus of opinion, not just on this project, but on future lobbying goals, marketing strategies, and product offerings.

The Association has two primary marketing strategies:

- Promote the “Underwood Agri-Tourism Loop” in a manner similar to the Hood River Fruit Loop.
 - The Hood River Fruit Loop is considered a national model for successful agri-tourism
 - See Appendix 2 (Fruit Loop) and Appendix 4 (Underwood Agri-Tourism Loop)
- Establish the Underwood Vineyard Trek as a “can’t be missed” one-of-a-kind opportunity to hike through 12 of the country’s premier vineyards while sampling world class wines and views.
 - Nowhere else in the U.S. have 12 contiguous vineyards collectively developed a private trek situated in the heart of a National Scenic Area.
 - See Appendix 4 (Underwood Vineyard Trek)

Underwood Agri-Tourism is not just about wine. Other members offer produce, free-range organic livestock, lavender viewing, and organic herbs. One of the original visionaries in Underwood is Hank Patton, who founded World Steward which is located in the Upper Underwood Agri-Tourism Loop, and is committed to environmental stewardship, sustainable farming, research and education. (See Appendix 4).

In addition, three wineries are already in operation in Underwood. One of those wineries is now considered by many to be the premier commercial events site in the Columbia Gorge. A number of other vineyards located in the Upper Loop have future winery plans which have been put on hold as a result of the potential negative impacts of this proposal.

As set forth in Appendix 4 to our comments, the economic and socioeconomic value of the existing Underwood Agri-Tourism industry is significant and quantifiable. It is diverse and sustainable and benefits citizens and governments throughout the region. The tremendous future potential is also quantifiable and dwarfs the tax benefits of the seven A Towers as projected by SDS Lumber. (See Appendix 1, 2, 3 & 4-Economics of Wine in Underwood).

AGRI-TOURISM & 40 STORY TURBINES DON'T MIX

Facts

SDS once told the Underwood community that wind turbines are “beautiful.” We are all welcome to our personal opinions, but in these proceedings facts should rule. And the fact is

that tourists, and especially tourists in the Gorge, don't want to see industrial development. This fact is set forth clearly in studies conducted by the U.S. Government, and the State of Oregon which are attached to our comments as Appendix 5 and Appendix 6. These facts are undisputed and need no further discussion.

As set forth above, the DEIS naively accepts the proponents claim that "Wine and Wind" projects are de facto compatible because the uses co-exist in Walla Walla. The problem with this claim is that it ignores the fact that the wind projects in Walla Walla (like State-Line) are many miles from the vineyard and winery sites. The proposed A Towers, on the other hand, directly border the heart of Skamania County agri-tourism. No one argues that they will not dominate the landscape from upper Underwood. Resiting or elimination of Towers A1-7 eliminates all such impacts.

MOVING THE "A TOWERS" MITIGATES TOURISM IMPACTS

Facts

The seven "A Towers" sit alone on a clear-cut ridge at the very most southern portion of the proposed project. If installed they would dominate views, day and night, from far more locations than are depicted in the application submitted to Council. To remove any uncertainty about the visual impacts of the seven A Towers, the Agri-Tourism Association hired a pilot to fly a photographer along the ridge where these towers are proposed. In Appendix 7 to our comments, you will find the results. Take note of the photograph that was taken directly over the ridge at an elevation of 300 feet above the ridge. This photograph tells the story of who will see the seven A Towers. Also note that the photograph was taken 120 feet below the top of the proposed towers.

Then take note of the next photograph that shows the locations of existing businesses along the Underwood Agri-Tourism Loop. The impacts are clear. The solution is also clear. The re-siting of the seven A Towers eliminates all visual impacts to the Underwood Agri-Tourism industry, as well as the visual impacts to a vast area throughout the Gorge.

CONCLUSION

We are very thankful that the Council brings to this process a broad perspective of the benefits and impacts of wind development. A perspective that is understandably missing from a county government in financial crisis.

We are also confident that this council will use its broad mitigation powers, its depth of experience and basic common sense to draw a line in the sand. A line that will make it clear to people throughout the country that in the Northwest, turbines don't have a right to dominate every ridgeline just because the wind blows.

We feel fortunate. Fortunate that each of you has visited the Gorge, and fortunate that during your site visit, you were able to experience the extraordinary beauty of our agricultural community and understand why it is a priceless resource in and of itself...not just to those of us who live Underwood, but to people throughout the Gorge who benefit economically from its snowballing reputation as one of the premier wine producing destinations in the United States.

For the reasons set forth above, we respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS:

1. Resiting of the seven most southerly "A Towers" (A1-A7) to a location within the proposed site that mitigates negative impacts;
2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW;
3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts;
4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and
5. Elimination of towers A1-A7 to mitigate negative impacts.

We also direct Council to our comments on the land use consistency issues which are attached hereto and incorporated herein by this reference.

WHISTLING RIDGE WIND TURBINE DEVELOPMENT
LAND USE CONSISTENCY HEARING
May 7, 2009

Written Comments of the Board of Directors
Skamania County Agri-Tourism Association,
a Washington Non-Profit Corporation

INTRODUCTION

My name is John Crumpacker; I live in Underwood, Washington. I am a member of the Board of Directors of the Skamania County Agri-Tourism Association. The Skamania County Agri-Tourism Association is a Washington non-profit corporation dedicated to the promotion and improvement of sustainable agri-tourism in Skamania County. Our mission is to create and maintain favorable business conditions for association members. All members own and operate agricultural businesses in Underwood, Washington which is located in eastern Skamania County. Members of the Skamania County Agri-Tourism Association include:

<u>Member</u>	<u>Business</u>
Acadia Vineyards	75 acre vineyard & orchard
Crooked Acres Vineyard	20 acre vineyard
The Davis Family Farm	50 acre farm & orchard
Energeia Vineyards	64 acre vineyard
Gorge Crest Vineyards & Winery	41 acre vineyard, winery & commercial event site
Gorge Estate Vineyards	95 acre vineyard & winery
Lamonti Vineyards	32 acre vineyard
Pearblossom Vineyards	18 acre vineyard & orchard
Sanctuary Herb Farm	18 acre herb farm and vineyard
Soluna Vineyards	34 acre vineyard
Underwood Gardens	6 acre lavender farm
Wine Spring	40 acre vineyard

The Agri-Tourism Association is here today to provide the Council with our comments on the Land Use Consistency issues posed by the proposed Whistling Ridge project and the potential impact on our members. Today we will again confine our comments to the seven "A Towers." We will address two issues: (1) Why the proposed "A Towers" are inconsistent with the county land use policy; and (2) Why simply moving them prevents these violations.

THE SEVEN "A TOWERS" ARE INCONSISTENT WITH CURRENT ZONING AND EXISTING USES

In the land use portion of its application, SDS suggests that this project will diversify the use of its land and, in turn, the county's economy. Next they state that this "natural resource-based land use would better insulate the Applicant from economic cycles that have undermined similar timber operations...." What they don't mention is that the "A Towers" would sit on land that is specifically set aside for just the opposite purpose: to protect and insulate existing uses such as the agricultural operations of the members of the Skamania County Agri-Tourism Association. Operations which continue to diversify the county's tourism based economy, and barring the "A Towers," are not at risk of economic failure.

We will discuss applicant's claims in the order they are presented in Part 4.2 of the application which addresses whether the "A Towers" would comply with the controlling conditional use requirements.

The first requirement is that the seven "A Towers"

Be either compatible with other uses in the surrounding area or is no more incompatible than are other outright permitted uses in the applicable zoning district.

The applicant, and for that matter, the county, never took the time to study the socio-economic value of agri-tourism and why the A Towers are incompatible with such outright permitted uses. Our appendix of data establishes complete incompatibility and is based on research conducted by the U.S. government, the State of Washington, and the State of Oregon. This is not a wheat field surrounded by nothing. The A Towers would loom over one of the country's premier winemaking regions and the most valuable agri-tourism land in Skamania County.

To claim that these towers are "no more incompatible with the surrounding area than other uses permitted in the County's zoning code," is uninformed. To say that this "project would in no way impair the use of any of the surrounding lands" conveniently ignores the years of work and the capital invested by members of the Agri-Tourism Association, not to mention the high regulatory hurdles we have so painstakingly cleared. The fact is that nowhere in this state have 420 foot turbines been approved as permanent fixtures on a ridge with such profound compatibility concerns.

The next requirement is that the project

Not materially endanger the health, safety, and welfare of the surrounding community to an extent greater than that associated with other permitted uses in the applicable zoning district.

The seven "A Towers" are the single greatest threat to the economic welfare of the Agri-Tourism community in Underwood. Our comments yesterday address this issue and no more needs to be said today.

Next, the project may

Not hinder or discourage the development of permitted uses on neighboring properties in the applicable zoning district as a result of the location, size or height of the buildings, structures, walls, or required fences or screening vegetation to a greater extent than other permitted uses in the applicable zoning district;

The application states that the "turbines in the corridor proposed in the For/Ag-20 zones would be approximately 426 feet tall" and that "the proposed turbines would be taller than other structures permitted outright in the For/Ag-20 zone." The application claims that their height and visibility would not hinder or discourage the development of any of the uses identified in Table 4.2-2. Just the opposite is true. Commercial agriculture, a permitted use in Table 4.2-2 is the very basis of agri-tourism, which as proven in Hood River, can drive the economy of an entire county. And as established in the data we submitted yesterday, the seven "A Towers" are incompatible with agri-tourism and have therefore caused a number of wineries to table development plans.

This council deserves better than applicant's bare claim that "the project would in no way hinder the use or development of surrounding properties."

MOVING THE "A TOWERS" ELIMINATES THE VIOLATION OF THE COUNTY'S ZONING POLICY

The last of the conditional use requirements for the "A Towers" leads us to the policies behind our county's land use law. It requires that this project:

Not be in conflict with the goals and policies expressed in the current version of the County's comprehensive plan.

The policies behind the For/Ag-20 zone more clearly explains why the "A Towers" don't belong. The county policy for the Resource Production Zone is:

To provide land for present and future commercial farm and forest operations in areas that have been and are currently suitable for such operations, and to prevent conflicts between forestry and farm practices and nonresource production uses by not allowing inappropriate development of land within this zone classification" (SCC 21.56.010[A]).

(Emphasis added.) This is a clear statement that the conflict the "A Towers" create should not be allowed.

This same conclusion must be reached by applying the County's own vision statement for our community which states that:

Skamania County is strongly committed to protecting our rural character and natural resource based industries while allowing for planned future development that is balanced with the protection of critical resources and ecologically sensitive areas, while preserving the community's high quality of life.

(Emphasis added.)

CONCLUDING REMARKS

As the Council may have gathered, the "A Towers" are very different than the rest of this project. And they deserve to be treated differently.

These comments, and the supporting data, will be submitted to Council and posted on the "News" page of the Skamania County Agri-Tourism Association web site which is located at www.scaassn.org Thank you.

WHISTLING RIDGE WIND TURBINE DEVELOPMENT
WRITTEN DEIS COMMENTS
AUGUST 26, 2010

Written Comments of the Board of Directors
Skamania County Agri-Tourism Association,
a Washington Non-Profit Corporation

INTRODUCTION

The Skamania County Agri-Tourism Association is a Washington non-profit corporation dedicated to the promotion and improvement of sustainable agri-tourism in Skamania County. Our mission is to create and maintain favorable business conditions for association members. All members own and operate agricultural businesses in Underwood, Washington which is located in eastern Skamania County. Our unincorporated community sits directly across the Columbia from Hood River, Oregon. Members of the Skamania County Agri-Tourism Association include:

<u>Member</u>	<u>Business</u>
Acadia Vineyards	75 acre vineyard & orchard
Crooked Acres Vineyard	20 acre vineyard
The Davis Family Farm	50 acre farm & orchard
Energeia Vineyards	64 acre vineyard
Gorge Crest Vineyards & Winery	41 acre vineyard, winery & commercial event site
Gorge Estate Vineyards	95 acre vineyard & winery
Lamonti Vineyards	32 acre vineyard
Pearblossom Vineyards	18 acre vineyard & orchard
Sanctuary Herb Farm	18 acre herb farm and vineyard
Soluna Vineyards	34 acre vineyard
Underwood Gardens	6 acre lavender farm
Wine Spring	40 acre vineyard

As a group, these farms, vineyards and wineries currently give thousands of people each year a reason to visit our community and share in the awe inspiring beauty and bucolic charm. Some bring the entire family and 50 of their closest friends to say “I do”; some come to taste wine and touch grapes on the vine; some come to buy an organic free-range pig for a celebration; and others simply come because the views of the river, the Gorge, and the Hood River Valley

are unsurpassed. But more importantly for the purposes of this hearing, each of these people brings with them a domino effect of economic activity that benefits our entire region.

The Agri-Tourism Association hereby provides the Council and BPA (collectively referred to as "Council" herein) with our comments on the Whistling Ridge DEIS and the potential impact on our members and on agri-tourism in Underwood as a whole if the deficiencies in the DEIS are not corrected. We respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS:

1. Resiting of the seven most southerly "A Towers" (A1-A7) to a location within the proposed site that mitigates negative impacts;
2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW;
3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts;
4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and
5. Elimination of towers A1-A7 to mitigate negative impacts.

Such alternatives should be considered in the DEIS and the Final EIS to mitigate negative impacts based on the following five facts:

1. That tourism is the life blood of Skamania County and all communities throughout the Columbia River Gorge;
2. That Agri-Tourism is the present day driver of tourism in the famous Hood River Valley and that Underwood is well on its way to duplicating that economic success in Eastern Skamania County;
3. That Underwood's historic transformation from pear orchards to Agri-Tourism and to one of the premier wine producing regions in the world has enormous present-day socio-economic value;

4. That the very real present-day economic value of Underwood Agri-Tourism, as well as its future potential, would be severely impacted by the seven “A Towers” as currently sited; and finally
5. That this Council has the authority and responsibility to put the reins on this project by requiring the responsible re-siting or elimination of the seven “A Towers”; towers that will otherwise dominate the skyline and become Underwood’s new “calling card.”

As we detail in our written comments, failure to re-site the seven “A Towers” would improperly force the blossoming Underwood Agri-Tourism industry to bear a disproportionate share of the negative environmental and socioeconomic impacts of this project in violation of WAC 463-60-085. Such a result is prohibited by WAC 463-47-110 which states that “[t]he overriding policy of the council is to avoid or mitigate adverse environmental impacts which may result from the council's decisions.”

TOURISM IS THE LIFE BLOOD OF THE GORGE

Facts

Skamania County is more dependent on tourism than any county in the State of Washington. (See Appendix 1). In 2007:

- 47% of all retail and lodging tax collections in the county came from visitors.
 - The highest percentage in the state.
- Almost 11% of all spending in Skamania County was travel related. Over 58 million dollars.
 - The highest percentage in the state.

Where do these figures come from? In December of 2008, the State of Washington, through the Department of Community Trade and Economic Development, which also employs the staff of this Council, released these findings in a report on the importance of Travel Impacts to the economy of this state.

The state concluded that the travel industry:

- Generates tax benefits for Washington residents.
- Generates job opportunities for Washington residents.
- And benefits all regions of the state.

This study found in particular that rural counties, including Skamania County, have a greater number of travel-generated jobs in relation to total employment. And that we are more dependent on the travel industry. They determined that over 10% of Skamania County's jobs are generated by tourism. Maybe this is no great surprise since we live in one of the most beautiful places on earth.

The State of Washington also released a report in 2002 titled "Travel Industry Employment." (See Appendix 1 to our DEIS Scoping Comments. All other references to appendices in these comments refer to the appendices attached to our Scoping Comments.). It was released by the Washington Department of Business & Tourism Development. They reached the same conclusions and found specifically that "[t]his is because some rural areas are recreation destinations and/or have little employment in manufacturing or other industries...." Once again topping the list are counties in the Columbia River Gorge.

Two key conclusions of this study:

- The travel industry develops and thrives "to the extent [it] has comparative advantages in the Northwest relative to other locations in the U.S.
- "[H]igh-quality, natural, and outdoor recreation resources" are an example of such an advantage.

Why does this all matter in the DEIS? Because any development proposal that has the potential to cut off the life blood of our economy needs to be closely monitored, carefully studied, and mitigated in a manner that eliminates damaging impacts.

AGRI-TOURISM DRIVES HOOD RIVER AND EASTERN SKAMANIA COUNTY

Facts

Hood River is a tourist mecca just like Skamania County. The Hood River Valley is famous worldwide for the breathtaking beauty of its farms, orchards and vineyards. In fact, Hood River is a case study in the economic power and sustainability of agri-tourism. You need look no further than the front page of the Hood River County Chamber of Commerce website. (See Appendix 2). The image of Hood River **IS** agri-tourism. It is plastered everywhere: pictures, events, festivals and links to other sites dedicated to agri-tourism in its many forms.

The other marketing push in Hood River? Recreation and scenery, of course. Just as the State of Washington has concluded in its studies, “high-quality, natural, and outdoor recreation resources” are our primary asset and must be leveraged. They must also be carefully guarded to assure our economic health and well being.

Why is Hood River important to consider? Because Underwood, which is in Eastern Skamania County, and which is the site of this proposal, sits directly across the Columbia from Hood River and is inextricably tied to Hood River: topographically, economically, and evolutionarily. Although our county seat is 30 miles away in Stevenson, we have a uniquely different set of issues and opportunities. Issues and opportunities that county government has failed to understand. This is evident in light of the county’s decision to publically endorse this project without consideration of the impacts to Underwood agri-tourism. Agri-tourism that holds the key to Underwood’s economic future... if it is responsibly cared for.

UNDERWOOD AGRITOURISM IS GROWING QUICKLY

Facts

The primary driver of agri-tourism in Underwood is its far reaching reputation as one of the premier wine producing regions in the world. (See Appendix 3). Amazing as it may sound, the new Columbia Gorge Wine Appellation was recently recognized as one of the best emerging regions in the world along with Paso Robles, California and the Maule Valley in Chile. The same accolades were earned in Seattle Magazine.

In fact the Washington wine industry is now ranked as the second largest premium wine producer in the U.S. Washington Winery of the Year in 2009 was Maryhill Winery, located here

in the Gorge. Winery of the Year in 2007 was Cathedral Ridge Winery in Hood River, also located directly across the river from Underwood, and often touting Underwood wines. (See Appendix 3).

Even more to the point, Celilo Vineyards in Underwood, is consistently ranked as one of the Top 10 vineyards in Washington, which as mentioned, is ranked second nationally in the production of premium wines. The entire south slope of Underwood Mountain is considered the cream of the crop. If any question remains regarding the value of the wine industry in Underwood, we need look no further than the seal of approval of SDS Lumber who recently informed the community that it has purchased potential vineyard land in Underwood.

The DEIS naively accepts the proponents claim that "Wine and Wind" projects are de facto compatible because the uses co-exist in Walla Walla. The problem with this claim is that it ignores the fact that the wind projects in Walla Walla (like State-Line) are many miles from the vineyard and winery sites. The proposed A Towers, on the other hand, directly border the heart of Skamania County agri-tourism. No one argues that they will not dominate the landscape from upper Underwood. Resiting or elimination of Towers A1-7 eliminates all such impacts.

SOCIO-ECONOMIC VALUE OF UNDERWOOD AGRI-TOURISM

Facts

Agri-Tourism is a reality in Underwood as we sit here today. There are over 30 large scale agricultural operations within the community. Some of these enterprises were started generations ago, and others have broken ground within the last year. In many ways, the Skamania County Agri-Tourism Association owes its new found status to the proposal before you. We have formally come together for the first time out of necessity. A necessity borne from the threat that this project poses to our very existence.

Although our members have each made extraordinary commitments of time and capital to the common vision of making Underwood the premier agri-tourism destination in the Gorge, until recently, we were working in parallel, rather than in concert. The threat that this project poses to that vision, however, immediately galvanized farm, winery, and vineyard owners across the community. We now stand here with a consensus of opinion, not just on this project, but on future lobbying goals, marketing strategies, and product offerings.

The Association has two primary marketing strategies:

- Promote the “Underwood Agri-Tourism Loop” in a manner similar to the Hood River Fruit Loop.
 - The Hood River Fruit Loop is considered a national model for successful agri-tourism
 - See Appendix 2 (Fruit Loop) and Appendix 4 (Underwood Agri-Tourism Loop)
- Establish the Underwood Vineyard Trek as a “can’t be missed” one-of-a-kind opportunity to hike through 12 of the country’s premier vineyards while sampling world class wines and views.
 - Nowhere else in the U.S. have 12 contiguous vineyards collectively developed a private trek situated in the heart of a National Scenic Area.
 - See Appendix 4 (Underwood Vineyard Trek)

Underwood Agri-Tourism is not just about wine. Other members offer produce, free-range organic livestock, lavender viewing, and organic herbs. One of the original visionaries in Underwood is Hank Patton, who founded World Steward which is located in the Upper Underwood Agri-Tourism Loop, and is committed to environmental stewardship, sustainable farming, research and education. (See Appendix 4).

In addition, three wineries are already in operation in Underwood. One of those wineries is now considered by many to be the premier commercial events site in the Columbia Gorge. A number of other vineyards located in the Upper Loop have future winery plans which have been put on hold as a result of the potential negative impacts of this proposal.

As set forth in Appendix 4 to our comments, the economic and socioeconomic value of the existing Underwood Agri-Tourism industry is significant and quantifiable. It is diverse and sustainable and benefits citizens and governments throughout the region. The tremendous future potential is also quantifiable and dwarfs the tax benefits of the seven A Towers as projected by SDS Lumber. (See Appendix 1, 2, 3 & 4-Economics of Wine in Underwood).

AGRI-TOURISM & 40 STORY TURBINES DON'T MIX

Facts

SDS once told the Underwood community that wind turbines are “beautiful.” We are all welcome to our personal opinions, but in these proceedings facts should rule. And the fact is

that tourists, and especially tourists in the Gorge, don't want to see industrial development. This fact is set forth clearly in studies conducted by the U.S. Government, and the State of Oregon which are attached to our comments as Appendix 5 and Appendix 6. These facts are undisputed and need no further discussion.

As set forth above, the DEIS naively accepts the proponents claim that "Wine and Wind" projects are de facto compatible because the uses co-exist in Walla Walla. The problem with this claim is that it ignores the fact that the wind projects in Walla Walla (like State-Line) are many miles from the vineyard and winery sites. The proposed A Towers, on the other hand, directly border the heart of Skamania County agri-tourism. No one argues that they will not dominate the landscape from upper Underwood. Resiting or elimination of Towers A1-7 eliminates all such impacts.

MOVING THE "A TOWERS" MITIGATES TOURISM IMPACTS

Facts

The seven "A Towers" sit alone on a clear-cut ridge at the very most southern portion of the proposed project. If installed they would dominate views, day and night, from far more locations than are depicted in the application submitted to Council. To remove any uncertainty about the visual impacts of the seven A Towers, the Agri-Tourism Association hired a pilot to fly a photographer along the ridge where these towers are proposed. In Appendix 7 to our comments, you will find the results. Take note of the photograph that was taken directly over the ridge at an elevation of 300 feet above the ridge. This photograph tells the story of who will see the seven A Towers. Also note that the photograph was taken 120 feet below the top of the proposed towers.

Then take note of the next photograph that shows the locations of existing businesses along the Underwood Agri-Tourism Loop. The impacts are clear. The solution is also clear. The re-siting of the seven A Towers eliminates all visual impacts to the Underwood Agri-Tourism industry, as well as the visual impacts to a vast area throughout the Gorge.

CONCLUSION

We are very thankful that the Council brings to this process a broad perspective of the benefits and impacts of wind development. A perspective that is understandably missing from a county government in financial crisis.

We are also confident that this council will use its broad mitigation powers, its depth of experience and basic common sense to draw a line in the sand. A line that will make it clear to people throughout the country that in the Northwest, turbines don't have a right to dominate every ridgeline just because the wind blows.

We feel fortunate. Fortunate that each of you has visited the Gorge, and fortunate that during your site visit, you were able to experience the extraordinary beauty of our agricultural community and understand why it is a priceless resource in and of itself...not just to those of us who live Underwood, but to people throughout the Gorge who benefit economically from its snowballing reputation as one of the premier wine producing destinations in the United States.

For the reasons set forth above, we respectfully request that the DEIS and the Final EIS include consideration of the following alternatives which are absent or rejected in the DEIS:

1. Resiting of the seven most southerly "A Towers" (A1-A7) to a location within the proposed site that mitigates negative impacts;
2. Use of towers across the project with greater megawatt per tower ratings that will allow for the elimination of Towers A1-A7 with minimal impact on the proponents total megawatt output target of 75 MW;
3. Use of low profile towers across the project, and in particular at tower locations A1-7 to minimize negative impacts;
4. Elimination of towers A1-A7 through micro-siting across the project as a whole; and
5. Elimination of towers A1-A7 to mitigate negative impacts.

We also direct Council to our comments on the land use consistency issues which are attached hereto and incorporated herein by this reference.

WHISTLING RIDGE WIND TURBINE DEVELOPMENT
LAND USE CONSISTENCY HEARING
May 7, 2009

Written Comments of the Board of Directors
Skamania County Agri-Tourism Association,
a Washington Non-Profit Corporation

INTRODUCTION

My name is John Crumpacker; I live in Underwood, Washington. I am a member of the Board of Directors of the Skamania County Agri-Tourism Association. The Skamania County Agri-Tourism Association is a Washington non-profit corporation dedicated to the promotion and improvement of sustainable agri-tourism in Skamania County. Our mission is to create and maintain favorable business conditions for association members. All members own and operate agricultural businesses in Underwood, Washington which is located in eastern Skamania County. Members of the Skamania County Agri-Tourism Association include:

<u>Member</u>	<u>Business</u>
Acadia Vineyards	75 acre vineyard & orchard
Crooked Acres Vineyard	20 acre vineyard
The Davis Family Farm	50 acre farm & orchard
Energeia Vineyards	64 acre vineyard
Gorge Crest Vineyards & Winery	41 acre vineyard, winery & commercial event site
Gorge Estate Vineyards	95 acre vineyard & winery
Lamonti Vineyards	32 acre vineyard
Pearblossom Vineyards	18 acre vineyard & orchard
Sanctuary Herb Farm	18 acre herb farm and vineyard
Soluna Vineyards	34 acre vineyard
Underwood Gardens	6 acre lavender farm
Wine Spring	40 acre vineyard

The Agri-Tourism Association is here today to provide the Council with our comments on the Land Use Consistency issues posed by the proposed Whistling Ridge project and the potential impact on our members. Today we will again confine our comments to the seven “A Towers.” We will address two issues: (1) Why the proposed “A Towers” are inconsistent with the county land use policy; and (2) Why simply moving them prevents these violations.

THE SEVEN “A TOWERS” ARE INCONSISTENT WITH CURRENT ZONING AND EXISTING USES

In the land use portion of its application, SDS suggests that this project will diversify the use of its land and, in turn, the county’s economy. Next they state that this “natural resource-based land use would better insulate the Applicant from economic cycles that have undermined similar timber operations...” What they don’t mention is that the “A Towers” would sit on land that is specifically set aside for just the opposite purpose: to protect and insulate existing uses such as the agricultural operations of the members of the Skamania County Agri-Tourism Association. Operations which continue to diversify the county’s tourism based economy, and barring the “A Towers,” are not at risk of economic failure.

We will discuss applicant’s claims in the order they are presented in Part 4.2 of the application which addresses whether the “A Towers” would comply with the controlling conditional use requirements.

The first requirement is that the seven “A Towers”

Be either compatible with other uses in the surrounding area or is no more incompatible than are other outright permitted uses in the applicable zoning district.

The applicant, and for that matter, the county, never took the time to study the socio-economic value of agri-tourism and why the A Towers are incompatible with such outright permitted uses. Our appendix of data establishes complete incompatibility and is based on research conducted by the U.S. government, the State of Washington, and the State of Oregon. This is not a wheat field surrounded by nothing. The A Towers would loom over one of the country’s premier winemaking regions and the most valuable agri-tourism land in Skamania County.

To claim that these towers are “no more incompatible with the surrounding area than other uses permitted in the County’s zoning code,” is uninformed. To say that this “project would in no way impair the use of any of the surrounding lands” conveniently ignores the years of work and the capital invested by members of the Agri-Tourism Association, not to mention the high regulatory hurdles we have so painstakingly cleared. The fact is that nowhere in this state have 420 foot turbines been approved as permanent fixtures on a ridge with such profound compatibility concerns.

The next requirement is that the project

Not materially endanger the health, safety, and welfare of the surrounding community to an extent greater than that associated with other permitted uses in the applicable zoning district.

The seven “A Towers” are the single greatest threat to the economic welfare of the Agri-Tourism community in Underwood. Our comments yesterday address this issue and no more needs to be said today.

Next, the project may

Not hinder or discourage the development of permitted uses on neighboring properties in the applicable zoning district as a result of the location, size or height of the buildings, structures, walls, or required fences or screening vegetation to a greater extent than other permitted uses in the applicable zoning district;

The application states that the “turbines in the corridor proposed in the For/Ag-20 zones would be approximately 426 feet tall” and that “the proposed turbines would be taller than other structures permitted outright in the For/Ag-20 zone.” The application claims that their height and visibility would not hinder or discourage the development of any of the uses identified in Table 4.2-2. Just the opposite is true. Commercial agriculture, a permitted use in Table 4.2-2 is the very basis of agri-tourism, which as proven in Hood River, can drive the economy of an entire county. And as established in the data we submitted yesterday, the seven “A Towers” are incompatible with agri-tourism and have therefore caused a number of wineries to table development plans.

This council deserves better than applicant’s bare claim that “the project would in no way hinder the use or development of surrounding properties.”

MOVING THE “A TOWERS” ELIMINATES THE VIOLATION OF THE COUNTY’S ZONING POLICY

The last of the conditional use requirements for the “A Towers” leads us to the policies behind our county’s land use law. It requires that this project:

Not be in conflict with the goals and policies expressed in the current version of the County's comprehensive plan.

The policies behind the For/Ag-20 zone more clearly explains why the "A Towers" don't belong. The county policy for the Resource Production Zone is:

To provide land for present and future commercial farm and forest operations in areas that have been and are currently suitable for such operations, and to prevent conflicts between forestry and farm practices and nonresource production uses by not allowing inappropriate development of land within this zone classification" (SCC 21.56.010[A]).

(Emphasis added.) This is a clear statement that the conflict the "A Towers" create should not be allowed.

This same conclusion must be reached by applying the County's own vision statement for our community which states that:

Skamania County is strongly committed to protecting our rural character and natural resource based industries while allowing for planned future development that is balanced with the protection of critical resources and ecologically sensitive areas, while preserving the community's high quality of life.

(Emphasis added.)

CONCLUDING REMARKS

As the Council may have gathered, the "A Towers" are very different than the rest of this project. And they deserve to be treated differently.

These comments, and the supporting data, will be submitted to Council and posted on the "News" page of the Skamania County Agri-Tourism Association web site which is located at www.scaassn.org Thank you.

Stephen Posner
Energy Facility Site Manager
Washington EFSEC
905 Plum Street Southeast, Third Floor
Olympia, WA 98504-3172

Dear Mr. Montañó and Mr. Posner :

Thank you for the opportunity to comment on the draft environmental impact statement for the Whistling Ridge project located in Skamania County. The Department of Ecology (Ecology) reviewed the information provided and has the following comment(s):

AIR QUALITY: Qing Chen (360) 407-6809

Best Management Practice for minimization of track out and windblown dust should be required in applicable permitting.

TOXICS CLEANUP: Connie Groven (360) 407-6254

Toxics Cleanup program comments submitted May 12, 2009, still apply to the project described (see enclosure). There are no new comments submitted at this time.

WASTE 2 RESOURCES: Mike Drumright (360) 407-6397

All grading and filling of land must utilize only clean fill, i.e., dirt or gravel. All other materials, including waste concrete and asphalt, are considered to be solid waste and permit approval must be obtained through the local jurisdictional health department prior to filling. Standards apply as defined by Washington Administrative Code (WAC) 173-350-990-Criteria for Inert Waste.

Property owners, developers, and contractors are encouraged to recycle all possible leftover construction, demolition, and land clearing (CDL) materials and reduce waste generated. Recycling construction debris is often less expensive than landfill disposal. Please visit <http://1800recycle.wa.gov> or call the 1-800-RECYCLE hotline to find facilities that that will accept your CDL materials for reuse or recycling.

WATER RESOURCES: Vicki Cline (360) 407-0278

All water wells shall be constructed in accordance with the provisions of Chapter 173-160 WAC by a driller licensed in the State of Washington. Well reports must be submitted to Ecology within 30 days after completion of a well.

August 25, 2010

Page 2

All water wells that may be drilled must be a minimum of 100 feet from any known, suspected, or potential source of contamination. Wells shall not be located within 1,000 feet of a solid waste landfill. WAC 173-160-171(1) The proposed water well shall be located where it is not subject to ponding and is not in the floodway, except as provided in Chapter 86.16 RCW. (2) It shall be protected from a one hundred year flood and from any surface or subsurface drainage capable of impairing the quality of the ground water supply.

The Growth Management Act (Section 63) requires an applicant to submit evidence of an adequate water supply before a building permit can be issued for any building requiring potable water.

Any ground water withdrawals anticipated exceeding 5,000 gallons a day for domestic uses or for commercial/industrial uses require a water right permit. Any modification to existing water rights must be approved by Ecology's Water Resources Program.

Ecology's comments are based upon information provided by the lead agency. As such, they may not constitute an exhaustive list of the various authorizations that must be obtained or legal requirements that must be fulfilled in order to carry out the proposed action.

If you have any questions or would like to respond to these comments, please contact the appropriate reviewing staff listed above.

Auto forwarded by a Rule

Mr. Montano and Mr. Posner,
Attached is our comments for the Whistling Ridge project (Ecology File Nos. 10-2884A).
Comments are due 8/27/10.

Please reply to this message for confirmation. Thank you.

Sonia Mendoza

Mr. Allen Fisksdal, EFSEC Manager
Energy Facility Site Evaluation Council
PO Box 43172
Olympia, WA 98504-3172

Dear Mr. Fisksdal:

Thank you for the opportunity to comment on the determination of significance scoping notice for the Whistling Ridge Energy project (Application No. 2009-01) located in Skamania County as proposed by Whistling Ridge Energy LLC. The Department of Ecology (Ecology) reviewed the environmental checklist and has the following comment(s):

SEPA REGIONAL PROJECT LEAD: Sarah Lukas (360) 407-7459

SHORELANDS:

The submitted scoping notice identifies the intent of preparing a floodplain and wetland assessment as part of the analysis used in the draft environmental impact statement (DEIS). The assessment should include: An inventory of all wetlands and areas of floodplain in the project area and within the vicinity of the proposal; the environmental values these aquatic features provide to the landscape; what and how the floodplain areas and wetlands will be impacted by the proposal; what environmental values will be lost from these impacts; and mitigation measures to offset the proposed environmental impacts that cannot be avoided.

The DEIS should also include an analysis of all other surface water bodies in, and within the vicinity of, the project site. An equivalent documentation of existing environmental values, proposed impacts, and proposed mitigation measures to unavoidable impacts should be outlined in the DEIS as requested for the wetlands and floodplain areas above.

TOXICS CLEANUP: Connie Groven (360) 407-6254

If contamination is currently known or suspected during construction, testing of the potentially contaminated media must be conducted. If contamination of soil or groundwater is readily visible, or is revealed by testing, Ecology must be notified. Contact the Environmental Report Tracking System Coordinator at the Southwest Regional Office at (360) 407-6300. For assistance and information about subsequent cleanup and to identify the type of testing that will be required contact Connie Groven with the Toxic Cleanup Program at the Southwest Regional Office at the phone number given above.

WATER QUALITY: Roberta Woods (360) 407-6269

Any discharge of sediment-laden runoff or other pollutants to waters of the state is in violation of Chapter 90.48 RCW, Water Pollution Control, and WAC 173-201A, Water Quality Standards for Surface Waters of the State of Washington, and is subject to enforcement action.

Erosion control measures must be in place prior to any clearing, grading, or construction. These control measures must be effective to prevent stormwater runoff from carrying soil and other

May 13, 2009

Page 2

pollutants into surface water or storm drains that lead to waters of the state. Sand, silt, clay particles, and soil will damage aquatic habitat and are considered to be pollutants.

Proper disposal of construction debris must be on land in such a manner that debris cannot enter buffers and waters of the state or cause water quality degradation of state waters.

During construction, all releases of oils, hydraulic fluids, fuels, other petroleum products, paints, solvents, and other deleterious materials must be contained and removed in a manner that will prevent their discharge to waters and soils of the state. The cleanup of spills should take precedence over other work on the site.

Clearing limits and/or any easements or required buffers should be identified and marked in the field, prior to the start of any clearing, grading, or construction. Some suggested methods are staking and flagging or high visibility fencing.

A permanent vegetative cover should be established on denuded areas at final grade if they are not otherwise permanently stabilized.

All temporary erosion control systems should be designed to contain the runoff from the developed two year, 24-hour design storm without eroding.

Coverage under the National Pollution Discharge Elimination System (NPDES) and State Waste Discharge General Permit for Stormwater Discharges Associated with Construction Activities is required for construction sites which disturb an area of one acre or more and which have or will have a discharge of stormwater to surface water or a storm sewer. An application can be downloaded from Ecology's website at <http://www.ecy.wa.gov/programs/wq/stormwater/construction/#Application> or you can contact Josh Klimek at (360) 407-7451 for an application form. To avoid project delays, we encourage the applicant(s) to submit a completed application form and to publish public notice more than 60 days before the planned start of the project.

Ecology's comments are based upon information provided by the lead agency. As such, they may not constitute an exhaustive list of the various authorizations that must be obtained or legal requirements that must be fulfilled in order to carry out the proposed action.

If you have any questions or would like to respond to these comments, please contact the appropriate reviewing staff listed above.

Olympia, WA 98504-3172

Dear Mr. Montaña and Mr. Posner :

Thank you for the opportunity to comment on the draft environmental impact statement for the Whistling Ridge project located in Skamania County. The Department of Ecology (Ecology) reviewed the information provided and has the following comment(s):

AIR QUALITY: Qing Chen (360) 407-6809

Best Management Practice for minimization of track out and windblown dust should be required in applicable permitting.

TOXICS CLEANUP: Connie Groven (360) 407-6254

Toxics Cleanup program comments submitted May 12, 2009, still apply to the project described (see enclosure). There are no new comments submitted at this time.

WASTE 2 RESOURCES: Mike Drumright (360) 407-6397

All grading and filling of land must utilize only clean fill, i.e., dirt or gravel. All other materials, including waste concrete and asphalt, are considered to be solid waste and permit approval must be obtained through the local jurisdictional health department prior to filling. Standards apply as defined by Washington Administrative Code (WAC) 173-350-990-Criteria for Inert Waste.

Property owners, developers, and contractors are encouraged to recycle all possible leftover construction, demolition, and land clearing (CDL) materials and reduce waste generated. Recycling construction debris is often less expensive than landfill disposal. Please visit <http://1800recycle.wa.gov> or call the 1-800-RECYCLE hotline to find facilities that that will accept your CDL materials for reuse or recycling.

WATER RESOURCES: Vicki Cline (360) 407-0278

All water wells shall be constructed in accordance with the provisions of Chapter 173-160 WAC by a driller licensed in the State of Washington. Well reports must be submitted to Ecology within 30 days after completion of a well.

August 25, 2010

Page 2

All water wells that may be drilled must be a minimum of 100 feet from any known, suspected, or potential source of contamination. Wells shall not be located within 1,000 feet of a solid waste landfill. WAC 173-160-171(1) The proposed water well shall be located where it is not subject to ponding and is not in the floodway, except as provided in Chapter 86.16 RCW. (2) It shall be protected from a one hundred year flood and from any surface or subsurface drainage capable of impairing the quality of the ground water supply.

The Growth Management Act (Section 63) requires an applicant to submit evidence of an adequate water supply before a building permit can be issued for any building requiring potable water.

Any ground water withdrawals anticipated exceeding 5,000 gallons a day for domestic uses or for commercial/industrial uses require a water right permit. Any modification to existing water rights must be approved by Ecology's Water Resources Program.

Ecology's comments are based upon information provided by the lead agency. As such, they may not constitute an exhaustive list of the various authorizations that must be obtained or legal requirements that must be fulfilled in order to carry out the proposed action.

If you have any questions or would like to respond to these comments, please contact the appropriate reviewing staff listed above.

COMMENT LETTER 188

Montano,Andrew M - KEC-4

From: Allan Dushan [REDACTED]
Sent: Thursday, August 26, 2010 11:54 AM
To: Montano,Andrew M - KEC-4
Subject: Whistling Ridge Energy Project Draft EIS - Comment on Wind Turbine lighting

SDS Lumber suggested I forward my comment/suggestion about the FAA lighting requirements for the wind turbines to your office.

Thanks for taking my comments below,

Allan Dushan

Comment on:
Whistling Ridge Energy Project Draft EIS

Concerning:
FAA aircraft safety lighting requirements

Viewpoint associated with my full-time year round residents:
Viewpoint 1: Pucker Huddle (Within Scenic Area), 16-25 Turbines visible.

Lighting Suggestion Based On Reference:
The U.S. Department of Transportation FAA Advisory Circular (AC 70/7460-1K)
"Obstruction Marking and Lighting"

Web Link to FAA Advisory Circular (AC 70/7460-1K):
http://www.airweb.faa.gov/Regulatory_and_Guidance_Library/rgAdvisoryCircular.nsf/0/B993DCDFC37FCDOpenDocument

My Lighting Suggestion:
First, I am in favor of the wind turbines.

My suggestions here are to help minimize the visual impact while still adhering to the FAA aircraft safety lighting requirements.

My house was built to take advantage of the view I have of Underwood Mountain, and because of this my Master Bedroom, Living Room, Dining Room and Kitchen windows all face Underwood Mountain.

During the day, the wind turbines for me add to the scenic view, but at night the flashing lights can be extremely distracting, if not configured properly. My reference for the lighting being distracting are the wind turbines outside of Goldendale. When you are driving south on hwy 97 from Goldendale, the flashing lights are surprisingly distracting due to the fact that every wind turbine in the row had a light on it and possibly the speed at which the lights were flashing. This drive south on hwy 97 seemed representable of what the view from my house would be.

My suggestions are based off of what I experienced driving south on hwy 97, and what I believe could reduce the distraction.

The greatest issues were:
1. The number of lights, since every wind turbine appeared to have one.
2. The rate at which they flashed.

3. How they flashed, which was either off or on.

My suggestion would be to:

1. Put lights on the minimum number of towers based on the FAA Advisory Circular (AC 70/7460-1K). For linear turbine configurations, this would be one at each end of the line with no more than 1/2 mile between lights in the line.

Based on this requirement, a possible lighting configuration for Whistling Ridge could be placing lights on: A1,A4,A7,A8,A13,F1,F3,B1,B7,B13,B18,B21,D1,D3,E1,E2,C1,C4,C5,C8.

2. Set the flash Per Minute of the lights to 20 FPM (Flashes Per Minute). This suggestion is based on if the L-864 light is used, which is allowed to flash between 20 and 40 FPM.

3. Have the lights fade off and then fade on, as opposed to being either completely on or completely off. There was nothing in the FAA Advisory Circular (AC 70/7460-1K) that indicated the lights could not fade off then on, as opposed to being on or off when flashing.

That is the extent of my suggestion.

Thanks for extending the comment period.

Bonneville Power Administration - KEC-4
905 NE 11th Avenue
Portland, Oregon 97208-3621

Re: Comments on the draft EIS for the Whistling Ridge Energy Project
EPA Project number 09-018-BPA

Dear Mr. Montañó:

The U.S. Environmental Protection Agency (EPA) has reviewed the Bonneville Power Administration (BPA) Draft Environmental Impact Statement (DEIS) for the proposed Whistling Ridge Energy Project (CEQ# 20100187) in Skamania County, Washington in accordance with our responsibilities under the National Environmental Policy Act (NEPA) and Clean Air Act (CAA) §309. Section 309 of the CAA directs EPA to review and comment in writing on the environmental impacts associated with all major federal actions.

The DEIS analyzes potential environmental impacts of a proposal to interconnect a 75-megawatt (MW) Whistling Ridge Wind Energy project to the Federal Columbia River Transmission System (FCRTS). Because the project would be sited on private land, BPA will decide whether to grant the interconnection request for the project or not. For this decision to be made and the public to understand its implications, BPA developed and analyzed the Proposed and No Action alternatives to evaluate what environmental impacts, if any, would be associated with the proposed action. An authorization to interconnect the project to the FCRTS at a point along BPA's existing North Bonneville-Midway transmission line would require about 4 acres for construction of a substation and up to 1,000 feet long corridor where poles would be placed to support aboveground power lines.

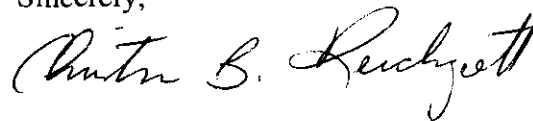

EPA supports development of alternative and environmentally sustainable sources of energy such as wind power. The DEIS for this project includes a good analysis of anticipated environmental impacts from the project and identifies mitigation measures to offset the impacts and monitor effectiveness. Also, the DEIS states that Best Management Practices (BMPs) would be used to minimize any potential impacts. Because wind power technology and configuration of wind turbines in the project area are still relatively new, and their impacts on birds and bats within forested sites remain unclear, effective adaptive management will be important to reduce and mitigate the project impacts.

The DEIS indicates that water quality may be adversely affected if construction alters the hydrology of springs and surface runoff such that erosion carries sediment to nearby waterbodies. We recommend that this aspect of the project be monitored to assure that water quality is protected. Please also note that antidegradation provisions of the Clean Water Act apply to those waterbodies where water quality standards are currently being met, and prohibit degradation of their water quality. Thus, BPA should coordinate with Washington State Department of Ecology (Ecology) and Tribes affected by the project to assure that the state and tribal water quality standards would be met during implementation of the proposed action. Since the project anticipates obtaining a National Pollutant Discharge Elimination System (NPDES) permit for planned construction activities likely to disturb 1 or more acres, the final EIS should include updated information on such permit application process and conditions to protect water quality.

Based on our review, we have assigned a rating of LO (Lack of Objections) to the DEIS. This rating and a summary of our comments will be published in the Federal Register. A copy of the rating system used in conducting our review is enclosed for your reference.

Thank you for the opportunity to review this DEIS. If you have questions or comments concerning this review, please contact Theo Mbabaliye of my staff at (206) 553-6322 or me at (206) 553-1601.

Sincerely,

Christine B. Reichgott, Manager
Environmental Review and Sediment Management Unit

Enclosure

**U.S. Environmental Protection Agency Rating System for
Draft Environmental Impact Statements
Definitions and Follow-Up Action***

Environmental Impact of the Action

LO – Lack of Objections

The U.S. Environmental Protection Agency (EPA) review has not identified any potential environmental impacts requiring substantive changes to the proposal. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal.

EC – Environmental Concerns

EPA review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce these impacts.

EO – Environmental Objections

EPA review has identified significant environmental impacts that should be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no-action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

EU – Environmentally Unsatisfactory

EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potential unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the Council on Environmental Quality (CEQ).

Adequacy of the Impact Statement

Category 1 – Adequate

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis of data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

Category 2 – Insufficient Information

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses or discussion should be included in the final EIS.

Category 3 – Inadequate

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the National Environmental Policy Act and or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

* From EPA Manual 1640 Policy and Procedures for the Review of Federal Actions Impacting the Environment, February, 1987.

Re: The Whistling Ridge Energy Project's Draft Environmental Impact Statement (DEIS)

I am writing to say the conclusions reached by the authors of the DEIS are wrong. It needs to be redone to reflect reality. I oppose the location of this project and think it's a bad idea for the vast majority of people who live in the area.

The DEIS wrongly concludes that visual impacts will be low to moderate. Page 3-171 describes the north facing view from Hood River Hospital, an urban setting in the middle of town, but fails to describe the impact to any of the viewpoints along the waterfront, residences in town

and recreation areas scattered throughout Hood River and The Gorge. These viewpoints are cherished and attract tourists and residents alike to the area. Industrial wind turbines 400' high will have a high impact on the scenic quality of these view sites, not a low impact.

The DEIS also fails to mention the impact on property values in the area. I own a home in Underwood. I would not consider buying there again if large wind turbines are near by. To conclude that wind turbines will promote eco-tourism is wishful thinking at best.

I request that you reject this DEIS and not allow the project to continue in its current form. The impact it will have on tourism and residents will far outweigh any benefits. A handful of jobs created in Skamania County will not offset the long-term losses to economic growth in The Gorge. We already get 49% of our power from renewable energy. There are much better places to put wind turbines than the edge of a national scenic area.

Subject: Comments on Whistling Ridge DEIS

To: The Bonneville Power Administration (BPA) and the State of Washington Energy Facility Site Evaluation Council (EFSEC)

<!--[if !supportEmptyParas]--> <!--[endif]-->

Re: The Whistling Ridge Energy Project's Draft Environmental Impact Statement (DEIS)

<!--[if !supportEmptyParas]--> <!--[endif]-->

I am writing to say the conclusions reached by the authors of the DEIS are wrong. It needs to be redone to reflect reality. I oppose the location of this project and think it's a bad idea for the vast majority of people who live in the area.

<!--[if !supportEmptyParas]--> <!--[endif]-->

The DEIS wrongly concludes that visual impacts will be low to moderate. Page 3-171 describes the north facing view from Hood River Hospital, an urban setting in the middle of town, but fails to describe the impact to any of the viewpoints along the waterfront, residences in town and recreation areas scattered throughout Hood River and The Gorge. These viewpoints are cherished and attract tourists and residents alike to the area. Industrial wind turbines 400' high will have a high impact on the scenic quality of these view sites, not a low impact.

<!--[if !supportEmptyParas]--> <!--[endif]-->

The DEIS also fails to mention the impact on property values in the area. I own a home in Underwood. I would not consider buying there again if large wind turbines are near by. To conclude that wind turbines will promote eco-tourism is wishful thinking at best.

<!--[if !supportEmptyParas]--> <!--[endif]-->

I request that you reject this DEIS and not allow the project to continue in its current form. The impact it will have on tourism and residents will far outweigh any benefits. A handful of jobs created in Skamania County will not offset the long-term losses to economic growth in The Gorge. We already get 49% of our power from renewable energy. There are much better places to put wind turbines than the edge of a national scenic area.

Subject: Whistling Ridge EIS

I am writing to comment on the DEIS and EFSC application for the Whistling Ridge Energy Project, proposed in the Underwood area, along the Skamania and Klickitat county line. I have sent under separate cover my comments to EFSC.

I have extensive background in ecological management and forest ecosystem in the Cascades. I am a member of a US Forest Service advisory committee for ecological restoration of east side ecosystem for the Northern Spotted Owl in Oregon. I was appointed to this Resource Advisory Committee by the Sec. of Agriculture. As such I have been involved in a number of ecosystem reviews and management plans involving areas of similar characteristics as the Whistling Ridge Project.

The proposed project would not have negative impacts to the environment. The project is located on commercial timberland that have been subject to decades of intensive harvesting operations under a sustain yield forestry program regulated by the Washington Department of Natural Resources. I have reviewed the wildlife baseline studies and I have visited the site. There are no significant sensitive wildlife and plant habitat areas associated with this project area. The ecology of this area is typical of a highly altered timber management property. Timber management operations will continue in this area for decades to come which is also evidence that the area is not currently or will it every evolve to a significant ecological resource area. It is a timber management area for industrial forest practices. Siting a wind farm in this area is an intelligent and appropriate compatible land use which will diversity the economic value of these timber lands and help to preserve these lands for timber production for decades to come. There is no evidence that the installation and operations of the proposed facility will have any significant impacts on sensitive or special status animal or plant species. The data and analysis by qualified third parties indicates that no significant impact will occur.

The Whistling Ridge Wind Farm is also outside of the Columbia River Gorge National Scenic Area. The Congressional intent of the Gorge Scenic Act was to allow for ongoing economic activity in areas adjacent to the Scenic Area regardless of the affect that these adjacent areas may have on the view from the scenic area. In other words, there was to be no buffer zones to the buffer zone already established by the Gorge Scenic Area boundary. Also I believe that the construction of the Whistling Ridge Wind Farm would not degrade the scenic beauty of the Columbia River Gorge National Scenic Area. As a point of law, EFSEC does not have the authorization to establish new exclusion zones such as buffers to the Gorge Scenic Area without additional authorization from either the legislature or the US Congress. Visual Impact on the Columbia River Gorge National Scenic Area should be an issue of consideration in any Environmental Impact Statement review, but the determination of significance of any impact is not capricious or arbitrary, it must be based on the rules that are in place today. Development outside of and adjacent to the Columbia River Gorge National Scenic Area is allowed under the law and as such visual impacts to the National Scenic Area are allowed because the proposed facility is not located within the Scenic Area.

I support renewable energy. I am the Vice Chairman of the Renewable Northwest Project and support BPA's involvement in developing wind resources. The Whistling Ridge resource will further diversify the BPA portfolio by including wind resources west of the transmission constraint areas. This site has significant positive impacts on the BPA system with regard to availability close to large load centers.

I also supported and participated in the creation of Columbia River Gorge National Scenic Area which is national scenic treasure. The creation of the Scenic Area involved a significant public involvement process that carefully consider the location of the boundary of the Scenic Area. The potential for wind energy development in the Columbia River Gorge area was a consideration when those of us who put pen to paper and drew the boundary participated in the creation of the Scenic Area. This boundary was established to buffer the significant resources of the Scenic Area and the legislation that created the Columbia River Gorge National Scenic Area clearly consider potential affects from development outside of the boundary and determined that such development would not be subject to the Scenic Act. It is not EFSEC's role to substitute its judgment for that of the US Congress on this issue.

BPA and EFSC should approve this project.

Sincerely,

David W. McClain

Attached is Mid-Columbia Economic Development District's letter regarding renewable energy projects. As requested, we are sending this along.

"Mid-Columbia Economic Development (MCEDD) supports the utilization of our renewable energy assets to diversify our economy and stabilize our economic base. We support development of wind, solar, biomass, geothermal, and other renewable energy projects in our region which are designed in a manner consistent with local regulations.

MCEDD has supported the creation of the Columbia Gorge Bi-State Renewable Energy Zone as a means to engage in a cross-jurisdiction, inter-agency, bi-state collaborative approach to renewable energy development. In establishing the Columbia Gorge Bi-State Renewable Energy Zone, we took into consideration a variety of factors, all linked by the regional economy. These include the renewable energy resource itself (wind, solar, hydro, geothermal, biofuels, and biomass), financial investment in those resources by renewable energy industry, existing transportation networks (roads, rail, river and air), high-speed telecommunications networks, education and workforce training capacity, public utilities, resident workforce, transmission capacity, industrial lands base, and quality of life. The economic benefits of renewable energy projects can provide a base for connecting all these components into a networked system that would generate family wage employment in a rural, traditionally depressed economy"

Subject: Whistling Ridge Comment - Meteorological Tower Design

Dear Mr. Andrew M. Montaña - Environmental Project Manager,
 Bonneville Power Administration - KEC-4,
 P.O. Box 3621, Portland, Oregon, 97208-3621;
 direct telephone number 503-230-4145;
 toll-free telephone number 1-800-282-3713;
 fax number 503-230-5699;
 e-mail address: ammontano@bpa.gov.

I have reviewed the following draft EIS and offer the following comment and recommendations. My comments are in blue/red, italic font.

Whistling Ridge Energy Facility Draft Environmental Impact Statement

-
The DRAFT states on page 1.24 – Mitigation Measures – Biological Resources; “Use of **tubular turbine towers**, avoiding the lattice type towers which creates areas where birds may congregate and perch thus decreasing the potential for turbine collisions.

- Use of un-guyed meteorological towers, reducing the potential for bird collision with wires”.

-
The DRAFT states on page 2-7 – Proposed Alternatives and Actions; “The **basic design** for the tower would depend on the style selected. Most towers are un-guyed **lattice towers** at heights equal to the hub heights of the proposed wind turbines.

The location for the permanent meteorological tower would be determined during the micrositing process. The selected site would be based on a meteorologist’s recommendations for an on-site location that best represents the site’s meteorological conditions.

2.1.3.5 Meteorological Tower

Greg Neely Comment – Jun 16, 10:

As the Meteorological Towers will be micro-sited amongst the wind turbines, where bird perching and collisions issues are paramount.

The Meteorological Towers should neither be a basic design nor a lattice design.

The Meteorological Towers should utilize a Tubular towers; pursuant to the same justification for turbine towers .

Construction of a Tubular Meteorological Tower may require a Custom design, in that the top of the tower would have to be adapted to support the equipment it supports.

Subject: Whistling Ridge Comment - Visual Resources

Dear Mr. Andrew M. Montañó - Environmental Project Manager,

Bonneville Power Administration - KEC-4,
 P.O. Box 3621, Portland, Oregon, 97208-3621;
 direct telephone number 503-230-4145;
 toll-free telephone number 1-800-282-3713;
 fax number 503-230-5699;
 e-mail address: ammontano@bpa.gov

I have reviewed the following draft EIS and offer the following comment and recommendations. My comments are in blue/red, italic font.

Whistling Ridge Energy Facility Draft Environmental Impact Statement

The DRAFT states on page 1-35 – Summary of Unavoidable Adverse Impacts – Table 1-1 – Visual Resources;

“The project would cause some visual impact to surrounding areas where turbines were visible, including some areas inside the Columbia River Gorge National Scenic Area. The visual impact analysis showed that the anticipated level of **visual impact would not be higher than low to moderate** at any of the viewpoints examined.”

Greg Neely Comment 6-16-10:

To state, “the visual impact would not be higher than low to moderate” is extremely subjective, given the proximity to the Columbia Gorge National Scenic Area.

It’s my opinion that the most crucial viewpoints are:

- ***Hood River***
- ***Columbia River Waterway (adjacent to Hood River)***
- ***Columbia River Shoreline Recreation Sites (Adjacent to Hood River and Mosier)***
- ***I-84 Freeway (From Hood River to Mosier in both directions)***

The DRAFT refers to “micrositing” of towers, however I do not see anywhere in the draft that a site-by-site, micrositing analysis was done for each specific turbine or meteorological tower.

Certainly the turbine & meteorological towers sited in the project area foreground as viewed the crucial viewpoints I identified above will have high visual impact.

I recommend site-by-site, micrositing analysis be done for each specific turbine or meteorological tower within view from:

- ***Hood River***

- *Columbia River Waterway (adjacent to Hood River)*
- *Columbia River Shoreline Recreation Sites (Adjacent to Hood River and Mosier)*
- *I-84 Freeway (From Hood River to Mosier in both directions)*

Greg Neely

Subject: Port of Vancouver Wind Energy Letter
Attachments: Wind Energy Letter.pdf

To Whom It May Concern:

Please see attached letter in support of wind energy business. This is forwarded at the request of Jason Spadaro of the SDS Lumber Company.

August 18, 2010

To Whom It May Concern:

The Port of Vancouver is an active participant in regional and national associations promoting alternative energy, particularly wind energy. We support alternative energy credit programs and state and national alternative energy standards. In addition, the port advocates for the expansion of the wind energy grid in the Pacific Northwest and nationwide.

Over the last five years wind energy cargoes have contributed to the diversification of cargoes at the Port of Vancouver, expanding overall revenues and stabilizing income through the tough economic times. Two large mobile harbor cranes acquired during this time have greatly enhanced the port's ability to attract and support the growth of the wind energy logistics trade. In 2009 alone the port handled 2,700 pieces of wind energy business, generating 55,897 labor hours.

Wind energy business means jobs and economic return for our community in southwest Washington. For this reason, the Port of Vancouver intends to continue its active role in the receipt and delivery of component parts for the wind energy business well into the future.

Sincerely,

A handwritten signature in black ink that reads "Larry Paulson".

RE: Whistling Ridge Energy Project, DOE/EIS - 0419

Dear Mr. Montano and Mr. Posner:

On behalf of the members of Seattle Audubon, I am submitting these comments in response to the May 2010 Draft Environmental Impact Statement (DEIS) for the proposed Whistling Ridge Energy Project. We are a formal intervenor in the EFSEC Site Certification proceeding for this project and we submitted scoping comments regarding the environmental evaluation of the project on May 18, 2009. Seattle Audubon was also an active participant in the development of the Washington Department of Fish and Wildlife's April 2009 *Wind Power Guidelines*.

The mission of Seattle Audubon is to cultivate and lead a community that values and protects birds and the natural environment. Since 1916, Seattle Audubon has worked to protect birds of our region whose habitats are at risk. Our members have a long history of engagement on forest-related issues in Washington state and an on-going interest in the inter-relationship between bird habitat and human development activities in the forested landscape.

Specific Comments

1. Independent Evaluation

In our scoping comments for this project, Seattle Audubon identified multiple issues in the application that needed thorough review to adequately evaluate the potential environmental impacts of this project. Unfortunately, the DEIS fails to address many of the issues we previously identified. In many instances, the DEIS simply repeats the information presented in the application with no new analysis or documentation. We urge your agencies to ensure that the Final Environmental Impact Statement (FEIS) fully addresses these inadequacies.

As one of the first wind power projects to be considered for a forested landscape in Washington state, this environmental review needs to include a more detailed analysis of several issues that make this proposal different from other wind power projects located on agricultural and/or shrub

steppe habitat; experience and knowledge gained from existing projects in the state may not be “transferable” to a project such as this being proposed for a very different environment.

2. Climate Change

We recognize the significant threat climate change poses to birds and bird habitat, including threatened and endangered bird species. That is why we support well-designed, appropriately-sited renewable energy projects as a critical step in reducing carbon emissions.

Seattle Audubon is greatly encouraged by the potential for this project to avoid the emissions from combustion of an estimated 114,000 barrels of crude oil or 654 million cubic feet of natural gas, leading to the displacement of over 131,000 tons of carbon dioxide annually. (DEIS at 3-20) The beneficial biological impact of such a displacement to birds and other wildlife in the region appears significant.

It is also important to evaluate how the project’s contribution to reducing carbon emissions would in turn impact at-risk species in the region such as the northern spotted owl. For example, climate change models predict that as a result of global warming, the Pacific Northwest will experience warmer and drier summers, thereby reducing the food supply for owls, as well as colder and wetter springs, resulting in a reduction in the survival chances of owl fledglings during nesting season. (for more details, see <http://ir.library.oregonstate.edu/jspui/bitstream/1957/11326/1/EGlennDisseration2009.pdf>)

While hard to quantify precisely, the FEIS should better evaluate the trade-off between potential benefits from the project to birds from avoided emissions (*through reduced carbon output and the resulting effects on forest habitat and food supply*) and the potential harm from the project to birds (*through loss of existing habitat, habitat fragmentation and potential collision mortality*). Your two agencies, together with the project proponent, are well positioned to facilitate a Northwest-specific study comparing the annual bird fatalities caused by wind farms versus those caused by fossil-fueled power stations, similar to the Sovacool study. (DEIS p. 3-276)

3. Northern Spotted Owls

The DEIS contains important information regarding northern spotted owls (NSO), including a description of survey history in the project vicinity. Subsequent to the completion of the DEIS, however, an NSO survey on state Department of Natural Resources (DNR) land adjacent to the proposed project site detected an NSO in May 2010. The presence of an NSO calls into questions many of the conclusions in the DEIS regarding NSO, including the statement that “*Given the extensive survey record confirming the absence of northern spotted owls, the proposed the Project [sic] will not pose a risk of taking northern spotted owls under the Endangered Species Act Section 9 and its regulations.*” (DEIS at 3-49)

The FEIS should add a fresh analysis of the potential impacts on NSO, including:

- a) An evaluation of the potential for NSO to fly through the project’s turbine string corridor. While the potential for an NSO to collide with a wind turbine (blade or tower) is likely low, the FEIS should include life history information on NSO behavior in comparable landscapes, including flight patterns in cleared areas and maximum height of flying (*i.e. within the rotor-swept area*). Telemetry data should be available from the U.S. Fish and Wildlife Service regarding radio tags studies on

- NSO that can provide information on NSO flight patterns in matrix lands with a combination of forested and commercially harvested lands.
- b) An evaluation of the specific amount and location of potentially suitable NSO habitat in the proposed project site. While the DEIS states that no forests with suitable structure for NSO nesting or roosting are present within the project site (DEIS p. 3-49), the map of Harvesting Schedule (DEIS Figure 2-3) indicates forest parcels over 70 years old inside the Mill Creek Core Area. In addition, there are multiple reference made to “suitable habitat” and “northern spotted owl habitat” located in the proposed project site (DEIS p. 3-50, 3-52). The FEIS should provide a much clearer and more detailed inventory of the existing NSO habitat conditions on both the project site and within the historic NSO activity centers (*including information on stand age, tree species diversity, snags per acre, etc.*). In addition, while the DEIS notes that the Mill Creek site center contains 48 percent suitable habitat (DEIS p. 3-56), Seattle Audubon is concerned that this calculation by DNR is based on outdated data. The FEIS should detail the specific process used for that calculation and ensure that it is based on up-to-date habitat mapping of the site center.
 - c) An evaluation of the potential for existing “degraded” habitat in the proposed project site to develop into suitable NSO habitat during the projected 30 year life span of the project. Although NSO may currently be absent from the project lands, the FEIS should evaluate the potential for NSO to utilize those lands in the future. One of the guiding principles in the 2009 Wind Power Guidelines states *“From a wildlife conservation perspective, a species in decline may be absent from an area ... yet the habitat remains important for the conservation or recovery of that species.”* (WDFW, p 2)
 - d) An evaluation of the likely NSO utilization of existing habitat in the project vicinity with the presence of project facilities (turbines, roads, etc.). The DNR land where the NSO was detected is covered by the state’s Habitat Conservation Plan (HCP) and is intended to serve as habitat for NSO. If the project is built, would it displace NSO from this habitat on DNR land as they sought to avoid the project facilities? The FEIS should evaluate the potential for project operations to interfere with NSO nesting, roosting, foraging or dispersal on the adjacent DNR lands. Would the human activity associated with project maintenance disrupt NSO activities during breeding season? Would the sound and/or vibrations from the spinning turbines affect the ability of NSO (which hunt largely by sound) to locate prey? For example, an NSO study looked at effects of road noise on NSO hormone levels and reproductive success. It measured sound level, annual reproductive success and fecal hormones including stress steroids and metabolic hormones. The study results suggest noise exposure has negative effects on NSO, increasing stress levels and decreasing reproductive success. (<http://conservationbiology.net/research-programs/northern-spotted-owl-research/>)

The FEIS should address all of these potential project impacts to NSO, including identification of additional monitoring and mitigation measures. (DEIS p. 3-82)

In addition, the DEIS notes that the project proponent considered locating turbines on the DNR lands directly north of the site. (DEIS p. 1-14) We appreciate that this option was rejected from further consideration due to comments from the public and DNR’s reluctance to consider leasing

the site. This decision gained significantly increased importance with the May 2010 detection of an NSO on this DNR land.

4. Baseline Avian Use

The DEIS does not adequately address the issue of comparable avian use data. It is vital that the FEIS include an evaluation of the species variety and abundance in the project vicinity in relation to baseline avian use data from other locations with similar landscape and climate features – mountainous conifer forests with cool, wet conditions. The DEIS makes comparisons of bird survey results from Whistling Ridge to data from other wind projects, either in eastern U.S. deciduous forests or shrub-steppe habitat in the Pacific Northwest (DEIS p 3-63, 3-64); such comparisons provide limited benefit for evaluating the potential impacts of this project. Seattle Audubon noted this problem in our scoping comments and we continue to be concerned that the environmental review for this project needs a more appropriate avian use comparison.

DNR and the Forest Service each are land managers with significant amounts of forest habitat comparable to the project site; either or both agencies may have / know of avian use survey data that could be used, as could other resource agencies or academic institutions. In order for the public (and the decision-makers regarding permits for Whistling Ridge) to have an accurate understanding of the potential impacts of this project on birds, the FEIS should include a meaningful “apples-to-apples” comparison of avian species. Without such an evaluation, any conclusions regarding the variety and concentration of bird species at the project site are likely to be misleading.

In addition, the FEIS should more clearly and specifically describe the results of the avian surveys conducted. While calculations such as the “*mean annual bird use*” and a “*relative index to collision risk*” do provide some useful information, the DEIS fails to identify the actual total number of birds detected during the study, nor does it reveal the number of birds and bats that were detected passing within the proposed rotor swept area, instead couching the data in terms of percentages. (DEIS p. 3-64) For instance, Table 3.4-5 should be modified to indicate the specific number of each species observed by season rather than burying that data solely in the Appendix. (DEIS p. 3-62, 3-63)

5. Olive-sided Flycatcher and Vaux’s Swift

The olive-sided flycatcher is a federal species of concern and the Vaux’s swift is a state candidate species for listing. Both species were detected at the project site during multiple avian surveys with the majority of detections within the rotor swept area. (DEIS p. 3-56, 3-57) Both forage for insect prey on the wing and would likely utilize the cleared areas associated with the project turbines. The DEIS does not adequately address the potential turbine-related mortality of these sensitive species, simply asserting that collisions would likely be rare and that it is unlikely that the project would have any negative impacts on population levels. (DEIS p. 3-79) The FEIS should more fully evaluate this issue and document the facts underlying these type of statements. In addition, the FEIS should specifically identify the “*appropriate mitigating measures*” BPA will ensure are employed to minimize and avoid the anticipated project-related impacts on these sensitive species under the Migratory Bird Treaty Act. (DEIS p. 4-5)

6. Size, Number and Type of Turbines

The DEIS states that the number of wind turbines at the project site already has been minimized to the extent practicable and that if any turbines are removed from the project design, other locations must be found to replace those turbines to maintain the viability of the project. (DEIS p. 1-14) It also states that the project would consist of up to 50 wind turbine generators that would range in size from 1.2 to 2.5 MW and have a total nameplate capacity of up to 75 MW. (DEIS p. 1-9) Yet if the project proponent were to select the 2.5 MW turbines, the number needed could be reduced by 40% without reducing the project capacity.

Reducing the number of turbines offers the potential to significantly reduce some of the adverse environmental impacts of the project. The amount of habitat permanently impacted could be reduced, including avoiding the loss of any suitable or potential NSO habitat. Turbine locations in close proximity to the DNR HCP lands could be removed from the project, lessening the potential to disturb NSO in the area. The FEIS should include at least one additional alternative that provides a detailed analysis of how different combinations of turbine sizes and numbers can best meet the identified minimum necessary project capacity while minimizing the habitat disruptions.

In addition, the FEIS should identify the specific turbine type that would be used at Whistling Ridge. Different turbine types can have different blade tip speeds as well as utilize either an upwind or downwind style. Research at other wind power projects indicates that these differences can have a direct correlation to avian mortalities (DEIS Appendix B, Wildlife Reports). An evaluation of the specific turbines to be used at the project is essential to the environmental review each of your agencies are responsible for completing.

7. Cumulative Impacts

The DEIS' evaluation of cumulative impacts makes only passing reference of the most significant incremental impacts this project would likely contribute to – wind power development in a forested landscape. There is no mention of either the proposed Radar Ridge or Coyote Crest wind projects, both in forested landscapes within the range of NSO. The DEIS lacks any analysis of either the impacts to bird habitat or avian collision mortalities that could reasonably be expected from significant “build out” of wind power on Northwest forested lands. There is no discussion of how additional wind projects within the range of NSO could impact that ESA-listed species, nor any analysis of how multiple wind power projects could impact the regional electrical transmission system.

The FEIS should include a much more robust evaluation of the potential cumulative impacts from the growing wave of wind power projects on forested lands. It should analyze the potential cumulative impacts of a “full build-out” of wind power in the region on avian species, similar to the 2007 National Research Council assessment done for the Mid-Atlantic Highlands or the 2008 West Inc. study done for the Columbia Plateau Eco-region. (DEIS p. 3-274, 3-275) Such an analysis should include an up-to-date projection for potential wind power development in the region as well as incorporate accurate monitoring data on avian mortality and displacement.

8. Mitigation

The project would entail approximately 384 acres of forest land being developed for wind turbine foundations, connecting roadways, overhead and underground transmission lines,

operation and maintenance yard, and substation. (DEIS p. 1-9, 2-4) This includes the permanent loss of 60.7 acres of habitat, as well as the temporary loss of another 53.6 acres of habitat. (DEIS p. 3-73) In addition, there would be significant additional acres impacted by a corridor of up to 500 feet from the base of the turbines that would have a height restriction on trees. (DEIS p. 2-4, 2-15) Despite this noted loss or degradation of habitat, the DEIS does not include any mitigation measures related to these habitat impacts. (DEIS p. 3-82)

The Wind Power Guidelines recommend mitigation for permanent habitat impacts by either acquisition of replacement habitat or “By Fee” option, or a combination of both. (WDFW, p. 9, 12) The Guidelines also recommend mitigation for temporary impacts to habitat, including a WDFW approved restoration plan and some acquisition of suitable replacement habitat. (WDFW, p.11-12)

The FEIS should include an explicit evaluation of the impacted habitat (*both temporary and permanent*) and identify the specific level of mitigation that will be required of the applicant. SEPA provides the authority to impose reasonable conditions to mitigate impacts from a proposed action. While the project lands are not pristine wildlife habitat, they do provide valuable habitat for numerous bird and other species as well as ecosystem services that would be adversely impacted by the project. This habitat provides foraging and breeding opportunities for different species as well as vegetative cover for wildlife. The project proponent, SDS Company, LLC, touts the importance of its forest lands for wildlife and biodiversity, stating that its timberlands “*provide habitat for various species of plants and wildlife, they protect watersheds, they emit oxygen into the atmosphere and consume carbon dioxide, and they provide beautiful spaces for recreation.*” (see <http://www.stevensonlandcompany.com/>) Permanently converting 60.7 acres of this habitat, as well as temporarily impacting an additional 53.6 acres of habitat, requires acquisition of replacement habitat.

Seattle Audubon recommends a ratio of at least 1:1 for replacing permanently impacted habitat and of 0.1:1 for temporarily impacted habitat, as the project lands appear to fit the Wind Power Guidelines’ description of Class III habitat – lands with lesser numbers of associated Species of Greatest Conservation Need but that are not currently cultivated, developed or disturbed by an active road or other corridor that eliminates natural habitat. (WDFW p. 9)

SDS manages numerous land parcels in the general vicinity of the projects that are like-kind and/or of equal or higher habitat value than the areas which would be impacted by the project. There are numerous SDS-owned sites in the Columbia River Gorge National Scenic Area and the White Salmon River Wild and Scenic River corridor that meet the criteria identified in the Wind Power Guidelines as being at risk of development or habitat degradation; these or other lands in the areas could serve as appropriate replacement habitat by donation to a land trust or given permanent legal protection through a conservation easement or other enforceable means. (WDFW, p. 9-10) A detailed mitigation package should be developed ***prior to*** project approval, not left to be determined after the fact.

In addition to inclusion of mitigation for impacts to habitat, the FEIS should also explicitly include mitigation for any direct impacts to at-risk species. As noted above in our comments above regarding NSO, olive-sided flycatcher and Vaux’s swift, the FEIS should include details

of the specific actions that will be required of the applicant to avoid, minimize and mitigate for any mortality of ESA-listed and other sensitive species.

9. Monitoring

Seattle Audubon appreciates the inclusion of a post-construction avian mortality study. (DEIS p. 3-82) More details on the protocol to be used for this study needs to be included in the FEIS in order to understand whether the proposed “two year minimum” is adequate to evaluate the ongoing impact of project operations on avian species. As the Wind Power Guidelines point out, the duration and scope of the monitoring depends in part on the availability of existing monitoring data at projects in similar habitat types. (WDFW p. 6) In accordance with RCW 80.50.040, EFSEC must prescribe the means for monitoring the effects of project operation in order to assure compliance with the certification. (DEIS p. 1-3) The FEIS should include greater detail on how EFSEC will meet this requirement.

In addition, the FEIS should evaluate the potential for use of canine detection for carcass surveys. The Center for Conservation Biology at the University of Washington has demonstrated the precision and efficiency of dogs in locating wildlife in forested settings (for more details, see <http://conservationbiology.net/conservation-canines>); as one of Washington’s first wind power projects in a forested landscape the Whistling Ridge project is an excellent candidate for looking at applying this methodology to post-construction mortality studies.

Beyond monitoring the direct avian mortalities caused by the project, it is important to also study the *indirect* project impacts such as species displacement from territory and cumulative impacts. (WDFW p. 6) The FEIS should require specific project monitoring strategies that include post-construction avian use surveys of live birds in the project area. It is not enough to just monitor the number of birds directly killed by project operations; post-construction monitoring should also look at how project operation impacts ongoing avian use of the site and adjacent areas. As with our comments regarding mitigation above, a detailed monitoring program should be developed prior to project approval, not left to be determined after the fact.

10. Adaptive Management

We appreciate the requirement for a Technical Advisory Committee (TAC) to evaluate and coordinate the mitigation and monitoring program, including potential adaptive management activities. (DEIS p. 3-82) Unfortunately the DEIS contains no information detailing the authority of and resources available to the TAC to carry out those responsibilities. As the Wind Power Guidelines point out, the range of potential adjustments the TAC could make to potential mitigation and monitoring requirements should be clearly stated in the project permit. (WDFW p. 6) In addition, the proposed composition of the TAC does not include any stakeholders from environmental groups, landowners or Native American tribes. (WDFW p. 6) The FEIS should identify an expanded TAC that includes representatives from these other stakeholder groups, as well as clearly identify TAC funding and authority.

As noted multiple times above, Whistling Ridge would be one of the first wind power projects to be considered for a forested landscape in Washington state. In light of this, there are several important environmental issues for which there is limited or no applicable comparative data for use in evaluating wind power projects in forested landscapes. In recognition of this type of challenge, the Wind Power Guidelines specifically call for research oriented studies that look at

issues such as species displacement or cumulative impacts that could provide important information for understanding wind energy / wildlife interactions. (WDFW p. 7)

The FEIS should identify specific research oriented studies that would directly relate to the proposed Whistling Ridge project, as well as the role of the TAC in determining the need for further studies. Potential studies include:

- a) A robust analysis of pre- and post-construction avian use study data at the project to better understand direct and indirect impacts to specific avian species, including changes to density and nesting success of targeted species.
- b) As noted in our cumulative impact comments above, an analysis focused on the Pacific Northwest region, including forested landscapes, of the potential cumulative impacts of a “full build-out” of wind power on avian species.
- c) As noted in our climate change comments above, a Pacific Northwest-specific study comparing the annual bird fatalities caused by wind farms versus those caused by fossil-fueled power stations, similar to the 2009 Sovacool study. (DEIS p. 3-276)
- d) As noted in our monitoring comments above, the use of canine detection of carcasses in the post-construction avian mortality study.

While funding for these and/or other research oriented studies should be solicited from multiple sources (WDFW p. 7), the FEIS should explicitly identify the level of funding to be provided by the project proponent.

11. Distribution of Project Power

One of the applicant’s stated objectives for this project is “ *to provide an additional renewable resource for electrical utilities in Washington.*” (DEIS p. 1-7) We welcome that intent and request that any certification for this project include a provision that the power from project be sold to Washington utility(s) as opposed to being sold into the California market. Because the potential adverse impacts of this project would be experienced locally, it makes sense to keep the project benefits local as well. In addition, such a provision would also help relieve some of the current pressure on the California intertie that is causing challenges for BPA in integrating wind resources into its transmission system.

We appreciate the opportunity to comment on the DEIS for this proposed project and look forward providing additional comment as the environmental review process and site certification proceeding move forward. If you have any questions regarding Seattle Audubon’s comments or would like additional information, feel free to contact me by telephone at 206/523-8243 ext. 15 or by email at shawnc@seattleaudubon.org.

Thank you for your consideration.

Sincerely,

Shawn Cantrell

Attached is Seattle Audubon's comment letter on the Whistling Ridge Draft Environmental Impact Statement (DEIS). Please contact me if you have any problems opening the attachment.

The exact same comment letter was also submitted via the BPA website.

Please confirm receipt of this message.

Thank you.

RE: Whistling Ridge Energy Project, DOE/EIS - 0419

Dear Mr. Montano and Mr. Posner:

On behalf of the members of Seattle Audubon, I am submitting these comments in response to the May 2010 Draft Environmental Impact Statement (DEIS) for the proposed Whistling Ridge Energy Project. We are a formal intervenor in the EFSEC Site Certification proceeding for this project and we submitted scoping comments regarding the environmental evaluation of the project on May 18, 2009. Seattle Audubon was also an active participant in the development of the Washington Department of Fish and Wildlife's April 2009 *Wind Power Guidelines*.

The mission of Seattle Audubon is to cultivate and lead a community that values and protects birds and the natural environment. Since 1916, Seattle Audubon has worked to protect birds of our region whose habitats are at risk. Our members have a long history of engagement on forest-related issues in Washington state and an on-going interest in the inter-relationship between bird habitat and human development activities in the forested landscape.

Specific Comments

1. Independent Evaluation

In our scoping comments for this project, Seattle Audubon identified multiple issues in the application that needed thorough review to adequately evaluate the potential environmental impacts of this project. Unfortunately, the DEIS fails to address many of the issues we previously identified. In many instances, the DEIS simply repeats the information presented in the application with no new analysis or documentation. We urge your agencies to ensure that the Final Environmental Impact Statement (FEIS) fully addresses these inadequacies.

As one of the first wind power projects to be considered for a forested landscape in Washington state, this environmental review needs to include a more detailed analysis of several issues that make this proposal different from other wind power projects located on agricultural and/or shrub

steppe habitat; experience and knowledge gained from existing projects in the state may not be “transferable” to a project such as this being proposed for a very different environment.

2. *Climate Change*

We recognize the significant threat climate change poses to birds and bird habitat, including threatened and endangered bird species. That is why we support well-designed, appropriately-sited renewable energy projects as a critical step in reducing carbon emissions.

Seattle Audubon is greatly encouraged by the potential for this project to avoid the emissions from combustion of an estimated 114,000 barrels of crude oil or 654 million cubic feet of natural gas, leading to the displacement of over 131,000 tons of carbon dioxide annually. (DEIS at 3-20) The beneficial biological impact of such a displacement to birds and other wildlife in the region appears significant.

It is also important to evaluate how the project’s contribution to reducing carbon emissions would in turn impact at-risk species in the region such as the northern spotted owl. For example, climate change models predict that as a result of global warming, the Pacific Northwest will experience warmer and drier summers, thereby reducing the food supply for owls, as well as colder and wetter springs, resulting in a reduction in the survival chances of owl fledglings during nesting season. (for more details, see <http://ir.library.oregonstate.edu/jspui/bitstream/1957/11326/1/EGlennDisseration2009.pdf>)

While hard to quantify precisely, the FEIS should better evaluate the trade-off between potential benefits from the project to birds from avoided emissions (*through reduced carbon output and the resulting effects on forest habitat and food supply*) and the potential harm from the project to birds (*through loss of existing habitat, habitat fragmentation and potential collision mortality*). Your two agencies, together with the project proponent, are well positioned to facilitate a Northwest-specific study comparing the annual bird fatalities caused by wind farms versus those caused by fossil-fueled power stations, similar to the Sovacool study. (DEIS p. 3-276)

3. *Northern Spotted Owls*

The DEIS contains important information regarding northern spotted owls (NSO), including a description of survey history in the project vicinity. Subsequent to the completion of the DEIS, however, an NSO survey on state Department of Natural Resources (DNR) land adjacent to the proposed project site detected an NSO in May 2010. The presence of an NSO calls into questions many of the conclusions in the DEIS regarding NSO, including the statement that “*Given the extensive survey record confirming the absence of northern spotted owls, the proposed the Project [sic] will not pose a risk of taking northern spotted owls under the Endangered Species Act Section 9 and its regulations.*” (DEIS at 3-49)

The FEIS should add a fresh analysis of the potential impacts on NSO, including:

- a) An evaluation of the potential for NSO to fly through the project’s turbine string corridor. While the potential for an NSO to collide with a wind turbine (blade or tower) is likely low, the FEIS should include life history information on NSO behavior in comparable landscapes, including flight patterns in cleared areas and maximum height of flying (*i.e. within the rotor-swept area*). Telemetry data should be available from the U.S. Fish and Wildlife Service regarding radio tags studies on

NSO that can provide information on NSO flight patterns in matrix lands with a combination of forested and commercially harvested lands.

- b) An evaluation of the specific amount and location of potentially suitable NSO habitat in the proposed project site. While the DEIS states that no forests with suitable structure for NSO nesting or roosting are present within the project site (DEIS p. 3-49), the map of Harvesting Schedule (DEIS Figure 2-3) indicates forest parcels over 70 years old inside the Mill Creek Core Area. In addition, there are multiple reference made to “suitable habitat” and “northern spotted owl habitat” located in the proposed project site (DEIS p. 3-50, 3-52). The FEIS should provide a much clearer and more detailed inventory of the existing NSO habitat conditions on both the project site and within the historic NSO activity centers (*including information on stand age, tree species diversity, snags per acre, etc.*). In addition, while the DEIS notes that the Mill Creek site center contains 48 percent suitable habitat (DEIS p. 3-56), Seattle Audubon is concerned that this calculation by DNR is based on outdated data. The FEIS should detail the specific process used for that calculation and ensure that it is based on up-to-date habitat mapping of the site center.
- c) An evaluation of the potential for existing “degraded” habitat in the proposed project site to develop into suitable NSO habitat during the projected 30 year life span of the project. Although NSO may currently be absent from the project lands, the FEIS should evaluate the potential for NSO to utilize those lands in the future. One of the guiding principles in the 2009 Wind Power Guidelines states *“From a wildlife conservation perspective, a species in decline may be absent from an area ... yet the habitat remains important for the conservation or recovery of that species.”* (WDFW, p 2)
- d) An evaluation of the likely NSO utilization of existing habitat in the project vicinity with the presence of project facilities (turbines, roads, etc.). The DNR land where the NSO was detected is covered by the state’s Habitat Conservation Plan (HCP) and is intended to serve as habitat for NSO. If the project is built, would it displace NSO from this habitat on DNR land as they sought to avoid the project facilities? The FEIS should evaluate the potential for project operations to interfere with NSO nesting, roosting, foraging or dispersal on the adjacent DNR lands. Would the human activity associated with project maintenance disrupt NSO activities during breeding season? Would the sound and/or vibrations from the spinning turbines affect the ability of NSO (which hunt largely by sound) to locate prey? For example, an NSO study looked at effects of road noise on NSO hormone levels and reproductive success. It measured sound level, annual reproductive success and fecal hormones including stress steroids and metabolic hormones. The study results suggest noise exposure has negative effects on NSO, increasing stress levels and decreasing reproductive success. (<http://conservationbiology.net/research-programs/northern-spotted-owl-research/>)

The FEIS should address all of these potential project impacts to NSO, including identification of additional monitoring and mitigation measures. (DEIS p. 3-82)

In addition, the DEIS notes that the project proponent considered locating turbines on the DNR lands directly north of the site. (DEIS p. 1-14) We appreciate that this option was rejected from further consideration due to comments from the public and DNR’s reluctance to consider leasing

the site. This decision gained significantly increased importance with the May 2010 detection of an NSO on this DNR land.

4. Baseline Avian Use

The DEIS does not adequately address the issue of comparable avian use data. It is vital that the FEIS include an evaluation of the species variety and abundance in the project vicinity in relation to baseline avian use data from other locations with similar landscape and climate features – mountainous conifer forests with cool, wet conditions. The DEIS makes comparisons of bird survey results from Whistling Ridge to data from other wind projects, either in eastern U.S. deciduous forests or shrub-steppe habitat in the Pacific Northwest (DEIS p 3-63, 3-64); such comparisons provide limited benefit for evaluating the potential impacts of this project. Seattle Audubon noted this problem in our scoping comments and we continue to be concerned that the environmental review for this project needs a more appropriate avian use comparison.

DNR and the Forest Service each are land managers with significant amounts of forest habitat comparable to the project site; either or both agencies may have / know of avian use survey data that could be used, as could other resource agencies or academic institutions. In order for the public (and the decision-makers regarding permits for Whistling Ridge) to have an accurate understanding of the potential impacts of this project on birds, the FEIS should include a meaningful “apples-to-apples” comparison of avian species. Without such an evaluation, any conclusions regarding the variety and concentration of bird species at the project site are likely to be misleading.

In addition, the FEIS should more clearly and specifically describe the results of the avian surveys conducted. While calculations such as the “*mean annual bird use*” and a “*relative index to collision risk*” do provide some useful information, the DEIS fails to identify the actual total number of birds detected during the study, nor does it reveal the number of birds and bats that were detected passing within the proposed rotor swept area, instead couching the data in terms of percentages. (DEIS p. 3-64) For instance, Table 3.4-5 should be modified to indicate the specific number of each species observed by season rather than burying that data solely in the Appendix. (DEIS p. 3-62, 3-63)

5. Olive-sided Flycatcher and Vaux's Swift

The olive-sided flycatcher is a federal species of concern and the Vaux's swift is a state candidate species for listing. Both species were detected at the project site during multiple avian surveys with the majority of detections within the rotor swept area. (DEIS p. 3-56, 3-57) Both forage for insect prey on the wing and would likely utilize the cleared areas associated with the project turbines. The DEIS does not adequately address the potential turbine-related mortality of these sensitive species, simply asserting that collisions would likely be rare and that it is unlikely that the project would have any negative impacts on population levels. (DEIS p. 3-79) The FEIS should more fully evaluate this issue and document the facts underlying these type of statements. In addition, the FEIS should specifically identify the “*appropriate mitigating measures*” BPA will ensure are employed to minimize and avoid the anticipated project-related impacts on these sensitive species under the Migratory Bird Treaty Act. (DEIS p. 4-5)

6. Size, Number and Type of Turbines

The DEIS states that the number of wind turbines at the project site already has been minimized to the extent practicable and that if any turbines are removed from the project design, other locations must be found to replace those turbines to maintain the viability of the project. (DEIS p. 1-14) It also states that the project would consist of up to 50 wind turbine generators that would range in size from 1.2 to 2.5 MW and have a total nameplate capacity of up to 75 MW. (DEIS p. 1-9) Yet if the project proponent were to select the 2.5 MW turbines, the number needed could be reduced by 40% without reducing the project capacity.

Reducing the number of turbines offers the potential to significantly reduce some of the adverse environmental impacts of the project. The amount of habitat permanently impacted could be reduced, including avoiding the loss of any suitable or potential NSO habitat. Turbine locations in close proximity to the DNR HCP lands could be removed from the project, lessening the potential to disturb NSO in the area. The FEIS should include at least one additional alternative that provides a detailed analysis of how different combinations of turbine sizes and numbers can best meet the identified minimum necessary project capacity while minimizing the habitat disruptions.

In addition, the FEIS should identify the specific turbine type that would be used at Whistling Ridge. Different turbine types can have different blade tip speeds as well as utilize either an upwind or downwind style. Research at other wind power projects indicates that these differences can have a direct correlation to avian mortalities (DEIS Appendix B, Wildlife Reports). An evaluation of the specific turbines to be used at the project is essential to the environmental review each of your agencies are responsible for completing.

7. Cumulative Impacts

The DEIS' evaluation of cumulative impacts makes only passing reference of the most significant incremental impacts this project would likely contribute to – wind power development in a forested landscape. There is no mention of either the proposed Radar Ridge or Coyote Crest wind projects, both in forested landscapes within the range of NSO. The DEIS lacks any analysis of either the impacts to bird habitat or avian collision mortalities that could reasonably be expected from significant “build out” of wind power on Northwest forested lands. There is no discussion of how additional wind projects within the range of NSO could impact that ESA-listed species, nor any analysis of how multiple wind power projects could impact the regional electrical transmission system.

The FEIS should include a much more robust evaluation of the potential cumulative impacts from the growing wave of wind power projects on forested lands. It should analyze the potential cumulative impacts of a “full build-out” of wind power in the region on avian species, similar to the 2007 National Research Council assessment done for the Mid-Atlantic Highlands or the 2008 West Inc. study done for the Columbia Plateau Eco-region. (DEIS p. 3-274, 3-275) Such an analysis should include an up-to-date projection for potential wind power development in the region as well as incorporate accurate monitoring data on avian mortality and displacement.

8. Mitigation

The project would entail approximately 384 acres of forest land being developed for wind turbine foundations, connecting roadways, overhead and underground transmission lines,

operation and maintenance yard, and substation. (DEIS p. 1-9, 2-4) This includes the permanent loss of 60.7 acres of habitat, as well as the temporary loss of another 53.6 acres of habitat. (DEIS p. 3-73) In addition, there would be significant additional acres impacted by a corridor of up to 500 feet from the base of the turbines that would have a height restriction on trees. (DEIS p. 2-4, 2-15) Despite this noted loss or degradation of habitat, the DEIS does not include any mitigation measures related to these habitat impacts. (DEIS p. 3-82)

The Wind Power Guidelines recommend mitigation for permanent habitat impacts by either acquisition of replacement habitat or "By Fee" option, or a combination of both. (WDFW, p. 9, 12) The Guidelines also recommend mitigation for temporary impacts to habitat, including a WDFW approved restoration plan and some acquisition of suitable replacement habitat. (WDFW, p.11-12)

The FEIS should include an explicit evaluation of the impacted habitat (*both temporary and permanent*) and identify the specific level of mitigation that will be required of the applicant. SEPA provides the authority to impose reasonable conditions to mitigate impacts from a proposed action. While the project lands are not pristine wildlife habitat, they do provide valuable habitat for numerous bird and other species as well as ecosystem services that would be adversely impacted by the project. This habitat provides foraging and breeding opportunities for different species as well as vegetative cover for wildlife. The project proponent, SDS Company, LLC, touts the importance of its forest lands for wildlife and biodiversity, stating that its timberlands "*provide habitat for various species of plants and wildlife, they protect watersheds, they emit oxygen into the atmosphere and consume carbon dioxide, and they provide beautiful spaces for recreation.*" (see <http://www.stevensonlandcompany.com/>) Permanently converting 60.7 acres of this habitat, as well as temporarily impacting an additional 53.6 acres of habitat, requires acquisition of replacement habitat.

Seattle Audubon recommends a ratio of at least 1:1 for replacing permanently impacted habitat and of 0.1:1 for temporarily impacted habitat, as the project lands appear to fit the Wind Power Guidelines' description of Class III habitat – lands with lesser numbers of associated Species of Greatest Conservation Need but that are not currently cultivated, developed or disturbed by an active road or other corridor that eliminates natural habitat. (WDFW p. 9)

SDS manages numerous land parcels in the general vicinity of the projects that are like-kind and/or of equal or higher habitat value than the areas which would be impacted by the project. There are numerous SDS-owned sites in the Columbia River Gorge National Scenic Area and the White Salmon River Wild and Scenic River corridor that meet the criteria identified in the Wind Power Guidelines as being at risk of development or habitat degradation; these or other lands in the areas could serve as appropriate replacement habitat by donation to a land trust or given permanent legal protection through a conservation easement or other enforceable means. (WDFW, p. 9-10) A detailed mitigation package should be developed *prior to* project approval, not left to be determined after the fact.

In addition to inclusion of mitigation for impacts to habitat, the FEIS should also explicitly include mitigation for any direct impacts to at-risk species. As noted above in our comments above regarding NSO, olive-sided flycatcher and Vaux's swift, the FEIS should include details

of the specific actions that will be required of the applicant to avoid, minimize and mitigate for any mortality of ESA-listed and other sensitive species.

9. Monitoring

Seattle Audubon appreciates the inclusion of a post-construction avian mortality study. (DEIS p. 3-82) More details on the protocol to be used for this study needs to be included in the FEIS in order to understand whether the proposed “two year minimum” is adequate to evaluate the ongoing impact of project operations on avian species. As the Wind Power Guidelines point out, the duration and scope of the monitoring depends in part on the availability of existing monitoring data at projects in similar habitat types. (WDFW p. 6) In accordance with RCW 80.50.040, EFSEC must prescribe the means for monitoring the effects of project operation in order to assure compliance with the certification. (DEIS p. 1-3) The FEIS should include greater detail on how EFSEC will meet this requirement.

In addition, the FEIS should evaluate the potential for use of canine detection for carcass surveys. The Center for Conservation Biology at the University of Washington has demonstrated the precision and efficiency of dogs in locating wildlife in forested settings (for more details, see <http://conservationbiology.net/conservation-canines>); as one of Washington’s first wind power projects in a forested landscape the Whistling Ridge project is an excellent candidate for looking at applying this methodology to post-construction mortality studies.

Beyond monitoring the direct avian mortalities caused by the project, it is important to also study the *indirect* project impacts such as species displacement from territory and cumulative impacts. (WDFW p. 6) The FEIS should require specific project monitoring strategies that include post-construction avian use surveys of live birds in the project area. It is not enough to just monitor the number of birds directly killed by project operations; post-construction monitoring should also look at how project operation impacts ongoing avian use of the site and adjacent areas. As with our comments regarding mitigation above, a detailed monitoring program should be developed *prior to* project approval, not left to be determined after the fact.

10. Adaptive Management

We appreciate the requirement for a Technical Advisory Committee (TAC) to evaluate and coordinate the mitigation and monitoring program, including potential adaptive management activities. (DEIS p. 3-82) Unfortunately the DEIS contains no information detailing the authority of and resources available to the TAC to carry out those responsibilities. As the Wind Power Guidelines point out, the range of potential adjustments the TAC could make to potential mitigation and monitoring requirements should be clearly stated in the project permit. (WDFW p. 6) In addition, the proposed composition of the TAC does not include any stakeholders from environmental groups, landowners or Native American tribes. (WDFW p. 6) The FEIS should identify an expanded TAC that includes representatives from these other stakeholder groups, as well as clearly identify TAC funding and authority.

As noted multiple times above, Whistling Ridge would be one of the first wind power projects to be considered for a forested landscape in Washington state. In light of this, there are several important environmental issues for which there is limited or no applicable comparative data for use in evaluating wind power projects in forested landscapes. In recognition of this type of challenge, the Wind Power Guidelines specifically call for research oriented studies that look at

issues such as species displacement or cumulative impacts that could provide important information for understanding wind energy / wildlife interactions. (WDFW p. 7)

The FEIS should identify specific research oriented studies that would directly relate to the proposed Whistling Ridge project, as well as the role of the TAC in determining the need for further studies. Potential studies include:

- a) A robust analysis of pre- and post-construction avian use study data at the project to better understand direct and indirect impacts to specific avian species, including changes to density and nesting success of targeted species.
- b) As noted in our cumulative impact comments above, an analysis focused on the Pacific Northwest region, including forested landscapes, of the potential cumulative impacts of a "full build-out" of wind power on avian species.
- c) As noted in our climate change comments above, a Pacific Northwest-specific study comparing the annual bird fatalities caused by wind farms versus those caused by fossil-fueled power stations, similar to the 2009 Sovacool study. (DEIS p. 3-276)
- d) As noted in our monitoring comments above, the use of canine detection of carcasses in the post-construction avian mortality study.

While funding for these and/or other research oriented studies should be solicited from multiple sources (WDFW p. 7), the FEIS should explicitly identify the level of funding to be provided by the project proponent.

11. Distribution of Project Power

One of the applicant's stated objectives for this project is "to provide an additional renewable resource for electrical utilities in Washington." (DEIS p. 1-7) We welcome that intent and request that any certification for this project include a provision that the power from project be sold to Washington utility(s) as opposed to being sold into the California market. Because the potential adverse impacts of this project would be experienced locally, it makes sense to keep the project benefits local as well. In addition, such a provision would also help relieve some of the current pressure on the California intertie that is causing challenges for BPA in integrating wind resources into its transmission system.

We appreciate the opportunity to comment on the DEIS for this proposed project and look forward providing additional comment as the environmental review process and site certification proceeding move forward. If you have any questions regarding Seattle Audubon's comments or would like additional information, feel free to contact me by telephone at 206/523-8243 ext. 15 or by email at shawnc@seattleaudubon.org.

Thank you for your consideration.

Sincerely,

Shawn Cantrell
Executive Director

Subject: FW: Resolution Demanding Retraction of Dept of Interior Comments on Whistling Ridge Wind Energy Project
Attachments: Interior Resolution.pdf; ER10_492_deis[1].pdf

Resolution from Skamania County Commissioners,. Please include in public comment on EIS for Whistling Ridge. Please call Commissioner Paul Pearce if you have any questions.

RESOLUTION 2010-51

(A Resolution Demanding Retraction of the Department of Interior Comments on the Draft Environmental Impact Statement for the Whistling Ridge Wind Energy Project and explanation of its Actions in Commenting without Authority or Jurisdiction against the Secretary's and Administration Policy)

WHEREAS, Whistling Ridge Energy Project filed an Application for Site Certification to the Washington Energy Facility Site Evaluation Council ("EFSEC") on March 10, 2009 for the Whistling Ridge Energy Project; and

WHEREAS, EFSEC is lead agency pursuant to the State Environmental Policy Act, and Bonneville Power Administration ("BPA") is federal lead agency pursuant to the National Environmental Policy Act; and

WHEREAS, EFSEC and BPA have independently issued a joint Draft Environmental Impact Statement for this Project and are seeking public comment on the DEIS; and

WHEREAS, the entire project is located outside of the Columbia River Gorge National Scenic Area ("Scenic Area") on privately owned lands in Skamania County; and

WHEREAS, Federal Government regulation of private lands as well as the economic survival of Skamania, other local counties and communities were major concerns when the Columbia River Gorge National Scenic Area ("Scenic Area Act") was debated in Congress; which resulted in several major compromises to address these concerns before passage of the Scenic Area Act in its final form, without which, Congress would not have enacted the Scenic Area Act and President Reagan would not have signed it into law. These compromises included the purchase or trade of private lands that were regulated for the protection of scenery in the Special Management Areas, the designation of Urban Areas that are completely exempt from restrictions and the designation of an external boundary that by Congressional direction is the absolute boundary with no buffers or setbacks outside of the Scenic Area. Congressional intent is found in the "Savings Provision" at 16 USC § 544o(a)(10) which states:

Nothing in [this Act] shall . . . establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas."; and

WHEREAS, The National Trail System Act, 16 USC §§ 1241 – 1251 authorizes Congress to designate National Scenic and Historic Trails but does not, by mandate or implication, authorize Interior to regulate or restrict private lands or to even negatively comment on or oppose private projects proposed on private lands nearby, or visible from, designated trail sections; and

WHEREAS, Skamania County recently received a copy of the U.S. Department of the Interior (“Interior”) DEIS comment letter dated July 19, 2010, wherein Interior raises concerns about visibility of the proposed project from the Scenic Area and the nationally designated Lewis and Clark National Historic Trail and suggests elimination of Whistling Ridge wind turbines that are visible from both the Scenic Area and the Lewis and Clark National Historic Trail; and

WHEREAS, many thousands of miles of trails are designated throughout the Western United States under the National Trail System Act. With the exception of federal lands, and lands acquired by the Federal Government for preservation of trails, the Federal Government has no authority to regulate or restrict the use of private lands near trails designated under the National Trail System Act, for any reason, especially for purported visual effects on trail segments. Moreover, as described in the Interior letter, the “trail” at issue here is coextensive with US Interstate 84 and Washington State Highway 14 which are not pristine “trail” segments—they are major, busy multi-modal transportation corridors, including the only sea level train route (on both sides of the Columbia River) through the Cascades, with over 80 commercial trains transiting per day.

NOW, THEREFORE, BE IT RESOLVED THAT THE Board of Commissioners being concerned and alarmed with Interior’s comments and apparent attempt at inappropriate Federal intervention on the consideration of the Whistling Ridge application, find as follows:

The Board finds: Interior’s reference to the National Trail Systems Act and the Scenic Area as authority for the comment letter is an abuse of federal authority that exceeds the legal and policy directives and Congressional intent of both the National Trail Systems Act and the Scenic Area Act. Interior’s comments are particularly egregious where they recommend that renewable wind energy construction (proposed on private lands outside of the Scenic Area and miles away from any trail segments in Skamania County) that are visible from the National Trail Systems Act and the Scenic Area should be eliminated from the Project, or that the proponent must justify “feasibility” for the locations visible from I-84.

The Board finds: Many man-made structures and activities are visible and will be visible along these “trails” that follow Interstate highways, where the most visible of “impacts” on travelers are the many semi trucks, trains, transmission lines, dams, industrial facilities, mines, and coal, gas and nuclear power generating facilities, as well as many cities, homes, commercial buildings, advertising signs and billboards, that they pass by. It is a gross abuse of federal authority to negatively comment on, and seek to obstruct a renewable energy project on private lands merely because a small portion is remotely visible from an Interstate highway.

The Board finds: Consistent with our concerns raised above regarding National Trail Systems Act authority, that Interior’s recommendation of restricting private land development in view of the Scenic Area is in direct violation of the critically important Scenic Area Act compromises and Savings Provisions the intent of which was to allow local counties economic development opportunity for their continued survival.

The Board finds: Interior's comments and recommendations have serious policy implications not only for renewable energy development but also for other non-wind energy related projects that are visible from the Scenic Area and National Historic Trails, such as electrical transmissions systems, dams, rail transportation, interstate commerce and traffic, as well as residential, commercial and industrial development in Skamania and other Counties near the Scenic Area and/or Counties located near similarly designated trails under the National Trails System Act.

The Board finds: Interiors comments contradict both the Secretary's publicly stated policy as it pertains to renewable energy as well as contradicting the clear energy policy direction of the current Administration.

The Board finds: Finally, in addition to the comment concerning the Scenic Area and the Interstate Highway corridor, Interior provided specific comments related to purported groundwater issues—issues raised by local citizen neighbor opponents at the NEPA/SEPA comment hearing. Skamania County has regulatory responsibility for groundwater issues, and will work with EFSEC to address the citizen comment. This is *not* a federal issue. Interior has no authority to insert itself into this uniquely local issue, and its decision to do so demonstrates its lack of regard for Skamania County's authority: strongly suggesting inappropriate collaboration with Whistling Ridge project opponents.

NOW, THEREFORE, BE IT FINALLY RESOLVED THAT THE Board of Commissioners reacting to this clear abuse of authority without jurisdiction, hereby demand, in the strongest possible terms, that Interior's comments be immediately retracted and removed from the public record on this matter, and further respectfully request that the Secretary and the Administration clarify how Interior has acted within its authority, consistent with the stated policy direction of the Secretary and the Administration, and what this letter means for the implementation of the Administration's declared land management and energy policies.

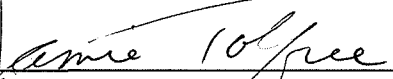

DATED this 3rd day of August 2010.

Electronically Filed

July 19, 2010

Andrew M. Montaña
Environmental Project Manager
Bonneville Power Administration – KEC-4
P.O. Box 3621
Portland, Oregon 97208

Dear Mr. Montaña:

The U.S. Department of the Interior (Department) has reviewed the Draft Environmental Impact Statement (DEIS) for the Bonneville Power Administration's Whistling Ridge Energy Project, Skamania County, Washington. The Department offers the following comments for use in developing the Final Environmental Impact Statement for the project.

Lewis and Clark National Historic Trail

The proposed Whistling Ridge Energy project is located within five miles of the Lewis and Clark National Historic Trail (NHT), a congressionally-designated NHT, which follows the Columbia River and is within the area analyzed in the DEIS for potential visual impacts. In addition, US Interstate 84 and Washington Route 14 are the state-designated Lewis and Clark auto tour routes in the project area. Many visitors experience Lewis and Clark NHT by traveling the auto tour routes and stopping at interpretive and recreational sites along the way. The Department considers the viewshed along the river and auto tour routes to be a critical part of the trail visitor experience.

The Lewis and Clark NHT was established by Congress in an amendment to the National Trails System Act in 1978. 16 U.S.C. § 1244(a). As administrator of the trail, the National Park Service (NPS) is charged under this Act with the identification and protection of the historic route, remnants, and artifacts of the trail for public use and enjoyment.

Based on the analysis of visual impacts in the DEIS, it appears that a varying number of turbines will be visible from the trail's historic river and auto tour routes from near

Koberg Beach State Park to Lindsey Creek State Park. This approximately 15-mile stretch of the Columbia River Gorge has numerous recreational opportunities and scenic views that add significantly to enjoyment of the historic trail. Of the five viewpoints along US Interstate 84 analyzed in the DEIS, Viewpoint 14 at Viento State Park, is rated in Table 3.9-2 as having an anticipated moderate to high level of visual impact. However, on page 3-193 of the DEIS, the potential visual impact for this viewpoint is stated as only moderate. Furthermore, it appears that the turbines were inadvertently omitted in the photomontage in Figure 3.9-11. While difficult to discern the impact at this location without clarification on the accuracy of the visual simulation, we believe that the impact should be rated as high given the placement of turbines on the skyline within four miles of a park located along the auto tour route.

Turbine string A1-A7 would be highly visible from numerous locations along the trail due to its placement on a ridgeline close to the Columbia River Gorge. The NPS recommends removing or relocating these seven turbines, if feasible. This would significantly reduce the impact to visual resources along the historic trail. The visual resources in this region—Columbia River Gorge National Scenic Area and Lewis and Clark NHT—are important resources that should be protected.

SPECIFIC COMMENTS

Water Resources Section 3.3

Pg. 3-26: Section 3.3.1.3 lacks sufficient information on the existing groundwater environment to support the finding of little or no impact. Suggest the section more fully address the depth to groundwater, flow direction, and transmissivity (permeability) of the aquifer as it relates to possible affects on the area domestic and agricultural ground-water resources (also see section 3.3.1.5). Helsel et.al. (2002) is a good reference for this type of analysis.

Pg. 3-29: Because section 3.3.3 addresses mitigation procedures for the isolation of groundwater from chemical spills, we assume that chemicals will be present on site during both construction and operation. Suggest the document include a discussion of potential chemical spills, and aquifer transmissivity (permeability), as it relates to the potential movement of contaminants toward nearby domestic or agricultural water wells.

Bonneville Power Administration – KEC-4
P.O. Box 3621
Portland, Oregon 97208

Dear Mr. Montañó:

The U.S. Department of the Interior (Department) has reviewed the Draft Environmental Impact Statement (DEIS) for the Bonneville Power Administration's Whistling Ridge Energy Project, Skamania County, Washington. The Department offers the following comments for use in developing the Final Environmental Impact Statement for the project.

Lewis and Clark National Historic Trail

The proposed Whistling Ridge Energy project is located within five miles of the Lewis and Clark National Historic Trail (NHT), a congressionally-designated NHT, which follows the Columbia River and is within the area analyzed in the DEIS for potential visual impacts. In addition, US Interstate 84 and Washington Route 14 are the state-designated Lewis and Clark auto tour routes in the project area. Many visitors experience Lewis and Clark NHT by traveling the auto tour routes and stopping at interpretive and recreational sites along the way. The Department considers the viewshed along the river and auto tour routes to be a critical part of the trail visitor experience.

The Lewis and Clark NHT was established by Congress in an amendment to the National Trails System Act in 1978. 16 U.S.C. § 1244(a). As administrator of the trail, the National Park Service (NPS) is charged under this Act with the identification and protection of the historic route, remnants, and artifacts of the trail for public use and enjoyment.

Based on the analysis of visual impacts in the DEIS, it appears that a varying number of turbines will be visible from the trail's historic river and auto tour routes from near

Koberg Beach State Park to Lindsey Creek State Park. This approximately 15-mile stretch of the Columbia River Gorge has numerous recreational opportunities and scenic views that add significantly to enjoyment of the historic trail. Of the five viewpoints along US Interstate 84 analyzed in the DEIS, Viewpoint 14 at Viento State Park, is rated in Table 3.9-2 as having an anticipated moderate to high level of visual impact. However, on page 3-193 of the DEIS, the potential visual impact for this viewpoint is stated as only moderate. Furthermore, it appears that the turbines were inadvertently omitted in the photomontage in Figure 3.9-11. While difficult to discern the impact at this location without clarification on the accuracy of the visual simulation, we believe that the impact should be rated as high given the placement of turbines on the skyline within four miles of a park located along the auto tour route.

Turbine string A1-A7 would be highly visible from numerous locations along the trail due to its placement on a ridgeline close to the Columbia River Gorge. The NPS recommends removing or relocating these seven turbines, if feasible. This would significantly reduce the impact to visual resources along the historic trail. The visual resources in this region—Columbia River Gorge National Scenic Area and Lewis and Clark NHT—are important resources that should be protected.

In looking at the map on the website for the EIS, it appears the interconnect won't affect us, but SDS's project appears to be in the area of our pipeline that runs east/west up the gorge through Skamania County. I need to be in contact with SDS or its developer, but want to be sure I get our information out there to all players and wasn't sure of BPA's involvement initially. Thank you for passing the information on and including us with notifications.

WRE100003 - Carvalho

(This comment corrects an error in the text of the prior one submitted in my name.) I have a comment on the impact of the Whistling Ridge wind project; it includes a photograph too large to submit here and is online at http://www.lensjoy.com/Blog/windmills_are_coming.htm. I am the author of the online article. Nestor Peak and Mitchell Point are key viewing areas used by hikers, mountain bikers, ATV enthusiasts, and horseback riders. If this project is built, the view of Mt. Hood from Nestor Peak and the view of Mt. Adams from points along the Oregon side of the Columbia Gorge will be permanently spoiled. In addition, the onslaught of wind turbines will continue to encircle the Columbia Gorge and destroy once-pristine views of the ridges and horizon that were one of the primary reasons the National Scenic Area was created. It is not suited for the proposed location. The Whistling Ridge site is in a forest, and is in owl habitat. It is a very different location compared to agricultural fields where prior developments have been sited. Forest sites have an order of magnitude greater wildlife population density, and wind farms are incompatible with them. Please deny the project application and institute a moratorium on further wind development within 20 miles of the Gorge Scenic Area boundary until we can understand the long-term impacts of wind development on animals and develop a meaningful plan that mitigates the visual impact of these projects. BPA and the Army Corps of Engineers took Celilo Falls away from us in 1957. Now it is 2010, and BPA plans to take away the horizon as well. The ongoing rape of natural beauty to fuel mankind's greed for energy and dollars must stop, here and now. Sincerely, Chris Carvalho

It is not suited for the proposed location. The Whistling Ridge site is in a forest, and is in owl habitat. It is a very different location compared to agricultural fields where prior developments have been sited. Forest sites have an order of magnitude greater wildlife population density, and wind farms are incompatible with them. Please deny the project application and institute a moratorium on further wind development within 20 miles of the Gorge Scenic Area boundary until we can understand the long-term impacts of wind development on animals and develop a meaningful plan that mitigates the visual impact of these projects. BPA and the Army Corps of Engineers took Celilo Falls away from us in 1957. Now it is 2010, and BPA plans to take away the horizon as well. The ongoing rape of natural beauty to fuel mankind's greed for energy and dollars must stop, here and now. Sincerely, Chris Carvalho

I am all for Alternative Energy Projects, but, not at the expense of despoiling one of our National Treasures. We live in the area and have many visitors, all those visitors comment on the pristine beauty of the area. We need to retain the vista, not only of the area covered by the Scenic act, but also of the area bordering this stunning scenery for future generations. These vistas would be adversely impacted by the proposed project and directly effect the enjoyment of visitors and locals alike. Please don't allow the project to go ahead.

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100006 - dewey

As residents of the area that will be able to see some of the turbines of this proposed project, my wife and I are in favor of it. We can't continue the practice of saying "Yes, we need these projects but not in my area". This will not get us where we need to be down the road. SDS is a good and responsible company that cares. It is their land, and they have the right to do this, and they will do it in a responsible manner. ps-it is sad that some of the people speaking out against this project were the same ones that were cutting hiking/biking trails on SDS property in this same general area. They want to tell SDS what they can't do but at the same time, don't respect the private property of others.

WRE100007 - Peyrollaz/County resident

I am part of that silent majority who does not like to attend meetings where people argue and intimidate me but I feel my voice does need to be heard. I support the Whistling Ridge Energy Project. Not only does it give an alternative source of clean energy, but it also will provide new jobs and tax revenues to our county which has been devastated with so many land set asides and regulations that our children have to leave the area in order to find jobs. Wind energy is a clean, quiet source which uses the natural winds of The Gorge. In my opinion, the people who are causing the obstacles in implementing this natural resource are the same people who have opposed most everything else that is proposed in The Gorge. They have personal agendas which are not for the good of the community but for their selfish interests. Wind Energy is a Good thing for The Gorge, a Good thing for the economy of The Gorge and a good, clean alternative that all the environmentalists have been insisting on. Let's move forward and let a Good thing happen.

I'm opposed to the project because this contradicts the spirit of the Columbia Gorge Scenic Area. Even though the project is outside the area, it was never envisioned that there would be this type of project that could be seen from within the scenic area.

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100010 - McKenna

While not technically within the boundaries of the Columbia Gorge Scenic Area, the Whistling Ridge Energy Project contradicts the spirit of the Scenic Area. Had anyone imagined the building of skyscraper-height structures just outside the scenic area, I'm confident that they would have designated a bigger area. We live in Hood River, Oregon, and the ridges upon which they are proposing the turbines are visible from all over the beautiful Hood River valley. Our economy on both sides of the Gorge is largely dependent on tourism due to the scenic beauty of the area. These turbines would negatively affect this industry in both Oregon and Washington. Everyone I know in Hood River is strongly opposed to the construction of these giant turbines looming over our natural and beautiful slice of the world. Please don't approve this project!

WRE100014 - Saufley

To Whom It May Concern: I support the decision to proceed with the Whistling Ridge Energy Project; however, a couple of things should be addressed: 1) The location of the project should not be too close to scenic wilderness areas. Primarily, areas which would affect the spotted owl and others species in wildlife. We should take pains not to disrupt their livelihood and habitat. 2) Frankly, I am also concerned of the increase in traffic, where congestion and the building of roads disrupt wildlife habitat. This includes not only land animals, but aquatic ones too. It would affect the vegetation in the area and reduce the food supply in the long term. Thank you.

WRE100017 - Kingsford-Smith & Family/Local Family

While supportive of clean energy, we are certainly concerned with the visual impact in the HEART of the scenic area. We are pleased with the development of the wind power further east in the Gorge and throughout various areas in the northwest. However, this development strikes at the core of the Scenic Act and would negatively impact the key tourist and scenic value of several communities within the heart of the gorge. Please reconsider other SDS properties to post wind towers. The ridges east of White Salmon are preferable, but frankly, all towers should be east of Lyle. Thank you for your time and consideration... -sks & co.

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100019 - Sliwa

I am in support of the Whistling Ridge project. I feel wind energy is one of the cleanest forms of energy generation possible, and those who live in areas amenable to wind generation need to make a few sacrifices to enable it. I personally think the generators are beautiful and do not detract from the Gorge view. However, I do feel that if the project managers can make some minor modifications to number or exact location of the towers to accommodate specific complaints of the local residents, they should do their best.

COMMENT LETTER 213

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE10020 - mooney

The mailing that SDS sent out was very troubling. Our neighborhood is comprised of \$500,000 and up homes that moved here for the view. Our view will now be looking at windmills all day and blinking lights all night. We will receive no benefit from these windmills and we are in a different county. SDS gains the money, we gain nothing except a destroyed skyline. My only compromise would be to lower the windmills below the ridgeline so we don't have to look at these unsightly beasts.

COMMENT LETTER 214

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE10022 - Fischer

Love the idea of a cleaner power source than coal. Not sure that it is fair for us to push the unsightly and dirty job of generating power with coal onto other communities when we have a chance to contribute our share locally. I think the turbines look graceful and I do not mind them during the day. At night the red hazard lights are an eyesore. I would vote no just to avoid seeing the lights at night. Probably not possible to get rid of the lights.... but it sure would be nice. My biggest concern is that there be a guaranteed set-aside fund to remove the turbines once they have reached the end of their useful life and stopped generating power. There should absolutely be a provision to restore the area once they stop generating power. It is inevitable that at some point a newer technology will replace wind and when it does please make sure that we don't have to look at something that we are not deriving benefit from. Thank you, HF

WRE100028 - Peterson/Vineyard View Bed and Breakfast, comment made by telephone.

Called to comment because he's too busy to attend the meetings for Whistling Ridge because he's hosting a beautiful event, a 15th birthday party, at the bed and breakfast. He loves to see the view of the gorge the way it's always been, and he believes it's inappropriate to place 50 decibel, 500 foot tall towers there. It's just not a good trade off for the small amount of power. When he got permits to build his B&B he had to plant lots of trees as to not upset his neighbors. There are appropriate places for wind turbines, but not in the scenic Columbia River gorge.

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100031 - Saulie-Rohman/Renewable Energy Student

My name is John Saulie-Rohman and I am writing in support of the Whistling Ridge Wind Project. I am a first year student at Columbia Gorge CC and my family is from this area (White Salmon) Because the timber industry is on the downward spiral and so much of the local economy depends on its funds I believe wind power is a viable option. There are negative qualities to every solution and there will always be somebody against everything. I have watched Underwood Mountain be clear cut for years now and public outcry was minimal. My main concern is that the power and the revenue generated by the wind farm stay local. I support turbines manufactured in the United States and I support local economies benefiting from the farm. It is very frustrating when the local people push green, green, green, but when it comes to their neighborhood they want it in their neighbor's backyard. I say stay local and keep up with the times because they are a changin'. Thank You. John Saulie-Rohman P.S. I would have showed up at the public hearings but I did not receive any literature and was not at all aware of the hearing until my classmate received the pamphlet after the hearings.

WRE100034 - Griswold

I am against siting any wind turbines in any key viewing area of the Columbia River Gorge NSA.

This wind farm will be visible from many points in the CRG NSA. More tourist dollars and real estate/property tax dollars will come to the area over the years than will be produced as income from this wind farm. Please do not approve Whistling Ridge in any form.

Please be part of maintaining the intent of the CRG NSA. Do not sell out this area for respite from the metropolis to the money-making interests of those wishing to benefit from wind-generated electricity. This, and any wind farm in view spaces of the CRG NSA should not be approved. I would be looking right at Whistling Ridge turbines every time I left my house to drive down the hill into Mosier.

Thank you for taking my comment.

After reviewing the EID I find it exceeding the requirements for this project. I support this project and see no environmental impacts that should delay it from advancing. I have used this area for recreation and while loosing this opportunity because of this project I still support the project. I do think this project is on the conservative side and should have been expanded.

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100046 - Andruss

Please do not put the wind turbines on Whistling Ridge. White Salmon and Hood River are known for the famed double mt. views. All of our property values will drop when the area becomes known for its multi-turbine views. We need wind power but not in such a beautiful place. The turbine mess out east is bad enough. I am always thankful when I get west of all those blinking lights. It is enough to ruin the eastern gorge with these industrial giants. I don't know how many turbines are out there but adding another 50 turbines to that mess won't make much difference now. To put up 50 turbines on Whistling ridge would blight the whole area. This is a world class scenic area and should be preserved as that. The project west of the Dalles has been canceled and the middle mt. project south of Hood River has been stopped. If we would have known that Whistling Ridge was to become an industrial wind factory we never would have bought property in Mill A. Common sense tells us this is a bad idea and should never be put in. I have been to meetings and listened to the talk about how safe for birds these mills are. The native americans told us that they could not imagine how a bird could fly into these blades. About 2 weeks later, front page of the Oregonian, Golden eagle killed by wind turbines at Goodnoe Hills. How many Golden Eagles are there in the gorge ? At least one is dead. We were told that up to 7000 bats would be killed if the Whistling Ridge project goes in. How many hawks and eagles will die because of this? What are the long term health effects? I have been told that 750 gallons of oil a year will be atomized in each of the turbines. That does not sound like clean energy. Putting these turbines on mountain tops has not been studied thoroughly so we really don't know what the impact will be. Many people are affected by the vibration and sound of the turbines. Again to put them so close to people and towns seems short sighted at best. To conclude I would say don't put the proposed Whistling Ridge turbines in as it is the wrong place to put them. Install them out east where there is less scenic beauty and already lots of turbines and more wind to turn them. Sincerely, Steve Andruss Mill A, WA

WRE100050 - Carroll

In regards to the whistling ridge wind farm proposal. I have to say that it is a poor location choice for a turbine farm for these reasons. 1. With-in the view corridor of a sensitive NATIONAL SCENIC AREA!!! ...Bad choice for people, national pride and the wind turbine industry. 2. WIND TURBULENCE, the whistling ridge is right in the wind venturie of the crest of the Cascade Mountains and the Columbia River gorge. Making one of the windiest spots in North America with very gusty turbulent conditions. ...Bad for big turbine efficiency and longevity, 3. WIND SHEAR, the Steep complex varied terrain (especially to the west) from the whistling ridge site accompanied by the Gusty Nature of the westerly Gorge winds will impair the turbine balance. ...Bad for turbine safety 4. This site is driven by Greed and not quality of location for wind turbines. ...Bad for the future of wind farming and turbine acceptance Please don't get me wrong, as I support wind farms and their development and was involved with a small wind turbine company in the late 70's and have witnessed the struggles that wind turbine development has faced. When I moved to the Gorge in 1984 there was a large Boeing proto type turbine in the Columbia hills, I visited often and spoke with the engineers. They were hopeful for this 120' span turbine but pointed out that the wind shear and turbulence was a huge factor in the placement of the turbine and it had to be taken down. This turbine was the prototype for all the turbines that are now being installed in the appropriate locations of the gently sweeping eastern basin of the Columbia River. Where topography and wind quality have created a rush of wind farms that are successful. A very positive point for the industry, Please do not make the a mistake of placing turbines in inappropriate locations as it will hurt the wind industry as well as disfigure a National treasure the Columbia River Gorge. Thank You for the opportunity to comment Jay Carroll

WRE100056 - Henley

I wanted to take the time to comment about this project. I think that the people objecting to this project must be the few people that have steady, good paying, dependable jobs--or are retired and don't care whether anyone else is able to feed their family or not. This county has more than their share of poverty level or lower incomes. What this county needs is more decent jobs, the wind energy industry is the only industry I see wanting to build here. By building here they are providing much needed jobs for this depressed community. We as a community should be rolling out the red carpet to them! I would like to stay in this community, but unless more jobs become available, because I am not independently wealthy, will have to look elsewhere to live. The people opposing this industry, only have their own interest in mind, and as long as they have jobs, wealth or a rich Daddy, don't care that a large portion of their neighbors are going hungry. I am looking at early retirement because of these factors. I want my children and grandchildren to be able to stay living in their homes, if they want. If they do move away, let it be because of other factors, not because there is no way to make a living here. Besides, these ignorant people are completely overlooking the fact that in forty years, we are going to be out of fossil fuel and are running out of time to generate alternative energy. Do they think this is going to happen without impacting anyone? They are all for cleaner, alternative energy--as long as it doesn't disturb the status quo, or cost them any money, but change for the better is always an adjustment, and we simply don't like to be disturbed. Alternative energy is here to stay, because we have no choice, we are running out of resources, so they might as well embrace these changes, they are here to stay!

COMMENT LETTER 230

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100057 - Tyler

While the Whistling Ridge Wind Project proponents deserve credit for responding thoughtfully to some of the previous objections to their earlier proposals, the revised proposal remains of great concern. If allowed the proposed wind mills will still seriously impact the beauty of the Gorge Scenic Area. As presently proposed viewers from numerous locations including parts of the cities of White Salmon, Underwood, and Hood River, as well as the Columbia River itself will have their views of the Gorge defaced by 425 foot towers of steel, rotating blades and flashing strobe lights. There are few areas in the world with as much natural beauty as we now have in this part of the Gorge. We could not sell it away. Granted our Nation needs alternative sources of energy and Skamania County needs new sources of revenue. But there are many less scenic areas of Washington, Oregon and the entire country which could also contain our windmills. Some things should not be traded for money. Related Concerns: 1. A first Gorge Windmill project will set a precedent. Other proposals and very likely other windmill farms will follow. New companies (for example a conglomerate such as General Electric) will be much less concerned about the welfare of this area than our neighbors at SDS. 2. Wind farm derived tax revenues will not be the only economic consequence of a local wind farm. Probable negative consequences include decreased property values, reduced appeal to future tourists and prospective new residents because of diminished attractiveness of the area and likely increased infrastructure costs associated with building and maintaining a windfarm (including road maintenance and additional fire protection). 3. Huge steel towers with massive concrete bases would be with us a very long time. The costs of removing an obsolete windmill would be substantial. But how long would a wind tower be useful? When I consider the dramatic and initially unforeseeable changes in energy demand and modes of production over the past 150 years (Particularly the last 50 or so) I am astounded. Who can predict whether 30, 50 or even 100 years from now massive 450 ft steel windmills will make any contribution to our energy needs? But if we allow them here we will be stuck with them and their various consequences. Please put windmill farms in a more suitable location. John Tyler

WRE100060 - Usen

I am an environmental planner by training and profession with over twenty years of experience writing, managing and reviewing environmental impact statements prepared in compliance with the State and National Environmental Policy Act. For nearly as long, I have worked and played in and around the Columbia River Gorge and am protective of its unique and spectacular scenic, natural, cultural and recreational resources. The Columbia River Gorge is a unique and irreplaceable treasure that includes federal and privately owned land and provides important regional economic development opportunities. The National Scenic Area designation was a compromise that offers a high level of protection against the threats posed by incompatible development in Special Management Areas, less protection and greater recognition of economic needs in General Management Areas and no regulation of activities in Urban Exempt Areas or lands outside of the Scenic Area boundaries. Interestingly, the Act provides these restrictions on land use but not against air pollution generated upwind that dims the Gorge's spectacular views on smoggy and hazy days. Our planet Earth is likewise a unique and irreplaceable treasure, just on a larger scale. It goes without saying that the scale of the numerous threats to our global environment is proportionately larger and more significant than those facing the Gorge. Of the many threats facing our planet, none are as grave or as irreversible as climate change. The only way to reduce the impacts of this global catastrophe is to drastically reduce our emissions of CO₂ and other Greenhouse Gases (GHGs). Realistically, this means optimizing every feasible opportunity to generate energy from non-polluting renewable sources, and there is no source less polluting or more renewable than the wind. Unfortunately, commercially viable wind farm locations like Whistling Ridge are extremely rare. For these reasons, I have reviewed the Whistling Ridge DEIS hoping to evaluate for myself how a special place I cherish would be impacted by the demands of power production for our future, estimated by the Northwest Power and Conservation Council to grow 1.2% annually for the next 20 years. Nearly all the impacts addressed by most EISs that I've worked on or reviewed are adverse to the environment. What makes this DEIS notable is the section on Avoided Emissions on page 3-20. According to this section: "Project operation would avoid the use of fossil fuel to meet the energy needs of the region. The project's annual electricity production is estimated at 197,000-megawatt hours (MWh). This energy is equivalent to 114,000 barrels of crude oil or 654 million cubic feet of natural gas." According to the U.S. Energy Information Administration, 197,000 MWh is roughly equivalent to the annual energy consumption of close to 18,000 homes. That's a huge amount of energy to be generated entirely by renewable, non-polluting sources. Perhaps even more significant is the annual displacement of 131,466 tons of the GHG Carbon Dioxide and 155 tons of the pollutant Sulfur Dioxide (Table 3.2-1) that would typically result from generating this quantity of electricity, benefitting both the smog-threatened Scenic Area and the GHG-threatened global climate. Whistling Ridge is outside the delineated boundary of the National Scenic Area and totally exempt from its restrictions but due to the scale and proximity of the proposed turbines to the boundary, the project applicant has not ignored evaluation of aesthetic and other impacts from within the National Scenic Area. The

Visual Resources section (3.9) consists of what appears to be a thorough and objective analysis of relevant impacts. I found no reason to doubt the completeness of the data or the validity of the methodology or findings. It is worth noting that the analysis rated no visual impacts as “High”. Rather, most were rated moderate or low and only one, Viento State Park rated up to “Moderate to High”. The DEIS’s evaluation of viewer sensitivity states on Page 3-171: “When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated as moderate to high.” This is the worst visual impact of this project documented by the DEIS thus it is reasonable to conclude that scenic resources of the National Scenic Area would not be compromised by the proposed action. Hidden behind Underwood Mountain from both the vast majority of the Scenic Area and view from local residents, yet accessible to wind and existing transmission lines, Whistling Ridge appears to be an ideal site for wind turbines. It is the Lead Agency’s responsibility under the State Environmental Policy Act to fully consider the environmental impacts of the Proposed Action. As Lead Agencies, EFSEC and BPA need to weigh the proposal’s limited environmental impacts against its relevant and consequential environmental benefits. Of the many EISs I’ve reviewed, I cannot think of a clearer example of where the significant positive regional and global environmental consequences outweigh the negligible, local adverse impacts.

WRE100062 - Freidman

Hello. This is Paula Freidman. I'm calling to comment on the Whistling Ridge Energy Project along the Skamania and Klickitat county line. I am VERY opposed to putting a wind turbine project there. The wildlife effects would be disastrous. The effects on human habitation, which is fairly close, would be for the persons living nearby, very, very bad and of course this is right in line of sight of the Columbia Gorge Highway, the national scenic area. So this is not a satisfactory project. I'm obviously not in the state of Washington, but in the area that would be impacted across the river more or less. We've had to fight this kind of project. This is the Cascades, you know. This is not some kind of away from people and away from lots of wildlife kind of area. And, of course, there's the little matter of the snowy owls. So this is not a good area for this project. Thank you.

I support the Whistling Ridge Energy Project. This project contributes to our country's energy independence and county's economy. I appreciate the fact that SDS Lumber is a local sponsor rather than an outfit that does not live or work in the Columbia River Gorge.

COMMENT LETTER 235

Proposed Whistling Ridge Energy Project
Draft Environmental Impact Statement

WRE 100064

1. I have the following comments about the Draft EIS for the Whistling Ridge Energy Project:

I very much support the success of this project because our schools and Skamania County really need it. I live in Wardenwood as did my father, and his father since 1903. I believe most of the people in the local area know this project will be good for our community.

The Whistling Ridge Energy Project does not breach the boundaries of the Columbia River National Scenic Area. As the so-called Friends of the Gorge would seem to want you to believe. They also were involved when the boundaries of the NSA were set, but that was apparently a stepping stone for further advances against the survival of our local government. Now they are trying to incite the people, saying the project is in a avian migration path. This kind of mis-information can only further prolong the financial help this project can bring to our community.

Sincerely,

James F. Ziegler

WRE100065 - pace

The analysis of economic impacts of the project is very weak and uninformative. The project will have substantial benefits. These are susceptible to quantification. The analysis does not do the project justice in this respect. The interconnection of this project (and other wind resources) is problematic. Bonneville has not analyzed the environmental and social impacts of integrating wind. It also has not considered the impacts of BPA operations on designated critical habitat for ESA. For this reason, the interconnection aspects of the project should be deferred until Bonneville complies with law. The facility siting aspects, however, should proceed. As a general comment, Bonneville is not above the law. It cannot continue to pretend that the Administrator has discretion to violate the law. The law requires that you assess the environmental and socio-economic impacts of Bonneville's activities. The Endangered Species Act and Magnuson-Stephens Act require such consultation. It is irresponsible for Bonneville to continue to develop resources and plan transmission upgrades without considering these factors.

WRE100069 - Prothero

Re: Whistling Ridge Energy Project I am a summer resident of White Salmon, near Northwestern Lake. I have visited wind farm sites to the East, in the Gorge, and have listened to the sound levels at various distances. I have also visited the farms at night and noted the impact of the flashing red lights on top of the windmills. I am in favor of wind power and applaud its development in relatively sparsely populated areas to the East. My observations lead me to believe that noise levels at distances of a mile or more will most likely not be noticeable. However, the visual impact of the large array of flashing red lights will create a disturbing visual impact when directly viewed at night, and may reflect off low clouds, when present, and seriously affect the darkness of the night sky. Direct observations of the red lights on wind farms in Washington, from the Oregon side, creates a very distracting and potentially disturbing effect on the darkness of the environment. After a good deal of thought about trade-offs between impact to local residents, the need for renewable energy, and the availability of sites in relatively unpopulated areas, I have concluded that the project is incompatible with the proposed site. It will affect many residents in the Gorge, which is a national scenic area. Other sites to the east exist. I do not believe that the local tourism and local residents deserve this impact. Another impact may be on property values, which would result in a decrease of income from this source, to the county. Thanks for accepting my comments.

WRE100072 - Penswick

I am interested in seeing this Whistling Ridge Energy Project go forward. Protecting the Columbia Gorge Scenic act is also very important, but we need to promote renewable energy sources when the opportunity presents itself. I feel this proposed site will project a low impact on our Gorge image. It's important to look at the wider scope of this project and the potential benefits it can bring to this area.

COMMENT LETTER 240

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100073 - Jackson

I support developing alternative energy sources, including in some cases, wind, but I oppose this project.

It would destroy important wildlife habitat, including for the northern spotted owl. It would cover more than 1,000 acres of land in an area that is prized as beautiful, wild recreation land, where people in Oregon and Washington go to get away from "civilization" and the city. This project would ruin the beautiful view in the area. I support alternative energy projects that are developed in areas with zero or very minimal impact on the native wildlife and forest; that do not decrease the liveability of the area; and that are in the best interests of all citizens, not a company that is trying to profit. Such projects should be "owned" and overseen by regional and/or federal government bodies and fully reviewed for environmental soundness before they are implemented. Thank you.

COMMENT

RECEIVED
AUG 3 2010

Subject : Whistling Ridge Energy Project Draft EIS

While the Whistling Ridge Wind Project proponents deserve credit for responding thoughtfully to some of the previous objections to their earlier proposals, the revised proposal remains of great concern. If allowed the proposed wind mills will still seriously impact the beauty of the Gorge Scenic Area. As presently proposed viewers from numerous locations including parts of the cities of White Salmon, Underwood, and Hood River, as well as the Columbia River itself will have their views of the Gorge defaced by 425 foot towers of steel, rotating blades and flashing strobe lights.

There are few areas in the world with as much natural beauty as we now have in this part of the Gorge. We should not sell it away. Granted our Nation needs alternative sources of energy and Skamania County needs new sources of revenue. But there are many less scenic areas of Washington, Oregon and the entire country which could also contain our windmills. Some things should not be traded for money.

Related Concerns:

1. A first Gorge Windmill project will set a precedent. Other proposals and very likely other windmill farms will follow. New companies (for example a conglomerate such as General Electric) will be much less concerned about the welfare of this area than our neighbors at SDS.

2. Wind farm derived tax revenues will not be the only economic consequence of a local wind farm. Probable negative consequences include decreased property values, reduced appeal to future tourists and prospective new residents because of diminished attractiveness of the area and likely increased infrastructure costs associated with building and maintaining a wind farm (including road maintenance and additional fire protection).

3. Huge steel towers with massive concrete bases would be with us a very long time. The costs of removing an obsolete windmill would be substantial. But how long would a wind tower be useful?

When I consider the dramatic and initially unforeseeable changes in energy demand and modes of production over the past 150 years (Particularly the last 50 or so) I am astounded. Who can predict whether 100, 50 or even 30 years from now massive 425 ft steel windmills will make any contribution to our energy needs?

But if we allow them here we will be stuck with them and their various consequences.

Please do not introduce wind farms into the Gorge Scenic Area. Encourage the Whistling Ridge proponents to relocate their project to a suitable site.

RE: Whistling Ridge Energy Project DEIS

Dear Ladies and Gentlemen,

The Friends of the Historic Columbia River Highway has sincere and strong concerns about the proposed Whistling Ridge Energy Project's potential impacts on the Historic Columbia River Highway, a district listed in the National Register of Historic Places.

The Historic Columbia River Highway (HCRH) is a linear scenic and historic resource in Oregon, extending from Troutdale to The Dalles. All of the HCRH is a Key Viewing Area within the Columbia River Gorge National Scenic Area (CRGNSA). Portions of the HCRH that are a trail are designated as a National Recreational Trail. Portions of the HCRH are closer to the proposed project than the sites chosen for visual resource analysis. In particular, Mitchell Point is due south of the proposed project and within the Special Management Area of the CRGNSA. There is an existing viewpoint/overlook within the Oregon Parks and Recreation Department (OPRD) property at Mitchell Point, including an interpretive sign at the edge of the cliff overlooking the Columbia River. See photo.

Mitchell Point was the site of the famous Mitchell Point Tunnel (also know as the Tunnel of Many Vistas because of its five "windows" overlooking the Columbia River) on the Columbia River Highway (see photos). While the original tunnel is gone, planning efforts since 1987 have looked at ways to reconnect the HCRH in this area. In 2008 the Friends of the Historic Columbia River Highway financed an engineering feasibility study that concluded that it is feasible to construct a new tunnel at this site, which could have "windows" at the former location of the viaduct. This proposal is included in the Mile Post 2016 Reconnection Projects, the most recent planning document published (see attachments). In addition, OPRD is currently developing a project to enhance the existing viewpoint.

The Mitchell Point overlook is even more visually sensitive than Interstate 84, both because it is higher in elevation and because it is a place where people stop and get out of their cars to take photos. It is closer to the proposed project than Viento State Park, Koberg Beach State Park and the single location on the Hood River to Mosier section of the Historic Columbia River Highway

State Trail that were analyzed. This site must be analyzed for visual impact from the proposed project.

When the highway was constructed in 1913-1922 Samuel C. Lancaster wrote: "our first business was to find the beauty spots, or those points where the most beautiful things along the line might be seen in the best advantage, and if possible to locate the road in such a way as to reach them." This was accomplished by directing curves to draw attention to dramatic viewsheds and design features that enhance the appreciation of dramatic scenic landscapes. These design techniques are a critical component of the historic value of the Historic Highway, the first scenic highway in the country. Harming the views from these viewing locations directly undermines the historic integrity of this nationally important historic resource. The view from Mitchell Point in particular highlights the important relationship between highway design and maximizing appreciation of scenic landscapes. The original Tunnel of Many Vistas provided enhanced views of the Columbia River and the geologic features across the river on Underwood Bluff. The recreated tunnel will also highlight similar views. The proposed development would directly harm these views.

As evidenced by the attached photos and the design features that highlight views from the "Tunnel of Many Vistas" underscore the views' significance to the highway designers. The significance of this view was further confirmed when the Management Plan for the CRGNSA was adopted in 1991. The Underwood Bluff was given an Open Space zoning designation and a Gorge Walls, Canyonlands, and Wildlands landscape setting designation. Both designations were adopted in part in response to scenic resource inventories that established visually quality objectives. The DEIS fails to acknowledge the scenic resource inventory or how the proposed development would impact this view. The development would include enormous industrial structures with moving parts and flashing lights that would break the sky-line of this view. Attention would be drawn away from the historic view and be focused on modern industrial development. This would cause significant adverse effects to the views.

While the most severe impacts would occur to views from the HCRH at Mitchell Point, significant adverse impacts to views from miles of the HCRH would occur. The DEIS must be revised to accurately reflect the impacts to the length of the HCRH. The single simulation of a view from the Mosier to Hood River section of the HCRH State Trail (Viewpoint 19) is both misleading in its presentation and incomplete. There is no analysis of impacts to the view corridor. Notably, this section of the HCRH are part of a separate multi-agency restoration project that reconnected and restored the HCRH for public enjoyment. Millions of dollars were spent to restore this resource so the public could enjoy pristine and historic views. The DEIS fails to take this context into account.

In sum the DEIS fails to adequately analyze the likely impacts to views from the Historic Columbia River Highway. Because the impacts were not adequately addressed, appropriate alternatives were not analyzed and appropriate avoidance and mitigation measures were not considered.

Friends of the Historic Columbia River Highway encourage EFSEC and the BPA to revise the DEIS to actually reflect the likely impacts of the proposed development on the Historic

Columbia River Highway. The revised DEIS must include alternatives that would not include any turbines within viewsheds from the HCRH. At the least, the agencies must consider an alternative that would avoid impacts viewsheds from important viewpoints such as Mitchell Point.

Thank you for the opportunity to comment on this DEIS.

Sincerely,

A handwritten signature in blue ink, appearing to read "Jeanette B. Kloos". The signature is fluid and cursive, with the first name being the most prominent.

Historic Views of Mitchell Point

8A

Segment 8 – Mitchell Point Tunnel

At this location, a tunnel originally connected the two intact historic highway segments on either side of Mitchell Point. The "Tunnel of Many Vistas" was 390 feet long and had five adits, or "windows," with magnificent views of the scenic Columbia River. The tunnel was 18 feet wide and 19 feet high at the crown. A viaduct was used to access the tunnel's west portal, and a cut into the hillside accessed the west end of this span. The state closed the old highway route through the Mitchell Point Tunnel in 1953 because of increased vehicle size and rockfall hazards. The tunnel and much of its approach route to the west, including the viaduct, were removed when the state removed the hillside to make room for full build-out of Interstate 84. The only remnants of the tunnel are narrow ledges at the west and east approaches. These benched areas are located about 200 feet above Interstate 84 and currently used as rockfall catchment areas in conjunction with other catchments adjacent to Interstate 84 below.

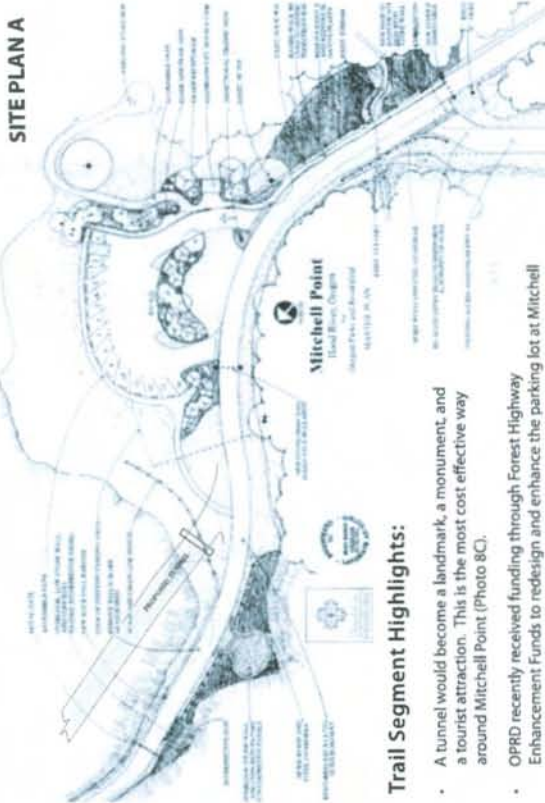

Reconstruction of Mitchell Point Tunnel would not only provide a way through Mitchell Point but also provide future trail users and visitors a unique way to experience the historic highway and Columbia River Gorge. In spring 2008, the Friends of the Historic Columbia River Highway contracted with GRI, geotechnical engineers, to prepare a geotechnical feasibility study for a new tunnel through Mitchell Point.

Their report envisions a tunnel that connects the two old highway segments east and west of Mitchell Point near the original grade of the historic highway. With a tunnel width and height of 18 feet and length of about 1,200 feet, tunnel report includes three to five adits (windows) from the main tunnel to the cliff face to the north to provide viewing areas and allow for natural light. The west portal is located at the existing rock outcrop near the northeast corner of the parking area. The east portal requires a cut in soil and decomposed rock before tunneling can begin.

Photo 8A : Oregon Parks and Recreation Department recently received funding to enhance the parking lot and interpretive opportunities at Mitchell Point, a scenic, yet often overlooked wayside and State Park.

Photo 8B : View from the west side of Mitchell Point looking northwest at a striking view of the Columbia River Gorge.

Photo 8C : View from the east side of Mitchell Point looking northwest towards the Columbia River. Remnants of the historic highway are visible in the foreground.

SITE PLAN A

Trail Segment Highlights:

- A tunnel would become a landmark, a monument, and a tourist attraction. This is the most cost effective way around Mitchell Point (Photo 8C).
- OPRD recently received funding through Forest Highway Enhancement Funds to redesign and enhance the parking lot at Mitchell Point (Site Plan A and Photo 8A).
- Most visually subordinate of the all options to get around Mitchell Point.
- Site is accessible to eastbound I-84 motorists.
- Incredible Columbia River Gorge views (Photo 8B).

8C

Segment 8 – Preliminary Cost Estimate

Station	Item	Cost
0+00 to 12+00	1200LF Tunnel with 3-5 Side Adits (Per GRI Geotechnical Evaluation)	\$ 5,654,000
0+00 to 12+00	Trail (3" AC x 12 wide, 10" CR Base X 16')	36,000
0+00 to 12+00	Lighting (Allowance)	150,000
0+00	West Portal (For Rockfall Protection)	90,000
N/A	Traffic Control on I-84 (Allowance)	100,000
Raw Construction		6,030,000
Engineering & Permits (20%)		1,206,000
Construction Engineering (15%)		904,500
Sub Total		8,140,500
Contingency @ 40%		3,256,200
Estimated Project Cost (2008)		11,396,700
Estimated Inflation (2008-10)		1,139,670
Project Cost Estimate (2010)		\$ 12,536,370

Please Note: Not all stations shown in the Preliminary Cost Estimate tables are shown on the segment Feasibility Maps.

Proposed Whistling Ridge Energy Project
Draft Environmental Impact StatementRECEIVED
AUG 9 2010

1. I have the following comments about the Draft EIS for the Whistling Ridge Energy Project:

Our home is located within sight and sound of the Whistling Ridge Project and we absolutely agree wind and solar time has come.

Opponents, fearful of the turbine "noise" probably don't even notice the "rumbles" of the trains at the bottom of Underwood mountain. As with many daily sounds, it is something to which we can become accustomed.

Technology has given us a chance to use the sun and the wind supplied to us each and every day.

Our family approves the project plan and we commend the people with the courage to fight for the Whistling Ridge project.

Russ and Lalonna Pollard

WRE100079 - Dye

I would like express my disapproval of the Whistling Ridge Energy Project. The project is inappropriate in that it addresses only the fiduciary interests of a local company and not overall needs of the County, it's residents or the Nation. In a time of rapidly decreasing forested areas in the world and climate change removing forest forever, i.e., 9 feet of concrete to support windmills, destroying watershed, creating lanes to move power with towers, destroying wildlife habitat, makes little sense. From an energy standpoint Eastern Oregon has thousands of square miles of useful high desert county that would be more useful. It appears that there is a stall on the April 2009 Wind Power Guidelines so that federal subsidies may be taken advantage of by proprietary interests. This also appears to be stalled so that there would be fewer costs for mitigation. Where is the oversight? The Gorge Commission appears to have been influenced by special interests.

WRE100082 - Bushman, comment made by telephone.

Laura Bushman phoned the comment line on 8/25 to register her opposition of the wind farms that is being proposed in the gorge (Whistling Ridge). Our area has this beautiful scenic area and she doesn't understand why people want to ruin it by adding windmills. Her and her husband were over at friends the other evening, and they had the perfect view of the river and the gorge. It was absolutely beautiful! If this wind farm has to be built (which she is opposed to), it should be built on the other side of the ridge so that it can't be seen. She knows this wind farm proposed is actually outside of the scenic corridor, but it still ruins the views of the gorge.

COMMENT LETTER 248

Vicki Pryse
Skamania County Resident
Underwood, WA
2 miles from Proposed WRE Project

Re: Comment regarding WRE DEIS

Bald Eagles are observed flying overhead in our area, including the proposed Whistling Ridge project site. The central Columbia River Gorge and its tributaries are becoming havens for the recently delisted Bald Eagle. This area in the central gorge is increasingly utilized by overwintering eagles from northern regions. Some eagles have found the area to be suitable for nesting and rearing young. The extent of use of the area, and the long term potential impacts of this project to those individuals and to the breeding and overwintering eagle

population as a whole is not enumerated or discussed in the DEIS.

Before the full impacts of the WRE project can be assessed by the decision makers, it is imperative that the a careful and honest analysis is performed. Obviously, the Applicant was not able to perform this task, so please see that qualified experts are involved in this issue. The future of the Bald Eagle, once on the brink of extinction is dependent on this.

The Bald Eagle is our nations symbol. Are we going to put at risk our nations symbol and replace it with a symbol of how the public was duped to pay for a sprawling, inefficient, unreliable and environmentally damaging power plant?

I have included the attached cartoon for emphasis, which is freely distributable from www.windtoons.com.

Thank you for your diligent review of this poorly placed renewable energy project.

You know, I think I felt safer back when we were an Endangered Species.

Idea contributed by a resident of Washington State

Comments posted to BPA's Comment Website, www.bpa.gov/comment

WRE100086 - Gresh

I am a resident of Oregon and live in Portland but my wife and I own a second home in Mill A, Washington. It is my feeling that the assessment of direct, indirect, and cumulative visual impacts caused by the project are inadequate. The methodology used was to evaluate the potential visual impacts from specific view points and that method does not account for the potential to the most common viewer of the Columbia River Gorge National Scenic Area, those that pass through and view the area as a whole, not the sum of its parts. I feel that this cumulative impacts analysis should include the following future projects: Cascade Locks Tribal Casino Broughton Mill Redevelopment. Both of these projects have been evaluated and have had more than enough analysis to include in the cumulative analysis. I feel this is particularly important because SDA Lumber is responsible for both the Broughton Mill development and the Whistling Ridge Energy project. While the CGNSA plan includes the allowances for economic development in addition to the preservation of the unique scenic beauty of the Gorge, it is crucial that such projects as Whistling Ridge include a thorough analysis of cumulative effects when such significant development projects threaten the scenic elements of the Gorge that warranted the creation of the NSA.

I am dead against the Whistling Ridge Energy Project. I can support wind energy projects but not with a location on the border of the National Scenic Area. The views from this protected region need to be protected also -- 400+ foot high turbines destroy part of what the Scenic Act stands to protect. These are not the views from a few local homes or a couple of small towns - these are the views of an entire region -- a protected region. Please do not degrade the Columbia River Gorge. I am also concerned about the environmental impacts on the area and wildlife.

To those charged with making a decision on the proposed Wind turbine project on Whistling Ridge: We support wind energy projects, however: Not near houses Not where they are visible to the National Scenic area. Not in the middle of a forest where animals become endangered. Perhaps the Broughton Lumber Company would be able to trade the proposed site for one further removed from houses and the Gorge. Alison and John Bryan

BPA

August 26, 2010

Re: Public comment on the proposed Whistling Ridge Energy Project.

Columbia Gorge Audubon Society opposes this project.

The history of NW wind power offers very little to be proud of. The first question regulators should be asking is why wind power is being developed in the NW when most or all of the power is being sold in the SW? The history of SW wind power would raise a lot of red flags for NW wind power development, issues that are being ignored here. It seems we are doomed to repeat all of the mistakes that are now fairly well understood in the SW.

When wind power burned too many bridges in the SW and they decided to move into our region, and the Federal government warned them that they would be facing arrest and jail if they killed federally protected birds, and that they had to solve the bird problem before they would be allowed to develop in the NW. They did solve it, but not in a way that would save even one bird, instead they did an end run and solved the problem politically. Ever since then the regulatory agencies have been playing the "Go along, to get along" song to protect their budgets from cuts from above. As a result, wind power has been allowed to develop projects just about anywhere they want, no matter the consequences.

If things are so bad, where are the environmental groups? Why aren't they out protesting? Early on the wind power industry effectively dealt with the environmental groups. They rounded them up in a BPA round table discussion to generate mutually agreeable siting standards for wind power. This kept the environmental groups busy and made them feel like they were involved in the process while wind power developers were out securing sites for their projects. The round table talks ended with agreement on five voluntary siting criteria, all five of which were violated in the first proposed projects.

Another aspect of the wind industries plan was to bring in wind power promotional groups. These "environmental" groups gave the appearance of a divided environmental community on the issues of wind power.

The third method that the wind power industry used to control environmental groups has been to give (or deny) them money. The Bullitt Foundation has been the major source of grant money used to control groups in the NW. The Bullitt Foundation promotes wind power. When wind power was planning on moving into the Hood River Valley it was not coincidence that the Hood River Valley Residence Committee had just received a Bullitt grant for \$17,000. That proved an effective grant. When The Friends of the Gorge protested wind power development overlooking the Columbia River Gorge they had their Bullitt grant pulled for the first time in years. National Audubon Society and Audubon Washington are major receivers of Bullitt grants, and we believe this has kept them from doing the one and only thing that Audubon could do that would effectively check wind power abuses, and that is to expose them in the media. We have pleaded with Audubon Washington to launch a media attack on wind power abuses, but they have ignored us. They know what would happen to their Bullitt grants if they were to take effective action against even the most abusive projects. Do not think that all is well, just because dozens of groups are not protesting Gorge wind power development. Most groups have been targeted and effectively muzzled.

Last year I attended an Underwood Community Council meeting because I read in the local news paper that the SDS wind power project proposed for the Underwood Mountain area was going to be discussed. A representative from SDS was there and there was an SDS wind power booster in the audience. The council was upset because they had not received proper public notice and the public hearing was to be held in Stevenson, 20 miles from the site, when the Underwood Hall was available and located in the community that would be impacted the most. The SDS representative and the booster in the audience did all they could to block effective council representation, including trying to block a letter in protest regarding the basic issues of public notification and moving the meeting to Underwood so locals could more easily participate. They also insisted that the council could not act until they contacted every community member and secured their approval of the protest letter or any other action. Interesting, they wanted every community member's approval on a motion, but they opposed holding the hearing in Underwood. Needless to say, requiring the approval of every citizen would bring any federal, state or county government to gridlock, but SDS tried to hold a local elected council to this ridiculous standard. This further illustrates how SDS seeks to control and manipulate all of the active parties, from the top to the bottom, that are considering the SDS proposal.

It was not that long ago when SDS proposed a major co-gen development for their mill. When they reached the public comment period for the proposal a member of the public discovered that the permit that they applied for was for a small mobile unit. The small mobile unit permit would have avoided major regulatory requirements. SDS immediately dropped their proposal. We seriously doubt that SDS or DOE could have gotten that far in the process without realizing that the wrong weaker permit was being applied for.

All of this provides context for this proposal. The context you are getting here is more relevant than the false context that tells you that NW wind power makes sense, that proper siting is being applied, that the regulatory agencies are on the ball, and that the groups that you would expect to be in opposition are holding back because they really believe that wind power is not a problem.

When new energy production is promoted you can take it as standard operating procedure that the need for energy will be over inflated. Studies are conducted to "prove" the inflated energy numbers. The nuclear industry did it when they promoted the infamous "WHOOOPS!" nuclear development, and we believe that the wind industry and their boosters are doing the same thing. Over the last few years the Columbia River aluminum industry has closed its doors and around one third of Oregon and Washington's electrical energy has become available for other uses. The recent recession only gets deeper and deeper and this is bound to cause a reduction in energy use. These major impacts on NW energy use are virtually ignored. But they are real, and to a large extent this is why our transmission lines are flooded to capacity and most of the energy is going to the SW. This is why about a third of the wind machines are turned off at any one time. This is why many of them that are spinning are not even hooked up to transmission lines. All of this is ignored while you focus of hocus-pocus studies that inflate-create a huge imaginary need for power. You cannot serve the real interest of the people if you cannot keep your feet grounded in reality.

About this time these objections are usually dismissed with the argument that we must save the world from green house gasses. The problem is that wind power will not accomplish that. Because wind power only produces energy when the wind is blowing – and even then it produces variable energy – it must have 100% back-up by conventional or nuclear energy sources. In this way, wind power is in fact driving the need for gas (preferred source) electrical plants that produce a lot of green house gasses.

Wind energy is expensive. It costs about four times the cost of hydropower. The 100% back up will add to the costs. The new transmission lines necessary for transmitting wind power and the conversion to "smart" lines will add to the costs. Using wind power to pump water up behind huge earthen dams – as are planned on the Columbia Hills – so that it can be released and run through generators when transmission lines are open will add to the expenses of wind

power. In the end, wind power will be so expensive that rate payers will not be able to afford it. The excessive expenses associated with wind power, combined with recent revelations of wind power corruption, are opening the eyes of people all over the NW. What will happen to wind power, and the extensive infrastructure that is being built to support it, if the citizens of Oregon and Washington decide to vote out the requirement that energy providers must incorporate wind energy in their portfolio? You had better give a lot of thought to that question, because in all likelihood that is where we are headed.

How can wind power continue on as such a powerhouse if it is economically infeasible? The answer is that the suppliers and builders are taking their profits off of the front end. That is the only place in the process of wind power development that is economically viable. They receive the tax credits, they are protected by the warranties and they get paid while the projects are relatively new and in good shape. The builders realize that the front end is the only place to be on these projects. That is why they usually sell the project even as it is being built. They realize the dangers of long term commitment. This is why we doubt SDS's claim that they want to diversify their holdings. If SDS is as smart as we believe them to be, they will sell and collect a handy monthly payment until the buyer pays off the loan, and then SDS will continue receiving monthly payments for each machine on their property.

Wind power promoters like to denigrate the sites of their proposed projects, and the Whistling Ridge proposal is no different. The DEIS states the site is commercial forest lacking native plants. (I.9) Perhaps SDS shipped those trees in from some other bio-region, but we doubt it. In fact, it is likely that just about all the plants on the site are native, and that they serve as habitat for animals and birds.

The location of the site is significant. The site is on a ridgeline bordered to the east by the White Salmon Wild and Scenic River and to the south by the Columbia River Gorge National Scenic Area. These rivers and the ridgeline the project would be on are known areas frequented by raptors, including bald and golden eagles. Raptors are known to be susceptible to wind power blade strike because they are looking down for prey. Just up the ridge and to the north is DNR land that has been identified by the DNR as significant habitat for spotted owls. DNR recently "forgot" that fact and were forging an agreement with SDS that was to allow them to extend their wind power project onto those public lands. It seems the development on public lands was necessary to make the proposal on the SDS land economically viable. Then members of the public, including CGAS, reminded DNR of their commitment to the spotted owl, and the SDS project on DNR lands was dropped. We believe this to be yet another example of how this powerful corporation seeks to manipulate agencies.

Would the proposed Whistling ridge wind power project negatively impact the nearby spotted owl habitat on DNR lands? We believe it would. If the project was built of SDS lands, would

the fact that a project is up and running so close to the DNR spotted owl protection zone make that zone less desirable as critical habitat? We believe that argument could be made. Would the fact that SDS has already claimed an economic need for the DNR site, and the fact that infrastructure like transmission lines and roads would be close by encourage SDS to bid once more for the public lands site? We believe they would. Is this how important bird habitat is encroached upon or lost? Yes, this is exactly how it happens.

The bird studies we have reviewed over the years are typically faulty or the conclusions are the opposite of what the information actually suggests. This is not just our opinion, it is the opinion of Washington Department of Fish and Wildlife and the Fish and Wildlife Service, both of whom have repeatedly been extremely critical of the bird "studies" for wind power proposals. Some of those studies have recently come home to roost in Klickitat County immediately to the east of the proposed project site. WDFW recently placed the first monitor on an eagle and it was immediately killed by a wind machine to become the first (known) eagle to be killed by a wind machine in the NW. Quite a coincidence! Then an independent study was done to determine bird kills on a Klickitat County wind power project, and the result was that eight to sixteen times more birds were killed than predicted. Since bird kill projections are important to securing permits for projects, we believe this to be the tip of the iceberg on deflated bird kill projections. We suggest that you increase the projected kills by eight to sixteen times. This means that most projects would not be allowed.

The DEIS summary emphasizes that no hazardous waste would be produced by the project. Actually there is a significant release of hazardous wastes by each machine. Lubricants run down the blades and are flung for quite a distance. Solvents and other cleaning materials are used to de-grease the tower and blades, and these hazardous wastes go right into the ground. When the first wind machines (the MOD-II's) were built on the Goodnoe Hills section of the Columbia Hills (and later removed due to engineering failure) Natives reported that they could no longer gather traditional herbs and roots on the site due to pollution by lubricants and solvents. While we have no authority to speak for Natives (nor would we attempt to do so), we do believe that we can report on what is public knowledge.

Proponents dismiss wind power noise, but we know that people do not like the noise. They may seem quiet to a casual listener passing by, but it is different if you live within the sound of the machines and must listen to them every day and every night. Sometimes they are noisier than other times, sometimes they can be very noisy, and as they age they can become extremely noisy. Industrial noise is significant in rural areas because people are used to hearing natural noises. When industrial noise is introduced the human ear goes right to it and experiences it as an annoyance. When industrial noise is heard in the country, where it is mostly unexpected, it is experienced as a 100% increase in noise. This fact is not reflected in

noise studies that tend to dismiss wind power noise as insignificant, and also to dismiss the impacts. It may be of interest to you that nearby Klickitat County had to raise the noise level allowed in rural areas twice before wind power was determined to be within allowed limits. To us, this suggests that noise is a genuine issue.

Washed out photographs and simulations of wind towers may lead you to conclude that the visual impact of wind power is insignificant. Once again, the studies do not reflect how the human mind actually works. First of all, the human eye is drawn to movement, and the wind tower blades are huge and moving. At night the blinking lights attract your attention. Then there is the problem of size. The human eye is attracted to size, especially on ridgelines. The photographs and simulations simply do not capture the actual human experience when these wind machines come into view. The studies diminish the impact where the actual experience is that the machines command your attention, even when you try to ignore them. It becomes difficult to see the natural environment when those big towers move and blink at you, and the natural environment is what most people living in the county are there to enjoy. It should be no surprise that rural people do not appreciate their county views turned into industrial zones, neither should it surprise us that proponent studies will seek to diminish the significance of this fact.

Wind power proponents dismiss the notion that wind power projects might decrease the value of people's properties. In fact, they claim that studies show that the value of your land does not decrease when wind power moves into your neighborhood. Perhaps if you are a large land owner and it is likely that you will be approached about having a wind farm on your property, the value of your land might not decrease. But if you own a smaller property that is or could become residential property, the value of your property is likely to diminish, especially if your property is view property, as most of the residential property within sight of this proposal is. In a discussion with a Klickitat County assessor we learned that they are having a difficult time estimating land values in areas where new wind power development has occurred because there have been no new sales in those areas. We have been told that at least one man let the county take his land – not because he could not pay the taxes – but because he could not sell his land and was tired of paying taxes on land that he could not sell. If you cannot sell your property for any price, how much is it worth? Can you really believe the notion that wind towers would not negatively impact residential properties within sight of wind power towers? We just do not believe that a reasonable person could come to that conclusion, unless you were paid to do so.

Proponents like to tout the long list of mitigation measures that they must comply with. After reviewing many such lists we have been hard pressed to discover how any of the mitigation measures will save even one bird. The hard fact is that mitigation is a fraud. There is no

mitigation for improperly sited wind power projects, and any project sited in or near the Gorge is an improperly sited project. The Gorge and the Cascades are major bird flyways, and projects here are bound to have major impacts, especially as cumulative affects set in, as we believe they already are. Also, we have noticed that mitigation measures are often worded in a manner that allows the proponent the choice of whether or not the mitigation measure will actually be implemented. And, we have noticed that proponents often ask that mitigation measures be quietly withdrawn once the permit is in hand, and very often that is exactly what happens.

Decommissioning of this project is a huge environmental issue and will involve a huge expense, and yet the DEIS contains no meaningful discussion about how this will actually occur. No plan is offered for project decommissioning, no commitments are made, let alone secured. How can the environmental impacts of "back end" project decommissioning be considered without a meaningful discussion about who will do what, and when? In fact, no environmental impacts of decommissioning can be considered without this information. We believe decommissioning is ignored because the proponent does not want to pay their fair share of decommissioning fees. Typically proponents "flip" (sell) their projects as soon as they can, but they retain legal right to the project until the buyers make their last payment. The proponents like to put off consideration of decommissioning plans until the buyer becomes the responsible party. This may be good for the proponent, but it is poor planning because it shifts decommissioning responsibilities to the back end of the project, where the profit margin is decreasing and the expenses are rising. If this is allowed to continue, it is very likely that the public will get stuck with the decommission expenses of thousands of NW wind power machines. This should not be allowed to occur. Bonding should be secured that will be sufficient to cover all of the decommissioning expenses and the bulk of the payments should be paid in the first half of the machines life, when the profits are the highest, and the expenses are the lowest.

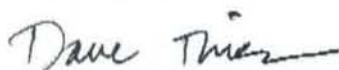

If you still believe that the wildlife agencies will step in to prohibit significant and unnecessary loss of birds to NW wind power, then considers the following true account that demonstrates what is actually occurring. National Audubon Society has designated the Columbia Hills in Klickitat County an Important Bird Area. The Important Bird Area program is National Audubon's plan for saving critical bird habitat areas with proven significant bird populations. It is not easy to secure the IBA designation, the review process is strictly run by NAS bird scientists. Federal and State wildlife agencies have repeatedly warned the wind power industry away from developing on the Columbia Hills, but even though they know the significance of the area for birds these agencies are allowing border to border wind power development of the Columbia Hills Important Bird Area. The next project for the Columbia Hills would involve the creation of huge holding dams that would allow wind power to store energy during periods that transmission lines are full. We thought things could not get worse on the Hills, but these man-

made lakes would prove us wrong when they attract even more birds to their doom. The agencies are failing in their duties to protect huge areas of very significant habitat, and they know it. And the wind power industry knows that if they can develop in this IBA, they can develop just about anywhere. The much touted claim that proper siting is the key to green wind power is just another fraud.

BPA shares in the responsibility for the wind power fiasco we are creating. Early on Columbia Gorge Audubon Society, a representative from Audubon Washington and Native spokesmen met with BPA representatives, and we pleaded with them to plan for wind power development and to determine which areas would be suitable and which would not be suitable. But we were snubbed and it became clear that wind power development would be allowed to proceed without any environmental planning by BPA. Now we are reaping the whirlwind of that decision, and BPA just continues to allow the situation to get worse. BPA has responsibilities to assure that the power they transmit is coming from responsibly sited projects that are not unnecessarily killing significant numbers of birds. How can BPA claim that power from the Columbia Hills IBA is environmentally responsible power? They cannot. Federally protected birds are being killed, and BPA looks the other way.

We beg you to not add yet another bird killing wind energy "farm" to the thousands of machines already up. The only good that would come out of this is more money for a few people who have more money than they know what to do with; the damages and the costs would be equally distributed among the rest of us. It is time – past time really – to say no to yet another wind power project, and to place a moratorium on further wind power development until the environmental impacts of so many projects and machines can be properly considered.

Sincerely,

EVALUATION COUNCIL

COMMENT LETTER 257

Stephen Posner
Energy Facility Site Manager
Washington EFSEC
905 Plum Street SE – Third Floor
Olympia, WA 98504-3172

Dear Mr. Posner:

Thank you for the opportunity to review the Draft environmental Impact Statement (DEIS) for the Whistling Ridge Energy Project.

The project has many positive features and will make a positive contribution to the region. The National Scenic Area supports renewable energy development and believes that the Whistling Ridge Energy Project will be enhanced with consideration given to the scenic values associated with the Columbia River Gorge National Scenic Area (CRGNSA).

As described in your analysis on Table 3.9.2 (Viewpoints 13 and 14) the Columbia River gorge has moderately high to high levels of visual quality. Visitors and residents within the gorge place a high value on scenic quality and viewer sensitivity is substantially higher than described in the DEIS. As such, I would ask that you consider potential scenic effects throughout project design and implementation. Considerations such as turbine placement, color and size through project design and implementation will help to ensure scenic quality, as viewed from within the CRGNSA, will be maintained and/or scenic modifications minimized.

Sincerely,

DANIEL T. HARKENRIDER
Area Manager

Subject: Wind Energy Letter from the Port of Vancouver
Attachments: Wind Energy Letter.pdf

To Whom It May Concern:

Please see attached letter in support of wind energy business. This is forwarded at the request of Jason Spadaro of the SDS Lumber Company.

Port of Vancouver USA

August 18, 2010

To Whom It May Concern:

The Port of Vancouver is an active participant in regional and national associations promoting alternative energy, particularly wind energy. We support alternative energy credit programs and state and national alternative energy standards. In addition, the port advocates for the expansion of the wind energy grid in the Pacific Northwest and nationwide.

Over the last five years wind energy cargoes have contributed to the diversification of cargoes at the Port of Vancouver, expanding overall revenues and stabilizing income through the tough economic times. Two large mobile harbor cranes acquired during this time have greatly enhanced the port's ability to attract and support the growth of the wind energy logistics trade. In 2009 alone the port handled 2,700 pieces of wind energy business, generating 55,897 labor hours.

Wind energy business means jobs and economic return for our community in southwest Washington. For this reason, the Port of Vancouver intends to continue its active role in the receipt and delivery of component parts for the wind energy business well into the future.

Sincerely,

Larry Paulson
Executive Director

Attached is Mid-Columbia Economic Development District's letter regarding renewable energy projects. As requested, we are sending this along.

"Mid-Columbia Economic Development (MCEDD) supports the utilization of our renewable energy assets to diversify our economy and stabilize our economic base. We support development of wind, solar, biomass, geothermal, and other renewable energy projects in our region which are designed in a manner consistent with local regulations.

MCEDD has supported the creation of the Columbia Gorge Bi-State Renewable Energy Zone as a means to engage in a cross-jurisdiction, inter-agency, bi-state collaborative approach to renewable energy development. In establishing the Columbia Gorge Bi-State Renewable Energy Zone, we took into consideration a variety of factors, all linked by the regional economy. These include the renewable energy resource itself (wind, solar, hydro, geothermal, biofuels, and biomass), financial investment in those resources by renewable energy industry, existing transportation networks (roads, rail, river and air), high-speed telecommunications networks, education and workforce training capacity, public utilities, resident workforce, transmission capacity, industrial lands base, and quality of life. The economic benefits of renewable energy projects can provide a base for connecting all these components into a networked system that would generate familywage employment in a rural, traditionally depressed economy"

SUBJECT: Whistling Ridge Energy Project Draft Environmental Impact Statement: EFSEC Application 2009-01

Dear Mr. Posner,

The Washington Department of Fish and Wildlife (WDFW) has reviewed the above-referenced documents and offer the following amended comments at this time. This letter replaces the previously submitted August 27th, letter from WDFW. Other comments may be offered as the project progresses.

WDFW has carefully reviewed the habitat evaluation prepared by the applicant. The Whistling Ridge Wind Resource Area (WRWRA) is a forested site managed for over 100 years. It is not in a natural or native coniferous forest condition. The pre-project assessment and avian/bat use surveys are consistent with standard protocols utilized throughout the U.S. and are consistent with the WDFW Wind Power Guidelines (WDFW 2009). Because the relationship between avian use and mortality has been reasonably consistent across other habitat types and locations, it is likely that the relationship between avian use and mortality would be similar to that evaluated in other projects. While no similar data exist for constructed wind energy projects in managed coniferous forest habitats that might help inform impact predictions for Whistling Ridge, as we previously confirmed in the attached letters, WDFW confirms that these data represent the best available science for predicting avian impacts at Whistling Ridge. Therefore, if the WRWRA is constructed, WDFW anticipates the opportunity to better understand the relationship between wind energy development in western coniferous forests and wildlife response.

WDFW would like to emphasize that fluctuations in raptor populations, as well as other avian species, may result in greater mortality than what is predicted in the *Final Report*. As a result, operational controls may be necessary to address avian mortality that exceeds predicted mortality.

In closing, WDFW would like to acknowledge that the applicant has submitted a preliminary mitigation plan that we are currently reviewing. This mitigation proposal was developed consistent with the WDFW Wind Power Guidelines at a 2:1 replacement ratio. The preliminary mitigation plan encompasses approximately 100 acres in Klickitat County 12 miles due east of the project site. The mitigation site is forested with Oregon White Oak with some Douglas fir and Ponderosa pine and shares a portion of its northern boundary with 40 acres of WDNR land and. This mitigation site provides habitat for several PHS entries including Western gray squirrels. Additionally, the site includes the fish-bearing Silva Creek, a tributary to the Klickitat River.

We look forward to working with the applicant as this project moves forward.

Sincerely,

SUBJECT: Preliminary Draft Environmental Impact Statement (DEIS), Whistling Ridge Energy Project

Dear Ms. Chaney:

The Washington Department of Fish and Wildlife (WDFW) has reviewed the above reference document and offers the following comments at this time. Other comments may be offered as the project progresses.

Overall, the Preliminary DEIS is consistent with the 2009 WDFW Wind Power Guidelines, including early and regular consultation, as well as avian and bat studies, habitat characterization, and impact analysis.

WDFW is in agreement with the following excerpt from *Section 3.0 Affected Environment*:

“For permanent impacts to vegetation and habitat, the Section 8.2 of the Wind Power Guidelines (WDFW 2009) recommend mitigation be tailored to specific classifications. The project is located within the classification for “Forestry,” which are those commercial forested areas defined and regulated under the Forest Practices Act. Minimization of conversion of forested areas is suggested, and consultation with WDFW is the only recommended mitigation. No form of acquisition, restoration or conservation of lands is suggested by the guidelines.”

However, we would like to further discuss the proposal as it relates to the table in Section 8.2 of the 2009 WDFW Wind Power Guidelines mitigation for both temporary and permanent impacts.

We support the two-year minimum post-construction avian mortality study, as well as the development of a Technical Advisory Committee (TAC)

WDFW is in general agreement with the proposed commercial forestry operations within the vicinity of each turbine as described in Section 3.0 ("turbine timber buffer") and would like to offer the following interpretation.

According to Section 3.0, "Vegetation surrounding each turbine would be managed according to the following specifications:

- A circular area extending 50 feet from each turbine tower base would be harvested and graveled
- From 50 feet to 150 feet from the base of the turbine towers, tree heights would be limited to 15 feet above the elevation of the base of the turbine
- From 150 feet to 500 feet from the base of the turbine towers, tree height would be limited to 50 feet above the turbine base within an area formed by a 90 degree arc centered on the ordinary downwind direction."

From this, we conclude that within a diameter of 100 to 300 feet surrounding each turbine, tree heights would be limited to 15 feet, and from a diameter of 300 to 500 feet, tree heights would be limited to 50 feet, but only within a 90-degree arc on either side of the turbine aligned with the direction of the prevailing wind. The other 90-degree arc on either side of the turbine perpendicular with the direction of the prevailing wind will essentially be unchanged habitat (i.e. existing commercial forest). We are interested in how this type of habitat and commercial forest management in the immediate vicinity of operating wind turbines will or will not affect the avian and bat mortality. We look forward to working with Whistling Ridge through the TAC to address this issue and cooperatively develop management strategies, if needed, to reduce avian and bat mortality.

Thank you for the opportunity to review the Preliminary DEIS and offer these comments.

Sincerely,

September 22, 2009

Mr. Jason Spadaro
SDS Lumber Company
Post Office Box 266
Bingen, Washington 98605

Dear Mr. Spadaro:

Thank you for your letter dated August 21, 2009, concerning the Whistling Ridge Energy Project. You requested clarification on several specific issues raised in correspondence from the Washington Department of Fish and Wildlife (WDFW) on May 14, 2009, and June 11, 2009.

You are concerned that the letters from WDFW provided an incomplete and inaccurate analysis of wildlife data that has been collected for the proposed project since 2003, and that our conclusions regarding potential project impacts to birds and bats are unwarranted and unsubstantiated. It is my goal to provide clarification to our previous letters that will allow you to continue to develop your proposal for this wind power project, at Whistling Ridge, using our Wind Power Guidelines.

You raised concern of how receptive WDFW is to Best Available Science (BAS) and its application to the project. WDFW views BAS as an integral component of your project assessment, therefore, we will consider all current and future BAS related to your existing and future proposals and review the findings objectively. Your supplemental information concerning goshawks, spotted owls and other avian species and Western grey squirrel use of the project site that you included in your August 21 letter, fits this definition of BAS. We will use this information to refine our analysis of the impacts of this project. Our analysis will focus on current habitat conditions and species presence. We will also treat any additional information you may submit in the future as BAS.

I acknowledge projections of post-construction bat mortalities that we made, that were based on pre-construction activity levels, are not necessarily a good predictor of numbers of post-construction mortalities; they only provide an indicator of relative risk, as documented at other wind farms around the country. Pre-construction activity levels are also important as a

Jason Spadaro
September 22, 2009
Page 2

guide to avoid and minimize collisions (post-construction) through the placement of the wind turbines, and to assess the potential length of post-construction fatality studies.

I am encouraged by your commitments to adaptive management for this project and am certain we will agree on a plan that will ensure that avoidance, minimization, and/or mitigation goals are met once the project is completed.

I look forward in working with you to get on track and to continue towards building a collaborative working relationship and to assist you in developing a proposal for the Whistling Ridge Energy Project that will be protective of wildlife.

Sincerely,

ENERGY FACILITY SITE
EVALUATION COUNCIL

**Energy Facility Site Evaluation Council
905 Plum Street SE
P.O. Box 43172
Olympia, WA 98504-3172**

August 20, 2010

Dear Council Members/BPA Representatives:

We appreciate that EFSEC and BPA recognized that more time was warranted in relation to public comment on the Whistling Ridge DEIS. We purposely limited our attention to the noise element portion of the DEIS and have continued to thoroughly review and research available information. Extensive and thorough perusal has deepened our concern and substantially confirmed the original deficiencies and suggestions we identified in our written and verbal testimonies dated June 16th and July 15th of 2010. We stand strongly by our original analysis.

The DEIS is a poorly constructed house of smoke and mirrors... 'don't look there, just over here', thus sadly misleading the public. It appears that rather than 'sleight of hand' it's 'sleight of facts'.

We offer the following DEIS statements as some specific examples of additional deficiencies which are amply contradicted by current research.

**"Low frequency sound typically ranges from 100 Hz to 20 Hz..." (DEIS p. 3-119)
Multiple sources indicate the upper range of low frequency noise is 200 Hz:
Leventhall (2004)
Waye (2004)
Kamperman and James (2008)
Jung et al (2008)
Thorne (2009)
And even the DEIS cited British Wind Energy Association (2006)**

**"These wind turbines are not a source of substantial low frequency noise." (DEIS p. 3-115)
"... low frequency noise is not anticipated to be an issue for this project." (DEIS p. 3-130)
"... modern turbine designs have been modified to reduce or eliminate low frequency sound." (DEIS p. 3-131)**

These statements are thoroughly contradicted by the following current research, journal articles and expert opinion, demonstrating that there is

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

significant low frequency noise emission by the upwind turbines slated for this project:

Jung et al (2008)

Thorne (2009 & 2010)

Punch et al (2010)

Kamperman and James (2008)

James (2010)

And even the DEIS cited van de berg (2006)

“Research studies of low-frequency noise emissions from wind turbines have determined that low frequency noise is a function of the wind itself... low frequency modulation of audible sound does not imply the presence of actual low frequency sound or infrasound... “ (DEIS p. 3-130)

The interaction of the blade with the wind creates low frequency noise.

“... the BPF (blade passing frequency) noise of modern large wind turbines belongs to infrasound and low-frequency noise.”

“... the low-frequency noise of ... wind turbines in the frequency range over 30 Hz is found to be audible (or capable of being felt) by the average person and would probably lead to psychological complaints from ordinary adults.” –Jung et al (2008)

“The extremely low-frequency nature of wind-turbine noise, in combination with the fluctuating blade sounds, also means that the noise is not easily masked by other environmental sounds.” –Punch et al (2010)

“The blade passage frequency of this “swoosh” is only a temporal modulation of sound and should not be confused with low frequency sounds.” (DEIS p. 3-130)

“Sound generated by wind turbines has particular characteristics and it creates a different type of nuisance compared to usual urban, industrial, or commercial noise. The interaction of the blades with air turbulences around the towers creates low frequency and infrasound components, which modulate the broadband noise and create fluctuations of sound level.” –Soysai and Soysai (2007)

This “only temporal modulation of sound” (infra-sound, low-frequency, and higher frequencies) is the factor that makes wind turbine noise far more disruptive and intrusive than smooth noise. –Thorne (2009)

Leventhall (2006) (your cited expert) states “A time varying sound is more annoying than a steady sound of the same average level” and should be “accounted for by reducing the permitted level of wind turbine noise.”

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

“... environmental noise effects are typically limited to subjective impacts (e.g., annoyance, nuisance, dissatisfaction) and activity interference (i.e., impacts to sleep, speech, and learning.). Despite attempts by prominent acousticians to quantify the association between measurable sounds levels and corresponding reactions of annoyance and dissatisfaction, there is no way to measure the subjective impacts of noise. Further, the aforementioned variability of individual human sensitivity and/or tolerance to noise defies creation of a common standard.” (DEIS p. 3-115)

“Scientific articles suggest that low frequency noise does not pose a health risk (Leventhall 2006). There may, however, be some correlation between an individual receptor’s psychological sensitivity to the noise source (like or dislike for the noise source) and complaints regarding discomfort from that noise source. These are sometimes associated with complaints regarding sleep disturbance. Because sensitivity to noise can be influenced by such psychological factors and can subjectively be deemed significant by an affected individual, regardless of measurable frequency or amplitude level, it is difficult to quantify these impacts or to impose mitigation.” (DEIS p. 3-130)

The cited article by Leventhall addresses primarily infrasound, noting the difference between infrasound and low frequency. It presents, however, no scientific evidence to prove that wind turbine low-frequency noise poses no health risk. Conversely...

“ There is no medical doubt that audible noise such as emitted by modern upwind industrial wind turbines sited close to human residences causes significant adverse health effects... This is settled medical science.”

“There are many peer-reviewed studies showing that infra and low frequency sound can cause adverse health effects, especially when dynamically modulated. Modern upwind industrial scale turbines of the types now being located in rural areas of North America require study. The extent to which infra and low frequency noise from wind turbines inside or outside homes causes direct adverse effects upon the human body remains an open question.” –The Society for Wind Vigilance (2010)

“There is ample scientific evidence to conclude that wind turbines cause serious health problems for some people living nearby.”

“The reported health effects, including insomnia, loss of concentration, anxiety, and general psychological distress are as real as physical ailments, and are part of accepted modern definitions of individual and public health.”

“The reports that claim that there is no evidence of health effects are based on a very simplistic understanding of epidemiology and self-serving definitions of what does not count as evidence. Though those reports probably seem convincing prima facie, they do not represent proper scientific reasoning and in some cases the conclusions of those reports do not even match their own analysis.” –Phillips (2010)

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

“In weighing the evidence, I find that, on the one hand there is a large number of reported cases of sleep disturbance and, in some cases, ill health, as a result of exposure to noise from wind turbines supported by a number of research reports that tend to confirm the validity of the anecdotal reports and provide a reasonable basis for the complaints. On the other, we have badly designed industry and government reports which seek to show that there is no problem. I find the latter unconvincing.” (emphasis added) – Hanning (2009)

Years of experience and the current research of Dr. Thorne (2010) compels his opinion that noise from wind turbine farms, if placed too close to a residence (within 2000 meters), does pose quantifiable risks for potential adverse health effects.

“There is increasingly clear evidence that audible and low-frequency acoustic energy from these turbines is sufficiently intense to cause extreme annoyance and inability to sleep or disturbed sleep in individuals living near them.” –Punch et al (2010)

The DEIS statements that “there is no way to measure the subjective impacts of noise”, and “it is difficult to quantify these impacts or to impose mitigation” lack credibility. The EPA standards were based upon measurements of the subjective impacts of noise. The European Union has invested considerable resources in investigating the impact of wind turbine noise. Current research by Pederson (2007) is devoted to determining subjective impact from various levels of wind turbine noise. The Thorne Ph.D. thesis 2009, Assessing Intrusive Noise and Low Amplitude Sound, specifically addresses this topic.

While it may require effort to determine subjective impact and annoyance, to suggest that it is impossible to mitigate for this flies in the face of all the scientific work that has been and is currently being done to mitigate the impact of highway, rail, airline and now wind turbine noise. Need we state the obvious? To mitigate, increase the setback distances so that the most sensitive individuals (typically young children and aging adults) are likely to be unaffected.

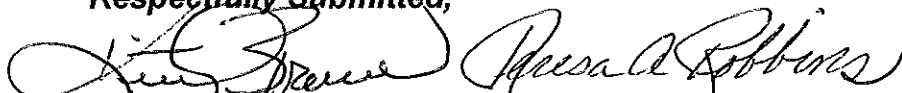

To provide for the welfare, health and an adequate margin of safety for people, Horonjeff (2010) forwards a well-researched argument based upon current evidence of adverse impact in rural areas. Reduce allowable decibel levels in a rural environment by 15 dB from that allowed in urban and/or suburban areas. This would be considered as recommended practice in the current American National Standard (ANSI S12.0-2005/Part 4). Another approach he recommends to achieve an adequate margin of safety would be to establish set back distances of 1.5 to 2 miles.

**Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins**

To determine necessary setbacks, the prediction models need to be based upon best available science and technology. The inadequacies of the prediction model used for the DEIS we identified in our earlier testimony are validated in Chapter 6 of Thorne's 2009 dissertation. It indicates that wind turbines need to be considered as a complex line source and further, that using the hub height in the prediction models (as done in the DEIS) can under predict by 7 decibels. He demonstrates that using broad lines for contours (rather than the fine line contours which are presented in the DEIS) presents a more complete picture of the probable impact. He also quantifies adjustments that must be made to account for other factors, such as 'in-phase beats', and fluctuations from two or more turbines (factors that significantly increase decibel levels experienced over and above the predicted levels). Such factors need to be built into the predictive calculations. These issues are also articulated in his Noise Impact Assessment Report Waubra Wind Farm. –Thorne 2010

A revised DEIS needs to be based on best available science... not the same old template that obscures reality and significantly underestimates the adverse impact. Continuing to turn a blind eye to the growing and ample body of scientific and medical evidence would simply be unacceptable and potentially tragic.

Respectfully Submitted,

Olympia, WA 98504-3172

August 20, 2010

Dear Council Members/BPA Representatives :

We appreciate that EFSEC and BPA recognized that more time was warranted in relation to public comment on the Whistling Ridge DEIS. We purposely limited our attention to the noise element portion of the DEIS and have continued to thoroughly review and research available information. Extensive and thorough perusal has deepened our concern and substantially confirmed the original deficiencies and suggestions we identified in our written and verbal testimonies dated June 16th and July 15th of 2010. We stand strongly by our original analysis.

The DEIS is a poorly constructed house of smoke and mirrors... 'don't look there, just over here', thus sadly misleading the public. It appears that rather than 'sleight of hand' it's 'sleight of facts'.

We offer the following DEIS statements as some specific examples of additional deficiencies which are amply contradicted by current research.

“Low frequency sound typically ranges from 100 Hz to 20 Hz...” (DEIS p. 3-119)
Multiple sources indicate the upper range of low frequency noise is 200 Hz:
Leventhall (2004)
Waye (2004)
Kamperman and James (2008)
Jung et al (2008)
Thorne (2009)
And even the DEIS cited British Wind Energy Association (2006)

“These wind turbines are not a source of substantial low frequency noise.” (DEIS p. 3-115)
“... low frequency noise is not anticipated to be an issue for this project.” (DEIS p. 3-130)
“... modern turbine designs have been modified to reduce or eliminate low frequency sound.” (DEIS p. 3-131)

These statements are thoroughly contradicted by the following current research, journal articles and expert opinion, demonstrating that there is

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

significant low frequency noise emission by the upwind turbines slated for this project:

Jung et al (2008)

Thorne (2009 & 2010)

Punch et al (2010)

Kamperman and James (2008)

James (2010)

And even the DEIS cited van de berg (2006)

“Research studies of low-frequency noise emissions from wind turbines have determined that low frequency noise is a function of the wind itself... low frequency modulation of audible sound does not imply the presence of actual low frequency sound or infrasound... “ (DEIS p. 3-130)

The interaction of the blade with the wind creates low frequency noise.

“... the BPF (blade passing frequency) noise of modern large wind turbines belongs to infrasound and low-frequency noise.”

“... the low-frequency noise of ... wind turbines in the frequency range over 30 Hz is found to be audible (or capable of being felt) by the average person and would probably lead to psychological complaints from ordinary adults.” –Jung et al (2008)

“The extremely low-frequency nature of wind-turbine noise, in combination with the fluctuating blade sounds, also means that the noise is not easily masked by other environmental sounds.” –Punch et al (2010)

“The blade passage frequency of this “swoosh” is only a temporal modulation of sound and should not be confused with low frequency sounds.” (DEIS p. 3-130)

“Sound generated by wind turbines has particular characteristics and it creates a different type of nuisance compared to usual urban, industrial, or commercial noise. The interaction of the blades with air turbulences around the towers creates low frequency and infrasound components, which modulate the broadband noise and create fluctuations of sound level.” –Soysai and Soysai (2007)

This “only temporal modulation of sound” (infra-sound, low-frequency, and higher frequencies) is the factor that makes wind turbine noise far more disruptive and intrusive than smooth noise. –Thorne (2009)

Leventhall (2006) (your cited expert) states “A time varying sound is more annoying than a steady sound of the same average level” and should be “accounted for by reducing the permitted level of wind turbine noise.”

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

“... environmental noise effects are typically limited to subjective impacts (e.g., annoyance, nuisance, dissatisfaction) and activity interference (i.e., impacts to sleep, speech, and learning.). Despite attempts by prominent acousticians to quantify the association between measurable sounds levels and corresponding reactions of annoyance and dissatisfaction, there is no way to measure the subjective impacts of noise. Further, the aforementioned variability of individual human sensitivity and/or tolerance to noise defies creation of a common standard.” (DEIS p. 3-115)

“Scientific articles suggest that low frequency noise does not pose a health risk (Leventhall 2006). There may, however, be some correlation between an individual receptor’s psychological sensitivity to the noise source (like or dislike for the noise source) and complaints regarding discomfort from that noise source. These are sometimes associated with complaints regarding sleep disturbance. Because sensitivity to noise can be influenced by such psychological factors and can subjectively be deemed significant by an affected individual, regardless of measurable frequency or amplitude level, it is difficult to quantify these impacts or to impose mitigation.” (DEIS p. 3-130)

The cited article by Leventhall addresses primarily infrasound, noting the difference between infrasound and low frequency. It presents, however, no scientific evidence to prove that wind turbine low-frequency noise poses no health risk. Conversely...

“ There is no medical doubt that audible noise such as emitted by modern upwind industrial wind turbines sited close to human residences causes significant adverse health effects ... This is settled medical science.”

“There are many peer-reviewed studies showing that infra and low frequency sound can cause adverse health effects, especially when dynamically modulated. Modern upwind industrial scale turbines of the types now being located in rural areas of North America require study. The extent to which infra and low frequency noise from wind turbines inside or outside homes causes direct adverse effects upon the human body remains an open question.” –The Society for Wind Vigilance (2010)

“There is ample scientific evidence to conclude that wind turbines cause serious health problems for some people living nearby.”

“The reported health effects, including insomnia, loss of concentration, anxiety, and general psychological distress are as real as physical ailments, and are part of accepted modern definitions of individual and public health.”

“The reports that claim that there is no evidence of health effects are based on a very simplistic understanding of epidemiology and self-serving definitions of what does not count as evidence. Though those reports probably seem convincing prima facie, they do not represent proper scientific reasoning and in some cases the conclusions of those reports do not even match their own analysis.” –Phillips (2010)

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

“In weighing the evidence, I find that, on the one hand there is a large number of reported cases of sleep disturbance and, in some cases, ill health, as a result of exposure to noise from wind turbines supported by a number of research reports that tend to confirm the validity of the anecdotal reports and provide a reasonable basis for the complaints. On the other, we have badly designed industry and government reports which seek to show that there is no problem. I find the latter unconvincing.” (emphasis added) – Hanning (2009)

Years of experience and the current research of Dr. Thorne (2010) compels his opinion that noise from wind turbine farms, if placed too close to a residence (within 2000 meters), does pose quantifiable risks for potential adverse health effects.

“There is increasingly clear evidence that audible and low-frequency acoustic energy from these turbines is sufficiently intense to cause extreme annoyance and inability to sleep or disturbed sleep in individuals living near them.” –Punch et al (2010)

The DEIS statements that “there is no way to measure the subjective impacts of noise”, and “it is difficult to quantify these impacts or to impose mitigation” lack credibility. The EPA standards were based upon measurements of the subjective impacts of noise. The European Union has invested considerable resources in investigating the impact of wind turbine noise. Current research by Pederson (2007) is devoted to determining subjective impact from various levels of wind turbine noise. The Thorne Ph.D. thesis 2009, Assessing Intrusive Noise and Low Amplitude Sound, specifically addresses this topic.

While it may require effort to determine subjective impact and annoyance, to suggest that it is impossible to mitigate for this flies in the face of all the scientific work that has been and is currently being done to mitigate the impact of highway, rail, airline and now wind turbine noise. Need we state the obvious? To mitigate, increase the setback distances so that the most sensitive individuals (typically young children and aging adults) are likely to be unaffected.

To provide for the welfare, health and an adequate margin of safety for people, Horonjeff (2010) forwards a well-researched argument based upon current evidence of adverse impact in rural areas. Reduce allowable decibel levels in a rural environment by 15 dB from that allowed in urban and/or suburban areas. This would be considered as recommended practice in the current American National Standard (ANSI S12.0-2005/Part 4). Another approach he recommends to achieve an adequate margin of safety would be to establish set back distances of 1.5 to 2 miles.

Additional Comments, Whistling Ridge DEIS
Keith Brown, Ph.D. and Teresa Robbins

To determine necessary setbacks, the prediction models need to be based upon best available science and technology. The inadequacies of the prediction model used for the DEIS we identified in our earlier testimony are validated in Chapter 6 of Thorne's 2009 dissertation. It indicates that wind turbines need to be considered as a complex line source and further, that using the hub height in the prediction models (as done in the DEIS) can under predict by 7 decibels. He demonstrates that using broad lines for contours (rather than the fine line contours which are presented in the DEIS) presents a more complete picture of the probable impact. He also quantifies adjustments that must be made to account for other factors, such as 'in-phase beats', and fluctuations from two or more turbines (factors that significantly increase decibel levels experienced over and above the predicted levels). Such factors need to be built into the predictive calculations. These issues are also articulated in his Noise Impact Assessment Report Waubra Wind Farm. -Thorne 2010

A revised DEIS needs to be based on best available science... not the same old template that obscures reality and significantly underestimates the adverse impact. Continuing to turn a blind eye to the growing and ample body of scientific and medical evidence would simply be unacceptable and potentially tragic.

COMMENT LETTER 262

Aug. 22, 2010

AUG 25 2010
**ENERGY FACILITY SITE
EVALUATION COUNCIL**

RE: Application No. 2009-1
Whistling Ridge Energy LLC

Dear EFSEC,

My name is Barbara Robinson. I live in the Columbia Gorge in Rowena, about 7 miles west of The Dalles, in OR. I will not see the proposed wind towers from my house. I strongly favor wind farms in eastern OR and WA, where the population density is low and the ranchers who live near the towers benefit financially. I frequently drive Wasco to Condon and enjoy seeing the towers. But I strongly oppose towers that are highly visible from National Parks and Scenic Areas, and other places valued and visited by many for their natural beauty, because wind towers are visually dominant and change the landscape. The specific thing that stimulated this letter was seeing a photo simulation of what the wind towers would look like from I-84 in a mailing sent to Gorge residents by wind farm advocates. I was quite shocked at how big and conspicuous they were, even in the advocate's literature. I am writing to oppose the Whistling Ridge wind farm, for the following reasons:

1. There are many appropriate places for Wind Farms in eastern WA where wind towers are currently going in, and many can be added. The big picture is that there is no pressing energy reason to put Wind Towers at the edge of the Columbia Gorge National Scenic Area where they are clearly visible in the Scenic Area and have a clear adverse affect on it. WA is not in short supply of good places for wind farms. In fact, the NW is getting close to capacity on how many wind farms the grid can handle. The only reason for putting wind towers in this particular place is to financially benefit a particular company - SDS Lumber owns the location and can make money this way.
2. The Wind Towers will have a clearly definable adverse impact on the CGNSA. In the Management Plan for the Gorge are a list of "Key Viewing Areas" and guidelines for color, height, etc. for anything built that can be seen from a key viewing area. (See below.) The guidelines are there to prevent new structures from having an adverse impact on key viewing areas. The wind towers proposed would be visible from several key viewing areas in the Gorge and do not meet the guidelines in the management plan, so they will have a clearly defined adverse impact.
3. Approving this siting will set a precedent for decisions in the rest of WA when a wind farm is near a National Park or other scenically beloved area. The towers are not in the CGNSA, but are set very close (I have heard 20 feet from the boundary, but in any case a look at the enclosed map shows that they are very close) to the boundary. Because they are not in the boundary, the CGNSA has no legal authority over the wind farm placement. In OR, however, the Dept. of Energy Facilities Siting Council has written standards (enclosed) for siting. Two of them are that new energy facilities shall not have adverse effects on certain places, the Columbia Gorge being one, and second that new facilities shall not adversely affect scenic values recognized in federal or local land use plans, and the CGNSA Key Viewing Areas would be a perfect example. If the WA EFSEC fails in this case to consider well defined adverse impacts on a federal National Scenic Area, you are setting a precedent. I realize it is easy for WA government to sacrifice the Columbia Gorge because it is not near Seattle, but if you site towers here, what grounds will you use

to deny siting near scenic areas like Mt Rainier, Puget Sound, and the Olympics?

4. The Management plan set the afore-mentioned standards to protect the natural beauty of the Gorge from being overwhelmed by human construction. If you allow wind towers on the rim of the Gorge where they will be very visible, that makes a mockery of all these standards that private landowners have to abide by in building their houses in the CGNSA. Why should someone have to paint their house an inconspicuous dark brown if above him can be seen white spinning towers with red lights at night?

5. If you allow these towers on the rim of the Gorge, you are setting a precedent in the Gorge. On what grounds could you deny any others near the Gorge? This will lead to all the rims of the Gorge, at least on the WA side, being lined with towers, since the wind is good everywhere. In turn, that may break down the objections to towers on the OR side.

I would now like to go into more detail on especially point 2 - Clearly defined adverse scenic impacts:

The Columbia Gorge National Scenic Area was created 25 years ago to protect the beauty of the Gorge. No buffer zone was created for its boundaries, but at the time no one envisioned the possibility of huge (greater than 400 ft. tall) wind towers on the tops of all its ridges. Recently wind towers went in just east of the Gorge Scenic Area boundary along Hwy. 97 as it winds up out of the Gorge going to Goldendale. If you doubt that wind towers impact the landscape, drive that road. You may like them or not, but they are now the first thing you notice, not the land. In fact, their movement is so hypnotic that I have trouble watching the road.

The Gorge Management Plan that was created to carry out the National Scenic Area Act lists "key viewing areas" in the Gorge that deserve special protection, and the Management Plan gives clear standards for anything built that can be seen from the key viewing areas. The proposed wind towers will be just outside the boundary of "General Management Area (GMA)" coniferous forest land. I enclose the relevant Management Plan pages (2007 revision) that govern building on that category of land if it is visible from a "key viewing area.". Some of these are:

"Each development shall be visually subordinate to its setting as seen from key viewing areas." (p.1-1-7)

"The silhouette of new buildings shall remain below the skyline of a bluff, cliff, or ridge as seen from key viewing areas." (p.1-1-8)

"..Colors of structures on sites visible from key viewing areas shall be dark earth-tones found at the specific site or in the surrounding landscape." (1-1-9)

"The exterior of buildings on lands seen from key viewing areas shall be composed of non-reflective materials or materials with low reflectivity.." (1-1-9)

*Exterior lighting shall be directed downward and sited, hooded, and shielded such that it is not highly visible from key viewing areas." (1-1-10)

"Structure height shall remain below the forest canopy level. (1-1-17)

These towers will be visible from several "key viewing areas" Two of these key viewing areas are I-84, the freeway on the OR side, and the Cook-Underwood Rd.in WA. I have put those on the enclosed map as dots. Again, the towers will not be within the Scenic Area boundary, so the Scenic Area rules do not apply directly. On the other hand, the

Scenic Area guidelines for building (see above) give clear standards for what “adversely affects” the Columbia Gorge. I have heard that the towers closest to the Scenic Area boundary will be only 20 ft. away from it, but let us say it is 200 ft. I have also heard that the towers are taller than 400 ft, but let us say they are 400 ft, including the blade. By the map enclosed, I find that the Cook-Underwood Rd. simulation viewpoint in the URS is about 1 3/8 miles from the closest tower. Let us say that tower is 200 ft out of the Scenic Area, and 400 ft. tall. A little math (enclosed) shows that this tower is the visual equivalent of a 389 foot tower built just on the boundary, as seen from the Cook Underwood Rd. Looking at the standards for building within the Scenic Area, it is clear that a 389 ft tower built just inside the boundary would violate every building guideline listed - it would be on the ridge against the sky, far above the trees, shiny white, with a red flashing light at night. In addition, it would be moving, and the human eye and brain instinctively focus on movement. (I taught perception in college, and that was one of the principles.) This tower would be about the furthest thing from “visually subordinate” that could be imagined. It would dominate the landscape. These building guidelines are in the Management Plan to prevent structures from having an adverse impact on the Gorge, and can therefore be taken as criterion for when something would have an adverse impact. In Oregon the Facilities Siting Council has written guidelines for siting energy facilities.(Division 22: General Standards for siting Non-Nuclear Energy Facilities) Two of these are:

(345-022-0040) Protected Areas

1)..the Council shall not issue a site certificate for a proposed facility located in the areas listed below. To issue a site certificate for a proposed facility located outside the areas listed below, the Council must find that, taking into account mitigation, the design, construction and operation of the facility are not likely to result in significant adverse impact to the areas listed below. (The Columbia Gorge National Scenic Area is a listed area.)

(345-022-0080) Scenic and Aesthetic Values

1) ..the Council must find that the design, construction, operation and retirement of the facility, taking into account mitigation, are not likely to result in significant adverse impact to scenic and aesthetic values identified as significant or important in applicable federal land management plans or in local land use plans in the analysis area described in the project order.

A proposed wind farm on the OR side of the Gorge on Sevenmile Hill also would have had towers next to the Scenic Area boundary and visible from many key viewing areas. The question was, is seeing wind towers an “adverse impact?” Given the standards for building structures visible from key viewing areas within the Scenic Area, and the fact that wind towers violate all those standards, there is an objective way of saying that seeing towers would be an adverse impact.

I do not know if the WA facilities siting authority has standards, but it should. Personally, I think that in certain cases it might be OK to see wind towers, and the standard could be quantified. I remember that in a previous version of the management plan, or in Wasco County’s ordinances, no house visible from Key Viewing Areas could be built more than 35 ft. high. On my calculations sheet I have figured how far a 400 ft

tower would have to be from the Cook-Underwood Rd. to be the visual equivalent of a structure 35 ft. tall at the Scenic Area boundary, 1 3/8 miles from Cook-Underwood. It would have to be 15.7 miles from the Cook-Underwood Rd. Maybe a standard could be made whereby any wind towers, rather than being totally invisible, would have to be equivalent to allowable heights of structures within the Scenic Area. This would mean nothing could be built really close to the boundary.

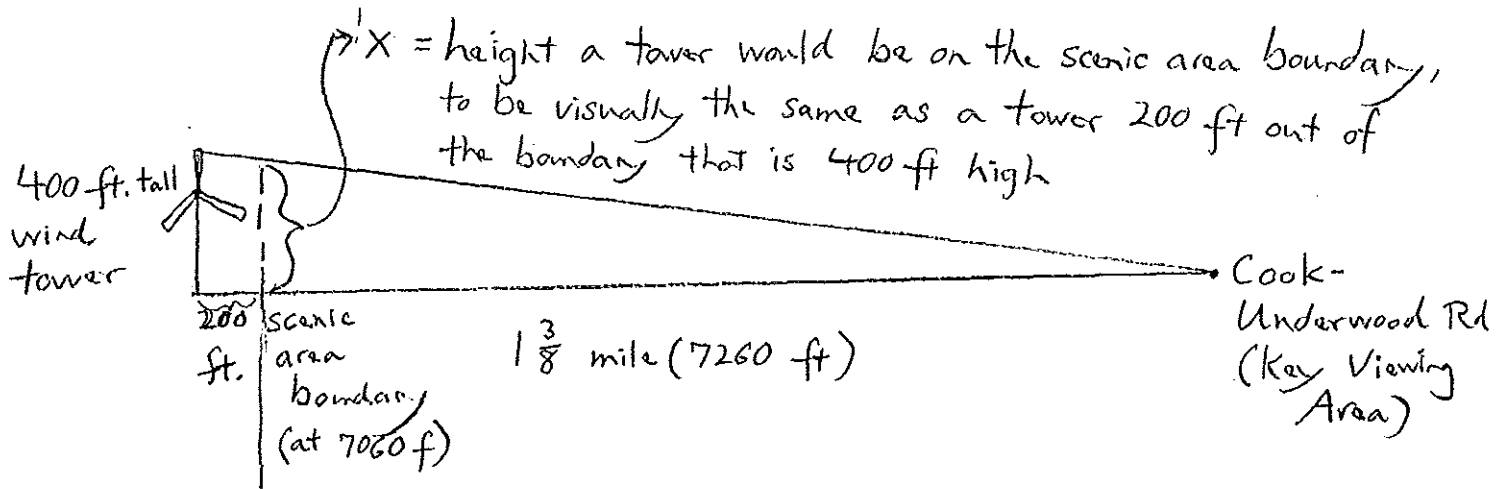

I hope that the WA council, like OR, will take into account large scenic values, especially when siting facilities near federally or state recognized preserved areas. I hope also that siting facilities of huge towers right on the boundary and very visible from a National Scenic Area will be rejected. I am for wind power, and find most of the wheat field siting satisfactory. But we do not need to put wind towers everywhere, just as we did not need to dam every river. Let us not make the same mistake again.

Very Sincerely,
Barbara Robinson

Barbara Robinson
8/22/10

Calculations

$$\frac{400 \text{ ft}}{7260 \text{ ft}} = \frac{X}{7060 \text{ ft.}} \quad X = 389 \text{ ft.}$$

How far away from the scenic area boundary would a 400-ft. tower have to be, to be the visual equivalent on the boundary of a 35-ft tall structure (typical house height) as seen from the Cook-Underwood Rd.?

$$\frac{35 \text{ ft.}}{7260 \text{ ft}} = \frac{400 \text{ ft}}{X}$$

$$X = 82,971 \text{ ft} = 15.7 \text{ miles}$$

DIVISION 22

GENERAL STANDARDS FOR SITING NON-NUCLEAR ENERGY FACILITIES

345-022-0000

General Standard of Review

(1) To issue a site certificate for a proposed facility or to amend a site certificate, the Council shall determine that the preponderance of evidence on the record supports the following conclusions:

(a) The facility complies with the requirements of the Oregon Energy Facility Siting statutes, ORS 469.300 to ORS 469.570 and 469.590 to 469.619, and the standards adopted by the Council pursuant to ORS 469.501 or the overall public benefits of the facility outweigh the damage to the resources protected by the standards the facility does not meet as described in section (2);

(b) Except as provided in OAR 345-022-0030 for land use compliance and except for those statutes and rules for which the decision on compliance has been delegated by the federal government to a state agency other than the Council, the facility complies with all other Oregon statutes and administrative rules identified in the project order, as amended, as applicable to the issuance of a site certificate for the proposed facility. If the Council finds that applicable Oregon statutes and rules, other than those involving federally delegated programs, would impose conflicting requirements, the Council shall resolve the conflict consistent with the public interest. In resolving the conflict, the council cannot waive any applicable state statute.

(2) The Council may issue or amend a site certificate for a facility that does not meet one or more of the standards adopted under ORS 469.501 if the Council determines that the overall public benefits of the facility outweigh the damage to the resources protected by the standards the facility does not meet. The Council shall make this balancing determination only when the applicant has shown that the proposed facility cannot meet Council standards or has shown, to the satisfaction of the Council, that there is no reasonable way to meet the Council standards through mitigation or avoidance of the damage to the protected resources. The applicant has the burden to show that the overall public benefits outweigh the damage to the resources, and the burden increases proportionately with the degree of damage to the resources. The Council shall weigh overall public benefits and damage to the resources as follows:

(a) The Council shall evaluate the damage to the resources by considering factors including, but not limited to, the following:

(A) The uniqueness and significance of the resource that would be affected;

(B) The degree to which current or future development may damage the resource, if the proposed facility is not built;

(C) Proposed measures to reduce the damage by avoidance of impacts;

and adverse impacts will be mitigated in accordance with rules of the Council applicable to the siting of the proposed facility; and

(C) The proposed facility is compatible with other adjacent uses or will be made compatible through measures designed to reduce adverse impacts.

(5) If the Council finds that applicable substantive local criteria and applicable statutes and state administrative rules would impose conflicting requirements, the Council shall resolve the conflict consistent with the public interest. In resolving the conflict, the Council cannot waive any applicable state statute.

(6) If the special advisory group recommends applicable substantive criteria for an energy facility described in ORS 469.300(10)(a)(C) to (E) or for a related or supporting facility that does not pass through more than one local government jurisdiction or more than three zones in any one jurisdiction, the Council shall apply the criteria recommended by the special advisory group. If the special advisory group recommends applicable substantive criteria for an energy facility described in ORS 469.300(10)(a)(C) to (E) or a related or supporting facility that passes through more than one jurisdiction or more than three zones in any one jurisdiction, the Council shall review the recommended criteria and decide whether to evaluate the proposed facility against the applicable substantive criteria recommended by the special advisory group, against the statewide planning goals or against a combination of the applicable substantive criteria and statewide planning goals. In making the decision, the Council shall consult with the special advisory group, and shall consider:

(a) The number of jurisdictions and zones in question;

(b) The degree to which the applicable substantive criteria reflect local government consideration of energy facilities in the planning process; and

(c) The level of consistence of the applicable substantive criteria from the various zones and jurisdictions.

Stat. Authority: ORS 469.470

Stat. Implemented: ORS 469.504

345-022-0040

→ Protected Areas

(1) Except as provided in sections (2) and (3), the Council shall not issue a site certificate for a proposed facility located in the areas listed below. To issue a site certificate for a proposed facility located outside the areas listed below, the Council must find that, taking into account mitigation, the design, construction and operation of the facility are not likely to result in significant adverse impact to the areas listed below. Cross-references in this rule to federal or state statutes or regulations are to the version of the statutes or regulations in effect as of August 28, 2003:

(a) National parks, including but not limited to Crater Lake National Park and Fort Clatsop National Memorial;

includes Columbia Gorge National Scenic Area on p. 7

345-022-0060

Fish and Wildlife Habitat

To issue a site certificate, the Council must find that the design, construction, operation and retirement of the facility, taking into account mitigation, are consistent with the fish and wildlife habitat mitigation goals and standards of OAR 635-415-0025 in effect as of September 1, 2000.

Stat. Authority: ORS 469.470, ORS 469.501

Stat. Implemented: ORS 469.501

345-022-0070

Threatened and Endangered Species

To issue a site certificate, the Council, after consultation with appropriate state agencies, must find that:

(1) For plant species that the Oregon Department of Agriculture has listed as threatened or endangered under ORS 564.105(2), the design, construction, operation and retirement of the proposed facility, taking into account mitigation:

(a) Are consistent with the protection and conservation program, if any, that the Oregon Department of Agriculture has adopted under ORS 564.105(3);
or

(b) If the Oregon Department of Agriculture has not adopted a protection and conservation program, are not likely to cause a significant reduction in the likelihood of survival or recovery of the species; and

(2) For wildlife species that the Oregon Fish and Wildlife Commission has listed as threatened or endangered under ORS 496.172(2), the design, construction, operation and retirement of the proposed facility, taking into account mitigation, are not likely to cause a significant reduction in the likelihood of survival or recovery of the species.

Stat. Authority: ORS 469.470, ORS 469.501

Stat. Implemented: ORS 469.501

345-022-0080

Scenic and Aesthetic Values

(1) Except for facilities described in section (2), to issue a site certificate, the Council must find that the design, construction, operation and retirement of the facility, taking into account mitigation, are not likely to result in significant adverse impact to scenic and aesthetic values identified as significant or important in applicable federal land management plans or in local land use plans in the analysis area described in the project order.

(2) The Council may issue a site certificate for a special criteria facility under OAR 345-015-0310 without making the findings described in section (1). However, the Council may apply the requirements of section (1) to impose conditions on a site certificate issued for such a facility.

Stat. Authority: ORS 469.470, ORS 469.501

Stat. Implemented: ORS 469.501

Section 2: first track process
for natural gas

- B. If subject to state jurisdiction, whether an application has been received for a state reclamation permit and, if so, the current status of the application; and
- C. For uses subject to state jurisdiction, any issues or concerns regarding consistency with state reclamation requirements, or any suggested modifications to comply with state reclamation requirements.

Scenic Area implementing agencies may request technical assistance from state agencies on reclamation plans for proposed mining not within the state agency's jurisdiction.

KEY VIEWING AREAS

GMA Goal

- Emphasize protection and enhancement of Gorge landscapes seen from key viewing areas.

GMA Objectives

1. Establish scenic enhancement programs prioritizing enhancement of lands seen from key viewing areas.
2. Establish a program to phase-out existing quarries and associated activities and develop reclamation plans for such quarries at sites where the Gorge Commission determines that such uses adversely affect scenic resources on land visible from key viewing areas. The Gorge Commission shall initiate this objective by inventorying existing quarries visible from key viewing areas. Phase-out plans may require some additional quarrying for a limited time to best achieve contours that blend with surrounding landforms. Phase-out and reclamation plans for particular quarries shall include a specified time period for completion, not to exceed 5 years from the commencement of such plans.
3. Encourage mining reclamation methods and features that enhance wildlife habitat and wetlands, ameliorate visual impacts of existing quarries, and accelerate achievement of desired visual quality objectives.
4. Encourage use of planned unit developments, clustering, lot reconfiguration and consolidation, and other techniques to reduce visual impacts of new development on lands that are visible from key viewing areas and that possess high or critical visual sensitivity.
5. Encourage plantings of native species or species characteristic of the landscape setting to screen existing development that is not visually subordinate on lands that are visible from key viewing areas and that possess high or critical visual sensitivity.

GMA Policies

- 1. Important public roads, parks, and other vantage points providing public scenic viewing opportunities shall be designated as key viewing areas, as identified in the glossary of the Management Plan.
- 2. Except for new production and/or development of mineral resources, new development on lands seen from key viewing areas shall be visually subordinate to its landscape setting. This policy shall not apply to specified developed settings that are not visually sensitive (as identified in the "Landscape Settings" section), rehabilitation or modifications to significant historic structures, shorelines on the main stem of the Columbia River that adjoin Urban Areas, or other developments expressly exempted from this requirement in this chapter.
3. In developing conditions of approval, agencies shall emphasize those elements that, in combination, provide effective, long-term scenic resource protection.
4. New utility transmission lines, transportation and communication facilities, docks and piers, and repairs and maintenance of existing lines, roads and facilities shall be visually subordinate as seen from key viewing areas to the maximum extent practicable.
5. New buildings shall be prohibited on steeply sloping lands visible from key viewing areas.
6. Proposed projects involving substantial grading on lands visible from key viewing areas shall include a grading plan addressing visual impacts of grading activities. All graded areas shall be revegetated to the maximum extent practicable.
7. Development along the shoreline of the Columbia River and on immediately adjacent lands shall be limited to water-dependent development and water-related recreation development.
8. New production and/or development of mineral resources on sites visible in the foreground or middle ground from key viewing areas shall be permitted if fully screened from view from those key viewing areas. New production and/or development of mineral resources on sites visible in the background from key viewing areas shall be permitted if visually subordinate to its setting as seen from those key viewing areas.
9. Expansion of existing quarries on sites visible from key viewing areas shall be permitted if visually subordinate to its setting as seen from key viewing areas. Existing quarries are those determined not to be discontinued, pursuant to Guideline 4.D in "Existing Uses and Discontinued Uses" (Part II, Chapter 7: General Policies and Guidelines). Expansion refers to lateral expansion (expansion of mining activities into land surfaces previously unaffected by mining).

10. In addition to the guidelines contained in this section, applicable design guidelines specified for a particular landscape setting shall be used to ensure that new development on lands seen from key viewing areas is visually subordinate to its setting in a manner responsive to the unique character of that setting.
- 11. The Commission and Forest Service shall maintain a *Scenic Resources Implementation Handbook*. The Handbook shall provide specific guidance for applicants and planners in implementing color, reflectivity, landscaping and other guidelines for development on sites visible from key viewing areas. It may be updated as needed, as determined by the Executive Director and Scenic Area Manager. In updating the *Handbook*, the Commission and Forest Service will collaborate with the implementing counties, and solicit other agency and public input.

The *Handbook* is intended to provide non-exclusive, recommended lists of exterior building materials (for reflectivity) and vegetation species.

GMA Guidelines

- 1. The guidelines in this section shall apply to proposed developments on sites topographically visible from key viewing areas.
- 2. Each development shall be visually subordinate to its setting as seen from key viewing areas.
3. Determination of potential visual effects and compliance with visual subordination policies shall include consideration of the cumulative effects of proposed developments.
4. The extent and type of conditions applied to a proposed development to achieve visual subordination shall be proportionate to its potential visual impacts as seen from key viewing areas.
 - A. Decisions shall include written findings addressing the factors influencing potential visual impact, including but not limited to:
 - (1) The amount of area of the building site exposed to key viewing areas.
 - (2) The degree of existing vegetation providing screening.
 - (3) The distance from the building site to the key viewing areas from which it is visible.
 - (4) The number of key viewing areas from which it is visible.

- (5) The linear distance along the key viewing areas from which the building site is visible (for linear key viewing areas, such as roads).
- B. Conditions may be applied to various elements of proposed developments to ensure they are visually subordinate to their setting as seen from key viewing areas, including but not limited to:
 - (1) Siting (location of development on the subject property, building orientation, and other elements).
 - (2) Retention of existing vegetation.
 - (3) Design (color, reflectivity, size, shape, height, architectural and design details and other elements).
 - (4) New landscaping.
5. New development shall be sited to achieve visual subordination from key viewing areas, unless the siting would place such development in a buffer specified for protection of wetlands, riparian corridors, sensitive plants, or sensitive wildlife sites or would conflict with guidelines to protect cultural resources. In such situations, development shall comply with this guideline to the maximum extent practicable.
6. New development shall be sited using existing topography and/or existing vegetation as needed to achieve visual subordination from key viewing areas.
7. Existing tree cover screening proposed development from key viewing areas shall be retained as specified in the Landscape Settings Design Guidelines section of this chapter.
- 8. The silhouette of new buildings shall remain below the skyline of a bluff, cliff, or ridge as seen from key viewing areas. Variances to this guideline may be granted if application of the guideline would leave the owner without a reasonable economic use. The variance shall be the minimum necessary to allow the use and may be applied only after all reasonable efforts to modify the design, building height, and site to comply with the guideline have been made.
9. An alteration to a building built before November 17, 1986, that already protrudes above the skyline of a bluff, cliff, or ridge as seen from a key viewing area, may itself protrude above the skyline if:
 - A. The altered building, through use of color, landscaping and/or other mitigation measures, contrasts less with its setting than before the alteration, and
 - B. There is no practicable alternative means of altering the building without increasing the protrusion.

-
10. The following guidelines shall apply to new landscaping used to screen development from key viewing areas:
 - A. New landscaping (including new earth berms) shall be required only when application of all other available guidelines in this chapter is not sufficient to make the development visually subordinate from key viewing areas. Alternate sites shall be considered prior to using new landscaping to achieve visual subordination. Development shall be sited to avoid the need for new landscaping wherever possible.
 - B. If new landscaping is required to make a proposed development visually subordinate from key viewing areas, existing on-site vegetative screening and other visibility factors shall be analyzed to determine the extent of new landscaping, and the size of new trees needed to achieve the standard. Any vegetation planted pursuant to this guideline shall be sized to provide sufficient screening to make the development visually subordinate within five years or less from the commencement of construction.
 - C. Unless as specified otherwise by provisions in this chapter, landscaping shall be installed as soon as practicable, and prior to project completion. Applicants and successors in interest for the subject parcel are responsible for the proper maintenance and survival of planted vegetation, and replacement of such vegetation that does not survive.
 - D. The *Scenic Resources Implementation Handbook* shall include recommended species for each landscape setting consistent with the Landscape Settings Design Guidelines in this chapter, and minimum recommended sizes of new trees planted (based on average growth rates expected for recommended species).
 11. Conditions regarding new landscaping or retention of existing vegetation for new developments on lands designated GMA Forest shall meet both scenic guidelines and fuel break requirements in Criterion 1.A of "Approval Criteria for Fire Protection".
 - 12. Unless expressly exempted by other provisions in this chapter, colors of structures on sites visible from key viewing areas shall be dark earth-tones found at the specific site or in the surrounding landscape. The specific colors or list of acceptable colors shall be included as a condition of approval. The *Scenic Resources Implementation Handbook* will include a recommended palette of colors.
 - 13. The exterior of buildings on lands seen from key viewing areas shall be composed of non-reflective materials or materials with low reflectivity, unless the structure would be fully screened from all key viewing areas by existing topographic features. The *Scenic Resources Implementation Handbook* will include a list of
-

recommended exterior materials. These recommended materials and other materials may be deemed consistent with this guideline, including those where the specific application meets recommended thresholds in the "Visibility and Reflectivity Matrices" in the *Implementation Handbook* (once they are created). Continuous surfaces of glass unscreened from key viewing areas shall be limited to ensure visual subordination. Recommended square footage limitations for such surfaces will be provided for guidance in the *Implementation Handbook*.

14. In addition to the site plan requirements in "Review Uses" (Part II, Chapter 7: General Policies and Guidelines), applications for all buildings visible from key viewing areas shall include a description of the proposed building(s)' height, shape, color, exterior building materials, exterior lighting, and landscaping details (type of plants used; number, size, locations of plantings; and any irrigation provisions or other measures to ensure the survival of landscaping planted for screening purposes).
15. For proposed mining and associated activities on lands visible from key viewing areas, in addition to submittal of plans and information pursuant to Guideline 6 in the "Overall Scenic Provisions" section of this chapter, project applicants shall submit perspective drawings of the proposed mining areas as seen from applicable key viewing areas.
- 16. Exterior lighting shall be directed downward and sited, hooded, and shielded such that it is not highly visible from key viewing areas. Shielding and hooding materials shall be composed of non-reflective, opaque materials.
17. Additions to existing buildings smaller in total square area than the existing building may be the same color as the existing building. Additions larger than the existing building shall be of dark earth-tone colors found at the specific site or in the surrounding landscape. The specific colors or list of acceptable colors shall be included as a condition of approval. The *Scenic Resources Implementation Handbook* will include a recommended palette of colors.
18. Rehabilitation of or modifications to existing significant historic structures shall be exempted from visual subordination requirements for lands seen from key viewing areas. To be eligible for such exemption, the structure must be included in, or eligible for inclusion in, the National Register of Historic Places or be in the process of applying for a determination of significance pursuant to such regulations. Rehabilitation of or modifications to structures meeting this guideline shall be consistent with National Park Service regulations for such structures.
19. New main lines on lands visible from key viewing areas for the transmission of electricity, gas, oil, other fuels, or communications, except for connections to individual users or small clusters of individual users, shall be built in existing transmission corridors unless it can be demonstrated that use of existing corridors

- is not practicable. Such new lines shall be underground as a first preference unless it can be demonstrated to be impracticable.
20. New communication facilities (antennae, dishes, etc.) on lands visible from key viewing areas that require an open and unobstructed site shall be built upon existing facilities unless it can be demonstrated that use of existing facilities is not practicable.
 21. New communications facilities may protrude above a skyline visible from a key viewing area only upon demonstration that:
 - A. The facility is necessary for public service,
 - B. The break in the skyline is seen only in the background, and
 - C. The break in the skyline is the minimum necessary to provide the service.
 22. Overpasses, safety and directional signs, and other road and highway facilities may protrude above a skyline visible from a key viewing area only upon a demonstration that:
 - A. The facility is necessary for public service, and
 - B. The break in the skyline is the minimum necessary to provide the service.
 23. Except for water-dependent development and for water-related recreation development, development shall be set back 100 feet from the ordinary high water mark of the Columbia River below Bonneville Dam, and 100 feet from the normal pool elevation of the Columbia River above Bonneville Dam, unless the setback would render a property unbuildable. In such cases, variances to this guideline may be authorized.
 24. New buildings shall not be permitted on lands visible from key viewing areas with slopes in excess of 30 percent. Variances to this guideline may be authorized if the guideline's application would render a property unbuildable. In determining the slope, the average percent slope of the proposed building site shall be used.
 25. Driveways and buildings shall be designed and sited to minimize visibility of cut banks and fill slopes from key viewing areas.
 26. All proposed structural development involving more than 200 cubic yards of grading on sites visible from key viewing areas shall include submittal of a grading plan. This plan shall be reviewed by the local government for compliance with key viewing area policies. The grading plan shall include the following:
-

established before approval. The interim time period shall be based on site-specific topographic and visual conditions, but shall not exceed 3 years beyond the date of approval.

30. An interim time period to achieve compliance with full screening requirements for new quarries located less than 3 miles from the nearest visible key viewing area shall be established before approval. The interim time period shall be based on site-specific topographic and visual conditions, but shall not exceed 1 year beyond the date of approval. Quarrying activity occurring before achieving compliance with full screening requirements shall be limited to activities necessary to provide such screening (creation of berms, etc.).

LANDSCAPE SETTINGS

GMA Goals

1. Maintain the diversity of Gorge landscapes to protect and enhance the Gorge's scenic beauty.
2. Retain the existing character of the Gorge's rural landscapes and two Rural Centers (Corbett and Skamania).
3. Protect existing riverfront landscape settings when providing additional recreational river access and ensure that riverfront recreation is provided in a manner compatible with those settings.

GMA Policies

1. New developments shall be compatible with their landscape setting and maintain the integrity of that setting. Expansion of existing developments shall be compatible with their landscape setting and maintain the integrity of that setting to the maximum extent practicable.
2. These goals, policies, and guidelines apply only to developments and uses subject to review, pursuant to the Management Plan. While agricultural and forest practices influence landscape settings, they are not subject to the goals, policies, and guidelines for landscape settings.
3. Because of the dynamic nature of landscape settings, these settings shall be reevaluated in the periodic plan review process. Substantial changes, particularly with respect to changes of large areas between wooded and agricultural settings, shall be reflected in periodic revisions to the Management Plan.
4. Maintenance of landscape settings shall be a key consideration in determining minimum parcel sizes for GMA land use designations. Recommended minimum parcel sizes for new land divisions to maintain landscape setting character are

included where applicable in the landscape settings descriptions. The Gorge Commission shall use these recommendations when considering minimum parcel sizes for either plan amendments or plan updates.

5. The "Compatible Recreation Use Guidelines" for each landscape setting shall provide the basis for evaluating cumulative effects of recreation proposals on landscape settings, including types and intensities of recreation uses.

GMA Descriptions and Guidelines

Pastoral

Overview and Land Use

Pastoral settings are essentially agrarian in character, typified by areas of pastures and intensive agriculture. This setting includes areas where orchards, vineyards, row crops, and irrigated pasture predominate the landscape. This setting often includes woodlots and scattered rural residential development. Visual features distinguishing this setting include large expanses of cultivated fields and pastures, punctuated by clusters of farm accessory buildings and hedgerows or poplar rows defining distinct fields. Some small parcels with residences occur, but many parcels range between forty and several hundred acres in size.

Landforms

These settings usually occur on level ground or gently rolling terrain. Some of these landscapes are found on relatively flat terraces and benches at the top of steep slopes that form the walls of the Gorge. Other pastoral areas occur in the fertile valleys of the major tributaries flowing into the Columbia River.

Vegetation

Non-native vegetation patterns are predominant. They include alfalfa fields and irrigated pasture, vineyards and fruit orchards, row crops, hedgerows, and poplar rows. Scattered woodlots interspersed throughout this setting reflect the natural vegetation of the portion of the Gorge in which they are located (e.g. Oregon oak and ponderosa pine in the eastern Gorge; Douglas-fir, big leaf maple, and western red cedar in the west).

Compatible Recreation Use Guideline

Resource-based recreation uses of a very low-intensity or low-intensity nature (as defined in the "Recreation Intensity Classes" section of Part I, Chapter 4: Recreation Resources), occurring infrequently in the landscape, are compatible with this setting.

Recommended Parcel Size for New Land Divisions

40 acres.

Design Guidelines

1. Accessory structures, outbuildings, and access ways shall be clustered together as much as possible, particularly towards the edges of existing meadows, pastures, and farm fields.
2. In portions of this setting visible from key viewing areas, the following guidelines shall be employed to achieve visual subordination for new development and expansion of existing development:
 - A. Except as is necessary for site development or safety purposes, the existing tree cover screening the development from key viewing areas shall be retained.
 - B. Vegetative landscaping shall, where feasible, retain the open character of existing pastures and fields.
 - C. At least half of any trees planted for screening purposes shall be species native to the setting or commonly found in the area. Such species include fruit trees, Douglas-fir, Lombardy poplar (usually in rows), Oregon white oak, big leaf maple, and black locust (primarily in the eastern Gorge).
 - D. At least one-quarter of any trees planted for screening shall be coniferous for winter screening.

Coniferous Woodland

Overview and Land Use

These are primarily thickly forested areas characterized by forest uses and scattered residential development. Forest uses are often small to moderate in scale, particularly in the more settled portions of this setting. Parcels typically range between 20 and 160 acres in size. Large-scale silvicultural operations also occur in the less developed portions of this setting where land holdings tend to be relatively large (several hundred acres and larger) and residences fairly uncommon.

Landforms

These settings are found in hilly and mountainous portions of the Gorge, particularly on the Washington side of the western Gorge (in the GMA). The more gently rolling and accessible portions of this setting contain small-scale agricultural use and relatively more residences.

Vegetation

This setting is generally dominated by large conifer tree species associated with the ecosystems of the wet western slopes of the Cascades. Such species include Douglas-fir, western hemlock, western red cedar, and grand fir. Deciduous trees frequent the riparian corridors and also cover many slopes in the westernmost portions of the Gorge. Common deciduous species include big leaf maple, red alder, black cottonwood, and various species of willow trees. In the eastern portions of this setting and on dry, south-facing slopes, ponderosa pine and Oregon white oak are also common.

Compatible Recreation Use Guideline

Resource-based recreation uses of varying intensities may be compatible with this setting. Typically, outdoor recreation uses in Coniferous Woodlands are low intensity, and include trails, small picnic areas, and scenic viewpoints. Although infrequent, some more intensive recreation uses, such as campgrounds, occur. They tend to be scattered rather than concentrated, interspersed with large areas of undeveloped land and low-intensity uses.

Recommended Parcel Size for New Land Divisions

20 acres.

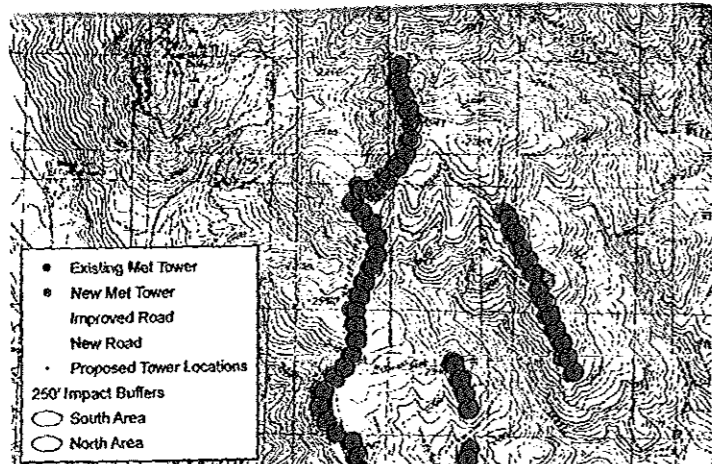

Design Guidelines

- 
1. Structure height shall remain below the forest canopy level.
 2. In portions of this setting visible from key viewing areas, the following guidelines shall be employed to achieve visual subordination for new development and expansion of existing development:
 - A. Except as is necessary for construction of access roads, building pads, leach fields, etc., the existing tree cover screening the development from key viewing areas shall be retained.
 - B. At least half of any trees planted for screening purposes shall be species native to the setting. Such species include: Douglas-fir, grand fir, western red cedar, western hemlock, big leaf maple, red alder, ponderosa pine and Oregon white oak, and various native willows (for riparian areas).
 - C. At least half of any trees planted for screening purposes shall be coniferous to provide winter screening.

COMMENT LETTER 263

Michelle, Kayce (UTC)

From: Loreley Drach [REDACTED]
Sent: Friday, August 20, 2010 12:54 PM.
To: EFSEC (UTC)
Subject: Whistling Ridge DEIS comment LD#1
Attachments: Jobs Watch_ Fresh breezes in the Gorge - Oregon Business.pdf

Dear EFSEC,

I wanted to submit the attached article and my comments, below, to the public comments for WRE DEIS.

Not identified or discussed in the DEIS is the fact that the Columbia River Gorge, and by overflow, Skamania County, are hotbeds of entrepreneurs. Insitu, one of the largest employers in the central gorge was founded by three people who moved here for the quality of life, the natural beauty of the Gorge. Still, to this day, this spirit lives. This area attracts and retains those educated innovative people who, partly out of necessity, create a living for themselves and as a result for others to continue living in this fabulous area.

Destroying the natural beauty which attracts well educated entrepreneurs is not going to help the Gorge or Skamania County in the long run.

Not stated is that MOST of the construction workers, if not nearly all, will be by people from out of the area. Just travel through the trailer parks in eastern Washington and Oregon where the turbines are becoming more common than cows, and take a gander at the license plates. This project will not solve the chronic unemployment problem that Skamania County has.

The DEIS FAILS to address EXACTLY what jobs are to be filled and how many FTE's will be performed for each job. Educational or skill status is not given, nor the pay scale they will be hired into. The 8-9 or so called longer term jobs are likely technical. The uneducated unemployed are NOT going to qualify for those jobs. Given the choice, I think the jobs produced by Insitu and other entrepreneurs are what the Gorge needs for its long term economic health, not jobs based on deforestation of our timber producing areas and scenic degradation of the Columbia Gorge National Scenic Area.

Additionally, this project is being subsidized by a Sales Tax exemption to the tune of approximately 7%. This amounts to roughly 7-10 million dollars. Eight or nine longer term jobs for the State of Washington at a cost of 7-10 million dollars does not sound like a good deal for Washington or the public. A lot of economic development agencies consider a public investment cost of \$5,000 dollars per full time employee a good deal. WRE would cost \$1M dollars per long term employee. This is approximately 200 times more expensive than traditional goals of economic development.

Perhaps instead we should be putting those dollars toward a state in need rather than a corporation in want.

Loreley Drach

Jobs Watch: Fresh breezes in the Gorge

Ben Jacklet
 Thursday, 19 August 2010

There aren't a lot of counties in Oregon with unemployment rates lower than the national average, but there are **three of them in the Columbia River Gorge**. Even as the state's economy has stagnated, the awesome rise of the robot plane pioneer Insitu as an aerospace powerhouse and other positive developments have done wonders for communities on both sides of the river, especially in the vicinity of Hood River.

I took a drive out to tiny Bingen, Washington just across the bridge from Hood River the other day, and it was nothing like it was in the not-so-distant past. No more cheap fried chicken at the convenience store as you pass through; we're talking gluten free crust on the pizza, locally brewed beers for four and a half bucks apiece, and specialty products like goat's milk hand lotion and local honey for sale by the register.

The venue was the **Solstice Wood Fire Cafe**, just next door to Insitu, and the event was a Pub Talk sponsored by the Oregon Entrepreneurs Network's Gorge chapter. Simply hosting such an event was a breakthrough for Bingen. Klickitat County economic development director Mike Canon had this to say: "If you'd mentioned that we'd get a pub talk on this side of the river a year ago, you'd have been hanging out in too many pubs yourself."

But there they were, investors and entrepreneurs and economic development evangelists, crammed into a small room to listen.

Three Gorge-based entrepreneurs spoke: Ken Levy of **4-Tell**, Richard Halpern of **EcoApprentice** and James Martin of **Copa Di Vino**.

Former Digimarc employee Levy launched 4-Tell, his fourth startup, 16 months ago with the goal of helping companies that sell products online increase sales through recommendations. He and his team have closed \$250,000 in seed capital, but it hasn't been easy. By his count he's had 68 meetings with 51 private investors, in addition to high-pressure public pitch contests before investment groups.

But he's made progress in a tough economy, and he credits his success to speed, determination and practicality. He went from concept to business plan in six weeks and began generating revenue shortly thereafter. In this economy, he says, "It's almost impossible to get money until you have a product and sales."

He's also had the wisdom to stick with professional investors who understand risk rather than friends and family who expect quick and easy returns. In addition, he received a nice "soft circle" boost from a local investor well known in the community. That investor, Vesta CEO Doug Fieldhouse, allowed Levy to use his name to raise money and committed to investing so long as Levy met requirements. The soft support paid off, but the road ahead remains hard.

Halpern, whose business plan involves crowd-sourcing among college students to help businesses turn environmental challenges into opportunities, is much earlier along in the game. In fact, he

- Maybe
- I don't know

made the unusual choice of telling attendees that he was not ready for their money. Mostly he wanted advice.

Still, his idea could have serious potential with some refinement. Asked how he planned to make money, Halpern explained, "It's a freebie until it becomes a product worth paying for, and when it becomes a product worth paying for it will be worth a lot."

Martin, the founder and CEO of Copa di Vino, comes from from a seven-generation The Dalles family, and he weighed in on the other end of the confidence spectrum. He has launched his wine-by-the-glass product in 20 states, and the 21st, California, could be huge. He believes he has solved a long-standing problem for the wine industry with a patented packaging technology that bottles wine in glasses instead of bottles. As the first company to move into the "ready to drink" individual servings market for good wine, Martin hopes to disrupt the market until the big wine producers cannot ignore his product, then convince the big boys to partner with him.

"We want to bottle for the industry," Martin told the crowd, noting that he already has established a partnership with Kendall-Jackson. "We're trying to raise a million and a half dollars over the next six months."

He didn't get a million and a half that night in Bingen, but he did receive a lot of encouragement for his enterprise, which could bring many jobs to The Dalles if things go as planned.

After the event, Martin told me that raising money in this economy has been a frustrating endeavor. But he's confident he'll succeed over time.

If he does, there will be one more reason to bet on the long-term economic future of the Gorge.

Ben Jacklet is managing editor for Oregon Business.

COMMENT LETTER 264

Michelle, Kayce (UTC)

From: [REDACTED]
Sent: Monday, August 23, 2010 2:12 PM
To: EFSEC (UTC)
Subject: I support Whistling Ridge

Hello Energy Facility Site Evaluation Council,

As I wrote during the public comment period in 2009, I support the Whistling Ridge project. (I live in Stevenson, WA, and I would not object to installations in my 'back yard' either, if it were possible.)

The EIS seems to me to be thorough and comprehensive. Obviously, there are potential problems/losses associated with wind turbines; but the outcomes, as described in the EIS, seem positive to me, overall.

I would like for EFSEC and the BPA to consider one aspect that is implied by some of the findings, but not stated (as far as I could find): a 'lookback' study by relevant staff from one or more of our state's universities. Such dedicated research seems to me to be a missing ingredient in many of our more far-reaching and controversial developments. I think that the scope of such a study could easily be designed by both opponents and the appropriate EIS consultants, after cost negotiations with the facility operator and the pertinent agencies.

Sincerely,
Paul Spencer

Subject: Whistling Ridge Negitively Impacts Columbia Gorge

I am writing about the DEIS for the Whistling Ridge Energy Project, proposed in Washington state, along the Skamania and Klickitat county lines.

Please help us protect the Gorge for future generations. It is a national treasure. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition the BPA and EFSEC have not adequately consulted with the Yakama Indian Nation to ensure the protection of cultural resources.

The Gorge is priceless. Please help protect it. Thank you very much.

COMMENT LETTER 266

Michelle, Kayce (UTC)

From: Cliff Snell [REDACTED]
Sent: Monday, August 23, 2010 6:17 PM
To: EFSEC (UTC)
Subject: Whistling Ridge Negitively Impacts Columbia Gorge

I am commenting on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, along the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition the BPA and EFSEC have not adequately consulted with the Yakama Indian Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines..

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains and on the boundary of the Columbia River Gorge National Scenic Area. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

COMMENT LETTER 267

Michelle, Kayce (UTC)

From: Andrew Grossman [REDACTED]
Sent: Monday, August 23, 2010 10:00 PM
To: EFSEC (UTC)
Subject: Whistling Ridge Negitively Impacts Columbia Gorge

I am a retired Fish and Wildlife Service biologist. I have studied impacts from wind turbines powerlines on wildlife resouces. I believe the location proposed by the developer for the Whistling Ridge Energy Project is ill advised, and potential impacts are not adequately analyzed in the DEIS. Ridgeline and forested boundaries would make this area highly hazardous for resident and migratory bird populations turbine construction and operation is allowed to go forth. Wind turbine Impacts to bats are only beginning to be addressed through research and are not adequately assessed in the DEIS. I can only surmise that land ownership and political considerations are driving this proposal at this location.

Such projects should be located in open country to the east, where potential wildlife impacts are considerably reduced. Furthermore, the high cultural and historic values of this area in the early exploration and settlement of this country dating to Lewis and Clark should make any development which affects land use subect to the highest scrutiny which has obviously not been the case with regard to this project.

The DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

This proposed project does not appear to have been adequately coordinated with the Yakima Indian tribes, and thereby places Native cultural resouces at risk. I would add that coordination with the general public seems deficient, and this critical purpose of NEPA has thereby fallen short.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: Proposed Wind Project

Dear Sirs: Like most folks with consciences, I certainly care about preserving our energy resources and producing clean energy. However, the proposed wind project will surely damage the scenic ridgeline bordering the Columbia Gorge National Scenic area. Moreover, the planned turbines will do damage to the wildlife of the area, especially to birds of prey. Please look elsewhere for such projects.

Thank you.

Andrew M. Montaño
Environmental Project Manager
Bonneville Power Administration
Public Affairs Office – DKE-7
PO Box 14428
Portland, OR 97293-4428

SUBJECT: Whistling Ridge Energy Project

Dear Mr. Posner and Mr. Montaño:

As a resident of Clark County and as one who has been involved in the decisions regarding the Columbia River Gorge since before and after the Columbia River Gorge National Scenic Areas was established, I have a deep appreciation for the Gorge and a deep awareness of what it takes to operate a successful business in the Scenic Area and in the Pacific Northwest. My family and I enjoy visiting the Gorge frequently from our Vancouver home, and we are not interested in seeing the character of the Gorge destroyed or significantly altered.

Currently, I am president of the Association of Washington Business (AWB), but I am commenting on behalf of myself. AWB is Washington's state chamber of commerce and manufacturing and technology association. Our 7,000 members employ more than 650,000 workers in our state's private sector.

Prior to joining AWB in 1986, I was Washington public affairs manager for Crown Zellerbach Corp. (CZ). At the time, CZ owned and operated the Camas pulp and paper operation just to the west of the Scenic Area boundary and owned thousands of acres of commercial timberlands inside and adjacent to the Scenic Area on both sides of the Columbia River.

I was involved in the negotiations with the state of Washington to exchange our Gorge lands with the state of Washington for state timber sale contract relief in 1982, 1983 and 1984. In that process, I learned a great deal about the forest land potential, the forest practices and view corridor considerations and alterations, the productivity of the timberlands, and the people and companies inside and adjacent to the Scenic area who are dependent upon the industry and businesses. I also came to learn that some of our forested sites along the ridge lines had higher potential for other uses such as a wind farm, although generating electricity from the wind was in its development stages.

While CZ believed that we could manage those lands and our Camas operations so as to protect the unique features of the Gorge inside and around the Scenic Area, we also worked with those who wrote the legislation establishing the Scenic Area to protect the commercial activities within and around the Gorge. We recognized this would be an ongoing challenge, but we also realized that many of our employees and their families lived in and around the Scenic Area, had jobs and livelihood which depended upon commercial activity. Therefore, it was important to maintain and preserve the

Don Brunell Comments
Whistling Ridge Energy Project

commercial viability of private and public lands and the industries and businesses within and adjacent to the Scenic Area.

I sincerely hope that the Council appreciates the unique challenges that the private sector confronts in operating within the Columbia River Gorge National Scenic Area. We fully understand the concerns of those who provide private sector jobs and generate the tax revenues for local governments and schools with and around the Scenic Area should be paramount. So, that is why I agree that SDS Lumber, a long-held family-owned business, should be allowed to move forward with its Whistling Ridge Energy Project. Further, it seems to me that it makes sense for the State of Washington to lease the adjacent ridgeline so as to extent the wind farm and allow our state, which is severely financially strapped, to earn income from the public lands for schools, colleges and universities and rural counties such as Skamania.

Those of us in Clark County are aware of the onerous requirements imposed by the Act. While much of Clark and Multnomah counties only have a peripheral stake in the Gorge, 6% of Skamania's land mass is privately held, and much of that falls within the Scenic Area. The point is when opportunities arise to enhance the economy in Skamania County, add much needed renewable electricity to the grid, and provide new family-wage jobs; we should not pass that opportunity up.

We are also keenly aware that the last monthly adjusted unemployment figure released for the Portland-Vancouver metro area was 13.3%. Rural counties are also feeling the bite of high unemployment and the Whistling Ridge Energy Project not only brings construction jobs in these recessionary times but ongoing employment maintaining the turbines and transmission system.

Council members should, if they are not already, be aware of the history behind the Act and what is becoming a remarkable and implicit disregard for the takings of property rights that the Act seems to have spawned. The bitterness which has developed since passage of the Act is troubling especially for the communities in the Scenic Area. That bitterness is regrettable and is growing. It remains because advocacy groups campaign constantly for expansion of restrictions within and extensions beyond the defined CRGNSA boundary.

The Energy Facility Site Evaluation Council has already heard considerable testimony along these lines; testimony that bears no repeating here. My point is simply that none of what has been entered into the record is supported by the legislative intent of the Act's authors, or in the language of the Act as written. The proposition that whatever can be seen from within the Scenic Area should be treated as if it were within its boundary is ludicrous. It is also outrageous. I can tell you personally that when the law was written that was never the intent.

This is outrageous because a reduction in the capacity of SDS' wind farm will render the entire project untenable. Outrageous because prohibiting SDS from pursuing the highest and best use of its lands in ways fully compatible with timber production, is a blatant property rights taking. Outrageous because Whistling Ridge, with the jobs and tax revenue and local purchases it will engender, is a private economic stimulus for a community that urgently needs one. And finally, asserting a de facto expansion of the Scenic Area boundary is outrageous because it pours salt on the wound of decades of local residents' bitterness toward the original Act despite its clearly limited mandate; there never was, nor should be, a buffer around or extension of the CRGNSA boundary.

Finally, reflecting as I do as a citizen of Washington State, I'm hopeful that the Council will, in its deliberations, take cognizance of existing state policies which promote renewable energy development.

8.14.2010

Don Brunell Comments
Whistling Ridge Energy Project

In other words, I trust that you will reflect in your decision, the policy priorities that the Governor and Legislature not to mention the electorate through I-937 have made law.

The Stevenson family and SDS as a company are good people who work hard and provide jobs and tax revenues. They are the kind of citizens and employers that our state and region needs. They are doing the right thing with Whistling Ridge project putting the land to its highest and best use while provided needed power to our business, hospitals, schools, factories and families.

It is inconceivable to me that a few people, with their own interests in mind, will succeed in stopping a well-designed wind farm project from being built on private land that is located outside the CRGNSA on the grounds that the project defiles the Gorge. Give me a break! It most surely does not, and their claims fail to approach any standard of common sense.

I strongly urge the Council to separate what is true from what is not, from what is self-service from what is in the best interests of the working families in south central Washington and north central Oregon, and that you recommend approval for the Whistling Ridge Energy Project to the governor. We also add that we hope that approval can be expedited.

Thank you for your consideration.

ENERGY FACILITY SITE
EVALUATION COUNCIL

Washington EFSEC
905 Plum Street SE
Olympia, WA 98504-3172

RE: DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, along the Skamania and Klickitat county lines.

Dear EFSEC,

This proposal is likely to have different and greater wildlife impacts than any other wind energy facility proposed in the State of Washington, because it is proposed along a forested ridgeline in the foothills of the Cascade Mountains. The proposed project would cause significant negative impacts to sensitive wildlife and plant habitat, and would degrade the outstanding scenic beauty of the Lewis and Clark National Historic Trail and Columbia River Gorge National Scenic Area.

I am concerned that the DEIS is fundamentally flawed because it fails to provide a fair and balanced alternative analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition the BPA and EFSEC have not adequately consulted with the Yakama Indian Nation to ensure the protection of cultural resources.

As the Gorge Commission has recently held EFSEC must determine if this project would require any road construction or ground-disturbing activities in the National Scenic Area.

In addition to these concerns above I am worried about the impact to human health due to turbine noise and light flicker.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS and issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Sincerely,

Kate McCarthy

RE: Whistling Ridge Energy Project DEIS

Thank you for providing an additional opportunity for comment regarding the Whistling Ridge Energy Project Draft Environmental Impact Statement (DEIS). The Whistling Ridge Energy Project is located within the Ceded Lands of the Yakama Nation, the legal rights to which were established by the Treaty of 1855, between the Yakama Nation and the United States Government. The Treaty set forth that the Yakama Nation shall retain rights to resources upon these lands and, therefore, it is with the assistance and backing of the United States Federal Government that Yakama Nation claims authority to protect traditional resources. Yakama Nation's comments are provided by the Cultural Resources Program (CRP) of the Yakama Nation, established by Tribal Resolution T-66-84 as an arm of the Tribal Government. Comments are respectfully submitted by those whom the Tribal Government has designated to speak on behalf of the Yakama Nation regarding the protection of cultural resources in this matter.

A Yakama Nation Traditional Cultural Property (TCP) has been identified within project boundaries on Chemawa Hill, the proposed location of turbines A1-A7. At this time, the Yakama Nation Tribal Council is meeting to discuss potential impacts, proper treatment, and recommendations regarding the TCP. These recommendations of the Tribal Council will be available by mid-September.

A report identifying the presence of a TCP on Chemawa Hill was provided to the applicant by Yakama Nation CRP in December 2009. However, despite the availability of that information to the applicant, discussion regarding impacts to the TCP were omitted from the DEIS. This omission is highly concerning. The applicant has, on numerous occasions, suggested a willingness to work with Yakama Nation, however, the omission of this important information from the DEIS, does not currently indicate a willingness to consider the Tribe's concerns.

Yakama Nation CRP was not the only agency to express concerns regarding construction of wind turbines on Chemawa Hill. Several other organizations and agencies stated similar concerns and were also omitted from the DEIS. The Skamania County Agri-Tourism Association asked that the "A Towers" be re-sited; the USDI National Park Service recommended removing the A1-A7 turbines to alleviate negative visual impacts; Friends of the Columbia Gorge identified sensitive viewsheds that would be affected by the proposal, and the USDA Forest Service Columbia River Gorge National Scenic Area expressed concerns about visual impacts of the project from key viewing areas of the National Scenic Area.

Additional comments not fully considered under the DEIS included comments from agencies such as the Washington State Department of Fish and Wildlife, which expressed concerns about impacts to bats and birds, and the Attorney General of Washington Counsel for the Environment, who requested analysis of plant and animal species and habitats. Further comments regarding impacts to the natural and cultural environment included the Washington Department of Archaeology and Historic Preservation, which discussed the TCP identified by the Yakama Nation among other topics; The Seattle Audubon Society, which brought attention to Northern Spotted owls and other avian species; Friends of the Columbia Gorge, which discussed threatened and sensitive animal species, and Save Our Scenic Areas who provided comments regarding a number of important environmental concerns.

Given the above listed omissions, the Yakama Nation does not believe that the current information provided in the DEIS has adequately analyzed the environmental impacts associated with development of a wind facility at the proposed location. Furthermore, placement of turbines on Chemawa Hill must be addressed and analyzed with the fair consideration of all concerns submitted through this process. Among the concerns identified, Yakama Nation has notified the applicant and EFSEC of the presence of a Yakama Nation TCP on Chemawa Hill. As mentioned above, this issue is currently before the Yakama Nation Tribal Council and a decision regarding the appropriate treatment of this site will be forthcoming.

The protection of traditional resources within the Ceded Lands of the Yakama Nation is of utmost importance to CRP and the Tribal Government, which it represents. Diminishing habitat caused by development has greatly increased the scarcity of traditional plant and animal resources, as well as diminished access to and altered traditionally important places. Continued and unchecked development will immeasurably harm the traditional resources enjoyed by tribal members if a true and careful analysis of impacts and alternatives is not practiced.

Sincerely,

A handwritten signature in black ink, appearing to read "George Colby". The signature is fluid and cursive, with the first name "George" written in a larger, more prominent script than the last name "Colby".

Subject: Whistling Ridge Draft EIS Comments
Attachments: August 15 comments re Wind farm.docx

Hi Tammy, I hope this works. Thanks for your help, Sallie

August 26, 2010

Washington Energy Facility Site Evaluation Council
905 Plum Street
Olympia, Washington 98504-3172

Re: Whistling Ridge Energy Project May 2010 Draft Environmental Impact Statement

Members of the Council:

Thank you for extending the deadline for comments. Although it arrived at the very last minute, it was a generous extension and I hope that you will also extend the time you will take to review what I imagine will be the many additional submissions.

For the following reasons, as well as those that others have taken the time to bring to your attention, I strongly feel that a completely revised document must be created to stand as an accurate and unbiased presentation of information that Council members can use to make an informed decision regarding this proposal.

The existing document shows a lack of professionalism in many important areas that is inappropriate to both the SEPA/NEPA requirements and the process, as well as to the scale and potential impact of the proposal upon the region and its varied resources. Following are a few of the things that I find the most disturbing. Thank you for considering them when the Draft document is revised.

Section 1, 1.1, Pg 1 Para. 2 Interconnection and Section 1, 2.2 Pg 4 BPA Purpose and Need for Action I do not believe that BPA has yet responded to the request for interconnection. The nearby BPA transmission lines are at carrying capacity with a backlog of other requests for interconnection. Although the location is referred to in Section 3, the precise location for the proposed Whistling Ridge Project interconnection is presently unknown, since no new transmission line has yet been constructed, nor has firm commitment from BPA to existing lines been granted. This renders the cumulative impacts assessment incomplete. It is also incomplete with respect to several other facets of this proposal as well. The BPA new line access corridor construction and interconnection costs, design and placement of any collector substation and interconnection structure, as well as an evaluation of the resulting environmental impacts of their construction and operation would be legitimate, mandatory elements for inclusion in this document.

Since BPA is partially responsible for the DEIS document, it should not be problematic for the agency to include an open and clearly understandable discussion of the agency's present interconnection problems as they relate to the current proposal, thus clarifying this aspect of the EIS. There is discussion of possibilities that were considered but rejected, however, the option finally chosen appears to be questionable, especially since BPA has offered no firm commitment.

Section 1, 2.3.2 Pg 6 “.....it is critical to locate projects in areas where transmission lines currently exist. The applicant thus needs to locate near existing high-voltage transmission , such as the FCRTS.” As noted above (in Section 1, 2.2 notes), the currently existing BPA transmission line is running at capacity, with no possibility for the addition of large additional sources, such as this project’s proposed output would comprise.

The critical issue regarding wind facilities is indeed appropriate siting, but not for the reason of proximity to transmission lines. The applicant (I assume this is the author) misunderstands the basic premise and need for an environmental impact statement. The lack of transparency regarding this issue is disturbing, and should be clarified in the BPA discussion of the issue, rendering this claim invalid. It should be removed from the document; it appears repeatedly in all Sections.

Section 1, 2.3.3 Pg 6 Business Needs of the Applicant An EIS is not a branch of any chamber of commerce nor is an EIS a forum for advertisement. The history of the applicant/company is already included in the Appendices. Other local background information is included in Section 3, 3.10.2.1 Historic Background and this is where it belongs. Every company has business needs but this is not the arena for such discussion. This heading and its text should be removed.

Section 1, 3.2 Pg 7 “The EIS will be used primarily to inform....” As it stands, I do not feel this document yet contains the essential information needed for informed, responsible decision-making, especially in the areas of wildlife impacts, soils/geology and cumulative impacts analysis. It must be improved significantly before it can serve its intended purpose. This may take more time, but it will certainly ensure that the final EIS is a more suitable document for unbiased decision-making, which at this point it is not.

Section 1, 3.3 and 4 Pgs 8, 9 NEPA Section 102 (2) (c) requires that alternatives to the proposed action be provided. There are no Action Alternatives offered in this document (the No Action Alternative is not considered a viable alternative.) Alternatives must be presented and discussed as real possibilities, not avoided by stating that alternatives were “considered but eliminated from detailed study” as is stated in Section 1, 4.3. The Applicant cannot choose to avoid this requirement. Although it is stated several times that the document “... is intended to fulfill the format and content requirements “ of a joint SEPA/NEPA EIS, it falls well short in many areas.

Section 1, 4.1 Pg 9 Proposed Action The project site is stated to have a “proven, robust wind resource.” There is no material to supply this “proof in the EIS document. If “robust ” is interpreted to mean “good”, then this statement is doubly inaccurate. The web-based National Renewable Energy Lab regional wind power mapping resource states that the proposal area provides only “marginal to fair” averaged wind resources compared to other sites in the state. The good to excellent areas are farther east. A BPA (among others)-sponsored wind mapping project on the Internet shows the area to have not particularly good wind resources as well. The wind mapping data, referenced above, conflicts with the applicant’s claim that the project site has a “proven, robust wind resource.” No scientifically stringent data is presented that supplies this “proof.” This “proven, robust” (“steady”) terminology appears repeatedly throughout the document and is misleading. A credible document needs to show at least an attempt at accuracy and objectivity.

There are other reasons as well, discussed on the following pages, that indicate the selected site may be a poor choice for a wind facility. Paramount to these, is the technical geologic study of the project site that has not yet, and must be performed before suitability evaluations begin.

One of the factors that the Applicant used to identify site suitability was stated to be the "associated lack of native habitat, reducing or eliminating the need to clear additional forest land." Section 3 discusses the initial "need to clear trees to prepare ridge top sites for construction of turbine base pads and of specially configured parts delivery roadways. Information is even provided regarding where the logs will be taken after being cut. The applicant needs to choose one statement or the other and ensure that references to the eliminated statement are removed from the document as well. Which will it be? A credible document displays consistency.

A current aerial photograph of the steep (70% or more) southern side of the project area, in the vicinity of proposed turbine string A1 – A7 shows standing trees that were restricted from being cut by Washington State DNR when the applicant applied for a Forest Practices Application permit in 2003. What were the constraints that prevented this harvest? Will project approval permit the cutting of these trees, in order to clear for turbine pads and access roads, overriding the earlier DNR prohibition? The Council would need to investigate the nature of the DNR constraint before the evaluation process proceeds.

Again, mention of the alleged availability of nearby BPA transmission lines as a site selection factor: transmission lines that do not have the capacity to carry significant additional power. This issue needs to be clarified as discussed under "Interconnection" on pages one and two.

Lastly, the site was stated to have been chosen because it is close to an SDS mill site (even though it was stated above that no additional trees would have to be cut for the project) and to SDS business offices! Surely this declaration could be deleted lest it be concluded that convenience has a higher value than environmental factors when choosing a suitable location for a wind power facility. Perhaps if the reasoning behind the statement was elucidated, it might seem an appropriate inclusion.

Section 1, 4.1.2 states that a trench, approximately 8.5 miles long and 5 feet wide would be required to place collector cables. The DEIS mentions reseeding with of grasses and native plants, but does not mention what species, nor whether trees or shrubs that were removed would be replaced in-kind. If the plantings are to minimize noxious weed colonization would the reseeding areas be watered to ensure germination in time to counteract opportunistic germination of undesirable species? If so, the amounts used should appear in the Section 3 water use list and a watering regime presented.

Will the removed soil be compacted as it is returned to the trench? Will the soil returned to the trench be returned in the same order that it was removed? What will the compaction guidelines entail? Who ensures that it is done properly? Since this extensive trench will likely disturb underground water flow patterns and create new, possibly undesirable flow patterns, it may be important to consider imposing certain requirements and ensuring that agency inspectors with authority to enforce, not proponents or contractors, oversee the work.

Section 1, 4.2 Pg 12 No Action Alternative To state that the No Action Alternative “would not help the state of Washington in achieving the renewable energy goals mandated by the state’s Renewable Portfolio Standard” is misleading. Washington State wishes to encourage renewable energy, but not to the exclusion of all else. Site selection is probably the most important way that negative environmental consequences can be avoided, especially with respect to wildlife. Moreover, BPA does not segregate power sources. Once it is produced and fed into the collection system, it is dealt with as any business commodity, in this case by bids. Much of the power we create here is used elsewhere, historically, to California. To imply that a rejection would flout state goals and policies is simplistic and a little misleading.

“(The No Action Alternative) would help to meet the region’s need for additional power in the coming years.” If by “region”, “local” is meant, our regions need is not great. The Columbia River, and other water-driven power-generating dams continue to supply more than ¾ of our power needs. The current trend is to improve efficiency and to encourage both business and the private sector to conservation. It has been estimated (Draft Sixth NPP, 2009) that almost 80% of our locality’s future energy demands can be met in this way. Existing and newly approved wind facilities in the region, with a focus in Klickitat County, are more than adequate to make up the difference. It would be not only misleading but inaccurate to state or imply that there is a “need” for additional wind power in this portion of the Northwest.

Section 1, 4.3 Pg 13 Alternatives Considered but Eliminated from Detailed Study The applicant’s response is in violation of the guidelines by virtue of not complying with the requirement to supply Alternatives. As mentioned above, an EIS requires that alternatives be provided and considered, with accompanying data and analysis to match all of the other Action Alternatives presented.

Section 1, 4.3.1 Pg 13 Alternative Project Locations The contents of this portion are redundant. Again, it avoids the EIS requirement regarding Alternatives. The points made here have all been stated previously (Section 1, 4.1), in the same bulleted form and with almost the same wording.

Section 1, Table 1 Pg 22 Earth: Construction: Design and Mitigation Measures All of the Design and Mitigation Measures listed are “would be” statements. They “should be” already part of the EIS! If, for instance there was a critical subsurface condition, it needs to be known and factored into the decision process, not “discovered” after approval. Only in this way can accurate and responsible evaluation occur. Because of the difficult terrain, there would appear to be very little possibility for adjustment, should geologic constraints be revealed initially. This could easily endanger the viability of the project, which underscores the importance of having data collected from rigorous studies, and analysis conducted by respected sources. Even with the added benefit of such information, the impacts of such radical alterations to a fragile topography can only be guessed. Stringent geologic study of the proposed site must be performed now and the results reported in another, hopefully improved Draft document. This information will be essential for the Council’s evaluation. Without it, the process will have no merit.

Section 1, Table 1 Pg 22 Earth: Construction and Operation – The considerable alterations to the terrain that are proposed for this project - 8.5 miles of three to four foot deep, five foot wide trenches for cable burial, 30-foot deep turbine pads that will require leveling with machinery and extensive blasting to excavate, the building of adequate access and delivery roadways on steep slopes - will certainly have more impacts, and ones that influence each other more closely, than

those listed. The changes made to accommodate the towers will forever alter the ridge tops and they will not revert to their pre-construction profiles after the project is decommissioned. It is inaccurate as well as disingenuous to state that the project construction requirements would be "minor to moderate."

Why is volcanic ash deposition of such concern that it is mentioned here? Granted, several of the soils present do contain a volcanic ash component, but it is not clear to me why this appears, since there is no control over the possible event and, depending on the severity of an ash fall, no mitigation measures would be possible. Large amounts of ash could be physically removed, but would that be mitigation?

Does the statement regarding mass wasting "No obvious recent mass wasting features" imply that there is evidence of the phenomena having occurred on the site in the not-so-recent past? If so, then this is another reason why a more thorough geologic assessment be conducted, before the project is evaluated by the Council.

Although the soil type present on part of the project site has low liquefaction potential, massive excavation and refill, as in the 8.5 mile trench, may disturb soil structure enough to render the possibility greater than in the undisturbed state. Although liquefaction of soils are generally associated with earthquake activity, a similar phenomenon may result when soils become over-saturated. As mentioned above, there is no doubt that the proposed excavated and refilled trench will impact and redirect existing subsoil water flows for 8.5 or more miles and may potentially influence an area far greater than the area of the trench. It is also possible that drainage may be improved in the trench after refill, but the possibility that it will not, must be at least considered.

Section 1, Table 1 Pg 22 Water: Construction and Operation On-site development will certainly impact ground and surface water drainage patterns as indicated above. It is well-recognized that new roadbeds alter water flow significantly and are responsible for a good deal of continuing erosive runoff. The replacement of natural soil and rock drainage on the site with impervious concrete pads constitute large surface areas that will prohibit slow drainage. Water will be quickly released from these surfaces in large quantities at approximately the same time, limiting the remaining soil's ability to absorb and release it slowly. Some of the remaining soil may be additionally compacted from heavy construction machinery, limiting even more its ability to absorb rainfall and melting snow slowly.

Section 3 downplays the impact these impervious surfaces may have upon soils, but this need to be seriously examined. Each of the 49 tower pads have a diameter of 60 feet, creating 2920 square feet of impervious surfaces at the top of steep ridges. These conditions produce fast runoff accompanied by high erosion which, over time may lead to catastrophic geologic events, as well as degrade waterways used by fish, amphibians and invertebrates. Amend this inaccurate denial of the project's impacts to ground and surface waters. A discussion, or at the very least a mention of the runoff potential should be presented, as well as possible impacts to the larger streambeds below, with potential to impact fish, amphibians and invertebrates, upon which fish depend for food. Larger game and non-game animals may be impacted as well through water quality degradation and the possible inability to even reach water. The standard BMP guidelines will not be adequate for this anticipated situation. In recognition of this, an individual plan to accommodate the special runoff problems of the project could be developed as part of a mitigation plan, implemented and monitored by an agent other than the applicant/contractors, if

the project is approved. The cumulative impacts discussion should deal with this possibility as well, but does not.

Section 1, Table 1 Pg 24 Biological Resources: Construction Soil compaction is an undesirable and irreversible impact that should be acknowledged since it affects soil drainage, the ability of certain plants to grow well and limits the species of plants that will grow.

In addition to "loss of suitable habitat," abandonment of adjacent suitable habitat due to construction activity should be considered a likely possibility. Some bird, mammal and invertebrate species are known to be more sensitive to intrusive activities, including noise, than others. Several of these species are listed as being present in the project area. Add "abandonment of suitable habitat due to construction activity" to the list on page 24.

Section 1, Table 1 Pg 24 Biological Resources: Operation "There would be some mortality to birds and bats due to turbine collision and displacement, though not in sufficient numbers to affect population viability." I restrain myself when I say that this statement is offensively inaccurate. It also reveals the applicant's misunderstanding of the "cumulative impact" concept. As wind farms proliferate in our region, the cumulative mortalities become increasingly significant for individual populations, regardless of their population status.

Just because there have been no studies addressing bird population declines in association with wind installations does not mean that one has a legitimate claim to deny that such a relationship may exist.

The bat studies cited, employed equipment that was not capable of determining the bat species present. How then, can an assessment of a particular population be made? Or, by extension, a statement regarding population viability? What authority provided the status information for each population? What is the source of data for western bat species population size? Eastern bat species are being threatened with mass extinctions from White Nose Syndrome, the etiology and causative organism of which is still unknown. The disease has not yet reached the western states; because of this, it is essential that ALL western bat populations be given added protection, regardless of their population status. The bat study data is inadequate in certain respects; the study plan assumptions were not adequately rigorous, there were discrepancies in data collection procedures from year to year, making comparisons and data merging ineffective; long-term sampling frequency was sparse. At the very least, a repeat survey should be conducted which would identify bat species.

The Columbia River Flyway is a major East to West migration route that has likely been used longer than mankind has been here. Raptors are known to use mountain ridges for North/South travel as well as for hunting in this part of the Columbia River. People come from many places outside of this area specifically to see the variety of birds that congregate and fly through this river corridor, some stopping to feed for a few days or weeks before moving on. This site would be an unconscionable choice for a development of this kind, with this knowledge.

"No impacts to listed species" – is this a wish, or a promise from an unknown deity? How can it possibly be known ahead of time that a listed species will not be impacted; especially when inadequate studies have failed to identify what species use the area and with what frequency? And when only a two year start-up mortality study is planned? This is not enough time to obtain meaningful data much less to make any conclusions from the data. The project location would be

an especially difficult one for such monitoring due to the terrain and planned forestry understory management activities. A recent eastern U. S. mortality study is employing dogs to find bat carcasses, because they are so difficult to locate by eye, even in dry flat grassland.

There is no body of information available documenting how wild animals might respond to the sound of wind turbine propellers. This should be at least briefly discussed and dealt with as a possible impact.

Section 1, Table 1 Pg 24 Biological Resources: Design and Mitigation Measures “In order to avoid or minimize impacts to any raptors potentially nesting on or near the project site, a raptor nest survey would be conducted” Then what? A survey is not a mitigation measure.

The composition of the proposed Technical Advisory Committee members is not well thought out. Entities or personages that have vested interests or have demonstrated no interest, cannot be relied upon to make responsible, nor to make informed mitigation recommendations. To include the developer on such a committee would be unwise as well as unfair to the resources. If this route is pursued, enforcement capabilities must be granted and there must be a preponderance of resource advocates as committee members. TAC groups are by reputation, generally ineffective when they have no powers. They are also rendered ineffective if members have conflicts in interest, as counties and developers often do. This would be a great opportunity to cast aside TACs, breaking out of the customary mold and devising a new and more effective way to resolve monitoring and mitigation issues associated with such a project.

“For potential impacts to big game species (deer and elk) coordination with WDFW will occur if appropriate.” Again, just to mention something does not comprise a mitigation measure. What about bears, and large cats? Who decides if a situation is “appropriate” warranting consultation? Under what circumstances would it be appropriate to coordinate? The project location is a designated wintering area for elk. What plant species are present that elk might use for winter forage? Will these species be replanted and therefore present in adequate quantities to continue to serve as winter forage during construction and operation of the proposed project? These considerations must be treated responsibly somewhere in the document. The quoted statement is vague and obtuse. It leaves the reader with **no information** about how big game species ‘ use of the area will be approached, nor does it correct nor solve any problems big game species may have because of the project.

Section 1, Table 1 Pg 25 Energy and Natural Resources: Operation The “Minor quantities of lubricating oils.....” should be specifically quantified, if only as an estimate, to be consistent with the remaining listed items.

Section 1, Table 1 Pg 25 Environmental health: Construction The project is located at the southern end of a wide contiguous band of lands termed “Fire-prone Landscape Management Strategy Area” by a USFWS 2008 Final Spotted Owl Recovery Plan map. This area runs from the Columbia River north to the Washington-Canada border. The increased risk of fire during the summer months must be seriously considered and aggressive prevention measures **above the usual standards** should be pursued and stipulated.

Prohibitions on conducting potential spark and fire-generating activities during the driest fire danger periods of the year could be part of a plan keyed to this project and would demonstrate

care and concern for nearby communities. A several month delay in certain construction activities and equipment use as a result of time-of-year prohibitions would be well justified and need not halt all building progress.

There WILL be blasting activity in association with this project, if approved. Getting rid of the “may” and “could” in the bullet dealing with blasting would be a more honest way of stating the realities of the massive environmental reshaping that this project will engender. If “Blasting could also create a fire hazard during dry weather”, then this activity should be curtailed during these periods. Likewise, an activities plan related to the regional weather patterns might suggest avoiding blasting during unusually wet times of the year to avoid problems similar to those encountered recently along Hwy 14. There is no doubt that the level of blasting activity alone has the potential to seriously destabilize this particular environment, which, as noted elsewhere, already has nearby unstable loci. Since there is no geologic assessment data provided, it is impossible to even guess what impacts such activity could produce. When the geologic assessment is conducted, it should address not only immediate impacts but the potential long-term impacts of blasting, even although this would only be predictive. Road department records from Underwood and Hwy 14 should give the Council a good idea of the areas’ historic instability.

Section 1, Table 1 Pg 25 Environmental health: Construction (Column 4) The second, bulleted statement in column 4 implies that a fossil-fuel- powered facility might supply fill-in power when a wind facility is unproductive (and that it would carry a higher risk of fire.) There is a federal requirement mandating that alternative power source facilities must accompany any new wind facility, based upon the amount of power generated. The proposed wind project would generate above the MW threshold, requiring the construction of an alternative power-generating facility to balance a wind farm’s unproductive periods of no wind or too high wind. The construction cost of this requirement building, inter-tie costs, should certainly be included in the cost analysis for this project, but it does not appear. Since the alternative power facility is a requirement , its location should be identified and the associated environmental impacts need to be included in the EIS, including the cumulative impacts portion.

Section 1, Table 1 Pg 26 Environmental Health: Operation Again, with respect to fire potential, local ordinances and other regulations and standards are not directed to such a project, and are not adequate, because of the unusual situation. An individually tailored, aggressive fire prevention plan and response tactic needs to be developed for the construction and operation phases of this proposed project. Relying on existing regulations will not adequately address the specific potential hazards nor protect the nearby population and environment.

“...none of the planned turbines are within 2,500 feet of existing residences.” This is not correct; there is one residence. Mitigation measures should be included in the proper column.

“EMF from the project ...would have no health and safety impacts.” I do not see any information in the document to support this assertion. There is certainly study regarding the issue, but conclusions are not definitive at this time. Can a pronouncement be made if there is inadequate documentation? Unless this can be produced, this statement needs to be removed or qualified in some manner in order to be objective.

Section 1, Table 1 Pg 27 Noise: Construction This section downplays construction noise, which will carry well into the valleys and bounce off of adjacent hillsides. Although construction is stated to occur during daylight hours, it will likely begin very early and continue through dusk.

The added noise of myriad transportation trucks will certainly impact local residents on a daily basis and should be included in the list.

The noise from blasting will certainly be noticeable and will last for awhile. In thoroughness, it should also be mentioned.

Section 1, Table 1 Pg 27 Noise: Operation An in-depth submission regarding wind turbine noise impacts upon humans has been submitted. Please consider it as a counter to the data presented in the EIS and take appropriate action to modify the table.

Section 1, Table 1 Pg 33 Socioeconomics: Operation There are several studies that identify undesirable affects of turbines upon humans (see K. Brown's testimony citations). One would not unreasonably conclude that properties in close proximity to such turbine arrays might be less desirable for habitation, at least to a percentage of the population. Proponents of wind power have issued statements derived from studies indicating that property values are not adversely affected by nearby wind turbines. As such studies continue, depending on the analyses, certainly there is the possibility that property values may be affected one way or another, but for now either position can support and document its claims.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts : Earth The enormously disruptive activity that will be required to complete this project, located in a geologically fragile environment that has already been subjected to considerable alteration, is very likely to respond with undesirable events. In potentially susceptible areas, no amount of "careful design" can prevent, nor can "mitigation measures" restore, areas where mass wasting has occurred. It should be added to the list of potential adverse impacts, especially since evidence of such an event was documented during a previous survey. The severe re-contouring, blasting, large-scale trenching and creation of impervious surfaces all increase the likelihood of minor or major responses from the environment. The soil types in some areas are acknowledged to be susceptible to erosion and the proposed "A" array is located precisely along a Class II (High Landslide Hazard Area) ridgeline. To dismiss these and other known geologic concerns with the two brief dismissive statements presented is unacceptable. Until a reputable geologic assessment study is performed, there will remain a glaring gap in this arena. Without professional scientific data, any predictive statements can only be considered arbitrary and of dubious merit.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts: Air Quality Construction activity would involve many more pieces of diesel-fueled machinery than any logging operation. It is absurd to think that the residents of the town of Underwood will not notice, nor be affected by, a continuing stream of diesel trucks heading up and down the roads every day for months. Peak morning hour numbers of trucks are estimated to be 210/hr for 3-5 months. Further, all major construction equipment is to be diesel-powered (Section 3 Table 6-5, Pg 109 Fire and Explosion Risk Mitigation.) It is disingenuous to claim that this would be comparable to "existing logging operations.", and equally so to state that "the project would contribute to a beneficial impact on overall air quality" Climatological data presented in the EIS indicates that the area is prone to air stagnation at all times of the year, but especially during the summer when pollutants from downriver may collect forming considerable haze. Even if this statement refers to the completed project, it is a bit of a stretch to claim "beneficial impacts on overall air quality" when the requirement to build alternative fuel power plants are a direct result of building wind powered

facilities. With this in mind, it might be fairer to consider that project would lead to a decline in overall air quality.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts: Biological Resources See previous comments regarding bats and birds (Section 1, Table 1 Biological Resources: Operation.) The Summary statement simply reiterates the document text statements, almost word for word, imparting the same inappropriate lack of concern. Why are no other wildlife groups mentioned? Certainly animal corridors will be interrupted, the areas in which young are raised may be pushed further away and populations may become fragmented. Even with the proposed mitigation measures in place, erosion runoff would affect the fishery and invertebrate communities downhill of this project. Blasting may obliterate pika or marmot populations that may have been overlooked. No mention of them occurs in the animal surveys. These could be significant impacts unless there is some oversight to ensure that mitigation measures are maintained to the standard for the duration of construction. Often, self-policing measures produce initial compliance, but over time may be seen to deteriorate.

Section 1, 8.2 Para 1 Pg 37 The last sentence in this paragraph appears to more of a running prepositional phrase. It is awkward and could be recast for a more professional presentation.

Section 1, 8.2 Para 2 Pg 37 The first sentence of the second paragraph is incomplete and needs structural as well as subjective clarification.

The last sentence of this paragraph still stretches my imagination – how will “introducing up to 75 MW” of wind power “contribute to efforts to improve air quality in the Columbia River Gorge vicinity?” If anything, fossil-fuel facilities will be added (producing a negative effect upon air quality) to make up for the irregular output of this wind facility.

Section 1, 10 Pg 38 References Again, BPA’s Wind Integration Plan might be an excellent addition to the references section if it might clarify the line access and interconnection issues.

Section 2, 1.4.1 Pg 9 Construction Activities “Transportation of construction materials” (gravel, concrete, rebar, etc.) could be added to the list but “Use of dynamite and machine re-contouring of ridges” should be added to the list.

Section 2, 1.4.2 Pg 12 Construction Schedule Earlier portions of the document state a construction time of one year. This section states “approximately 15 months” would be required for construction ; all other sections repeatedly mention one year. Consistency throughout the document would enhance credibility. Are the construction cost estimates based upon 12 or “approximately 15 months?” The suggested time-of-year prohibitions to pro-actively address fire danger could be inserted into the detailed construction schedule, possibly changing the time frame even beyond 15 months.

Section 2, 1.4.4 Pg 13 Construction Costs An extra three months or more added to the construction time estimate of one year stated early in the EIS will add to the construction cost estimate presented in Section 2, 1.4.4 Pg 13, assuming that it is based upon a 12-month time frame.

Another cost that has not been discussed, although it may not be considered a bona fide construction cost, is that of the required alternative/fossil fuel facility that would make up for non-production times at the wind facility. Interconnection, substation and line link costs associated with this facility should be also be added and later considered in cumulative impact analyses. The total cost of building an alternative power supply facility to offset erratic wind generation is possibly not the responsibility of the applicant, but possibly some monetary responsibility exists? Who pays for the construction of such a facility? Is the cost partially subsidized? If so, by whom?

Section 2, 1.5 Pg. 14 Project Operations The project is stated to “operate 24 hours per day, seven days per week,” implying that generation also occurs on that schedule. It might be a bit more objective to modify the statement to reflect the reality of wind power generation for those who do not know.

Is there any capability

The first U. S. study of reduced (bat) fatalities and economic costs of “low-wind mitigation” began in 2008, continued in 2009 and 2010. The research is being conducted in Pennsylvania with Casselman turbines and has demonstrated that bat fatalities were reduced an average 73% when turbines were left off-line, at night, during low wind conditions (<11.2 – 14.5 mph). An additional benefit to bats was to use the nighttime limitation during the migration season in the fall. The second year of the study, 2009, was funded wholly by USFWS. I will provide the Council with the citations. The calculated loss of production resulting from the temporary stoppage in that area of the country was 0.3 to 1.0% of the facilities’ yearly output.

Some studies have indicated that certain individual towers in an array produce more mortalities than others. Will this project have the capability of shutting down a single turbine? Will it be possible to shut down individual arrays in this project? Will the strategy above be a possibility for these turbines or is their operation wholly automatic? What would the cost difference be if this capability was part of the design plan for these proposed turbines? This approach might be one that could be applied to bird mortality as well.

Section 2, 3 Pg 19 Alternatives Considered but Eliminated from Detailed Study As in Section 1, the applicant has substituted a list of self-generated criteria instead of fulfilling the mandated subject matter identified in the heading.

Section 3, 44.1.5 Special Status Wildlife Species Northern Spotted Owl Although the two historical northern spotted owl nesting sites at Moss and Mill Creeks, near the northern boundary of the proposed project are not believed to be presently occupied, these areas still carry the potential for occupation and use. Little is known about long-term northern spotted owl reoccupation patterns and current agency attempts to halt population declines are not encouraging. Forested habitats that have supported northern spotted owls in the past are likely to support a diverse suite of life forms and hold the potential to support one another, given enough space.

The proposed project is located within one of Washington States ten designated SOSEAs (Spotted Owl Special Emphasis Areas.) Although the project location and proposed construction activities do not impinge upon the parameters specified in the state regulations regarding SOSEAs, a favorable decision for this proposal would lead to extensive re-contouring and dynamiting the

outer boundary of a select habitat resource. Regardless of the legality of the proposed actions, to actually go ahead with the proposed habitat alterations would seem to flout the intent of the regulation. Eliminating the northern portion of the B array and the entire C5 to C8 array might allow the outer edges of the historic nest range that overlap the project boundary some protection as well as respect the spirit of the SOSEA. This might even serve as one of the as-yet-unsupplied Action Alternatives.

It is interesting and disturbing at the same time, to see the large list of bird and mammal species observed at the proposal site and to realize that a number of them are "threatened," federal species of concern, or Washington State candidates for listing. Townsend's big-eared bat is both a federal species of concern and a Washington State Candidate for listing, although the incomplete bat studies conducted at the proposal site did not determine bats to species, it is a possibility that this bat may be using the area as well as Keen's Myotis, another Washington State Candidate for listing.

Although it is acknowledged in **Section 3, page 81** that "Some bat fatalities are anticipated as a result of the operation of the proposed project" the only mention of bats in **Section 3, 4.3 Mitigation Measures** is to minimize turbine lighting "thereby reducing the potential for birds and bats to be disoriented by lights....." Bats are not attracted nor disoriented by lights, although they are attracted by some night-flying insects that are. Essentially then, there is no mitigation measure directed toward bat mortalities; should there not be one suggested? If one cannot be suggested then it is assumed that the proposed project's bat mortalities will have to be considered unavoidable.

On the next page, **Section 3, 4.4 Unavoidable Adverse Impacts**, the second paragraph states that bird and bat mortalities will occur, but that "the level of mortality is not anticipated to be sufficient to negatively affect the population viability of any single species." This fallacy of this statement has been discussed before (page 5); the Applicant has presented no credible documentation to support such a claim. As wind farms proliferate in our region, cumulative mortalities become increasingly significant for individual populations, regardless of their population status. In this case, since population status is an unknown, it would not be possible to make a statement about viability.

Section 3, 4.4 Unavoidable Adverse Impacts, Paragraph three "It appears unlikely that the project would cause any mortality to a threatened or endangered species." Northern goshawks, golden and bald eagles were reported to be present at the proposed turbine sites. This project has an operating time estimate of 30 years. Even a non-statistician might consider the "likelihood" of such an event over thirty years to be at least "somewhat likely." Death can occur from a rare visitation, as well as from frequent visitations and although the number of mortalities may be small, the cumulative impacts for certain bird and bat species could affect overall species survival.

Section 3, 5.2.1 Pg 89 Impacts: Proposed Action: Construction There is no mention of re-using the material removed from blasting in order to lessen the need for 100,000 yards of gravel the project is expected to require. Is this a possibility?

Section 3, 5.4 Pg 92 Unavoidable Adverse Impacts The proposal is stated to have "minor unavoidable adverse impacts to energy and natural resources." The crushed rock requirement by

itself (100,000 yards) would deplete local supplies and possibly drive prices higher locally after construction since it might have to be hauled from greater distances.

The preceding statement is immediately followed by another, claiming that “The overall impact of the project to energy and natural resources would be positive since it would provide the region with low-cost, clean, renewable energy...” etc. This has been commented on previously. The power generated from the proposed facility will not necessarily be used in this region due to the nature of BPA’s power brokering activities. Our region’s power costs in the past were indeed comparatively inexpensive, but prices are not low now, nor will they be in the future. P.U.D. newsletters have been explaining this fact to customers for several years. There is a growing discussion about making power costs equal across the country, so that those living in “power-poor” areas will not be unfairly penalized. Clean? Not as clean as solar, and certainly this proposal will require radical environmental destruction.

Section 3 14.3 Pg 269 Cumulative Impacts Rhetoric, political pressure, or private interest should never be allowed to override thorough and thoughtful, unhurried evaluation. Scientific rigor is essential to the cumulative impacts analysis. I am very sorry to see this section displaying an alarming number of mis-statements as well as faulty logic. Some of these statements have been carried over from Sections one and two, but there are several statements introduced in Section 3, clearly meant to justify the EIS’s approach to the cumulative impacts analysis, that are simply a result of poor logic and misapplication of conclusions or data that has been taken out of context.

One example is a statement that appears on page 274 of Section 3, and is partially quoted below. The NAS Mid-Atlantic Highlands study conducted in 2007, only three years ago is not as relevant (in 2010) for analysis of cumulative impacts to wildlife, especially birds and bats; the rapid pace of wind power development has changed the dynamic entirely not only in the location of the study but especially in the northwest, making this study unsuitable for cumulative impact use in this EIS. This study moreover, quoted in the EIS in **Section 3, Pg 2, 74 Bird and Bat Species** (last sentence in paragraph 2), concluded that “for rare and local populations” the predicted level of fatalities when combined with all other man-made sources of mortality could affect population viability.” This statement was made three years ago. Note that the study referred to predictions of mortality, not documented mortalities per se. It has been found that predictions in the arena of wind power mortalities have often been underestimated.

The “other man-made sources of mortality,” contrary to the opening statement in paragraph three (**Section 3, Pg 274 Bird and Bat Species**) is hardly an “inherent difficulty” to a cumulative impacts analysis focusing on wind turbine mortalities. The “other man-made mortalities” are merely ancillary; they existed before wind turbine facilities and comprise a background level inherent to our cultural lifestyle. The “cumulative” aspect of the bird and bat analysis attempts to determine what impact wind turbines have regionally, to sometimes unknown population numbers of migrating, foraging and, nesting species.

State protections, USFWS and other specific, reputable wildlife data also must be considered in the analysis, as should a comparison analysis of costs. Although it is difficult to attribute monetary values to wildlife resources, standards are available to do so.

An essential element in any study is the study plan. Basic assumptions must be scientifically (logically) rigorous and the data collection schedules equally well-planned in order to produce

meaningful results. Data collection on wildlife takes many years. Conclusions from the results of such studies must employ scientific rigor. This is where peer-reviewed papers and respected sources can assist reviewers. To ensure adequately broad and equitable cumulative impacts analysis for this proposed project, it would be appropriate to engage another analyst, other than those that have already provided information and conclusions in association with this proposal. There are well-respected scientists available who would be able to perform this service with expertise and lack of bias. I strongly recommend this action, and the inclusion of such a consultation in the final EIS document.

I have made my points along the way, as I followed through the EIS document and will not summarize my concerns. I realize that this may be an inconvenient way to deal with such a large amount of material, but this is page 14 already! The specific shortcomings of the cumulative impacts section are noted throughout this letter but my main concern is for the apparent lack of understanding about what it should be, and to the lack of critical logic used to justify some of the conclusions.

Thank you for the opportunity to comment further and for considering my comments.

Sincerely,

Sallie Tucker Jones

Washington Energy Facility Site Evaluation Council
905 Plum Street
Olympia, Washington 98504-3172

Re: Whistling Ridge Energy Project May 2010 Draft Environmental Impact Statement

Members of the Council:

Thank you for extending the deadline for comments. Although it arrived at the very last minute, it was a generous extension and I hope that you will also extend the time you will take to review what I imagine will be the many additional submissions.

For the following reasons, as well as those that others have taken the time to bring to your attention, I strongly feel that a completely revised document must be created to stand as an accurate and unbiased presentation of information that Council members can use to make an informed decision regarding this proposal.

The existing document shows a lack of professionalism in many important areas that is inappropriate to both the SEPA/NEPA requirements and the process, as well as to the scale and potential impact of the proposal upon the region and its varied resources. Following are a few of the things that I find the most disturbing. Thank you for considering them when the Draft document is revised.

Section 1, 1.1, Pg 1 Para. 2 Interconnection and Section 1, 2.2 Pg 4 BPA Purpose and Need for Action I do not believe that BPA has yet responded to the request for interconnection. The nearby BPA transmission lines are at carrying capacity with a backlog of other requests for interconnection. Although the location is referred to in Section 3, the precise location for the proposed Whistling Ridge Project interconnection is presently unknown, since no new transmission line has yet been constructed, nor has firm commitment from BPA to existing lines been granted. This renders the cumulative impacts assessment incomplete. It is also incomplete with respect to several other facets of this proposal as well. The BPA new line access corridor construction and interconnection costs, design and placement of any collector substation and interconnection structure, as well as an evaluation of the resulting environmental impacts of their construction and operation would be legitimate, mandatory elements for inclusion in this document.

Since BPA is partially responsible for the DEIS document, it should not be problematic for the agency to include an open and clearly understandable discussion of the agency's present interconnection problems as they relate to the current proposal, thus clarifying this aspect of the EIS. There is discussion of possibilities that were considered but rejected, however, the option finally chosen appears to be questionable, especially since BPA has offered no firm commitment.

Section 1, 2.3.2 Pg 6 “.....it is critical to locate projects in areas where transmission lines currently exist. The applicant thus needs to locate near existing high-voltage transmission , such as the FCRTS.” As noted above (in Section 1, 2.2 notes), the currently existing BPA transmission line is running at capacity, with no possibility for the addition of large additional sources, such as this project’s proposed output would comprise.

The critical issue regarding wind facilities is indeed appropriate siting, but not for the reason of proximity to transmission lines. The applicant (I assume this is the author) misunderstands the basic premise and need for an environmental impact statement. The lack of transparency regarding this issue is disturbing, and should be clarified in the BPA discussion of the issue, rendering this claim invalid. It should be removed from the document; it appears repeatedly in all Sections.

Section 1, 2.3.3 Pg 6 Business Needs of the Applicant An EIS is not a branch of any chamber of commerce nor is an EIS a forum for advertisement. The history of the applicant/company is already included in the Appendices. Other local background information is included in Section 3, 3.10.2.1 Historic Background and this is where it belongs. Every company has business needs but this is not the arena for such discussion. This heading and its text should be removed.

Section 1, 3.2 Pg 7 “The EIS will be used primarily to inform....” As it stands, I do not feel this document yet contains the essential information needed for informed, responsible decision-making, especially in the areas of wildlife impacts, soils/geology and cumulative impacts analysis. It must be improved significantly before it can serve its intended purpose. This may take more time, but it will certainly ensure that the final EIS is a more suitable document for unbiased decision-making, which at this point it is not.

Section 1, 3.3 and 4 Pgs 8, 9 NEPA Section 102 (2) (c) requires that alternatives to the proposed action be provided. There are no Action Alternatives offered in this document (the No Action Alternative is not considered a viable alternative.) Alternatives must be presented and discussed as real possibilities, not avoided by stating that alternatives were “considered but eliminated from detailed study” as is stated in Section 1, 4.3. The Applicant cannot choose to avoid this requirement. Although it is stated several times that the document “... is intended to fulfill the format and content requirements “ of a joint SEPA/NEPA EIS, it falls well short in many areas.

Section 1, 4.1 Pg 9 Proposed Action The project site is stated to have a “proven, robust wind resource.” There is no material to supply this “proof in the EIS document. If “robust ” is interpreted to mean “good”, then this statement is doubly inaccurate. The web-based National Renewable Energy Lab regional wind power mapping resource states that the proposal area provides only “marginal to fair” averaged wind resources compared to other sites in the state. The good to excellent areas are farther east. A BPA (among others)-sponsored wind mapping project on the Internet shows the area to have not particularly good wind resources as well. The wind mapping data, referenced above, conflicts with the applicant’s claim that the project site has a “proven, robust wind resource.” No scientifically stringent data is presented that supplies this “proof.” This “proven, robust” (“steady”) terminology appears repeatedly throughout the document and is misleading. A credible document needs to show at least an attempt at accuracy and objectivity.

There are other reasons as well, discussed on the following pages, that indicate the selected site may be a poor choice for a wind facility. Paramount to these, is the technical geologic study of the project site that has not yet, and must be performed before suitability evaluations begin.

One of the factors that the Applicant used to identify site suitability was stated to be the "associated lack of native habitat, reducing or eliminating the need to clear additional forest land." Section 3 discusses the initial "need to clear trees to prepare ridge top sites for construction of turbine base pads and of specially configured parts delivery roadways. Information is even provided regarding where the logs will be taken after being cut. The applicant needs to choose one statement or the other and ensure that references to the eliminated statement are removed from the document as well. Which will it be? A credible document displays consistency.

A current aerial photograph of the steep (70% or more) southern side of the project area, in the vicinity of proposed turbine string A1 – A7 shows standing trees that were restricted from being cut by Washington State DNR when the applicant applied for a Forest Practices Application permit in 2003. What were the constraints that prevented this harvest? Will project approval permit the cutting of these trees, in order to clear for turbine pads and access roads, overriding the earlier DNR prohibition? The Council would need to investigate the nature of the DNR constraint before the evaluation process proceeds.

Again, mention of the alleged availability of nearby BPA transmission lines as a site selection factor: transmission lines that do not have the capacity to carry significant additional power. This issue needs to be clarified as discussed under "Interconnection" on pages one and two.

Lastly, the site was stated to have been chosen because it is close to an SDS mill site (even though it was stated above that no additional trees would have to be cut for the project) and to SDS business offices! Surely this declaration could be deleted lest it be concluded that convenience has a higher value than environmental factors when choosing a suitable location for a wind power facility. Perhaps if the reasoning behind the statement was elucidated, it might seem an appropriate inclusion.

Section 1, 4.1.2 states that a trench, approximately 8.5 miles long and 5 feet wide would be required to place collector cables. The DEIS mentions reseeding with of grasses and native plants, but does not mention what species, nor whether trees or shrubs that were removed would be replaced in-kind. If the plantings are to minimize noxious weed colonization would the reseeding areas be watered to ensure germination in time to counteract opportunistic germination of undesirable species? If so, the amounts used should appear in the Section 3 water use list and a watering regime presented.

Will the removed soil be compacted as it is returned to the trench? Will the soil returned to the trench be returned in the same order that it was removed? What will the compaction guidelines entail? Who ensures that it is done properly? Since this extensive trench will likely disturb underground water flow patterns and create new, possibly undesirable flow patterns, it may be important to consider imposing certain requirements and ensuring that agency inspectors with authority to enforce, not proponents or contractors, oversee the work.

Section 1, 4.2 Pg 12 No Action Alternative To state that the No Action Alternative “would not help the state of Washington in achieving the renewable energy goals mandated by the state’s Renewable Portfolio Standard” is misleading. Washington State wishes to encourage renewable energy, but not to the exclusion of all else. Site selection is probably the most important way that negative environmental consequences can be avoided, especially with respect to wildlife. Moreover, BPA does not segregate power sources. Once it is produced and fed into the collection system, it is dealt with as any business commodity, in this case by bids. Much of the power we create here is used elsewhere, historically, to California. To imply that a rejection would flout state goals and policies is simplistic and a little misleading.

“(The No Action Alternative) would help to meet the region’s need for additional power in the coming years.” If by “region”, “local” is meant, our regions need is not great. The Columbia River, and other water-driven power-generating dams continue to supply more than ¾ of our power needs. The current trend is to improve efficiency and to encourage both business and the private sector to conservation. It has been estimated (Draft Sixth NPP, 2009) that almost 80% of our locality’s future energy demands can be met in this way. Existing and newly approved wind facilities in the region, with a focus in Klickitat County, are more than adequate to make up the difference. It would be not only misleading but inaccurate to state or imply that there is a “need” for additional wind power in this portion of the Northwest.

Section 1, 4.3 Pg 13 Alternatives Considered but Eliminated from Detailed Study The applicant’s response is in violation of the guidelines by virtue of not complying with the requirement to supply Alternatives. As mentioned above, an EIS requires that alternatives be provided and considered, with accompanying data and analysis to match all of the other Action Alternatives presented.

Section 1, 4.3.1 Pg 13 Alternative Project Locations The contents of this portion are redundant. Again, it avoids the EIS requirement regarding Alternatives. The points made here have all been stated previously (Section 1, 4.1), in the same bulleted form and with almost the same wording.

Section 1, Table 1 Pg 22 Earth: Construction: Design and Mitigation Measures All of the Design and Mitigation Measures listed are “would be” statements. They “should be” already part of the EIS! If, for instance there was a critical subsurface condition, it needs to be known and factored into the decision process, not “discovered” after approval. Only in this way can accurate and responsible evaluation occur. Because of the difficult terrain, there would appear to be very little possibility for adjustment, should geologic constraints be revealed initially. This could easily endanger the viability of the project, which underscores the importance of having data collected from rigorous studies, and analysis conducted by respected sources. Even with the added benefit of such information, the impacts of such radical alterations to a fragile topography can only be guessed. Stringent geologic study of the proposed site must be performed now and the results reported in another, hopefully improved Draft document. This information will be essential for the Council’s evaluation. Without it, the process will have no merit.

Section 1, Table 1 Pg 22 Earth: Construction and Operation – The considerable alterations to the terrain that are proposed for this project - 8.5 miles of three to four foot deep, five foot wide trenches for cable burial, 30-foot deep turbine pads that will require leveling with machinery and extensive blasting to excavate, the building of adequate access and delivery roadways on steep slopes - will certainly have more impacts, and ones that influence each other more closely, than

those listed. The changes made to accommodate the towers will forever alter the ridge tops and they will not revert to their pre-construction profiles after the project is decommissioned. It is inaccurate as well as disingenuous to state that the project construction requirements would be "minor to moderate."

Why is volcanic ash deposition of such concern that it is mentioned here? Granted, several of the soils present do contain a volcanic ash component, but it is not clear to me why this appears, since there is no control over the possible event and, depending on the severity of an ash fall, no mitigation measures would be possible. Large amounts of ash could be physically removed, but would that be mitigation?

Does the statement regarding mass wasting "No obvious recent mass wasting features" imply that there is evidence of the phenomena having occurred on the site in the not-so-recent past? If so, then this is another reason why a more thorough geologic assessment be conducted, **before** the project is evaluated by the Council.

Although the soil type present on part of the project site has low liquefaction potential, massive excavation and refill, as in the 8.5 mile trench, may disturb soil structure enough to render the possibility greater than in the undisturbed state. Although liquefaction of soils are generally associated with earthquake activity, a similar phenomenon may result when soils become over-saturated. As mentioned above, there is no doubt that the proposed excavated and refilled trench will impact and redirect existing subsoil water flows for 8.5 or more miles and may potentially influence an area far greater than the area of the trench. It is also possible that drainage may be improved in the trench after refill, but the possibility that it will not, must be at least considered.

Section 1, Table 1 Pg 22 Water: Construction and Operation On-site development will certainly impact ground and surface water drainage patterns as indicated above. It is well-recognized that new roadbeds alter water flow significantly and are responsible for a good deal of continuing erosive runoff. The replacement of natural soil and rock drainage on the site with impervious concrete pads constitute large surface areas that will prohibit slow drainage. Water will be quickly released from these surfaces in large quantities at approximately the same time, limiting the remaining soil's ability to absorb and release it slowly. Some of the remaining soil may be additionally compacted from heavy construction machinery, limiting even more its ability to absorb rainfall and melting snow slowly.

Section 3 downplays the impact these impervious surfaces may have upon soils, but this need to be seriously examined. Each of the 49 tower pads have a diameter of 60 feet, creating 2920 square feet of impervious surfaces at the top of steep ridges. These conditions produce fast runoff accompanied by high erosion which, over time may lead to catastrophic geologic events, as well as degrade waterways used by fish, amphibians and invertebrates. Amend this inaccurate denial of the project's impacts to ground and surface waters. A discussion, or at the very least a mention of the runoff potential should be presented, as well as possible impacts to the larger streambeds below, with potential to impact fish, amphibians and invertebrates, upon which fish depend for food. Larger game and non-game animals may be impacted as well through water quality degradation and the possible inability to even reach water. The standard BMP guidelines will not be adequate for this anticipated situation. In recognition of this, an individual plan to accommodate the special runoff problems of the project could be developed as part of a mitigation plan, implemented and monitored by an agent other than the applicant/contractors, if

the project is approved. The cumulative impacts discussion should deal with this possibility as well, but does not.

Section 1, Table 1 Pg 24 Biological Resources: Construction Soil compaction is an undesirable and irreversible impact that should be acknowledged since it affects soil drainage, the ability of certain plants to grow well and limits the species of plants that will grow.

In addition to "loss of suitable habitat," abandonment of adjacent suitable habitat due to construction activity should be considered a likely possibility. Some bird, mammal and invertebrate species are known to be more sensitive to intrusive activities, including noise, than others. Several of these species are listed as being present in the project area. Add "abandonment of suitable habitat due to construction activity" to the list on page 24.

Section 1, Table 1 Pg 24 Biological Resources: Operation "There would be some mortality to birds and bats due to turbine collision and displacement, though not in sufficient numbers to affect population viability." I restrain myself when I say that this statement is offensively inaccurate. It also reveals the applicant's misunderstanding of the "cumulative impact" concept. As wind farms proliferate in our region, the cumulative mortalities become increasingly significant for individual populations, regardless of their population status.

Just because there have been no studies addressing bird population declines in association with wind installations does not mean that one has a legitimate claim to deny that such a relationship may exist.

The bat studies cited, employed equipment that was not capable of determining the bat species e present. How then, can an assessment of a particular population be made? Or, by extension, a statement regarding population viability? What authority provided the status information for each population? What is the source of data for western bat species population size? Eastern bat species are being threatened with mass extinctions from White Nose Syndrome, the etiology and causative organism of which is still unknown. The disease has not yet reached the western states; because of this, it is essential that ALL western bat populations be given added protection, regardless of their population status. The bat study data is inadequate in certain respects; the study plan assumptions were not adequately rigorous, there were discrepancies in data collection procedures from year to year, making comparisons and data merging ineffective; long-term sampling frequency was sparse. At the very least, a repeat survey should be conducted which would identify bat species.

The Columbia River Flyway is a major East to West migration route that has likely been used longer than mankind has been here. Raptors are known to use mountain ridges for North/South travel as well as for hunting in this part of the Columbia River. People come from many places outside of this area specifically to see the variety of birds that congregate and fly through this river corridor, some stopping to feed for a few days or weeks before moving on. This site would be an unconscionable choice for a development of this kind, with this knowledge.

"No impacts to listed species" – is this a wish, or a promise from an unknown deity? How can it possibly be known ahead of time that a listed species will not be impacted; especially when inadequate studies have failed to identify what species use the area and with what frequency? And when only a two year start-up mortality study is planned? This is not enough time to obtain meaningful data much less to make any conclusions from the data. The project location would be

an especially difficult one for such monitoring due to the terrain and planned forestry understory management activities. A recent eastern U. S. mortality study is employing dogs to find bat carcasses, because they are so difficult to locate by eye, even in dry flat grassland.

There is no body of information available documenting how wild animals might respond to the sound of wind turbine propellers. This should be at least briefly discussed and dealt with as a possible impact.

Section 1, Table 1 Pg 24 Biological Resources: Design and Mitigation Measures “In order to avoid or minimize impacts to any raptors potentially nesting on or near the project site, a raptor nest survey would be conducted” Then what? A survey is not a mitigation measure.

The composition of the proposed Technical Advisory Committee members is not well thought out. Entities or personages that have vested interests or have demonstrated no interest, cannot be relied upon to make responsible, nor to make informed mitigation recommendations. To include the developer on such a committee would be unwise as well as unfair to the resources. If this route is pursued, enforcement capabilities must be granted and there must be a preponderance of resource advocates as committee members. TAC groups are by reputation, generally ineffective when they have no powers. They are also rendered ineffective if members have conflicts in interest, as counties and developers often do. This would be a great opportunity to cast aside TACs, breaking out of the customary mold and devising a new and more effective way to resolve monitoring and mitigation issues associated with such a project.

“For potential impacts to big game species (deer and elk) coordination with WDFW will occur if appropriate.” Again, just to mention something does not comprise a mitigation measure. What about bears, and large cats? Who decides if a situation is “appropriate” warranting consultation? Under what circumstances would it be appropriate to coordinate? The project location is a designated wintering area for elk. What plant species are present that elk might use for winter forage? Will these species be replanted and therefore present in adequate quantities to continue to serve as winter forage during construction and operation of the proposed project? These considerations must be treated responsibly somewhere in the document. The quoted statement is vague and obtuse. It leaves the reader with **no information** about how big game species ‘ use of the area will be approached, nor does it correct nor solve any problems big game species may have because of the project.

Section 1, Table 1 Pg 25 Energy and Natural Resources: Operation The “Minor quantities of lubricating oils.....” should be specifically quantified, if only as an estimate, to be consistent with the remaining listed items.

Section 1, Table 1 Pg 25 Environmental health: Construction The project is located at the southern end of a wide contiguous band of lands termed “Fire-prone Landscape Management Strategy Area” by a USFWS 2008 Final Spotted Owl Recovery Plan map. This area runs from the Columbia River north to the Washington-Canada border. The increased risk of fire during the summer months must be seriously considered and aggressive prevention measures **above the usual standards** should be pursued and stipulated.

Prohibitions on conducting potential spark and fire-generating activities during the driest fire danger periods of the year could be part of a plan keyed to this project and would demonstrate

care and concern for nearby communities. A several month delay in certain construction activities and equipment use as a result of time-of-year prohibitions would be well justified and need not halt all building progress.

There WILL be blasting activity in association with this project, if approved. Getting rid of the “may” and “could” in the bullet dealing with blasting would be a more honest way of stating the realities of the massive environmental reshaping that this project will engender. If “Blasting could also create a fire hazard during dry weather”, then this activity should be curtailed during these periods. Likewise, an activities plan related to the regional weather patterns might suggest avoiding blasting during unusually wet times of the year to avoid problems similar to those encountered recently along Hwy 14. There is no doubt that the level of blasting activity alone has the potential to seriously destabilize this particular environment, which, as noted elsewhere, already has nearby unstable loci. Since there is no geologic assessment data provided, it is impossible to even guess what impacts such activity could produce. When the geologic assessment is conducted, it should address not only immediate impacts but the potential long-term impacts of blasting, even although this would only be predictive. Road department records from Underwood and Hwy 14 should give the Council a good idea of the areas’ historic instability.

Section 1, Table 1 Pg 25 Environmental health: Construction (Column 4) The second, bulleted statement in column 4 implies that a fossil-fuel- powered facility might supply fill-in power when a wind facility is unproductive (and that it would carry a higher risk of fire.) There is a federal requirement mandating that alternative power source facilities must accompany any new wind facility, based upon the amount of power generated. The proposed wind project would generate above the MW threshold, requiring the construction of an alternative power-generating facility to balance a wind farm’s unproductive periods of no wind or too high wind. The construction cost of this requirement building, inter-tie costs, should certainly be included in the cost analysis for this project, but it does not appear. Since the alternative power facility is a requirement , its location should be identified and the associated environmental impacts need to be included in the EIS, including the cumulative impacts portion.

Section 1, Table 1 Pg 26 Environmental Health: Operation Again, with respect to fire potential, local ordinances and other regulations and standards are not directed to such a project, and are not adequate, because of the unusual situation. An individually tailored, aggressive fire prevention plan and response tactic needs to be developed for the construction and operation phases of this proposed project. Relying on existing regulations will not adequately address the specific potential hazards nor protect the nearby population and environment.

“...none of the planned turbines are within 2,500 feet of existing residences.” This is not correct; there is one residence. Mitigation measures should be included in the proper column.

“EMF from the project ...would have no health and safety impacts.” I do not see any information in the document to support this assertion. There is certainly study regarding the issue, but conclusions are not definitive at this time. Can a pronouncement be made if there is inadequate documentation? Unless this can be produced, this statement needs to be removed or qualified in some manner in order to be objective.

Section 1, Table 1 Pg 27 Noise: Construction This section downplays construction noise, which will carry well into the valleys and bounce off of adjacent hillsides. Although construction is stated to occur during daylight hours, it will likely begin very early and continue through dusk.

The added noise of myriad transportation trucks will certainly impact local residents on a daily basis and should be included in the list.

The noise from blasting will certainly be noticeable and will last for awhile. In thoroughness, it should also be mentioned.

Section 1, Table 1 Pg 27 Noise: Operation An in-depth submission regarding wind turbine noise impacts upon humans has been submitted. Please consider it as a counter to the data presented in the EIS and take appropriate action to modify the table.

Section 1, Table 1 Pg 33 Socioeconomics: Operation There are several studies that identify undesirable affects of turbines upon humans (see K. Brown's testimony citations). One would not unreasonably conclude that properties in close proximity to such turbine arrays might be less desirable for habitation, at least to a percentage of the population. Proponents of wind power have issued statements derived from studies indicating that property values are not adversely affected by nearby wind turbines. As such studies continue, depending on the analyses, certainly there is the possibility that property values may be affected one way or another, but for now either position can support and document its claims.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts : Earth The enormously disruptive activity that will be required to complete this project, located in a geologically fragile environment that has already been subjected to considerable alteration, is very likely to respond with undesirable events. In potentially susceptible areas, no amount of "careful design" can prevent, nor can "mitigation measures" restore, areas where mass wasting has occurred. It should be added to the list of potential adverse impacts, especially since evidence of such an event was documented during a previous survey. The severe re-contouring, blasting, large-scale trenching and creation of impervious surfaces all increase the likelihood of minor or major responses from the environment. The soil types in some areas are acknowledged to be susceptible to erosion and the proposed "A" array is located precisely along a Class II (High Landslide Hazard Area) ridgeline. To dismiss these and other known geologic concerns with the two brief dismissive statements presented is unacceptable. Until a reputable geologic assessment study is performed, there will remain a glaring gap in this arena. Without professional scientific data, any predictive statements can only be considered arbitrary and of dubious merit.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts: Air Quality Construction activity would involve many more pieces of diesel-fueled machinery than any logging operation. It is absurd to think that the residents of the town of Underwood will not notice, nor be affected by, a continuing stream of diesel trucks heading up and down the roads every day for months. Peak morning hour numbers of trucks are estimated to be 210/hr for 3-5 months. Further, all major construction equipment is to be diesel-powered (Section 3 Table 6-5, Pg 109 Fire and Explosion Risk Mitigation.) It is disingenuous to claim that this would be comparable to "existing logging operations.", and equally so to state that "the project would contribute to a beneficial impact on overall air quality" Climatological data presented in the EIS indicates that the area is prone to air stagnation at all times of the year, but especially during the summer when pollutants from downriver may collect forming considerable haze. Even if this statement refers to the completed project, it is a bit of a stretch to claim "beneficial impacts on overall air quality" when the requirement to build alternative fuel power plants are a direct result of building wind powered

facilities. With this in mind, it might be fairer to consider that project would lead to a decline in overall air quality.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts: Biological Resources See previous comments regarding bats and birds (Section 1, Table 1 Biological Resources: Operation.) The Summary statement simply reiterates the document text statements, almost word for word, imparting the same inappropriate lack of concern. Why are no other wildlife groups mentioned? Certainly animal corridors will be interrupted, the areas in which young are raised may be pushed further away and populations may become fragmented. Even with the proposed mitigation measures in place, erosion runoff would affect the fishery and invertebrate communities downhill of this project. Blasting may obliterate pika or marmot populations that may have been overlooked. No mention of them occurs in the animal surveys. These could be significant impacts unless there is some oversight to ensure that mitigation measures are maintained to the standard for the duration of construction. Often, self-policing measures produce initial compliance, but over time may be seen to deteriorate.

Section 1, 8.2 Para 1 Pg 37 The last sentence in this paragraph appears to more of a running prepositional phrase. It is awkward and could be recast for a more professional presentation.

Section 1, 8.2 Para 2 Pg 37 The first sentence of the second paragraph is incomplete and needs structural as well as subjective clarification.

The last sentence of this paragraph still stretches my imagination – how will “introducing up to 75 MW” of wind power “contribute to efforts to improve air quality in the Columbia River Gorge vicinity?” If anything, fossil-fuel facilities will be added (producing a negative effect upon air quality) to make up for the irregular output of this wind facility.

Section 1, 10 Pg 38 References Again, BPA’s Wind Integration Plan might be an excellent addition to the references section if it might clarify the line access and interconnection issues.

Section 2, 1.4.1 Pg 9 Construction Activities “Transportation of construction materials” (gravel, concrete, rebar, etc.) could be added to the list but “Use of dynamite and machine re-contouring of ridges” should be added to the list.

Section 2, 1.4.2 Pg 12 Construction Schedule Earlier portions of the document state a construction time of one year. This section states “approximately 15 months” would be required for construction ; all other sections repeatedly mention one year. Consistency throughout the document would enhance credibility. Are the construction cost estimates based upon 12 or “approximately 15 months?” The suggested time-of-year prohibitions to pro-actively address fire danger could be inserted into the detailed construction schedule, possibly changing the time frame even beyond 15 months.

Section 2, 1.4.4 Pg 13 Construction Costs An extra three months or more added to the construction time estimate of one year stated early in the EIS will add to the construction cost estimate presented in Section 2, 1.4.4 Pg 13, assuming that it is based upon a 12-month time frame.

Another cost that has not been discussed, although it may not be considered a bona fide construction cost, is that of the required alternative/fossil fuel facility that would make up for non-production times at the wind facility. Interconnection, substation and line link costs associated with this facility should be also be added and later considered in cumulative impact analyses. The total cost of building an alternative power supply facility to offset erratic wind generation is possibly not the responsibility of the applicant, but possibly some monetary responsibility exists? Who pays for the construction of such a facility? Is the cost partially subsidized? If so, by whom?

Section 2, 1.5 Pg. 14 Project Operations The project is stated to “operate 24 hours per day, seven days per week,” implying that generation also occurs on that schedule. It might be a bit more objective to modify the statement to reflect the reality of wind power generation for those who do not know.

Is there any capability

The first U. S. study of reduced (bat) fatalities and economic costs of “low-wind mitigation” began in 2008, continued in 2009 and 2010. The research is being conducted in Pennsylvania with Casselman turbines and has demonstrated that bat fatalities were reduced an average 73% when turbines were left off-line, at night, during low wind conditions (<11.2 – 14.5 mph). An additional benefit to bats was to use the nighttime limitation during the migration season in the fall. The second year of the study, 2009, was funded wholly by USFWS. I will provide the Council with the citations. The calculated loss of production resulting from the temporary stoppage in that area of the country was 0.3 to 1.0% of the facilities’ yearly output.

Some studies have indicated that certain individual towers in an array produce more mortalities than others. Will this project have the capability of shutting down a single turbine? Will it be possible to shut down individual arrays in this project? Will the strategy above be a possibility for these turbines or is their operation wholly automatic? What would the cost difference be if this capability was part of the design plan for these proposed turbines? This approach might be one that could be applied to bird mortality as well.

Section 2, 3 Pg 19 Alternatives Considered but Eliminated from Detailed Study As in Section 1, the applicant has substituted a list of self-generated criteria instead of fulfilling the mandated subject matter identified in the heading.

Section 3, 44.1.5 Special Status Wildlife Species Northern Spotted Owl Although the two historical northern spotted owl nesting sites at Moss and Mill Creeks, near the northern boundary of the proposed project are not believed to be presently occupied, these areas still carry the potential for occupation and use. Little is known about long-term northern spotted owl reoccupation patterns and current agency attempts to halt population declines are not encouraging. Forested habitats that have supported northern spotted owls in the past are likely to support a diverse suite of life forms and hold the potential to support one another, given enough space.

The proposed project is located within one of Washington States ten designated SOSEAs (Spotted Owl Special Emphasis Areas.) Although the project location and proposed construction activities do not impinge upon the parameters specified in the state regulations regarding SOSEAs, a favorable decision for this proposal would lead to extensive re-contouring and dynamiting the

outer boundary of a select habitat resource. Regardless of the legality of the proposed actions, to actually go ahead with the proposed habitat alterations would seem to flout the intent of the regulation. Eliminating the northern portion of the B array and the entire C5 to C8 array might allow the outer edges of the historic nest range that overlap the project boundary some protection as well as respect the spirit of the SOSEA. This might even serve as one of the as-yet-unsupplied Action Alternatives.

It is interesting and disturbing at the same time, to see the large list of bird and mammal species observed at the proposal site and to realize that a number of them are "threatened," federal species of concern, or Washington State candidates for listing. Townsend's big-eared bat is both a federal species of concern and a Washington State Candidate for listing, although the incomplete bat studies conducted at the proposal site did not determine bats to species, it is a possibility that this bat may be using the area as well as Keen's Myotis, another Washington State Candidate for listing.

Although it is acknowledged in **Section 3, page 81** that "Some bat fatalities are anticipated as a result of the operation of the proposed project" the only mention of bats in **Section 3, 4.3 Mitigation Measures** is to minimize turbine lighting "thereby reducing the potential for birds and bats to be disoriented by lights...." Bats are not attracted nor disoriented by lights, although they are attracted by some night-flying insects that are. Essentially then, there is no mitigation measure directed toward bat mortalities; should there not be one suggested? If one cannot be suggested then it is assumed that the proposed project's bat mortalities will have to be considered unavoidable.

On the next page, **Section 3, 4.4 Unavoidable Adverse Impacts**, the second paragraph states that bird and bat mortalities will occur, but that "the level of mortality is not anticipated to be sufficient to negatively affect the population viability of any single species." This fallacy of this statement has been discussed before (page 5); the Applicant has presented no credible documentation to support such a claim. As wind farms proliferate in our region, cumulative mortalities become increasingly significant for individual populations, regardless of their population status. In this case, since population status is an unknown, it would not be possible to make a statement about viability.

Section 3, 4.4 Unavoidable Adverse Impacts, Paragraph three "It appears unlikely that the project would cause any mortality to a threatened or endangered species." Northern goshawks, golden and bald eagles were reported to be present at the proposed turbine sites. This project has an operating time estimate of 30 years. Even a non-statistician might consider the "likelihood" of such an event over thirty years to be at least "somewhat likely." Death can occur from a rare visitation, as well as from frequent visitations and although the number of mortalities may be small, the cumulative impacts for certain bird and bat species could affect overall species survival.

Section 3, 5.2.1 Pg 89 Impacts: Proposed Action: Construction There is no mention of re-using the material removed from blasting in order to lessen the need for 100,000 yards of gravel the project is expected to require. Is this a possibility?

Section 3, 5.4 Pg 92 Unavoidable Adverse Impacts The proposal is stated to have "minor unavoidable adverse impacts to energy and natural resources." The crushed rock requirement by

itself (100,000 yards) would deplete local supplies and possibly drive prices higher locally after construction since it might have to be hauled from greater distances.

The preceding statement is immediately followed by another, claiming that “The overall impact of the project to energy and natural resources would be positive since it would provide the region with low-cost, clean, renewable energy...” etc. This has been commented on previously. The power generated from the proposed facility will not necessarily be used in this region due to the nature of BPA’s power brokering activities. Our region’s power costs in the past were indeed comparatively inexpensive, but prices are not low now, nor will they be in the future. P.U.D. newsletters have been explaining this fact to customers for several years. There is a growing discussion about making power costs equal across the country, so that those living in “power-poor” areas will not be unfairly penalized. Clean? Not as clean as solar, and certainly this proposal will require radical environmental destruction.

Section 3 14.3 Pg 269 Cumulative Impacts Rhetoric, political pressure, or private interest should never be allowed to override thorough and thoughtful, unhurried evaluation. Scientific rigor is essential to the cumulative impacts analysis. I am very sorry to see this section displaying an alarming number of mis-statements as well as faulty logic. Some of these statements have been carried over from Sections one and two, but there are several statements introduced in Section 3, clearly meant to justify the EIS’s approach to the cumulative impacts analysis, that are simply a result of poor logic and misapplication of conclusions or data that has been taken out of context.

One example is a statement that appears on page 274 of Section 3, and is partially quoted below. The NAS Mid-Atlantic Highlands study conducted in 2007, only three years ago is not as relevant (in 2010) for analysis of cumulative impacts to wildlife, especially birds and bats; the rapid pace of wind power development has changed the dynamic entirely not only in the location of the study but especially in the northwest, making this study unsuitable for cumulative impact use in this EIS. This study moreover, quoted in the EIS in **Section 3, Pg 2, 74 Bird and Bat Species** (last sentence in paragraph 2), concluded that “for rare and local populations” the predicted level of fatalities when combined with all other man-made sources of mortality could affect population viability.” This statement was made three years ago. Note that the study referred to predictions of mortality, not documented mortalities per se. It has been found that predictions in the arena of wind power mortalities have often been underestimated.

The “other man-made sources of mortality,” contrary to the opening statement in paragraph three (**Section 3, Pg 274 Bird and Bat Species**) is hardly an “inherent difficulty” to a cumulative impacts analysis focusing on wind turbine mortalities. The “other man-made mortalities” are merely ancillary; they existed before wind turbine facilities and comprise a background level inherent to our cultural lifestyle. The “cumulative” aspect of the bird and bat analysis attempts to determine what impact wind turbines have regionally, to sometimes unknown population numbers of migrating, foraging and, nesting species.

State protections, USFWS and other specific, reputable wildlife data also must be considered in the analysis, as should a comparison analysis of costs. Although it is difficult to attribute monetary values to wildlife resources, standards are available to do so.

An essential element in any study is the study plan. Basic assumptions must be scientifically (logically) rigorous and the data collection schedules equally well-planned in order to produce

meaningful results. Data collection on wildlife takes many years. Conclusions from the results of such studies must employ scientific rigor. This is where peer-reviewed papers and respected sources can assist reviewers. To ensure adequately broad and equitable cumulative impacts analysis for this proposed project, it would be appropriate to engage another analyst, other than those that have already provided information and conclusions in association with this proposal. There are well-respected scientists available who would be able to perform this service with expertise and lack of bias. I strongly recommend this action, and the inclusion of such a consultation in the final EIS document.

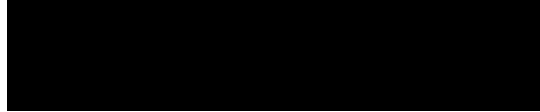

I have made my points along the way, as I followed through the EIS document and will not summarize my concerns. I realize that this may be an inconvenient way to deal with such a large amount of material, but this is page 14 already! The specific shortcomings of the cumulative impacts section are noted throughout this letter but my main concern is for the apparent lack of understanding about what it should be, and to the lack of critical logic used to justify some of the conclusions.

Thank you for the opportunity to comment further and for considering my comments.

Sincerely,

Sallie Tucker Jones

Re: Whistling Ridge Energy Project May 2010 Draft Environmental Impact Statement

Members of the Council:

Thank you for extending the deadline for comments. Although it arrived at the very last minute, it was a generous extension and I hope that you will also extend the time you will take to review what I imagine will be the many additional submissions.

For the following reasons, as well as those that others have taken the time to bring to your attention, I strongly feel that a completely revised document must be created to stand as an accurate and unbiased presentation of information that Council members can use to make an informed decision regarding this proposal.

The existing document shows a lack of professionalism in many important areas that is inappropriate to both the SEPA/NEPA requirements and the process, as well as to the scale and potential impact of the proposal upon the region and its varied resources. Following are a few of the things that I find the most disturbing. Thank you for considering them when the Draft document is revised.

Section 1, 1.1, Pg 1 Para. 2 Interconnection and Section 1, 2.2 Pg 4 BPA Purpose and Need for Action I do not believe that BPA has yet responded to the request for interconnection. The nearby BPA transmission lines are at carrying capacity with a backlog of other requests for interconnection. Although the location is referred to in Section 3, the precise location for the proposed Whistling Ridge Project interconnection is presently unknown, since no new transmission line has yet been constructed, nor has firm commitment from BPA to existing lines been granted. This renders the cumulative impacts assessment incomplete. It is also incomplete with respect to several other facets of this proposal as well. The BPA new line access corridor construction and interconnection costs, design and placement of any collector substation and interconnection structure, as well as an evaluation of the resulting environmental impacts of their construction and operation would be legitimate, mandatory elements for inclusion in this document.

Since BPA is partially responsible for the DEIS document, it should not be problematic for the agency to include an open and clearly understandable discussion of the agency's present interconnection problems as they relate to the current proposal, thus clarifying this aspect of the EIS. There is discussion of possibilities that were considered but rejected, however, the option finally chosen appears to be questionable, especially since BPA has offered no firm commitment.

Section 1, 2.3.2 Pg 6 “.....it is critical to locate projects in areas where transmission lines currently exist. The applicant thus needs to locate near existing high-voltage transmission , such as the FCRTS.” As noted above (in Section 1, 2.2 notes), the currently existing BPA transmission line is running at capacity, with no possibility for the addition of large additional sources, such as this project’s proposed output would comprise.

The critical issue regarding wind facilities is indeed appropriate siting, but not for the reason of proximity to transmission lines. The applicant (I assume this is the author) misunderstands the basic premise and need for an environmental impact statement. The lack of transparency regarding this issue is disturbing, and should be clarified in the BPA discussion of the issue, rendering this claim invalid. It should be removed from the document; it appears repeatedly in all Sections.

Section 1, 2.3.3 Pg 6 Business Needs of the Applicant An EIS is not a branch of any chamber of commerce nor is an EIS a forum for advertisement. The history of the applicant/company is already included in the Appendices. Other local background information is included in Section 3, 3.10.2.1 Historic Background and this is where it belongs. Every company has business needs but this is not the arena for such discussion. This heading and its text should be removed.

Section 1, 3.2 Pg 7 “The EIS will be used primarily to inform....” As it stands, I do not feel this document yet contains the essential information needed for informed, responsible decision-making, especially in the areas of wildlife impacts, soils/geology and cumulative impacts analysis. It must be improved significantly before it can serve its intended purpose. This may take more time, but it will certainly ensure that the final EIS is a more suitable document for unbiased decision-making, which at this point it is not.

Section 1, 3.3 and 4 Pgs 8, 9 NEPA Section 102 (2) (c) requires that alternatives to the proposed action be provided. There are no Action Alternatives offered in this document (the No Action Alternative is not considered a viable alternative.) Alternatives must be presented and discussed as real possibilities, not avoided by stating that alternatives were “considered but eliminated from detailed study” as is stated in Section 1, 4.3. The Applicant cannot choose to avoid this requirement. Although it is stated several times that the document “... is intended to fulfill the format and content requirements “ of a joint SEPA/NEPA EIS, it falls well short in many areas.

Section 1, 4.1 Pg 9 Proposed Action The project site is stated to have a “proven, robust wind resource.” There is no material to supply this “proof in the EIS document. If “robust ” is interpreted to mean “good”, then this statement is doubly inaccurate. The web-based National Renewable Energy Lab regional wind power mapping resource states that the proposal area provides only “marginal to fair” averaged wind resources compared to other sites in the state. The good to excellent areas are farther east. A BPA (among others)-sponsored wind mapping project on the Internet shows the area to have not particularly good wind resources as well. The wind mapping data, referenced above, conflicts with the applicant’s claim that the project site has a “proven, robust wind resource.” No scientifically stringent data is presented that supplies this “proof.” This “proven, robust” (“steady”) terminology appears repeatedly throughout the document and is misleading. A credible document needs to show at least an attempt at accuracy and objectivity.

There are other reasons as well, discussed on the following pages, that indicate the selected site may be a poor choice for a wind facility. Paramount to these, is the technical geologic study of the project site that has not yet, and must be performed before suitability evaluations begin.

One of the factors that the Applicant used to identify site suitability was stated to be the "associated lack of native habitat, reducing or eliminating the need to clear additional forest land." Section 3 discusses the initial "need to clear trees to prepare ridge top sites for construction of turbine base pads and of specially configured parts delivery roadways. Information is even provided regarding where the logs will be taken after being cut. The applicant needs to choose one statement or the other and ensure that references to the eliminated statement are removed from the document as well. Which will it be? A credible document displays consistency.

A current aerial photograph of the steep (70% or more) southern side of the project area, in the vicinity of proposed turbine string A1 – A7 shows standing trees that were restricted from being cut by Washington State DNR when the applicant applied for a Forest Practices Application permit in 2003. What were the constraints that prevented this harvest? Will project approval permit the cutting of these trees, in order to clear for turbine pads and access roads, overriding the earlier DNR prohibition? The Council would need to investigate the nature of the DNR constraint before the evaluation process proceeds.

Again, mention of the alleged availability of nearby BPA transmission lines as a site selection factor: transmission lines that do not have the capacity to carry significant additional power. This issue needs to be clarified as discussed under "Interconnection" on pages one and two.

Lastly, the site was stated to have been chosen because it is close to an SDS mill site (even though it was stated above that no additional trees would have to be cut for the project) and to SDS business offices! Surely this declaration could be deleted lest it be concluded that convenience has a higher value than environmental factors when choosing a suitable location for a wind power facility. Perhaps if the reasoning behind the statement was elucidated, it might seem an appropriate inclusion.

Section 1, 4.1.2 states that a trench, approximately 8.5 miles long and 5 feet wide would be required to place collector cables. The DEIS mentions reseeding with of grasses and native plants, but does not mention what species, nor whether trees or shrubs that were removed would be replaced in-kind. If the plantings are to minimize noxious weed colonization would the reseeding areas be watered to ensure germination in time to counteract opportunistic germination of undesirable species? If so, the amounts used should appear in the Section 3 water use list and a watering regime presented.

Will the removed soil be compacted as it is returned to the trench? Will the soil returned to the trench be returned in the same order that it was removed? What will the compaction guidelines entail? Who ensures that it is done properly? Since this extensive trench will likely disturb underground water flow patterns and create new, possibly undesirable flow patterns, it may be important to consider imposing certain requirements and ensuring that agency inspectors with authority to enforce, not proponents or contractors, oversee the work.

Section 1, 4.2 Pg 12 No Action Alternative To state that the No Action Alternative “would not help the state of Washington in achieving the renewable energy goals mandated by the state’s Renewable Portfolio Standard” is misleading. Washington State wishes to encourage renewable energy, but not to the exclusion of all else. Site selection is probably the most important way that negative environmental consequences can be avoided, especially with respect to wildlife. Moreover, BPA does not segregate power sources. Once it is produced and fed into the collection system, it is dealt with as any business commodity, in this case by bids. Much of the power we create here is used elsewhere, historically, to California. To imply that a rejection would flout state goals and policies is simplistic and a little misleading.

“(The No Action Alternative) would help to meet the region’s need for additional power in the coming years.” If by “region”, “local” is meant, our regions need is not great. The Columbia River, and other water-driven power-generating dams continue to supply more than ¾ of our power needs. The current trend is to improve efficiency and to encourage both business and the private sector to conservation. It has been estimated (Draft Sixth NPP, 2009) that almost 80% of our locality’s future energy demands can be met in this way. Existing and newly approved wind facilities in the region, with a focus in Klickitat County, are more than adequate to make up the difference. It would be not only misleading but inaccurate to state or imply that there is a “need” for additional wind power in this portion of the Northwest.

Section 1, 4.3 Pg 13 Alternatives Considered but Eliminated from Detailed Study The applicant’s response is in violation of the guidelines by virtue of not complying with the requirement to supply Alternatives. As mentioned above, an EIS requires that alternatives be provided and considered, with accompanying data and analysis to match all of the other Action Alternatives presented.

Section 1, 4.3.1 Pg 13 Alternative Project Locations The contents of this portion are redundant. Again, it avoids the EIS requirement regarding Alternatives. The points made here have all been stated previously (Section 1, 4.1), in the same bulleted form and with almost the same wording.

Section 1, Table 1 Pg 22 Earth: Construction: Design and Mitigation Measures All of the Design and Mitigation Measures listed are “would be” statements. They “should be” already part of the EIS! If, for instance there was a critical subsurface condition, it needs to be known and factored into the decision process, not “discovered” after approval. Only in this way can accurate and responsible evaluation occur. Because of the difficult terrain, there would appear to be very little possibility for adjustment, should geologic constraints be revealed initially. This could easily endanger the viability of the project, which underscores the importance of having data collected from rigorous studies, and analysis conducted by respected sources. Even with the added benefit of such information, the impacts of such radical alterations to a fragile topography can only be guessed. Stringent geologic study of the proposed site must be performed now and the results reported in another, hopefully improved Draft document. This information will be essential for the Council’s evaluation. Without it, the process will have no merit.

Section 1, Table 1 Pg 22 Earth: Construction and Operation – The considerable alterations to the terrain that are proposed for this project - 8.5 miles of three to four foot deep, five foot wide trenches for cable burial, 30-foot deep turbine pads that will require leveling with machinery and extensive blasting to excavate, the building of adequate access and delivery roadways on steep slopes - will certainly have more impacts, and ones that influence each other more closely, than

those listed. The changes made to accommodate the towers will forever alter the ridge tops and they will not revert to their pre-construction profiles after the project is decommissioned. It is inaccurate as well as disingenuous to state that the project construction requirements would be "minor to moderate."

Why is volcanic ash deposition of such concern that it is mentioned here? Granted, several of the soils present do contain a volcanic ash component, but it is not clear to me why this appears, since there is no control over the possible event and, depending on the severity of an ash fall, no mitigation measures would be possible. Large amounts of ash could be physically removed, but would that be mitigation?

Does the statement regarding mass wasting "No obvious recent mass wasting features" imply that there is evidence of the phenomena having occurred on the site in the not-so-recent past? If so, then this is another reason why a more thorough geologic assessment be conducted, before the project is evaluated by the Council.

Although the soil type present on part of the project site has low liquefaction potential, massive excavation and refill, as in the 8.5 mile trench, may disturb soil structure enough to render the possibility greater than in the undisturbed state. Although liquefaction of soils are generally associated with earthquake activity, a similar phenomenon may result when soils become over-saturated. As mentioned above, there is no doubt that the proposed excavated and refilled trench will impact and redirect existing subsoil water flows for 8.5 or more miles and may potentially influence an area far greater than the area of the trench. It is also possible that drainage may be improved in the trench after refill, but the possibility that it will not, must be at least considered.

Section 1, Table 1 Pg 22 Water: Construction and Operation On-site development will certainly impact ground and surface water drainage patterns as indicated above. It is well-recognized that new roadbeds alter water flow significantly and are responsible for a good deal of continuing erosive runoff. The replacement of natural soil and rock drainage on the site with impervious concrete pads constitute large surface areas that will prohibit slow drainage. Water will be quickly released from these surfaces in large quantities at approximately the same time, limiting the remaining soil's ability to absorb and release it slowly. Some of the remaining soil may be additionally compacted from heavy construction machinery, limiting even more its ability to absorb rainfall and melting snow slowly.

Section 3 downplays the impact these impervious surfaces may have upon soils, but this need to be seriously examined. Each of the 49 tower pads have a diameter of 60 feet, creating 2920 square feet of impervious surfaces at the top of steep ridges. These conditions produce fast runoff accompanied by high erosion which, over time may lead to catastrophic geologic events, as well as degrade waterways used by fish, amphibians and invertebrates. Amend this inaccurate denial of the project's impacts to ground and surface waters. A discussion, or at the very least a mention of the runoff potential should be presented, as well as possible impacts to the larger streambeds below, with potential to impact fish, amphibians and invertebrates, upon which fish depend for food. Larger game and non-game animals may be impacted as well through water quality degradation and the possible inability to even reach water. The standard BMP guidelines will not be adequate for this anticipated situation. In recognition of this, an individual plan to accommodate the special runoff problems of the project could be developed as part of a mitigation plan, implemented and monitored by an agent other than the applicant/contractors, if

the project is approved. The cumulative impacts discussion should deal with this possibility as well, but does not.

Section 1, Table 1 Pg 24 Biological Resources: Construction Soil compaction is an undesirable and irreversible impact that should be acknowledged since it affects soil drainage, the ability of certain plants to grow well and limits the species of plants that will grow.

In addition to "loss of suitable habitat," abandonment of adjacent suitable habitat due to construction activity should be considered a likely possibility. Some bird, mammal and invertebrate species are known to be more sensitive to intrusive activities, including noise, than others. Several of these species are listed as being present in the project area. Add "abandonment of suitable habitat due to construction activity" to the list on page 24.

Section 1, Table 1 Pg 24 Biological Resources: Operation "There would be some mortality to birds and bats due to turbine collision and displacement, though not in sufficient numbers to affect population viability." I restrain myself when I say that this statement is offensively inaccurate. It also reveals the applicant's misunderstanding of the "cumulative impact" concept. As wind farms proliferate in our region, the cumulative mortalities become increasingly significant for individual populations, regardless of their population status.

Just because there have been no studies addressing bird population declines in association with wind installations does not mean that one has a legitimate claim to deny that such a relationship may exist.

The bat studies cited, employed equipment that was not capable of determining the bat species present. How then, can an assessment of a particular population be made? Or, by extension, a statement regarding population viability? What authority provided the status information for each population? What is the source of data for western bat species population size? Eastern bat species are being threatened with mass extinctions from White Nose Syndrome, the etiology and causative organism of which is still unknown. The disease has not yet reached the western states; because of this, it is essential that ALL western bat populations be given added protection, regardless of their population status. The bat study data is inadequate in certain respects; the study plan assumptions were not adequately rigorous, there were discrepancies in data collection procedures from year to year, making comparisons and data merging ineffective; long-term sampling frequency was sparse. At the very least, a repeat survey should be conducted which would identify bat species.

The Columbia River Flyway is a major East to West migration route that has likely been used longer than mankind has been here. Raptors are known to use mountain ridges for North/South travel as well as for hunting in this part of the Columbia River. People come from many places outside of this area specifically to see the variety of birds that congregate and fly through this river corridor, some stopping to feed for a few days or weeks before moving on. This site would be an unconscionable choice for a development of this kind, with this knowledge.

"No impacts to listed species" – is this a wish, or a promise from an unknown deity? How can it possibly be known ahead of time that a listed species will not be impacted; especially when inadequate studies have failed to identify what species use the area and with what frequency? And when only a two year start-up mortality study is planned? This is not enough time to obtain meaningful data much less to make any conclusions from the data. The project location would be

an especially difficult one for such monitoring due to the terrain and planned forestry understory management activities. A recent eastern U. S. mortality study is employing dogs to find bat carcasses, because they are so difficult to locate by eye, even in dry flat grassland.

There is no body of information available documenting how wild animals might respond to the sound of wind turbine propellers. This should be at least briefly discussed and dealt with as a possible impact.

Section 1, Table 1 Pg 24 Biological Resources: Design and Mitigation Measures “In order to avoid or minimize impacts to any raptors potentially nesting on or near the project site, a raptor nest survey would be conducted” Then what? A survey is not a mitigation measure.

The composition of the proposed Technical Advisory Committee members is not well thought out. Entities or personages that have vested interests or have demonstrated no interest, cannot be relied upon to make responsible, nor to make informed mitigation recommendations. To include the developer on such a committee would be unwise as well as unfair to the resources. If this route is pursued, enforcement capabilities must be granted and there must be a preponderance of resource advocates as committee members. TAC groups are by reputation, generally ineffective when they have no powers. They are also rendered ineffective if members have conflicts in interest, as counties and developers often do. This would be a great opportunity to cast aside TACs, breaking out of the customary mold and devising a new and more effective way to resolve monitoring and mitigation issues associated with such a project.

“For potential impacts to big game species (deer and elk) coordination with WDFW will occur if appropriate.” Again, just to mention something does not comprise a mitigation measure. What about bears, and large cats? Who decides if a situation is “appropriate” warranting consultation? Under what circumstances would it be appropriate to coordinate? The project location is a designated wintering area for elk. What plant species are present that elk might use for winter forage? Will these species be replanted and therefore present in adequate quantities to continue to serve as winter forage during construction and operation of the proposed project? These considerations must be treated responsibly somewhere in the document. The quoted statement is vague and obtuse. It leaves the reader with **no information** about how big game species ‘ use of the area will be approached, nor does it correct nor solve any problems big game species may have because of the project.

Section 1, Table 1 Pg 25 Energy and Natural Resources: Operation The “Minor quantities of lubricating oils.....” should be specifically quantified, if only as an estimate, to be consistent with the remaining listed items.

Section 1, Table 1 Pg 25 Environmental health: Construction The project is located at the southern end of a wide contiguous band of lands termed “Fire-prone Landscape Management Strategy Area” by a USFWS 2008 Final Spotted Owl Recovery Plan map. This area runs from the Columbia River north to the Washington-Canada border. The increased risk of fire during the summer months must be seriously considered and aggressive prevention measures **above the usual standards** should be pursued and stipulated.

Prohibitions on conducting potential spark and fire-generating activities during the driest fire danger periods of the year could be part of a plan keyed to this project and would demonstrate

care and concern for nearby communities. A several month delay in certain construction activities and equipment use as a result of time-of-year prohibitions would be well justified and need not halt all building progress.

There WILL be blasting activity in association with this project, if approved. Getting rid of the “may” and “could” in the bullet dealing with blasting would be a more honest way of stating the realities of the massive environmental reshaping that this project will engender. If “Blasting could also create a fire hazard during dry weather”, then this activity should be curtailed during these periods. Likewise, an activities plan related to the regional weather patterns might suggest avoiding blasting during unusually wet times of the year to avoid problems similar to those encountered recently along Hwy 14. There is no doubt that the level of blasting activity alone has the potential to seriously destabilize this particular environment, which, as noted elsewhere, already has nearby unstable loci. Since there is no geologic assessment data provided, it is impossible to even guess what impacts such activity could produce. When the geologic assessment is conducted, it should address not only immediate impacts but the potential long-term impacts of blasting, even although this would only be predictive. Road department records from Underwood and Hwy 14 should give the Council a good idea of the areas’ historic instability.

Section 1, Table 1 Pg 25 Environmental health: Construction (Column 4) The second, bulleted statement in column 4 implies that a fossil-fuel- powered facility might supply fill-in power when a wind facility is unproductive (and that it would carry a higher risk of fire.) There is a federal requirement mandating that alternative power source facilities must accompany any new wind facility, based upon the amount of power generated. The proposed wind project would generate above the MW threshold, requiring the construction of an alternative power-generating facility to balance a wind farm’s unproductive periods of no wind or too high wind. The construction cost of this requirement building, inter-tie costs, should certainly be included in the cost analysis for this project, but it does not appear. Since the alternative power facility is a requirement , its location should be identified and the associated environmental impacts need to be included in the EIS, including the cumulative impacts portion.

Section 1, Table 1 Pg 26 Environmental Health: Operation Again, with respect to fire potential, local ordinances and other regulations and standards are not directed to such a project, and are not adequate, because of the unusual situation. An individually tailored, aggressive fire prevention plan and response tactic needs to be developed for the construction and operation phases of this proposed project. Relying on existing regulations will not adequately address the specific potential hazards nor protect the nearby population and environment.

“...none of the planned turbines are within 2,500 feet of existing residences.” This is not correct; there is one residence. Mitigation measures should be included in the proper column.

“EMF from the project ...would have no health and safety impacts.” I do not see any information in the document to support this assertion. There is certainly study regarding the issue, but conclusions are not definitive at this time. Can a pronouncement be made if there is inadequate documentation? Unless this can be produced, this statement needs to be removed or qualified in some manner in order to be objective.

Section 1, Table 1 Pg 27 Noise: Construction This section downplays construction noise, which will carry well into the valleys and bounce off of adjacent hillsides. Although construction is stated to occur during daylight hours, it will likely begin very early and continue through dusk.

The added noise of myriad transportation trucks will certainly impact local residents on a daily basis and should be included in the list.

The noise from blasting will certainly be noticeable and will last for awhile. In thoroughness, it should also be mentioned.

Section 1, Table 1 Pg 27 Noise: Operation An in-depth submission regarding wind turbine noise impacts upon humans has been submitted. Please consider it as a counter to the data presented in the EIS and take appropriate action to modify the table.

Section 1, Table 1 Pg 33 Socioeconomics: Operation There are several studies that identify undesirable affects of turbines upon humans (see K. Brown's testimony citations). One would not unreasonably conclude that properties in close proximity to such turbine arrays might be less desirable for habitation, at least to a percentage of the population. Proponents of wind power have issued statements derived from studies indicating that property values are not adversely affected by nearby wind turbines. As such studies continue, depending on the analyses, certainly there is the possibility that property values may be affected one way or another, but for now either position can support and document its claims.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts : Earth The enormously disruptive activity that will be required to complete this project, located in a geologically fragile environment that has already been subjected to considerable alteration, is very likely to respond with undesirable events. In potentially susceptible areas, no amount of "careful design" can prevent, nor can "mitigation measures" restore, areas where mass wasting has occurred. It should be added to the list of potential adverse impacts, especially since evidence of such an event was documented during a previous survey. The severe re-contouring, blasting, large-scale trenching and creation of impervious surfaces all increase the likelihood of minor or major responses from the environment. The soil types in some areas are acknowledged to be susceptible to erosion and the proposed "A" array is located precisely along a Class II (High Landslide Hazard Area) ridgeline. To dismiss these and other known geologic concerns with the two brief dismissive statements presented is unacceptable. Until a reputable geologic assessment study is performed, there will remain a glaring gap in this arena. Without professional scientific data, any predictive statements can only be considered arbitrary and of dubious merit.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts: Air Quality Construction activity would involve many more pieces of diesel-fueled machinery than any logging operation. It is absurd to think that the residents of the town of Underwood will not notice, nor be affected by, a continuing stream of diesel trucks heading up and down the roads every day for months. Peak morning hour numbers of trucks are estimated to be 210/hr for 3-5 months. Further, all major construction equipment is to be diesel-powered (Section 3 Table 6-5, Pg 109 Fire and Explosion Risk Mitigation.) It is disingenuous to claim that this would be comparable to "existing logging operations.", and equally so to state that "the project would contribute to a beneficial impact on overall air quality" Climatological data presented in the EIS indicates that the area is prone to air stagnation at all times of the year, but especially during the summer when pollutants from downriver may collect forming considerable haze. Even if this statement refers to the completed project, it is a bit of a stretch to claim "beneficial impacts on overall air quality" when the requirement to build alternative fuel power plants are a direct result of building wind powered

facilities. With this in mind, it might be fairer to consider that project would lead to a decline in overall air quality.

Section 1, 7 Pg 34 Summary of Unavoidable Adverse Impacts: Biological Resources See previous comments regarding bats and birds (Section 1, Table 1 Biological Resources: Operation.) The Summary statement simply reiterates the document text statements, almost word for word, imparting the same inappropriate lack of concern. Why are no other wildlife groups mentioned? Certainly animal corridors will be interrupted, the areas in which young are raised may be pushed further away and populations may become fragmented. Even with the proposed mitigation measures in place, erosion runoff would affect the fishery and invertebrate communities downhill of this project. Blasting may obliterate pika or marmot populations that may have been overlooked. No mention of them occurs in the animal surveys. These could be significant impacts unless there is some oversight to ensure that mitigation measures are maintained to the standard for the duration of construction. Often, self-policing measures produce initial compliance, but over time may be seen to deteriorate.

Section 1, 8.2 Para 1 Pg 37 The last sentence in this paragraph appears to more of a running prepositional phrase. It is awkward and could be recast for a more professional presentation.

Section 1, 8.2 Para 2 Pg 37 The first sentence of the second paragraph is incomplete and needs structural as well as subjective clarification.

The last sentence of this paragraph still stretches my imagination – how will “introducing up to 75 MW” of wind power “contribute to efforts to improve air quality in the Columbia River Gorge vicinity?” If anything, fossil-fuel facilities will be **added** (producing a negative effect upon air quality) to make up for the irregular output of this wind facility.

Section 1, 10 Pg 38 References Again, BPA’s Wind Integration Plan might be an excellent addition to the references section if it might clarify the line access and interconnection issues.

Section 2, 1.4.1 Pg 9 Construction Activities “Transportation of construction materials” (gravel, concrete, rebar, etc.) could be added to the list but “Use of dynamite and machine re-contouring of ridges” should be added to the list.

Section 2, 1.4.2 Pg 12 Construction Schedule Earlier portions of the document state a construction time of one year. This section states “approximately 15 months” would be required for construction ; all other sections repeatedly mention one year. Consistency throughout the document would enhance credibility. Are the construction cost estimates based upon 12 or “approximately 15 months?” The suggested time-of-year prohibitions to pro-actively address fire danger could be inserted into the detailed construction schedule, possibly changing the time frame even beyond 15 months.

Section 2, 1.4.4 Pg 13 Construction Costs An extra three months or more added to the construction time estimate of one year stated early in the EIS will add to the construction cost estimate presented in Section 2, 1.4.4 Pg 13, assuming that it is based upon a 12-month time frame.

Another cost that has not been discussed, although it may not be considered a bona fide construction cost, is that of the required alternative/fossil fuel facility that would make up for non-production times at the wind facility. Interconnection, substation and line link costs associated with this facility should be also be added and later considered in cumulative impact analyses. The total cost of building an alternative power supply facility to offset erratic wind generation is possibly not the responsibility of the applicant, but possibly some monetary responsibility exists? Who pays for the construction of such a facility? Is the cost partially subsidized? If so, by whom?

Section 2, 1.5 Pg. 14 Project Operations The project is stated to “operate 24 hours per day, seven days per week,” implying that generation also occurs on that schedule. It might be a bit more objective to modify the statement to reflect the reality of wind power generation for those who do not know.

Is there any capability

The first U. S. study of reduced (bat) fatalities and economic costs of “low-wind mitigation” began in 2008, continued in 2009 and 2010. The research is being conducted in Pennsylvania with Casselman turbines and has demonstrated that bat fatalities were reduced an average 73% when turbines were left off-line, at night, during low wind conditions (<11.2 – 14.5 mph). An additional benefit to bats was to use the nighttime limitation during the migration season in the fall. The second year of the study, 2009, was funded wholly by USFWS. I will provide the Council with the citations. The calculated loss of production resulting from the temporary stoppage in that area of the country was 0.3 to 1.0% of the facilities’ yearly output.

Some studies have indicated that certain individual towers in an array produce more mortalities than others. Will this project have the capability of shutting down a single turbine? Will it be possible to shut down individual arrays in this project? Will the strategy above be a possibility for these turbines or is their operation wholly automatic? What would the cost difference be if this capability was part of the design plan for these proposed turbines? This approach might be one that could be applied to bird mortality as well.

Section 2, 3 Pg 19 Alternatives Considered but Eliminated from Detailed Study As in Section 1, the applicant has substituted a list of self-generated criteria instead of fulfilling the mandated subject matter identified in the heading.

Section 3, 44.1.5 Special Status Wildlife Species Northern Spotted Owl Although the two historical northern spotted owl nesting sites at Moss and Mill Creeks, near the northern boundary of the proposed project are not believed to be presently occupied, these areas still carry the potential for occupation and use. Little is known about long-term northern spotted owl reoccupation patterns and current agency attempts to halt population declines are not encouraging. Forested habitats that have supported northern spotted owls in the past are likely to support a diverse suite of life forms and hold the potential to support one another, given enough space.

The proposed project is located within one of Washington States ten designated SOSEAs (Spotted Owl Special Emphasis Areas.) Although the project location and proposed construction activities do not impinge upon the parameters specified in the state regulations regarding SOSEAs, a favorable decision for this proposal would lead to extensive re-contouring and dynamiting the

outer boundary of a select habitat resource. Regardless of the legality of the proposed actions, to actually go ahead with the proposed habitat alterations would seem to flout the intent of the regulation. Eliminating the northern portion of the B array and the entire C5 to C8 array might allow the outer edges of the historic nest range that overlap the project boundary some protection as well as respect the spirit of the SOSEA. This might even serve as one of the as-yet-unsupplied Action Alternatives.

It is interesting and disturbing at the same time, to see the large list of of bird and mammal species observed at the proposal site and to realize that a number of them are "threatened," federal species of concern, or Washington State candidates for listing. Townsend's big-eared bat is both a federal species of concern and a Washington State Candidate for listing, although the incomplete bat studies conducted at the proposal site did not determine bats to species, it is a possibility that this bat may be using the area as well as Keen's Myotis, another Washington State Candidate for listing.

Although it is acknowledged in **Section 3, page 81** that "Some bat fatalities are anticipated as a result of the operation of the proposed project" the only mention of bats in **Section 3, 4.3 Mitigation Measures** is to minimize turbine lighting "thereby reducing the potential for birds and bats to be disoriented by lights....." Bats are not attracted nor disoriented by lights, although they are attracted by some night-flying insects that are. Essentially then, there is no mitigation measure directed toward bat mortalities; should there not be one suggested? If one cannot be suggested then it is assumed that the proposed project's bat mortalities will have to be considered unavoidable.

On the next page, **Section 3, 4.4 Unavoidable Adverse Impacts**, the second paragraph states that bird and bat mortalities will occur, but that "the level of mortality is not anticipated to be sufficient to negatively affect the population viability of any single species." This fallacy of this statement has been discussed before (page 5); the Applicant has presented no credible documentation to support such a claim. As wind farms proliferate in our region, cumulative mortalities become increasingly significant for individual populations, regardless of their population status. In this case, since population status is an unknown, it would not be possible to make a statement about viability.

Section 3, 4.4 Unavoidable Adverse Impacts, Paragraph three "It appears unlikely that the project would cause any mortality to a threatened or endangered species." Northern goshawks, golden and bald eagles were reported to be present at the proposed turbine sites. This project has an operating time estimate of 30 years. Even a non-statistician might consider the "likelihood" of such an event over thirty years to be at least "somewhat likely." Death can occur from a rare visitation, as well as from frequent visitations and although the number of mortalities may be small, the cumulative impacts for certain bird and bat species could affect overall species survival.

Section 3, 5.2.1 Pg 89 Impacts: Proposed Action: Construction There is no mention of re-using the material removed from blasting in order to lessen the need for 100,000 yards of gravel the project is expected to require. Is this a possibility?

Section 3, 5.4 Pg 92 Unavoidable Adverse Impacts The proposal is stated to have "minor unavoidable adverse impacts to energy and natural resources." The crushed rock requirement by

itself (100,000 yards) would deplete local supplies and possibly drive prices higher locally after construction since it might have to be hauled from greater distances.

The preceding statement is immediately followed by another, claiming that “The overall impact of the project to energy and natural resources would be positive since it would provide the region with low-cost, clean, renewable energy...” etc. This has been commented on previously. The power generated from the proposed facility will not necessarily be used in this region due to the nature of BPA’s power brokering activities. Our region’s power costs in the past were indeed comparatively inexpensive, but prices are not low now, nor will they be in the future. P.U.D. newsletters have been explaining this fact to customers for several years. There is a growing discussion about making power costs equal across the country, so that those living in “power-poor” areas will not be unfairly penalized. Clean? Not as clean as solar, and certainly this proposal will require radical environmental destruction.

Section 3 14.3 Pg 269 Cumulative Impacts Rhetoric, political pressure, or private interest should never be allowed to override thorough and thoughtful, unhurried evaluation. Scientific rigor is essential to the cumulative impacts analysis. I am very sorry to see this section displaying an alarming number of mis-statements as well as faulty logic. Some of these statements have been carried over from Sections one and two, but there are several statements introduced in Section 3, clearly meant to justify the EIS’s approach to the cumulative impacts analysis, that are simply a result of poor logic and misapplication of conclusions or data that has been taken out of context.

One example is a statement that appears on page 274 of Section 3, and is partially quoted below. The NAS Mid-Atlantic Highlands study conducted in 2007, only three years ago is not as relevant (in 2010) for analysis of cumulative impacts to wildlife, especially birds and bats; the rapid pace of wind power development has changed the dynamic entirely not only in the location of the study but especially in the northwest, making this study unsuitable for cumulative impact use in this EIS. This study moreover, quoted in the EIS in **Section 3, Pg 2, 74 Bird and Bat Species** (last sentence in paragraph 2), concluded that “for rare and local populations” the predicted level of fatalities when combined with all other man-made sources of mortality could affect population viability.” This statement was made three years ago. Note that the study referred to predictions of mortality, not documented mortalities per se. It has been found that predictions in the arena of wind power mortalities have often been underestimated.

The “other man-made sources of mortality,” contrary to the opening statement in paragraph three (**Section 3, Pg 274 Bird and Bat Species**) is hardly an “inherent difficulty” to a cumulative impacts analysis focusing on wind turbine mortalities. The “other man-made mortalities” are merely ancillary; they existed before wind turbine facilities and comprise a background level inherent to our cultural lifestyle. The “cumulative” aspect of the bird and bat analysis attempts to determine what impact wind turbines have regionally, to sometimes unknown population numbers of migrating, foraging and, nesting species.

State protections, USFWS and other specific, reputable wildlife data also must be considered in the analysis, as should a comparison analysis of costs. Although it is difficult to attribute monetary values to wildlife resources, standards are available to do so.

An essential element in any study is the study plan. Basic assumptions must be scientifically (logically) rigorous and the data collection schedules equally well-planned in order to produce

meaningful results. Data collection on wildlife takes many years. Conclusions from the results of such studies must employ scientific rigor. This is where peer-reviewed papers and respected sources can assist reviewers. To ensure adequately broad and equitable cumulative impacts analysis for this proposed project, it would be appropriate to engage another analyst, other than those that have already provided information and conclusions in association with this proposal. There are well-respected scientists available who would be able to perform this service with expertise and lack of bias. I strongly recommend this action, and the inclusion of such a consultation in the final EIS document.

I have made my points along the way, as I followed through the EIS document and will not summarize my concerns. I realize that this may be an inconvenient way to deal with such a large amount of material, but this is page 14 already! The specific shortcomings of the cumulative impacts section are noted throughout this letter but my main concern is for the apparent lack of understanding about what it should be, and to the lack of critical logic used to justify some of the conclusions.

Thank you for the opportunity to comment further and for considering my comments.

Sincerely,

Sallie Tucker Jones

Whistling Ridge Energy LLC

Whistling Ridge Energy Project

Comments by Barbara Bleakley, a private citizen

My husband and I live in White Salmon, WA. We, like thousands of other families, have purchased homes in this area because of the “protected” beauty of the National Scenic Area (NSA). It should continue to be protected as a priceless asset to the NW and our country. It is time for our government to stop supporting any project that is politically expedient at the expense of the citizens. We are hopeful that reason will prevail and that the powers that be perform a careful and thorough analysis of every single possible negative impact to our local communities and environment by this project.

We have grave concerns over locating the Whistling Ridge wind farm on the proposed ridge immediately outside the NSA, including but not limited to the points made below. We can easily conclude that there are better locations in unpopulated or otherwise unproductive areas, and that other more appropriate green technologies should be considered a higher priority.

1. **Precedent.** We feel that if Whistling Ridge is allowed to move forward, the Governor of WA would be setting a dangerous precedent here in the Columbia River Gorge. What will stop other wind farms from being allowed just outside the geographical boundaries but visually impacting the NSA? We have already sacrificed the natural beauty of the Columbia Hills east of the NSA to hundreds and perhaps even thousands of wind turbines on both sides of the Columbia in the interest of this green energy that must be subsidized to make ANY economic sense. How far should we go with this philosophy of creating green energy. At what cost? As common sense tells us, if it sounds too good to be true, it probably is, as evidenced by the ethanol political boondoggle. Allowing this project is outrageous considering all the blood, sweat and tears expended over the creation and management of the nation’s ONLY National Scenic Area. Hundreds of millions of dollars of residential view property will immediately be impacted and devalued. Our scenic resources should NOT be held for ransom under the guise of “green energy” without definitive studies of the many significantly adverse impacts to people, wildlife, transportation, management of our electrical grid and its capacity, and our nation’s and state’s limited monetary resources. How could anyone have ever anticipated that when the NSA act was created by Congress that the most politically powerful family in the Gorge would many years later propose siting a huge industrial wind farm over 400 feet above a ridge immediately outside the boundary lines of the NSA and in plain view of their own White Salmon, Hood River, and Skamania County neighbors?

2. **Inadequate Electrical Grid.** An article published in the Oregonian Newspaper dated July 17, 2010 written by Ted Sickenger titled, “Too Much of a Good Thing: Growth in wind power makes life difficult for grid managers”

(http://www.oregonlive.com/business/index.ssf/2010/07/too_much_of_a_good_thing_growt.html) provides a great summary of the enormous limitations of the current grid system for handling the CURRENT number of wind turbines. It is a very complicated issue that needs to be rectified BEFORE we decide which green energy makes the most sense to invest government dollars in. Why are we spending huge amounts of subsidy money to build what will most likely be an obsolete technology by the time the electrical grid can handle the capacity of these giant wind turbines so they do not have to sit idle when the wind is blowing! There are promising new wind energy technologies under development right now that will very soon be economically viable without subsidies and have less visual and environmental impact. (See <http://www.makanipower.com/> for example.)

3. **Facts**. The promoters of this project have concentrated their money and power on a sales job based on selective misinformation in an attempt to promote the economic and political benefits (which have been grossly exaggerated) to Skamania and Klickitat Counties and WA State. Photos and “facts” have been specifically chosen or rejected to distort the realities as well as to quote old studies that are no longer appropriate. For example, there is a blatant omission (and highly selective inclusions) in the Draft EIS document of any photos of potential visual impacts from the Strawberry Mountain area in White Salmon. How about from the Mark O. Hatfield State Park scenic hike/bike trail along the Columbia River between Hood River and Mosier?

4. **Transportation Studies**. Now that the Oregon Court of Appeals recently upheld the Gorge Commission’s right to approve the Broughton Mill development project, new transportation studies should be incorporated in the EIS to address the impact of these two Stevenson family projects, perhaps concurrent, on transportation.

5. **Wildlife Concerns**. There are wildlife concerns that need further study and have been addressed by other opponents to this project. I’m not a biologist, but the impacts on just bat populations by wind turbines has been sited by the USGS in this article: <http://www.fort.usgs.gov/batswindmills/>. ” Dead bats are turning up beneath wind turbines all over the world. Bat fatalities have now been documented at nearly every wind facility in North America where adequate surveys for bats have been conducted, and several of these sites are estimated to cause the deaths of thousands of bats per year. This unanticipated and unprecedented problem for bats has moved to the forefront of conservation and management efforts directed toward this poorly understood group of mammals.” These affects on bats and the other 300 species of birds in the Gorge, migratory birds, and other wildlife should be studied further before blindly accepting the notion that wind turbines are “green”. Obviously this point isn’t limited to just the Whistling Ridge project, but is relevant to all current technology wind farms including this one.

6. **Light pollution**. Visualize a peaceful summer evening enjoying the sunset view of the Gorge from Strawberry Mountain in White Salmon where we live (and from many other areas in the Gorge), and seeing 50 blinking red lights all going off at once as the sun goes down behind them! One of the big draws to rural areas is the beauty of the night sky devoid of city lights.

We hope you will conclude as we have that this is the absolute wrong location for this project, and probably the wrong technology for this time. Please let’s use some good old NW common sense that we are known for. Rely on facts and not just somebody’s sales pitch, political pressure, and the enticement

of big "free" subsidies, going into private pockets paid for by all US citizens. Please recommend the denial of this project in its proposed location to Governor Gregoire. It is the right decision.

Whistling Ridge Energy Project

Comments by Barbara Bleakley, a private citizen

My husband and I live in White Salmon, WA. We, like thousands of other families, have purchased homes in this area because of the "protected" beauty of the National Scenic Area (NSA). It should continue to be protected as a priceless asset to the NW and our country. It is time for our government to stop supporting any project that is politically expedient at the expense of the citizens. We are hopeful that reason will prevail and that the powers that be perform a careful and thorough analysis of every single possible negative impact to our local communities and environment by this project.

We have grave concerns over locating the Whistling Ridge wind farm on the proposed ridge immediately outside the NSA, including but not limited to the points made below. We can easily conclude that there are better locations in unpopulated or otherwise unproductive areas, and that other more appropriate green technologies should be considered a higher priority.

1. **Precedent.** We feel that if Whistling Ridge is allowed to move forward, the Governor of WA would be setting a dangerous precedent here in the Columbia River Gorge. What will stop other wind farms from being allowed just outside the geographical boundaries but visually impacting the NSA? We have already sacrificed the natural beauty of the Columbia Hills east of the NSA to hundreds and perhaps even thousands of wind turbines on both sides of the Columbia in the interest of this green energy that must be subsidized to make ANY economic sense. How far should we go with this philosophy of creating green energy. At what cost? As common sense tells us, if it sounds too good to be true, it probably is, as evidenced by the ethanol political boondoggle. Allowing this project is outrageous considering all the blood, sweat and tears expended over the creation and management of the nation's ONLY National Scenic Area. Hundreds of millions of dollars of residential view property will immediately be impacted and devalued. Our scenic resources should NOT be held for ransom under the guise of "green energy" without definitive studies of the many significantly adverse impacts to people, wildlife, transportation, management of our electrical grid and its capacity, and our nation's and state's limited monetary resources. How could anyone have ever anticipated that when the NSA act was created by Congress that the most politically powerful family in the Gorge would many years later propose siting a huge industrial wind farm over 400 feet above a ridge immediately outside the boundary lines of the NSA and in plain view of their own White Salmon, Hood River, and Skamania County neighbors?

2. **Inadequate Electrical Grid.** An article published in the Oregonian Newspaper dated July 17, 2010 written by Ted Sickenger titled, "Too Much of a Good Thing: Growth in wind power makes life difficult for grid managers"

(http://www.oregonlive.com/business/index.ssf/2010/07/too_much_of_a_good_thing_growt.html)

provides a great summary of the enormous limitations of the current grid system for handling the CURRENT number of wind turbines. It is a very complicated issue that needs to be rectified BEFORE we decide which green energy makes the most sense to invest government dollars in. Why are we spending huge amounts of subsidy money to build what will most likely be an obsolete technology by the time the electrical grid can handle the capacity of these giant wind turbines so they do not have to sit idle when the wind is blowing! There are promising new wind energy technologies under development right now that will very soon be economically viable without subsidies and have less visual and environmental impact. (See <http://www.makanipower.com/> for example.)

3. **Facts**. The promoters of this project have concentrated their money and power on a sales job based on selective misinformation in an attempt to promote the economic and political benefits (which have been grossly exaggerated) to Skamania and Klickitat Counties and WA State. Photos and “facts” have been specifically chosen or rejected to distort the realities as well as to quote old studies that are no longer appropriate. For example, there is a blatant omission (and highly selective inclusions) in the Draft EIS document of any photos of potential visual impacts from the Strawberry Mountain area in White Salmon. How about from the Mark O. Hatfield State Park scenic hike/bike trail along the Columbia River between Hood River and Mosier?

4. **Transportation Studies**. Now that the Oregon Court of Appeals recently upheld the Gorge Commission’s right to approve the Broughton Mill development project, new transportation studies should be incorporated in the EIS to address the impact of these two Stevenson family projects, perhaps concurrent, on transportation.

5. **Wildlife Concerns**. There are wildlife concerns that need further study and have been addressed by other opponents to this project. I’m not a biologist, but the impacts on just bat populations by wind turbines has been sited by the USGS in this article: <http://www.fort.usgs.gov/batswindmills/>. ” Dead bats are turning up beneath wind turbines all over the world. Bat fatalities have now been documented at nearly every wind facility in North America where adequate surveys for bats have been conducted, and several of these sites are estimated to cause the deaths of thousands of bats per year. This unanticipated and unprecedented problem for bats has moved to the forefront of conservation and management efforts directed toward this poorly understood group of mammals.” These affects on bats and the other 300 species of birds in the Gorge, migratory birds, and other wildlife should be studied further before blindly accepting the notion that wind turbines are “green”. Obviously this point isn’t limited to just the Whistling Ridge project, but is relevant to all current technology wind farms including this one.

6. **Light pollution**. Visualize a peaceful summer evening enjoying the sunset view of the Gorge from Strawberry Mountain in White Salmon where we live (and from many other areas in the Gorge), and seeing 50 blinking red lights all going off at once as the sun goes down behind them! One of the big draws to rural areas is the beauty of the night sky devoid of city lights.

We hope you will conclude as we have that this is the absolute wrong location for this project, and probably the wrong technology for this time. Please let’s use some good old NW common sense that we are known for. Rely on facts and not just somebody’s sales pitch, political pressure, and the enticement

of big "free" subsidies, going into private pockets paid for by all US citizens. Please recommend the denial of this project in its proposed location to Governor Gregoire. It is the right decision.

Subject: Whistling Ridge Negatively Impacts Columbia Gorge

I am writing to comment on the DEIS for the Whistling Ridge Energy Project, proposed in the Underwood, WA area, near the Skamania and Klickitat county lines.

The Columbia River Gorge National Scenic Area (CRGNSA) will be impacted again through the unnecessary slaughter of raptors being hit by the turbine blades. Raptors that are very important to the species food chain in the Gorge in that certain species will over produce with the demise of the raptors. The sight lines that are preserved in the Gorge with regulations will be invasive to the beautiful sights of the CRGNCA and the Lewis and Clark National Historic Trail from even the Columbia River itself.

The Washington Department of Natural Resources has clear cut forest on both sides of the Pacific National Scenic Trail within the CRGNSA. Why now would huge wind turbines be located upon a forested ridge line where industrial clear cutting would again most likely be utilized to place the huge turbine wind generators on that scenic destroying and forest destroying ridgeline?

I am concerned that the DEIS is fundamentally flawed because it fails to provide a credible alternatives analysis. EFSEC and BPA need to consider other alternatives, including other means of providing electricity (including increasing efficiency and reducing consumption), other sites for wind energy, other configurations, deleting turbines to reduce impacts, alternative routes for hauling turbines to avoid traffic impacts to the National Scenic Area, etc. Only two alternatives are meaningfully considered in the DEIS (the proposal and the no-action alternative). This is inadequate.

The DEIS has other flaws. The DEIS fails to adequately analyze the potential cumulative impacts of this project when considered with other existing and likely future wind energy projects and other development projects in the region. The photo simulations in the DEIS are inadequate and misleading. Some of them have cloudy backgrounds, thus not adequately representing the full extent of the impacts, and other simulations are out scale. Additional viewpoints need to be considered, including views from the Historic Columbia River Highway. The DEIS erroneously concludes that the scenic impacts would not be significant, even though most of the turbines would be visible from designated key viewing areas within the National Scenic Area. In addition, the BPA and EFSEC have not adequately consulted with the Yakama Nation to ensure the protection of cultural resources.

Lastly, EFSEC and BPA need to fix the flaws in the DEIS, issue a revised or supplemental DEIS, and make substantial revisions to the EIS to fully inform the public about the true environmental impacts of the project. If another DEIS is issued the 50-turbine layout should be rejected.

Thank you for extending the public comment period and allowing me to submit these comments into the record.

Subject: I support Whistling Ridge

Hello Energy Facility Site Evaluation Council,

I would like to voice my strong support for the Whistling Ridge Energy Project. Washington State utilities must reach the goals set by Initiative 937. Wind is the most feasible and most cost-effective option for bringing 15% new renewable energy on the grid by 2020, which means we need to build more wind farms. Lewis County has the wind, Weyerhaeuser Lumber has the land: it is a match made in heaven. Many studies have shown that the environmental impact of the Whistling Ridge Energy Project would be minimal. For the last century, the site has been used in commercial forest operations. The land has already been cleared, roads built, transmission lines already installed, and wildlife habitats already fragmented. The impacts on a few other species that might be affected are rated low-risk. The environmental benefits are numerous. Wind is clean, renewable, and does not consume water or produce waste. Whistling Ridge will generate 75 megawatts of electricity; enough to power 20,000 homes a year, without contributing to global climate change. The choice is clear: support Whistling Ridge and Lewis County by approving this project.

Sincerely,
Rod Davidson

RE: WHISTLING RIDGE ENERGY PROJECT – APPLICATION NO. 2009-01

Dear Mr. Posner and Mr. Montano:

Our sister organization, the Seattle Audubon Society, is the intervener in the process of this site certification and will have more detailed comments. Nevertheless, as an organization dedicated to the welfare of birds and all wildlife, the Vancouver Audubon Society has an interest in this project. It is also in the Columbia River Gorge area, an area that we have long been concerned with.

In reading this DEIS, one thing stands out. Rather than being a decision making document, which DEISs are supposed to be, this appears to be a justification document, providing support for a decision that is already in the mind of the preparers. The failure to analyze more than two alternatives -- the applicants desired outcome and the required do-nothing alternative -- strengthens that impression. The alternatives considered (briefly?) but eliminated from detailed study were given short shrift. The perceived economic shortcomings of some of these possible alternatives is not reason enough to fail to analyze and compare to see if a smaller size or different configuration might be less harmful to wildlife. Economics change with changing conditions, whereas the needs of wildlife are seldom so flexible.

In looking at the avian survey section (3-30 to 3-65), it is not possible to determine how many of which species were found. Therefore, we have no idea of the value of this site to many birds,

especially the songbirds. Rufous hummingbirds were found in the spring and summer, but how many? Were they males or females? During the migration season, how many warblers passed through? Were they in the strike zone of the blades? Percentages are not useful for analysis without knowing what they were percentage of. Further, it would be more useful to be able to compare the use and species composition, in numbers, of this site to the use and species composition, in numbers, of the nearby Forest Service and Department of Natural Resources land.

The northern spotted owl has been declining in Washington about seven percent a year. Therefore it is no wonder that many historical nest sites are no longer used. There are fewer birds to use them. It stands to reason, however, that to eliminate historical nest sites is to eliminate that chance for a pair of owls to use that site ever again. How, then, is the population to recover? The fact that nearby owl habitat areas are no longer used does not mean that they should be dismissed as potential owl habitat. They must be taken into consideration. It should have been noted that all DNR land in the state is covered by a Habitat Conservation Plan that *includes the northern spotted owl* along with salmon and many other species.

The fact that Vaux's swifts were seen during the fall migration is of concern. Yet, there is inadequate discussion of mitigation measures to avoid mortality of swifts, as well as songbirds and other small birds during migration.

We concur with the Seattle Audubon Society in their observation of the weakness of the cumulative impact analysis in the DEIS. In addition, considering that any kind of development causes loss of habitat, the DEIS should have considered, not only potential future wind power development in forested areas, but the impact of many other types of development, such as housing, that permanently destroys habitat.

We appreciate the opportunity to comment on this DEIS.

Sincerely,

Gretchen Starke

Mr. Jim Luce, Chair

Washington Energy Facility Siting Council

905 Plum St. SE, Third Floor

P.O. Box 43172

Olympia, WA 98504-3172

Dear Mr. Luce,

Thank you for the opportunity to comment on the Draft Environmental Impact Statement for the Whistling Ridge Energy Project. We deeply appreciate the extension of time allowed to review the document, as it has allowed us a fuller understanding of the impacts that the state intends to consider relative to this project.

The DEIS overall appears to us to be a shallow (in spite of its sheer mass) analysis of the impacts of the proposed project. Since our expertise in the field of natural resource studies is limited, we will rely on others to address the project's impacts on bird and bat populations, although we note that reliance on studies conducted by the project proponents seem suspect. A party with a vested interest in the construction of a windfarm would not necessarily be the party we would select to provide unbiased data on any aspect of the potential harm to the public or resources. We would be much more comfortable with analysis by independent professionals in the various fields of study, selected by the state agencies the public employs to safeguard these important public resources.

We will focus on three areas in which we feel we do have a certain amount of expertise: Scenic resources, Transportation resources and Recreation resources.

As a former Commissioner serving at the pleasure of Governor Mike Lowry on the Columbia River Gorge Commission, Sally has a more than passing interest in (and acquaintance with) the local landscape. She also worked as a school bus driver for Mill A School, traversing Cook-Underwood Road between Mill A School and the Underwood Community Center for over 10 years. As a professional driver, she had a unique perspective on the safety aspects of this road, as well as SR14, which was often used to transport students to games and field trips. Paul has lived in Underwood all his life, and for the first 10 years of his adult life worked for Broughton Lumber Company at the Willard Mill, commuting on Cook-Underwood Road from Underwood to Willard. Both of us are avid horsemen, riding and packing in and around Underwood, Mill A and Willard, as well as on the nearby Buck Creek Trail System and in the Gifford Pinchot National Forest.

To the scenic component of the DEIS, we would point out that the photographs purporting to depict the scenic impacts from various vantage points were obviously selected to minimize the impacts in the eye of the beholder. Importantly, NONE of the photographs depict the way these views will look at night, with red aviation lights destroying the appearance of the ridgelines in the moonlight. After all, it is dark about half of the time, and we think the scenic value of the project area at night should be a consideration, especially since there is currently nothing in the area that generates the kind of scenic distraction that a string of red aviation lights (visible for 20 miles) strobing every few seconds will. These are not low to moderate impacts, especially if they are visible from YOUR living room windows.

While the project is (just barely) outside the Columbia River Gorge National Scenic Area, we feel that a project that impacts a national treasure should be evaluated carefully. Buckets of money, not to mention blood, sweat, tears and emotional distress on all sides have been expended to preserve the scenic, natural, cultural and recreation resources of this place, and to encourage economic development in a way that is compatible with that preservation. It makes no sense to us, after 25 years of effort, for the State of Washington to produce a 1500 page document that fails to properly consider the impact this project would have on the CRGNSA. When the boundaries for the scenic area were established, no one could possibly have conceived that just 25 years later, the state would be considering allowing structures 400 feet high a mere 50 feet outside that boundary, and clearly visible from major viewing areas, including two population centers within the CRGNSA.

We are among the many people who have invested their lives and their life savings in this beautiful place with the understanding that is a special, protected place, recognized by our government with special status to allow it to remain beautiful for future generations to enjoy. We are among the people who willingly, through design and landscaping, try to make our homes and other structures blend with the surrounding landscape. We are among the many people who understand that even though we own a fairly large piece of land, will not be able to divide it among our children and grandchildren, in the service of a larger public ideal. And that's okay with us, as long as the sacrifice is shared equally. It seems to us that for the state to allow a desecration of the scenery of this kind makes a mockery of that sacrifice in the name of lining the pockets of a wealthy local dynasty. We didn't notice any analysis of that in the DEIS.

We feel it is worth mentioning that the wealthy local dynasty mentioned above recently won a decision from the Oregon Court of Appeals that will enable it to construct a major destination resort along SR14 on the site of the old Broughton Mill at Hood, directly south of Underwood. Construction and operation of that resort will significantly impact local traffic as well as recreation uses at the Hatchery State Park, and needs to be considered in the transportation and recreation sections of the DEIS.

The transportation section of the DEIS fails to mention the five tunnels between Cook and Underwood on SR 14. It does mention the tunnels at Lyle in its analysis of potential haul routes, but the ones between Cook and Underwood are omitted. Those tunnels are so dangerous that Mill A School doesn't allow its busses to use them when students are being transported. They are so low that there are very few local drivers who haven't witnessed semi trucks crossing the center line inside those tunnels to take advantage of the added height in the center of the tunnel's arc. We were nearly killed by one of these ourselves. We would not have considered that to be a moderate impact.

The only viable way for SDS to get those turbines to Bingen would be by barge or rail, in our opinion. Getting them to the proposed project site with "low to moderate impacts," will be far more difficult.

Section 4.3 purports to analyze transportation issues associated with the project. Section 4.3.1.1 Regional and Site Area, fails to even mention the community of Underwood. While it is an unincorporated community, we would guess the population at (conservatively) 2500, based on information obtained from the Skamania County Assessor in the early 1990's. Attempts to update that information from several county departments were unsuccessful, but with the new census nearing completion, we would hope that EFSEC would obtain that information for a final EIS. We contest the DEIS's conclusion that impacts to these residents during construction would be low to moderate. Underwood has only one road connecting it to SR14, and there is no viable alternative route to any other state or county road that would get one to White Salmon or Stevenson. Cook-Underwood Road is Underwood's lifeline to the outside world, and any disruption to its use will impact residents, especially in emergency situations.

The proposed haul route from Bingen to Underwood over SR14 underestimates the dangers posed by existing local conditions. The DEIS fails to even mention the dangers posed by traffic attempting to enter SR14 at Dock Grade Road. This intersection is the site of many accidents every year, and these will be exacerbated by the presence of many oversized, overweight trucks westbound on SR14. Dock Grade is the main route for folks from White Salmon to SR14, commuting to Hood River or elsewhere for work, shopping and recreation. People take crazy chances there, and sight distances are deceiving. The intersection of SR14 and SR141 is so dangerous that WDOT placed a warning sign with flashing lights just east of the blind corner leading into it. SR141 is the main route to the White Salmon River Valley, and the communities of Husum, BZ Corners, Glenwood and Trout Lake. Population in these places has grown considerably over the past 20 years or so, along with recreation use. Trout Lake is the gateway to Mt. Adams and the Gifford Pinchot National Forest in this area. It is the road to the White Salmon Wild and Scenic River and associated rafting and kayaking opportunities.

SR14 is so narrow between these two intersections that it is a challenge for a passenger car, a semi truck and a bicycle to share the road. There is no shoulder whatsoever in many places, and we'd measure the lanes in a couple of spots to contest the DEIS's assertion of 12 foot lanes if it wasn't such a dangerous proposition. An Underwood man was killed there a couple of years ago walking his dog. In order to safely move oversized loads through there, we think one-way traffic with flaggers will be needed, but the DEIS does not mention this. Traffic volume through this stretch is heavy by local standards, but the DEIS contains no analysis. It uses "typical rural highway traffic patterns," to reach its conclusions. Is it too much to ask that counters be placed on the roadways to determine actual usage during the proposed construction season?? The mix of traffic is horrendous, especially in the summer and early fall months . . . you'll see bicycles, pedestrians (crazy people), long-haul semi's and log trucks, along with RV's of every description, school busses and passenger vehicles. The DEIS generalizes the width of SR14 from SR97 and SR395, and doesn't really talk about SR14 from Bingen to Underwood. This is an unconscionable omission.

The analysis of Cook-Underwood is all rosey, too. At the top of page 4.3-5, the DEIS states that "very little as-built information is available regarding existing pavement and base thickness along the proposed haul route." Cook-Underwood Road was built many years ago to accommodate local traffic, agricultural hauling and log trucks. Maintenance has consisted of occasional treatments with chipseal and gravel. There are many sections where the asphalt is already showing some distress, and it runs along a steep, unstable bluff up to 1000 feet above SR14. SR14 runs along the river at almost sea level, and most of Cook-Underwood is 500-1000 feet in elevation. The DEIS doesn't mention the very steep grade coming up from SR14 at both ends, and it doesn't say anything about how slow those big overweight loads will be going, but there will be serious deterioration of LOS going on there, too! Table 4.3-1 indicates 240 commuters will be trying to come up the hill at Underwood at peak pm drive time . . . we'd like to see counters on that, too. Imagine those folks following these slow, giant trucks all the way to their driveways, because many of them will have to. A trucker friend of ours said they would need to hook two semis together to move the heaviest loads up the worst part of the grade . . . would there be a delay associated with that practice? Where is the analysis of that? Between Highland Orchard Road and Chenoweth Road is a steep hill with a series of sharp curves and limited shoulder. There will likely be lots of delays for local traffic there, too, but there is no mention in the DEIS. There are many parts of Cook-Underwood which are narrow with little or no shoulder, and as mentioned before, a steep, high and unstable bluff on the south side. What happens to the folks up here if the road just gives way at some point? Our guess is that the LOS would suffer for years to come. It could even cause a home to have to give up its yard to enable the road to be re-routed. The DEIS is silent on this point. If the rest of this DEIS is as deficient as the transportation section, it is a shoddy document indeed!

Garbage in; garbage out. EFSEC needs to calculate LOS using real traffic counts and hard data, not HCS+algorithms. It is not unusual to wait 10-30 seconds to enter SR14 from the east outlet of Cook-Underwood Road as it is. Add traffic associated with a major construction project at the old Broughton mill site and oversized loads for windmill construction to the current situation and there will be serious impacts to local transportation. In addition, parts of Cook-Underwood along the bluff are narrow

enough that flaggers and one-way traffic would be needed to allow the big loads through, but there is no mention of the LOS impact of that. Kids on school busses in Underwood have a 45 minute ride to Mill A School, and about the same to White Salmon. Traffic delays could mean the difference between arriving at school ready to learn, and missing breakfast and playing catch-up all day long for them.

We were struck by the lack of information about the numbers of local people who will be impacted by the construction phase. The economic impact of the jobs generated by the construction phase could well be offset by visitors who will never return after tangling with the traffic nightmare that will ensue.

There is nothing in the DEIS speaking to the roads themselves, about the damage those giant loads are liable to cause. The road being built on SDS land is 60 feet wide. How on earth will our little, old, 24 foot roadways accommodate these trucks and cranes? The DEIS needs to tell us that. The fact that Skamania County has no over-size or over-weight restrictions in place at this time doesn't mean the roads will accommodate these loads . . . this county has been through 4 or 5 county engineers in the past few years. The head of the county's Public Works department has no engineering credentials.

The DEIS is also deficient in the area of recreation. The Buck Creek Trail System receives short shrift in the DEIS. This trail system was built years ago by a local couple, with the cooperation and assistance of the Washington Department of Natural Resources. There was a trailhead, known as the Whistling Ridge Trailhead, complete with corral and campsite immediately adjoining the project area to the north. That trailhead has disappeared, along with the trail connecting it to the rest of the Buck Creek Trail System. The local chapter of Backcountry Horsemen of Washington recently had a work party on the trail system, and after much searching, found the northern end of the trail, but lost it in the clearcut to the south. The trailhead is depicted on the wooden map near Northwestern Lake, and on paper maps distributed by DNR as recently as three years ago.

Figure 4.2-27 purports to depict recreation facilities and key viewpoints. It shows the trailheads, but fails to clearly depict the trails and topography in a way to meaningfully show the potential visual impact on trail users. These include, but are not limited to the Buck Creek Trail System, and the Monte Cristo and Monte Carlo trails north of it. There are many places in the Gifford Pinchot that the project would be visible from, like Little Huckleberry Trail north of Willard. The project will be highly visible from the best southerly views from Little Huckleberry and the Buck Creek Trails, and could preclude the rebuilding of the Whistling Ridge Trail due to degradation of the trail experience. The DEIS does not discuss the disruption of a backcountry campout by aviation lights flashing to the south, and generally makes light of the impacts that will be suffered by recreationists subjected to the deterioration of their experience due to the scenic impacts associated with the project.

In sum, we think your DEIS is deficient and that the Whistling Ridge Energy Project has the wrong name, in the wrong place.

Sincerely,

Paul and Sally Newell

Re: The Whistling Ridge DEIS and the inadequacy of the data and analyses for impacts to transportation in the region

Dear EFSEC and BPA,

I am greatly concerned about what I feel is a very inadequate analysis of the actual impacts to our roads and byways by the transport of the wind turbines and other construction paraphernalia for the Whistling Ridge wind farm project. The “specialized” trucks that are needed would, I believe, create havoc on our roads and there would also be serious damage to our rural, scenic public roads. The whole issue of which roads SDS would actually use if this wind farm is approved, has not been adequately addressed in the DEIS. Skamania County authorities also fail to address impacts to our roads and byways from all the over-weight traffic for this wind farm proposal. Waiting to figure it all out after the fact is not good public policy and it certainly is not public disclosure.

I needed to educate myself on this issue and the following disturbing information is about what it really takes to transport wind turbine components. My emphasis is in **bold red**. The following is an article on what makes wind energy possible:

http://www.go-explore-trans.org/2009/nov-dec/wind_turbines.cfm

Trains, trucks, and ships make wind energy possible

by Katie Greenwood

Imagine yourself in a flat, wide-open field. Next to you, extending about 400 feet into the air is a wind turbine. Its 3 gigantic steel blades whoosh around and around hundreds of feet above your head.

A wind farm in Kansas

Photo courtesy: Brent Danley via flickr

Standing next to a wind turbine, you can witness the incredible power of the wind to move this massive machine.

But before the wind could move the turbine, something else had to move it first.

Trucks, ships, and trains move wind turbines from the factory to the wind farm. A wind farm is a group of wind turbines in the same location used to produce electricity. (Wind farms are also called wind power plants.)

In the United States, Texas and Iowa have the greatest number of wind farms because flat plains are the best sites for wind farms, but **many turbines come from factories outside of the United States.**

Just how big are they?

Wind farms range in size from a few dozen to 421 turbines. **A single turbine is transported in up to 12 pieces.**

Wind turbines are manufactured and shipped in several parts, and each part is huge.

The tall, vertical piece is called the tower. It's usually made in 3 parts but sometimes more.

A crane lifting the huge blades and hub of a wind turbine
Photo courtesy: rockymountaincrane.com

Each section of the tower is about 120 feet long and weighs up to 70 tons. An empty semi-truck and trailer weighs about 15 tons.

Attached to the top of the tower is the nacelle. The nacelle houses the generator, power electronics, and the gears that turn the wind into electrical energy. **Nacelles weigh 50–70 tons.**

Most turbines have 3 blades that are attached to the nacelle by the rotor hub. Some blades are up to 50 yards long. **A 3-blade rotor hub can almost cover a football field!**

Curriculum connection

Using geometry in a transport route survey

Before construction of a land wind farm can begin, route planners consider several possible trucking routes for the turbines.

Route planners study several factors including traffic, road construction, surrounding buildings, and environmental issues to determine the best route.

With the help of a surveyor, the route planner **assesses the steepness of hills and inclines along the route.** A surveyor can take the necessary measurements using a transit.

Students practice using a surveyor's transit.

The steepness of a road's incline is called the *grade*. Turbines can safely ascend and descend grades of less than 15%. Steeper grades can potentially lead to accidents that damage turbine parts or cause erosion of the soil and structure beneath the road.

If the surveyor assesses the grade at greater than 15%, it may be necessary to level the roads or put in erosion control measures for that part of the route.

Getting the grade

How do they get the grade?

The illustration below shows a highway in profile. Notice that a right triangle has been constructed in the diagram.

An illustration of the the verticle and horizontal distances of an inclined road.

The bottom of the triangle is the horizontal distance a particular section of highway covers. This horizontal distance, or the “run” of the highway, indicates how far a vehicle would travel on the road if it were level.

The “rise,” or vertical distance, is a measure of how much higher a vehicle is after driving along the road. To find the “rise,” the surveyor must determine the difference in elevation from the bottom of a slope to the top.

Putting it together

Similar to calculating the slope of a line in your geometry class, calculating the incline of a road is simply “rise over run.”

Slope is the measure of the vertical rise in the road divided by the horizontal distance or:

$$s=y/x$$

Grade is the slope expressed as a percentage. To find the percent, the slope is multiplied by 100.

$$G=100s$$

Try it out: If a highway rises 375 feet over 1 mile, is the grade safe for trucks hauling turbine components?

Check your answer.

So to build even small wind farms, there are many large loads that must travel long distances.

How in the world are these hulking parts moved?

The type of transportation used depends on the location of the wind farm. Often, a combination of transportation modes is used for each wind farm.

By train

A large number of turbines manufactured in the United States are first transported by train, according to Dr. Nadia Gkritza, who is currently researching sustainable energy and transportation systems at Iowa State University.

A single train can haul 50–70 cars of wind turbine parts. *Photo courtesy: kedziers via flickr*

A single train can haul 50–70 cars of wind turbine parts. It costs less to move turbine parts by train because more can be moved at a time, but the train routes **must avoid low overpasses** when hauling the large components.

But since trains don't directly connect to the wind farms, the final transportation leg must be done by truck.

By trucks

Trucking has been the most common method of transporting turbines because trucks can go directly to a wind farm.

Each wind turbine requires 8–12 semi-truck trailers. Many turbine loads weigh more than 100,000 pounds. *Photo courtesy: Bill Weaver via flickr*

Transporting by truck requires 8–12 trailers for each turbine.

Hauling the oversized loads requires a permit from the state Department of Transportation. The trucks must follow paths that avoid road construction, low bridges, and busy city centers. **Often, trucks have to take a long route to their destination when transporting turbines.**

Many wind farms are located within crop farmland. **This means that these heavy parts travel on narrow, unpaved roads that are not designed to accommodate the heavy loads. Immediately after a wind farm is completed, maintenance workers must repair and level the roads.**

Highways and interstates can handle about 80,000 pounds. Many turbine loads weigh more than 100,000 pounds, so transporting turbines can cause damage to even these roads over time.

By ships

When turbine components come from overseas, they are imported in several shipments. Each ship carries only 1 type of component.

When Vestas imported 60 turbines into the Port of Longview in Washington, **all the components arrived in 5 shipments. The towers arrived in 3 separate shipments followed by 2 shipments of nacelles and blades.**

The fragile loads must be packed tightly but carefully to avoid damage. Safety must also be considered to avoid interfering with the ship's stability and navigation.

Ships and barges don't have to negotiate tight turns or avoid overpasses like trucks and trains.
Photo courtesy: GrahamAndDairne via flickr

There are specific ways of lashing and securing the parts to the ship. When shipped long distance, blades are shipped in transport containers to keep them from shifting around.

As wind energy technology advances, new wind farms are being erected off shore. An offshore wind farm in Nantucket Sound, Massachusetts, is scheduled to begin in 2010. The project is being called Cape Wind.

One advantage to transporting by ships and barges: **they don't have to negotiate tight turns or avoid overpasses like trucks and trains.**

IOWA STATE UNIVERSITY
Institute for Transportation

In conclusion, some of the issues and disturbing facts about what it really takes to transport and build a wind farm:

- many turbines come from factories outside of the United States;
- **A single turbine is transported in up to 12 pieces;**
- **Each section of the tower is about 120 feet long and weighs up to 70 tons. An empty semi-truck and trailer weighs about 15 tons;**
- **Nacelles weigh 50–70 tons;**
- A 3-blade rotor hub can almost cover a football field!;
- Route planners study several factors including traffic, road construction, surrounding buildings, and environmental issues to determine the best route; assesses the steepness of hills and inclines along the route;
- **Turbines can safely ascend and descend grades of less than 15%. Steeper grades can potentially lead to accidents that damage turbine parts or cause erosion of the soil and structure beneath the road;**
- If the surveyor assesses the grade at greater than 15%, it may be necessary to level the roads or put in erosion control measures for that part of the route;
- So to build even small wind farms, there are many large loads that must travel long distances;
- A single train can haul 50–70 cars of wind turbine parts. It costs less to move turbine parts by train because more can be moved at a time, but the train routes must avoid low overpasses;
- Transporting by truck requires 8–12 trailers for each turbine;
- Often, trucks have to take a long route to their destination when transporting turbines;
- Many wind farms are located within crop farmland. **This means that these heavy parts travel on narrow, unpaved roads that are not designed to accommodate the heavy loads. Immediately after a wind farm is completed, maintenance workers must repair and level the roads;**
- Highways and interstates can handle about 80,000 pounds. Many turbine loads weigh more than 100,000 pounds, so transporting turbines can cause damage to even these roads over time;
- When turbine components come from overseas, they are imported in several shipments;
- When Vestas imported 60 turbines into the Port of Longview in Washington, **all the components arrived in 5 shipments. The towers arrived in 3 separate shipments followed by 2 shipments of nacelles and blades;**
- One advantage to transporting by ships and barges: **they don't have to negotiate tight turns or avoid overpasses like trucks and trains.**

Analysis on grades and transportation requirements is totally inadequate in the DEIS. The Whistling Ridge proposal involves grades ranging from 5% to 70%. More expert survey data is needed for the DEIS. More analysis and data is needed on just how much the transport trucks and the wind infrastructure materiel actually weigh and how much damage they might do to our rural roads and byways. And, I think we all need to know just how SDS really proposes to get these huge, heavy, and unwieldy turbines up steep slopes that are prone to

erosion and mass wasting! (Mass wasting and soils will be addressed in a separate memo.)

The DEIS is totally inadequate on the transport issue. Thank you.

Importance: High

Dear EFSEC,

Attached, please find a pdf file, DEIS_turbine_specifications_27Aug2010.pdf, that I wish to be attached to my previous e-mail on transportation. It was #4 in the subject line. I'm sorry that some of the pictures are cut off—my technical expertise has failed me late in the day! Thank you very much.

Mary J. Repar

Dimensions & Weights

Hub height – 80 meters or 253.6 feet

Tower Components

Component	Weight(lbs)	Length(Ft.)	Diameter(Ft.)
Base Section	126,766	73.2	15 to 14.1
Middle Section	83,445	82	14.1 to 11.2
Top Section	65,936	98.4	11.1 to 8.4

Other Components

Component	Weight (lbs)	Length(Ft.)	Diameter (Ft.)
Hub	37,479	N/A	10.5
Blade	13,889	121.4	6.4

Rotor (assembly)	79,146	N/A	252.6
Nacelle	121,916	28.9	12.5x12.5

Foundation

Foundation is 45 feet across by 9 feet thick and is installed below the existing ground plane:

12,150 cubic feet

450 cubic yards

742 Tons of concrete (using 3,300 lb/yd³)

45 trucks of concrete

Tower Section Transportation

Wind Turbine arrived October 14th, 2008.

There was 7 trucks hauling the turbine but only some were just normal trucks. For tower segments, transportation used Schnable type trailers, the tower section is connected to the Schnable attachments of the trailers. The tower section thus forms an integral part of the trailer arrangement and is not supported on any kind of chassis

6 AND 9 AXLE SCHNABLE WITH STEERABLE DOLLY

A Schnable trailer with the base tower loaded is the least maneuverable transport arrangement

that will negotiate the site roads. Although Schnable trailers are the most prevalent mode of transportation for tower section, it cannot be guaranteed that these trailers will be used on a specific project.

Other turbine components are shipped using special designed trailers.

Traffic Volume

Traffic:

- 45 - concrete trucks
- 7 - trucks hauling wind turbine
- 6 - trucks hauling 2 cranes (largest is 400 ton crane)
- 2 - trucks hauling 20 tons of rebar
- 2 – trucks hauling various moving equipments such as fork lifts

Wind Turbine Logistics

- Observers were asked to remain on the East side of 11th Street
- Bleachers were provided on the East side of 11th Street
- Cars were not allowed on the West side of 11th Street
- Police Escort was required from I-40 Exit 329
- Point of origin for tower sections was Trinity, Texas
 - Transit time 8 hours
- Point of origin for nacelle was Pensacola, Florida
 - Transit time 22 hours
- Point of origin for blades was Tecis, Port of Import – Houston, Texas
 - Transit time 14 hours

Re: Comments on the inadequacy of Whistling Ridge DEIS in regard to the integration of wind power into the power grid; backup sources for wind when there isn't any; wind powers effects on the energy grid, etc.

Dear EFSEC and BPA,

I would like to further address the issue of wind power generation in the Pacific NW and the fact that “wind generation needs back-up, flexible sources to handle unexpected changes in its output.” I have made comments in the memo entitled [Comments_DEIS_Chap. 3_Environment_Impacts_Mitigation_27Aug2010](#), but in this document I would like to go further in depth about my concerns that were not addressed in the Whistling Ridge DEIS, concerns that I feel BPA should have addressed in the DEIS and they did not. The document that helped to crystallize my concerns about the lack of information on wind power integration and the integration of wind power into the energy grid, is the Sixth Power Plan done by the NW Energy Council, and the document is located at http://www.nwcouncil.org/energy/powerplan/6/final/SixthPowerPlan_Overview.pdf.

My comments are *bolded and italicized, located after sections upon which I wish to comment*. Most of this information was not included in the DEIS and it should have been part and parcel of the discussion. Its lack of inclusion is a fatal flaw in the DEIS and should be addressed by BPA, SDS, and EFSEC. I have not included the entire document. The document is in quotation marks:

“As a result, planners must now consider potential resources in terms of their energy, capacity, and flexibility contributions. The rapid growth of wind generation (which has little capacity value and increases the need for flexibility reserves) means that

meeting growing peak load and flexibility reserves will require adding these capabilities to the power system. Changes can be made to the operation of the power and transmission system that will reduce flexibility reserve needs. These operational changes are expected to cost less than adding peaking generation, demand response, or flexibility storage, and they can be implemented more quickly. **Wind generation needs back-up, flexible resources to handle unexpected changes in its output.**

Comment: Wind power has "little capacity value and increases the need for flexibility reserves" which basically means that wind power needs backup sources, which means coal-power, gas plants, hydro power, or some other sources. Sources which probably contribute more CO2 to the environment. The DEIS does not address the issue of the unreliability of wind, the lack of storage capacity in wind power, and the need for - backups to the power system to balance or leaven the production of wind energy. Why isn't this information in BPA's portion of the DEIS? Oh, I forgot. BPA didn't contribute very much pertinent energy production and infrastructure information to the DEIS so that's why we don't have all the information needed to make a thoughtful and studied decision about the feasibility or desirability of this wind farm proposal! How much flexibility and capacity will have to be added to BPA's energy production in order to balance wind power?

While the problems appear daunting, particularly in integrating new wind generation with a more constrained hydrosystem, there are solutions. The first step is to change system operating procedures and business practices to more fully utilize the inherent flexibility of the existing system. The Council believes these changes will be significantly cheaper to achieve, and can be implemented sooner than adding additional generating capacity solely to provide flexibility. It will also set the stage for determining how much flexibility will ultimately be needed from new generation.

Actions for these operating and business practice changes include: **establishing metrics for measuring system flexibility; developing methods to quantify the flexibility of the region's existing resources; improving forecasting of the region's future demand for flexible capacity; improving wind forecasting and scheduling; transitioning from the current whole-hour scheduling framework to an intra-hour scheduling framework; and increasing the availability and use of dynamic scheduling.** Fully implementing these improvements may also require physical upgrades to transmission, communication, and control facilities, though the cost of these upgrades is expected to be relatively small compared to the cost of adding new flexible capacity.

Comment: What are the metrics for measuring system flexibility? What are the methods to be used to quantify the flexibility of the region's existing resources? How will BPA improve forecasting of the region's future demand for flexible capacity? How will BPA and the wind industry improve wind forecasting and scheduling? How will BPA transition from current whole-hour scheduling to intra-hour scheduling? How will BPA increase the availability and use of dynamic scheduling? What is dynamic scheduling? Will it cost the rate payers more money to implement all of these

efforts to integrate unreliable wind power into the existing power grid? If physical upgrades to transmission, communication, and control facilities will be required, what are the costs going to be? To the regional rate payers? Tax payers? What are the cumulative regional impacts of the existing transmission lines? What would be the future cumulative impacts of new transmission lines? Where would these new transmission lines be located? How big would they be? How would they affect wildlife and wildlife habitats? Habitat fragmentation? These are only some of the questions that BPA should have addressed in the Whistling Ridge DEIS. They did not and this is a fatal flaw in the DEIS.

The Northwest Resource Adequacy Forum, jointly chaired by the Council and Bonneville, with participation by other regional utilities and interest groups, has devoted considerable effort over the past several years to reaching an understanding of the hydrosystem's sustainable capacity value. The work of the forum is described more fully in Chapter 14.

Comment: So Bonneville, which is BPA, sits on the Northwest Resource Adequacy Forum, and they have "devoted considerable effort...to reaching an understanding of the hydrosystem's sustainable capacity value." Care to share with the rest of us, BPA? What is the sustainable capacity value of our hydrosystem? How much sustainable capacity does BPA actually have? If there is too much capacity, from all these regional wind farms, does it become unsustainable? What happens to unsustainable capacity? Does too much capacity affect the BPA infrastructure? How is the infrastructure affected if capacity reaches unsustainable levels? Are there inherent dangers in unsustainable capacity? Dangers to the BPA infrastructure? Dangers to the general public and energy users? These questions, and many more relevant ones, should be addressed in the DEIS, by BPA. They are not. A fatal flaw.

Wind generation capacity also raises capacity issues because it is not controllable. Wind generation is variable; operators can reduce generation when the wind is blowing, but they cannot make it produce more, even if the rated wind capacity is much higher. Furthermore, the output level is relatively unpredictable and, in the Northwest, is unlikely to be available at times of extreme peak load--for example when load is high because of a winter cold spell or a summer hot spell.

Comment: If wind generation is not controllable, why is the Federal government subsidizing the wind industry? Why aren't we using our monies to work on conservation and raising efficiencies in the ways that we now use energy? If "the output level is relatively unpredictable and, in the Northwest, is unlikely to be available at times of extreme peak load...a winter cold spell or a summer hot spell" why are all these wind farms being built? Probably because they are highly subsidized by taxpayer money, and the producers get tax credits which they use for God knows what, but they are tax credits. Why are we spending so much money and effort on wind if it won't be available to cool us in summer and warm us in winter because wind is uncontrollable, variable, and unpredictable? These questions should be answered in the DEIS. There should be a rationale, by the proponents, as to why they are proposing for this wind

farm, and all the others in WA and OR and other areas. If wind is variable, then how is BPA going to balance the power generated by wind turbines? How is BPA going to maintain its flexibility and consistency of power production if wind is so variable, unpredictable, and uncontrollable? More questions that should be answered in the DEIS.

The amount of installed capacity expected to be available during peak-load hours is often called a generator's "peak contribution" or "reliable capacity." There is a body of technical literature on methods for the calculation of this value. **Analysis done by Bonneville and the Resource Adequacy Forum suggests that, for the wind area at the east end of the Columbia River Gorge, where much of the region's current wind generation is located, there is an inverse relationship between wind generation and extreme temperatures, both in winter and summer.** This is likely due to widespread high pressure zones covering the region's load centers (the biggest ones being west of the Cascades) and the area of wind generation east of the Cascades during periods of extreme low and extreme high temperatures. Figure 12-1 illustrates the loss of wind generation during a recent winter period. While efforts to better define the reliable capacity of wind generators are ongoing, both in the Northwest and in NERC and WECC, the Resource Adequacy Forum has adopted a provisional peak contribution for wind of 5 percent of installed capacity. This work will need to address the impact of future wind development in other areas, such as Montana and Wyoming, that may have different weather patterns and could improve the overall capacity contribution of wind.

*Comment: So, analysis done by Bonneville and the Resource Adequacy Forum "...suggests that, for the wind area at the east end of the Columbia Gorge, where much of the region's current wind generation is located [as is the Whistling Ridge proposal] there is an inverse relationship between wind generation and extreme temperatures, both in winter and summer." Well, gosh darn, does this mean that when it's really hot, like in the summer time, there is less wind and therefore there is less wind power generation and therefore less energy is available for cooling? Summer time also means less water in the Columbia River and that means less water available to BPA for power generation. And, in the winter time, when it is really cold there is less wind power generation available to heat our homes and businesses? Why aren't these issues and concerns addressed in the DEIS? When we most need energy is when it is not being produced. Hmm, that does not make sense. Common sense, that is. Why are we even subsidizing more wind farms? Further, "the Resource Adequacy Forum has adopted a provisional peak contribution for wind of 5 percent of installed capacity." Does this mean that all the wind farms that litter the landscape only produce, and **WILL ONLY PRODUCE** and are **ONLY CAPABLE OF PRODUCING**, "5 percent of installed capacity"? This is a stunning statement. Whole ecosystems are being destroyed by wind turbines, pads, and impermeable maintenance roads that criss-cross our environments and ecosystems, and these wind farms will **ONLY PRODUCE** "5 percent of installed capacity"?!? Well, I would be speechless if this didn't make me so angry. This stunning analysis **MUST** be part of the DEIS and must be addressed in the future. A deep fatal flaw in this very inadequate, and getting more inadequate by the minute, DEIS.*

Adding Flexible Capacity

System planners and operators are looking at resources that can be used to meet peak-hour demand and respond to **variations in wind output**. These flexible-duty resources do not necessarily need to generate large amounts of energy over the course of the year. **Resources typically placed in this category include: rapid-response natural gas-fired generators; storage resources such as pumped-storage hydro plants; and utility demand response programs.** *In the near term, natural gas-fired turbines and reciprocating engines* appear to be good options for meeting the increased demand for flexibility. To offset unexpected changes in wind output, these resources need rapid-start capability and efficient operation at output levels less than full capacity.

Comment: So, now we have come to the crux of the wind generation matter—wind is not a reliable source of energy and needs backup from “natural gas-fired generators; storage resources such as pumped-storage hydro plants; and utility demand response programs...natural gas-fired turbines and reciprocating engines appear to be good options.” What is the carbon footprint of these backup systems? If I recall correctly, pumped-storage hydro plants are really reservoirs at high elevations to which water is pumped uphill, stored, and then released to go downhill and produce power through turbines. What are utility demand response programs? What are the cumulative regional impacts of these backup systems? These questions and issues should be addressed in the DEIS and are not. The DEIS is supposed to be a document that contains information so that we can all make reasoned, objective decisions about the proposed project and its regional cumulative effects. This DEIS is by no means that type of document.

The LM6000 Sprint (50-megawatt) and LMS100 (100-megawatt) aeroderivative turbines are two good candidates for flexibility augmentation. Starting cold, both turbines can be ramped to their maximum output within 10 minutes. These aeroderivative turbines are more efficient than comparable frame turbines, and therefore more cost-effective to operate at partial output levels. The LM6000 Sprint is a commercially mature technology with more than 200 units in operation. The first LMS100 unit went into commercial operation at the Groton Generating Station in South Dakota in 2006.

Comment: These “two good candidates for flexibility augmentation” sound good. But what is their carbon footprint? How do they affect the environment? Do they cause air pollution? Could we achieve better energy-saving results through conservation and increasing our efficiencies capabilities?

Gas-fired reciprocating engines are also a good flexibility option. The Plains End Generating Facility in Colorado is a 20-unit plant that has an output range of anywhere from 3 megawatts to 113 megawatts. The engines have a 10-minute quick start capability and can ramp up and down in response to an AGC signal. All of the above options can be constructed with short lead times, and therefore are good near-term flexibility options. A

more complete description of these natural gas-fired generating technologies is provided in Chapter 6.

Comment: Gas is a hydrocarbon. Hydrocarbon use produces greenhouse gasses. Greenhouse gasses are known to cause global climate changes. Using “gas-fired reciprocating engines” will produce greenhouse gasses. What is the carbon footprint of these gas-fired reciprocating engines? How many of them would be needed to balance out the unpredictability of wind power generation? What is their cumulative impact on air and water quality?

Pumped-storage hydro is a good mid-term option for meeting increased demand for flexibility since it can quickly change its operating level. These hydro plants operate in either a pumping mode or a generating mode. Traditional operation of pumped-storage hydro is based on the price of electric power. When the price of electric power is low, water is pumped from a source to a storage reservoir located at a higher elevation. When the price of electric power is high, the stored water is released and passed through a turbine to generate power. **As more wind power is added to the system, pumped-storage operation is likely to respond to the price of regulation and load-following services.** For example, operators of pumped-storage plants can commit in advance to increase pumping when there are unexpected increases in wind output. Plants with variable-speed pumps are likely to be more responsive in these circumstances. Likewise, operators can also commit to increase generation when wind power output unexpectedly drops. Furthermore, operating the plant in this manner is not likely to result in dramatic operating cost increases or reduced revenue. However, with a 13-year construction lead time, and high capital cost, risk is high. Other options may capture a large share of the ancillary services market before a new pumped-storage plant can be brought on-line.

Comment: Well, I don't want to burst anybody's bubble of happiness, but where are you all planning on getting the water that's necessary to produce pumped-storage hydro power? There is no chance on this green Earth that any water is coming out of the Columbia River. There are already too many users and abusers feasting on the Columbia. This is probably a non-starter idea. But, it should have been addressed in the DEIS. BPA's failure to do so is irresponsible.

The potential use of hot water heaters, plug-in hybrid vehicles, and other demand response options to provide regulation and load-following services is described in Chapter 5, Appendix H, and Appendix K.”

Comment: The DEIS should have included a section on other ways and means of conserving and producing energy, as a contrast to wind power generation. BPA should more fully explain how our Pacific NW energy demands can be met by means other than wind power. They should also explain why this proposed wind farm is needed, or if it really is needed, in the energy grid.

Subject: A comment on the proposed Whistling Ridge energy project

I am writing to submit a comment on the proposed Whistling Ridge energy project.

I believe wind power will be an essential and large part of the future mix of energy sources, and generally do support wind projects, but I also think that each site that has been proposed for a project must be evaluated according to local criteria.

I've heard that the Whistling Ridge project site is located in very important northern spotted owl habitat; and, considering the continuing decline of the spotted owls, this argues strongly against citing the project.

Also, a significant and large area of the Columbia Gorge National Scenic Area will have sightlines negatively affected if the project goes ahead.

Therefore, I ask that the State of Washington deny the proposal.

Re: Regarding the inadequacy of analysis of impacts to land and soils from the proposed Whistling Ridge (WR) wind farm project in Skamania County, wind turbine size and weight, and geologic mass wasting, etc.

The Draft Environmental Impact Statement (DEIS) shows that the soils on the proposed Whistling Ridge wind farm site, 1152 acres located in Sections 5, 6, 7, 8, and 18 of T3N, R10E, and on Section 13 of T3N, R9E, are unstable and should not be disturbed through the building of this project, a project that would involve thousands of tons of ground movement and disturbance, with the addition of thousands of tons of concrete and wind turbines on top of this unstable soil. In reading the DEIS, it also came to my attention that the soil descriptions used by the proponent were not as complete and not as informative as the soil descriptions in the Soil Survey of Skamania County, Washington, done by the U.S. Department of Agriculture, Soil Conservation Service, dated October 1990. It is as if certain, very pertinent information was left out of the DEIS. I have attempted to put this information in this memo.

On p. 3-1, 3.1.1.2, Regional Geology, the DEIS states, "*Regional geologic maps indicate the presence of Quaternary-age mass wasting landslide deposits located north of Underwood Mountain [my emphasis] (Figure 3.1-2). These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. However, based on field work conducted in 2007, there is no obvious evidence to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they have been exposed long enough that most or all of the geomorphic evidence has been removed by erosion.*" (p. 3-3) This is not an acceptable analysis. See Reference A, at the end of this document for more information on mass wasting but, briefly, "Mass wasting, the downhill movement of soil and rock under the influence of gravity, encompasses a variety of physical processes by which mountain ranges are eroded. These processes include:

- Creep - slow, nearly continuous downslope movement that is induced by either freeze/thaw cycles or wet/dry cycles.

- Slides - sudden downhill movement of masses of rock or sediment.
- Debris flows- dense, fluid mixtures of rock, sand, mud, and water

There are other categories of mass wasting processes such as slumps, rock flows, rockfalls, block glides (etc...) that can be grouped together or separately with creep, slides, and debris flows depending on which characteristics that share in common. **All of these processes share one thing in common, namely, that they are caused by the incessant downward pull of gravity, which moves loose slope material downwards.** [my emphasis]

“These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. However, based on field work conducted in 2007, there is no obvious evidence to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they have been exposed long enough that most or all of the geomorphic evidence has been removed by erosion.” “No obvious evidence...If landslide deposits are present...they have been exposed long enough that most or all of the geomorphic evidence has been removed...”!!! These are astonishing statements, made without any type of real, geological evidence, i.e., a sub-surface hazard survey, drill holes, etc., in the DEIS. **An in-depth geological study should be made of the entire proposed site—before the project is approved, not after.** Geomorphic evidence of landslides does not just disappear—a near-surface hazard survey is a tool to find out just what is going on under the exposed, eroded surface. This has not, apparently, been done for this DEIS, and it should be. This proposed wind farm would be situated on top of a unstable ridge line, subject to mass wasting¹.

A. http://www.geology.wisc.edu/courses/g112/mass_wasting.html

I. Physical and chemical weathering

Weathering is the destructive process by which rocks and minerals are broken down through exposure to atmospheric agents such as air, wind, water, and ice. Weathering processes can be grouped into two broad categories, consisting of

Physical weathering - the fragmentation of a larger rock into smaller pieces by mechanical processes. These processes include

- abrasion (erosion of a rock due to the impact of grains carried by wind, water, or ice)
- fragmentation during downslope movement via rockfalls, landslides, etc.
- frost wedging via the freeze/thaw cycle.
- thermal expansion and contraction via heating and cooling

Chemical weathering - breakdown of rock or mineral through reactions between rocks/minerals and atmospheric constituents such as water, oxygen, and carbon dioxide. The most common reactions include

- Solution - molecules and elements in rocks and minerals dissolve directly into water
- Oxidation and hydration - reaction between oxygen, water, and iron-bearing minerals that helps to break down minerals
- Hydrolysis - a complex weathering reaction that forms clays, the primary constituent of soils.

Ice and Physical weathering

The two principal mechanisms by which ice causes rock weathering (and erosion) are via **frost wedging** and **glaciation**.

- **Frost wedging** is the process by which water that has trickled into cracks in rocks (ranging from microscopic to large cracks) alternates between freezing and thawing. Frozen water (ice) occupies 10% greater volume than does its liquid equivalent. Water that freezes thus pushes outward on the sides of a fracture with tremendous force. This eventually breaks rocks apart.
- **Glaciation** - Glaciers are large masses of ice that rest on or adjacent to a land surface and typically move. Glacial ice forms when snow accumulates in deep enough piles (tens of meters) to cause individual snow flakes to recrystallize and form ice. Glaciers are extremely effective weathering and erosional agents. A glacier is capable of carving deep valleys into bedrock as well as scraping all loose material (soil and weathered bedrock) off from a landscape. In alpine regions, mountain glaciers are important elements in both weathering and erosion; most alpine mountain peaks have been shaped (or carved) by small mountain glaciers.

II. Mass wasting and gravity

Mass wasting, the downhill movement of soil and rock under the influence of gravity, encompasses a variety of physical processes by which mountain ranges are eroded. These processes include

- Creep - slow, nearly continuous downslope movement that is induced by either freeze/thaw cycles or wet/dry cycles.
- Slides - sudden downhill movement of masses of rock or sediment.
- Debris flows- dense, fluid mixtures of rock, sand, mud, and water

There are other categories of mass wasting processes such as slumps, rock flows, rockfalls, block glides (etc...) that can be grouped together or separately with creep, slides, and debris flows depending on which characteristics that share in common. All of these processes share one thing in common, namely, that they are caused by the incessant downward pull of **gravity**, which moves loose slope material downwards.

Gravity-driven mass wasting processes are a subset of larger set of processes that transport weathered and unweathered earth materials. These processes are classified as **erosional processes**, which include all processes that remove and transport weathered or unweathered soil and rocks. Erosional processes include

- Wind
- Running water
- Waves
- Glaciers
- Water flowing underground
- Gravity-driven processes (mass-wasting)

Mass-wasting processes

Mass-wasting processes such as creep, landslides, and debris flows are distinguished from each other in part by whether they occur rapidly or slowly. Landslides are capable of transporting massive amounts of rock and soil downslope for miles in very short periods (e.g. minutes). Creep can also transport much material, but at rates of only millimeters per year. Both are important erosional processes. **Rapid mass**

Earthquakes

Earthquakes are the result of sudden releases of built-up stress within the tectonic plates that make up the earth's surface. Stress accumulates where movement between plates or on faults produces friction. No faults are mapped within the footprint of the proposed project area. However, faults are mapped approximately 1.5 miles to the southwest and northeast. (Pezzopane 1993 and Geomatrix 1995) Many of these faults are inferred, and shown as dotted lines buried by younger surficial deposits. While the activity of the area faults is unknown, a review of aerial photography showed no indication of recent movement along the trace of the inferred faults.

There have been no surface-rupture earthquakes on any fault within northwestern Oregon or southwestern Washington in historic times, and investigations of the regional faults have been limited.

According to the updated National Seismic Hazard Maps published by the US Geological Survey (USGS) in 2008 (Petersen et al. 2008 and USGS 2009), the peak ground acceleration estimated for the area of the Whistling Ridge site is 0.18g for a 475-year return period earthquake (i.e., ground motion with a 10 percent chance of being exceeded in 50 years) and 0.40g for a 2,475-year return period earthquake (i.e., ground motion with a 2 percent chance of being exceeded in 50 years).

Large earthquakes at more distant faults could cause prolonged ground movement at the project site. Information on historic large earthquakes can be found in the Application for Site Certification Section 3.1 (Appendix A).

Landslides

The landslide evaluation conducted for the Application for Site Certification concluded that the project could be constructed and operated without danger to human life or the surrounding environment due to landslide hazards.

Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the project site (Tower Lines A and B) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70 percent). Based on studies conducted for the Application for Site Certification, it appears that the primary concern for towers located adjacent to the Class II LHAs is the potential for headward erosion of the steep drainages by debris or earth flow processes. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site

wasting events such as massive landslides or debris flows are typically triggered by events that destabilize material that resides on steep slopes. Such events include earthquakes, volcanic eruptions, rain or melting snow, and poorly planned landscape alterations by humans (e.g. road cuts or developments that require the removal of material at the bases of slopes). [my emphasis]

reconnaissance. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock underlying the ridgelines.

The soils on the proposed wind farm site can be found in the U.S. Department of Agriculture's Soil Conservation Service's Soil Survey of Skamania County Area, Washington, October 1990. The DEIS descriptions are in ITALICS; other descriptions and information for each soil type is from the Soil Survey book (I have copied freely!). The soil types are numbered, as follows:

#66, McElroy Series (included in this unit are small areas of Chemawa, Timberhead, Underwood, and Undusk soils) gravelly loam, 5 – 15 percent slopes. *“The McElroy series consists of very deep soils (up to 5 feet) formed in colluvium and residuum from basalt with a mantle of volcanic ash that influences soils in the top 9 to 13 inches. The soils exist on the footslopes and backslopes of mountains on slopes from 5 to 90 percent at elevations from 400 to 2,600 feet in eastern Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.”* The average annual precipitation is 55 inches, average air temperature is about 46 degrees Fahrenheit (F), and the average frost-free period is 105 – 125 days. Hazard of water erosion is moderate. This unit is used for woodland, hayland, pastureland, homesites, wildlife habitat, and recreation. Douglas fir, ponderosa pine, and grand fir are the main woodland species. Oregon white oak and bigleaf maple are trees of limited extent in this soil unit. Main limitation for harvesting timber is seasonal soil wetness...wheeled and tracked equipment produces ruts, compacts the soil, and damages the roots of trees...Unsurfaced roads and skid trails are soft and slippery and can be impassable when wet...Occasional snowpack hinders the use of equipment and limits access in winter. This unit is well suited to use as hayland and pastureland. The main limitation of this unit for use as homesites is the steepness of slope. Erosion is a hazard in the steeper areas. Capability sub-class IIIe.

#67, McElroy Series (included in this unit are small areas of Chemawa, Timberhead, Underwood, and Undusk soils), gravelly loam, 15 to 30 percent slopes. It formed in colluvium derived dominantly from basalt with a mantle of volcanic ash. The native vegetation is mixed conifers and shrubs. Elevation is from 400 to 2300 feet. [Note: the DEIS states that the McElroy Series is from 400 to 2600.] The average annual precipitation is 55 inches, average air temperature is about 46 degrees F, and the average frost-free period is 105 – 125 days. Runoff is medium and the hazard of water erosion is moderate. Most areas of this unit are used for woodland, pastureland, hayland, wildlife habitat, recreation, and **watershed**. A few areas are used as homesites. Douglas fir, ponderosa pine, and grand fir are the main woodland species on this unit. Limited extent trees are Oregon white oak and bigleaf maple. Main limitation for harvesting timber is seasonal soil wetness...wheeled and tracked equipment produces ruts, compacts the soil, and damages the roots of trees...Unsurfaced roads and skid trails are soft and slippery and can be impassable when wet... Occasional snowpack hinders the use of equipment and limits access in winter. This unit is well suited to use as hayland and pastureland. The main limitations are steepness of slope and the hazard of erosion. Main limitation for use as homesites

is the steepness of slope and erosion. **Restricted permeability and steepness of slope increase the possibility of failure of septic tank absorption fields.** Access roads should be designed to provide adequate cut-slope grade, and drains are needed to control surface runoff and keep soil losses to a minimum. Capability subclass IVe.

Watersheds are very important and should be protected from industrial wind farms.

#68, McElroy Series (included in this unit are small areas of Chemawa, Timberhead, Underwood, and Undusk soils), gravelly loam, 30 – 65 percent slopes. Very deep, well-drained soil is on the back slopes of mountains. It formed in colluvium derived dominantly from basalt with a mantle of volcanic ash. The native vegetation is mainly mixed conifers and shrubs. Elevation is 400 to 2300 feet. The average annual precipitation is 55 inches, average air temperature is about 46 degrees F, and the average frost-free period is 105 – 125 days. **Runoff is rapid, and the hazard of water erosion is severe.** This unit is used for woodland, wildlife habitat, recreation, and **watershed**. Douglas fir, ponderosa pine, and grand fir are the main woodland species on this unit. Oregon white oak and bigleaf maple are limited extent trees on the unit. Steep slopes restrict the use of wheeled and tracked equipment in skidding. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Logging roads require suitable surfacing for year-round use. Occasional snowpack hinders the use of equipment and limits access in winter. Steep yarding paths, skid trails, and firebreaks are subject to rilling and gullying unless plant cover is maintained or adequate water bars are provided. Capability sub-class VIe.

#135, Timberhead Series, gravelly loam, 5 to 30 percent slopes. *The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium from basalt mixed with volcanic ash. The soils exist on mountain ridges between 5 and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability.* [Note: The Soil Survey book states that this unit is at 2000 to 2800 feet elevation.] Average annual precipitation is about 60 inches, the average annual air temp is 44 degrees F, and the average frost-free period is 95 to 115 days. Included in this unit are small areas of McElroy, Underwood, and Undusk soils. Runoff is medium, and the hazard of water erosion is moderate. Most areas of this unit are used for woodland, recreation, wildlife habitat, and watershed. A few areas are used as grazeable woodland. Douglas fir, grand fir, and western hemlock are the main woodland species on this unit. [Would there be bats here, just like at the canopy crane, because of the hemlock?] Among the trees of limited extent is western redcedar. Areas on ridge tops that are subject to **strong, persistent winds** [how strong and how persistent?] are less productive than other areas of this unit. The main limitation of harvesting timber is seasonal soil wetness. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Unsurfaced roads and skid trails are soft and slippery and can be impassable when wet. Occasional snowpack hinder the use of equipment and limits access in winter. This map unit is in capability subclass IVe.

#136, Timberhead Series, gravelly loam, 30 to 65 percent slopes. *The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium from basalt mixed*

with volcanic ash. The soils exist on mountain ridges between 5 and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability. [Note: the Soil Survey book states that this soil unit is in the 2000 to 2800 foot elevation range.] Average annual precipitation is about 60 inches, the average annual air temp is 44 degrees F, and the average frost-free period is 95 to 115 days. Included in this unit are small areas of McElroy, Underwood, and Undusk soils. Also included are small areas of Rock outcrop and moderately deep soils over basalt. Available water capacity is moderately high. **The hazard of water erosion is severe.** Most areas of this unit are used for woodland, recreation, wildlife habitat, and watershed. Douglas fir, grand fir, and western hemlock are the main woodland species on this unit. Western redcedar is a tree of limited extent. The main limitation for harvesting timber is steepness of slope, which restricts the use of wheeled and tracked equipment. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Occasional snowpack hinders the use of equipment and limits access in winter. Steep yarding paths, skid trails, and firebreaks, are subject to rilling and gullyng unless plant cover is maintained or adequate water bars are provided. Capability subclass VIIe.

#144, Underwood loam, 2 to 15 percent slopes. *The Underwood series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 2 and 50 percent at elevations between 500 and 2,700 feet in southeast Skamania County and west Klickitat County. Underwood Series soils are well drained with slow to medium runoff and moderately high permeability.* [Note: The Soil Survey book states that this unit is at 500 to 2000 feet elevation.] The native vegetation is mainly mixed conifers and shrubs. The average annual precipitation is about 50 inches, the average annual air temperature is about 46 degrees F, and the average frost-free period is 100 to 150 days. Included in this unit are small areas of Chemawa and McElroy soils on terraces and foot slopes and Timberhead and Undusk soils on ridgetops. Also included are small areas of soils that are more than 35 percent clay. Included areas make up about 10 percent of the total acreage. Permeability of this Underwood soil is moderately slow. **Available water capacity is high. Runoff is medium, and the hazard of water erosion is moderate.** This unit is used for woodland, hayland, pastureland, orchards, homesites, wildlife habitat, and recreation. Douglas fir, ponderosa pine, and grand fir are the main woodland species on this unit. Among the trees of limited extent are Oregon white oak and bigleaf maple. The main limitation for harvesting timber is seasonal soil wetness. **Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees.** Unsurfaced roads and skid trails are soft and can be impassable when wet. Logging roads require suitable surfacing for year-round use. **Occasional snowpack hinders the use of equipment and limits access in winter.** The main limitations of this unit for use as homesites are steepness of slope, shrink-swell potential, moderately slow permeability, **and the hazard of erosion in the steeper areas.** Use of sandy backfill for the trench and long absorption lines helps to compensate for the moderately slow permeability of the soil. **During the rainy season, effluent from onsite sewage disposal systems may seep at points downslope.** If the density of housing is moderate to high, community sewage systems are needed to prevent contamination of water supplies as a result of seepage from onsite disposal systems. The effects of shrinking and swelling can be minimized by using proper engineering designs. **Buildings and roads should be designed to offset**

the limited ability of the soil in this unit to support a load. This map unit is in capability subclass Ille.

#147, Undusk gravelly loam, 5 to 30 percent slopes. *The Undusk series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 5 and 65 percent at elevations between 2,000 and 2,800 feet in southeast Skamania County and west Klickitat County. Undusk Series soils are well drained with slow to medium runoff and moderately high permeability.*

Based on the current test pits and field observations, the site soil is best represented as Soil Site Class D (stiff soils). Rock with varying strength and weathering characteristics was encountered at depths ranging from 3 to 12 feet bgs. The average annual precipitation is about 55 inches, the average annual air temperature is about 44 degrees F, and the average frost-free period is 90 to 120 days. The subsoil to a depth of 60 inches or more is dark brown very gravelly loam and extremely gravelly loam. Included in this unit are small areas of Chemawa, McElroy, Timberhead, and Underwood soils on ridges and back slopes and St. Martin soils on landslides. Also included are small areas of soils that are less than 35 percent rock fragments and soils that are shallow to bedrock. Included areas make up about 12 percent of the total acreage.

*Permeability of this Undusk soil is moderate. **Available water capacity is moderately high. Runoff is medium, and the hazard of water erosion is moderate.** This unit is used for woodland, wildlife habitat, recreation, and watershed. Douglas fir, grand fir, and western hemlock are the main woodland species on this unit. Among the trees of limited extent are red alder and western redcedar. **Areas on ridgetops that are subject to strong, persistent winds are less productive than other areas of this unit.** The main limitation for harvesting timber is seasonal soil wetness. Use of wheeled and tracked equipment when the soil is moist produces ruts, compacts the soil, and damages the roots of trees. Unsurfaced roads and skid trails are soft and can be impassable when wet. Logging roads require suitable surfacing for year-round use. **Occasional snowpack hinders the use of equipment and limits access in winter.** Logging activities can readily displace the surface layer. This map unit is in capability subclass IVe.*

#177, Undefined Soil Unit located West of wind turbine string C1-C4. ??????

These units sit next to the turbine strings—????

Turbines are heavy, unwieldy machines. In my research, I came across the following information, several articles—one from Wind Watch, one from aweo.org, and one on transporting wind turbines--which provide insight on just how big and weighty wind turbines actually are, and I believe this information is very pertinent to the evaluation of weight effects on the soils located in the proposed area of the Whistling Ridge wind farm:

Article #1

<http://www.wind-watch.org/faq-size-p.php>

FAQ -- Size

How big is a wind turbine?

Industrial wind turbines are a lot bigger than ones you might see in a schoolyard or behind someone's house.

The widely used GE 1.5-megawatt model, for example, consists of **116-ft blades atop a 212-ft tower for a total height of 328 feet**. The blades sweep a vertical airspace of just under an acre.

The 1.8-megawatt Vestas V90 from Denmark is also common. Its 148-ft blades (sweeping more than 1.5 acres) are on a 262-ft tower, totaling 410 feet.

Another model being seen more in the U.S. is the 2-megawatt Gamesa G87 from Spain, which sports 143-ft blades (just under 1.5 acres) on a 256-ft tower, totaling 399 feet.

Many existing models and new ones being introduced reach well over 400 feet high.

How are the wind turbine components transported?

Transport of such large items and the cranes needed to assemble them often presents problems in the remote areas where they are typically built. Roads must be widened, curves straightened, and in wild areas new roads built altogether.

What kind of platform is a wind turbine set in?

The steel tower is anchored in a platform of more than a thousand tons of concrete and steel rebar, 30 to 50 feet across and anywhere from 6 to 30 feet deep. Shafts are sometimes driven down farther to help anchor it. **Mountain tops must be blasted to accommodate it.** The platform is critical to stabilizing the immense weight of the turbine assembly.

How much do wind turbines weigh?

In the GE 1.5-megawatt model, **the nacelle alone weighs more than 56 tons, the blade assembly weighs more than 36 tons, and the tower itself weighs about 71 tons -- a total weight of 164 tons.** The corresponding weights for the Vestas V90 are 75, 40, and 152, total 267 tons; and for the Gamesa G87 72, 42, and 220, total 334 tons.

What is the nacelle?

The gearbox -- which transforms the slow turning of the blades to a faster rotor speed -- and the generator are massive pieces of machinery housed in a bus-sized container, called the nacelle, at the top of the tower. The blades are attached to the rotor hub at one end of the nacelle. Some nacelles include a helicopter landing pad.

Are wind turbines more intrusive than other structures of similar size?

Besides the noise and vibrations such huge moving machines unavoidably generate, they must be topped with flashing lights day and night to increase their visibility. The moving blades attract attention.

How much area is required for a wind power facility?

The huge turbines require a correspondingly large area around them clear of trees and other turbines to maximize the effect of the wind and avoid interference. They should have 10 rotor diameters of clearance in the direction of the wind and 3 rotor diameters in every other direction. In a line of several turbines perpendicular to the wind (as on a mountain ridge), the GE 1.5-MW model would need at least 32 acres and the Vestas V90 78 acres for each tower. In an array that can take advantage of the wind from any direction, the GE needs 82 acres and the Vestas V90 111 acres per tower.

In practice, the area varies, averaging about 50 acres per megawatt of capacity. On mountain ridges, the turbines are generally squeezed in about eight per mile.

Can the area around a wind turbine continue to be used?

Only by putting oneself in danger. Besides the unpleasant noises and distracting motion, wind turbines are not safe. They are high-voltage electrical devices with large moving parts. It is estimated that for every 100 turbines, one blade will break off (see Larwood, 2005). In the winter, heavy sheets of ice can build up and then fall or be thrown off. Access to the land around wind turbines is usually restricted, even to the landowner.

Are bigger turbines more efficient?

No, they are just bigger. Output depends on wind speed and the combination of blade diameter and generator size. **Bigger blades on a taller tower can capture more wind to run a bigger generator, but they don't do so more efficiently than smaller models.**

<http://www.aweo.org/windmodels.html>

Size specifications of common industrial wind turbines

Vestas and General Electric (GE) dominate the market for industrial wind turbines in the U.S. Many older U.S. facilities use NEG Micon turbines, and Vestas has absorbed that manufacturer. Other older facilities use turbines from Zond, which was acquired by Enron (the inventor of "green tags"), whose wind business GE acquired in turn to take over the racket. Information about Vestas models can be found at www.vestas.com, Gamesa models at www.gamesa.es/en/products/wind-turbines/catalogue, GE models at www.gepower.com/prod_serv/products/wind_turbines/en, Siemens models at www.powergeneration.siemens.com/products-solutions-services/products-packages/wind-turbines/products/Products.htm, Suzlon models at www.suzlon.com, Clipper models at www.clipperwind.com, and Repower (acquired by Suzlon in May 2007) models at www.repower.de/index.php?id=12&L=1. Americas Wind Energy, Enercon, Fuhrlander, Mitsubishi, Goldwind, Nordex, AAER, Dewind, and Ecotècnia are also major manufacturers, but their turbines are less common in the U.S.

*This figure is actually half the rotor diameter. The blade itself may be about a meter shorter, because it is attached to a large hub.

†Hub (tower) heights may vary; the more commonly used sizes are presented.

‡Rotor diameter (m) $\times \pi \times \text{rpm} \div 26.82$

§The rated, or nominal, wind speed is the speed at which the turbine produces power at its full capacity. For example the GE 1.5s does not generate 1.5 MW of power until the wind is blowing steadily at 27 mph or more. As the wind falls below that, power production falls exponentially.

<http://www.cn.ca/documents/WhitePapers/Transporting-Wind-Turbines-White-Paper-en.pdf>
HOW BIG IS BIG?

To understand and appreciate the logistics of transporting such massive parts it helps to understand the makeup of a wind turbine. The specs for a 1.8 MW turbine provided by the Canadian Wind Energy Association (CanWEA):

- **The nacelle (generator components)** is the size of a small motor home and weighs 63,000 kg (138,891 lb).
- **Each blade** is 39 m (128 ') long – the same length as a Boeing 737, and the 3-blade rotor weighs 35,000 kg (77,162 lb).
- **The 65 m (213 ') tower** is made up of rolled steel and comes in three pieces. The entire tower weighs 132,000 kg and contains enough steel to manufacture 206 average cars.
- **The foundation concrete** is 9 – 10 m (33 ') deep and 4 m (13 ') across. 102 tension type bolts run the full depth of the foundation.
- **Swept area** of the blades is 5,024 sq. m, (16,483 ') the size of 3 NHL hockey rinks combined or about 1.25 acres.
- **Total weight** of the entire turbine is 230,000 kg (507,063 lb) – about the same as two fully fueled 3,200 HP diesel electric locomotives.

This is just one example, however even the wind turbine components above are often even bigger than this.

WWW.CN.CA 4 THE LOGISTICS, NOT EXACTLY A BREEZE

Understanding the size of wind turbines provides an appreciation for the complexity of their transportation. A single turbine can require up to 8 loads (one nacelle, one hub, three blades and three tower sections). **For an entire project of 150 MW, transportation requirements have been as much as 689 truckloads, 140 railcars and 8 vessels to the United States.** And, many projects today are much larger than 150 MW (the largest operating project in the US is currently 736 MW, and projects of more than 4,000 MWs are in the early stages of development).⁵

It is no wonder that one of the biggest challenges facing the industry are the logistics of transporting such oversized parts sometimes over extremely long distances. **Among the issues; traffic backups, road damage, coordination and cost.**

TRAFFIC CONGESTION

As suggested in a recent article in the New York Times, *“As demand for clean energy grows, towns around the country are finding their traffic patterns roiled as convoys carrying disassembled towers that will reach more than 250 feet (76.2 m) in height, as well as motors, blades and other parts roll through. Escorted by patrol cars and gawked at by pedestrians, the equipment must often travel hundreds of miles from ports or factories to the remote, windy destinations where the turbines are erected.”*⁶

ROAD DAMAGE

Normal wear and tear of any road is expected over time, but **whenever there is extensive pressure and constant flow of traffic, road damage becomes inevitable.** In Texas for example, the state with the most wind turbines, the **constant truck traffic is tearing up small roads** in the western part of the state, where the turbines are being rapidly erected.

Conclusions and Comments:

- 1. An in-depth geological study should be made of the entire proposed site—before the project is approved, not after. A near-surface seismic hazard survey and deep coring should be required before this project is approved.**
- 2. No watershed studies have been done for this project site, even though the Soil Surveys clearly state that this is a watershed area.**
- 3. The impacts of the turbines’ weights on the mountain ridges in the DEIS has not been fully addressed. Could mass wasting result from ridges being flattened, heavy machinery being installed, deep anchors disturbing the soils, etc?**
- 4. “The steel tower is anchored in a platform of more than a thousand tons of concrete and steel rebar, 30 to 50 feet across and anywhere from 6 to 30 feet deep. Shafts are sometimes driven down farther to help anchor it. Mountain tops must be blasted to accommodate it.** The platform is critical to stabilizing the immense weight of the turbine assembly.” This statement is from the National Windwatch article. I really don’t want to see mountain tops “blasted,” and residents near the wind farm proposal probably don’t want to see it, either! The proposed wind farm has 50 some turbines proposed. That is 50 x 1000 tons of concrete and steel rebar = to 50,000 tons of concrete and steel rebar weighing down on soils that are susceptible to erosion; one ton equals 2000 pounds, 2000 pounds x 50,000 tons = 50,000,000 pounds. What are the cumulative impacts of putting 50,000,000 pounds of stress on mountain ridges in Skamania County, and what are the cumulative effects of all the other wind farms’ weights on all the lands and soils in BPA’s area of interest? What does all this weight do to water tables? Any other effects? This issue of weight should be addressed more fully in the DEIS and its lack makes the DEIS inadequate and incomplete.

5. Wind turbines are dangerous pieces of noisy machinery and they should not be put on top of ridges or on steep slopes. At least this is what I think. The lack of information on the environmental, cumulative impacts of wind turbines on lands and soils is a critical deficiency in the Whistling Ridge DEIS and this is a fatal flaw in the DEIS.

6. Mass wasting is a real concern in the proposal area and it has not been adequately addressed in the DEIS. There are real consequences to area residents from erosion and mass wasting events. How would people be evacuated if a wind turbine's weight causes a mass wasting event or other types of erosion? What are the evacuation routes?

There are a lot of questions about the geology of the proposal area that have not been adequately answered in the DEIS. We need complete data in order to properly evaluate the DEIS.

Subject: I support Whistling Ridge

Hello Energy Facility Site Evaluation Council,

I would like to express my strong support for the Whistling Ridge Energy Project. I am proud to live in a community adjacent to this project. I am proud to say we will have such a project here. We are doing our part to help our Country become as environmentally conscious as possible in our energy production and use.

I will see the turbines from our property, and most likely also hear them. And although I live up in the Little White Salmon River Canyon Valley I can hear the trains running along both sides of the Columbia River, I hear the barges as they go up and down the River, and I hear the generators and alarms from the US Federal Fish Hatchery down in the Canyon. I hear all this while I live in the beautiful forest and so do the deer eating my Blueberries, the Turkey\'s eating my bird seed, the Cougar that crossed our road a while back, and the bear that smashed our drinking water spring roof last week. Surprise, we all seem to be flourishing here in the woods side by side!

SDS has an excellent reputation as a supporter of our community, citizens, our fire departments, schools, etc., and they go out of their way to allow public use of their lands and conduct their business with consideration of us as their neighbors. Surprise, industry working side-by-side private homes in the wilderness, it works!

I am proud to live here in Mill A, in Skamania County Washington.

Turn the tables everyone, use the Whistling Ridge Energy Project as an asset!!

Anita Gahimer Crow
Resident and Business Owner
Mill A/Cook, Washington

Sincerely,
Anita Gahimer Crow

Subject: Re: Whistling Ridge DEIS Comments

Ladies and Gentlemen,

Thank you for the opportunity to submit comments regarding the above captioned proposed industrial wind generating facility in Underwood, Washington. I strongly believe that this proposed industrial facility clearly warrants a siting denial by your Council. There are fatal flaws in the concept, location, design, construction and operation of an industrial energy facility in Underwood, Washington and the Columbia River Gorge.

The concept of locating such a facility on ridge lines of dense old growth forested land is ill conceived for numerous reasons. It is of great importance that the approval of such a facility would have far reaching precedential repercussions, encouraging the deforestation and development of thousands of acres of both habitat and scenic resources. Developers are already viewing the potential for the development of similar facilities to the west, which could result in facilities scattered from the western Columbia Gorge to Portland, despoiling the natural ambiance of the area and reducing habitat, carbon sequestration and tourism. Your approval of an industrial facility impacting, but not technically in the boundary of The Columbia Gorge National Scenic Area (NSA) would set a precedent that could open the flood gates for any development visible from the NSA but not technically within its boundaries, including, but not limited to Las Vegas style casino signs, Space Needle type establishments, and high rise developments on formerly forested ridges. You have the power and authority to prevent setting the precedent that the Columbia River Gorge is open to a gold rush of industrial development.

The concept of ridge line deforestation and industrial development is also faulty in its failure to address additional factors such as the earthquake prone conditions of this area, the impact of blasting and construction on known water resources, including springs and aquifers. The steepness of the proposed site, once deforested further, will result in unacceptable water run off, erosion and extreme habitat loss.

The concept of clear cutting thousands of acres of old growth forest for industrial development in favor of select harvesting is ecologically and economically unsound for this region. Alternative sites that have already been cleared and that do not impact the scenic value of the Gorge are plentiful and should be preferred to the siting of the current proposal.

The concept that one developer's desire to achieve "economic diversity" at the expense of the impact of the project to Gorge wildlife, residents and tourists of both Washington and Oregon is selfish at best, arrogant at worst. The concept of this proposed project is fatally flawed and siting of this proposed industrial facility should be denied.

The location of the proposed project is also fatally flawed for many of the reasons discussed previously and for additional reasons. The proposed location will severely impact local Underwood residents. You are aware of the numerous non wind industry sponsored studies detailing both physical and mental health impacts on both adults and children, so I will not reiterate those findings.

Please do not discount the life altering effect that an industrial energy facility will impose on local residents. Please do not credit the wind industry sponsored studies that such a facility would not negatively impact home values severely. Really, would any of you chose a residence within close proximity to 425 foot loud twirling lighted structures if given the choice of an equally pleasing quiet rural residence unencumbered by such structures? I think not.

The proposed location of the project also discounts the very real threat of fire in what is now a strictly no burn tinder box. This location is not a flat insured wheat field. This location is a forested steeply graded terrain which is home to a wide variety of wildlife, domesticated livestock and people and their homes. Both construction and operation of an industrial facility poses an unacceptable threat to the aforementioned as well as to travelers and the very scenic vistas that make up the Gorge. The location of the proposed facility by its very nature would be difficult or impossible to adequately access with fire fighting equipment. The helicopter water drops so instrumental in fighting the Underwood fire of the summer of 2008 which destroyed trees, vegetation, wildlife and homes, would not be available for use in and around the proposed structures because of the proximity prohibition for helicopters and turbines or towers. A developer's pet project should not instill fear and concern and potential devastation to the surrounding inhabitants and a potentially severe loss of scenic value to the Gorge community and tourists.

The proposed location is flawed for reasons of cumulative impact. Existing industrial wind facilities and the rate of development of additional industrial wind facilities in the surrounding areas to the east have created an unacceptable cumulative impact on the wildlife populations of the area, as well as for many of the residents. Approval of the proposed WRE project would exacerbate this effect due to its established migratory paths as well as the non migratory bat and avian populations, not to mention the wildlife habitat devastation that would result from the sheer amount of deforestation required.

The proposed project location is ill conceived from another cumulative impact circumstance. Recent legal and government decisions related to the Broughton Mill resort and the Cascade Locks Casino make it possible that those facilities could become a reality. If so, the cumulative impact of these establishments, coupled with the construction of an industrial wind facility (and the precedent for other industrial developments) in a relative proximity to each other, could cumulatively negatively impact the Gorge in ways that we cannot now fully conceive. We must be good stewards of this national scenic area, not its destroyers.

The design of the proposed facility is fatally flawed for lack of statutorily required alternatives and insufficient mitigation analysis.

The construction of the proposed facility would entail unacceptable traffic and emergency response impacts for residents and visitors to the NSA, particularly to key viewing points in the Underwood area. Construction of this facility would create unacceptable impacts on ground water supplies, and contribute to the already high fire hazard.

The operation of the proposed industrial facility raises unanswered questions regarding the use of the power generated and the ownership of the facility. It is common knowledge that 80% of the wind power generated in the northwest is sold outside of Washington, principally to California, and thus not contributing to Washington's mandated green energy requirements. It is also common knowledge that a high percentage of the smaller wind energy facilities themselves are sold to out of state buyers, or are under contracts for sale to such buyers who frequently employ their own in-house employees, not resulting in local permanent jobs. Is the proponent's staunch resistance to alternative designs related to a minimum output required for just such a sale? Should the residents and visitors to the Columbia River Gorge National Scenic Area be subjected to the intrusion of the construction and

presence of an industrial wind energy facility that statistically is likely to become owned by an out of state entity that sells its power out of state?

The Whistling Ridge Energy proposed project is the wrong project for the Gorge, at the wrong time and wrong place.

Sincerely,

Rebecca Maxey

Re: Comments on the Whistling Ridge DEIS and the inadequacy of information on the cumulative effects of wind farm development on avian species and possible and probable violations of the Migratory Bird Treaty Act of 1918 (MBTA)

Dear EFSEC and BPA,

I voiced some concerns about birds and bats in my previous comments on Chapter 3 and cumulative effects, but I wanted to voice even more concern and trepidation about the cumulative effects and impacts that regional wind farms, and BPA energy production facilities en toto, have on migratory species. The Migratory Bird Treaty Act, see Reference #1, below, is mentioned in the DEIS but I am very concerned that the topic of migrating avian species should have more in-depth and thorough regional data presented in the DEIS. As I have stated before, cumulative impacts, both direct and indirect, are not done on a project by project basis, but, according to NEPA regulations, must be done on a reference geographical and/or regional basis. This was not done by either SDS or BPA, the two proponents for this wind farm project.

Briefly, some of my concerns:

- Cumulative effects and impacts on species viability are not adequately addressed in the DEIS—there is no supporting data to show if avian species birth rates, replacement rates, genetic diversity, etc., would or would not be affected by regional wind farms. This must be addressed;
- Will there be “taking” by the wind turbines? How will “taking,” basically killing of an avian, be addressed? What type of monitoring will be done throughout the life of the project to collect data on “taking”?
- Where are the migratory bird maps for the region? I did not find them in the DEIS.

- Are there other species, besides avian, that migrate through the area and might be affected by the regional wind farms and BPA's energy generation infrastructure? Apparently, the MBTA was amended to include other species: "The 1974 statute (P.L. 93-300) amended the MBTA to include the provisions of the 1972 Convention between the U.S. and Japan for the Protection of Migratory Birds and Birds in Danger of Extinction. This law also amended the title of the MBTA to read: **"An Act to give effect to the conventions between the U.S. and other nations for the protection of migratory birds, birds in danger of extinction, game mammals, and their environment."**

I'm sure that I have many more questions, but the 5 p.m. deadline is upon me and I want to make sure that I get these comments in on time. I do think that the Whistling Ridge DEIS is extremely deficient in data on migration pathways for avian species. This lack of regional data must be addressed or the DEIS is incomplete. It is an established fact that wind farms kill birds. How many is hotly debated. However, that does not mean that we should not attempt to gather data so that we can better understand the regional cumulative impacts and effects of wind farms and energy production infrastructures on avian species, and, of course, on other species.

Thank you.

Sincerely,

/e-signature/Mary J. Repar

Migratory Bird Treaty Act of 1918

[Migratory Bird Treaty Act of 1918](#) (16 U.S.C. 703-712; Ch. 128; July 13, 1918; 40 Stat. 755) as amended by: Chapter 634; June 20, 1936; 49 Stat. 1556; P.L. 86-732; September 8, 1960; 74 Stat. 866; P.L. 90-578; October 17, 1968; 82 Stat. 1118; P.L. 91-135; December 5, 1969; 83 Stat. 282; P.L. 93-300; June 1, 1974; 88 Stat. 190; P.L. 95-616; November 8, 1978; 92 Stat. 3111; P.L. 99-645; November 10, 1986; 100 Stat. 3590 and P.L. 105-312; October 30, 1998; 112 Stat. 2956

The original 1918 statute implemented the 1916 Convention between the U.S. and Great Britain (for Canada) for the protection of migratory birds. Later amendments implemented treaties between the U.S. and Mexico, the U.S. and Japan, and the U.S. and the Soviet Union (now Russia).

Specific provisions in the statute include:

Establishment of a Federal prohibition, unless permitted by regulations, to "pursue, hunt, take, capture, kill, attempt to take, capture or kill, possess, offer for sale, sell, offer to purchase, purchase, deliver for shipment, ship, cause to be shipped, deliver for transportation, transport, cause to be transported, carry, or cause to be carried by any means whatever, receive for shipment, transportation or carriage, or export, at any time, or in any manner, any migratory bird, included in the terms of this Convention . . . for the protection of migratory birds . . . or any part, nest, or egg of any such bird." (16 U.S.C. 703)

This prohibition applies to birds included in the respective international conventions between the U.S. and Great Britain, the U.S. and Mexico, the U.S. and Japan, and the U.S. and the Russia.

Authority for the Secretary of the Interior to determine, periodically, when, consistent with the Conventions, "hunting, taking, capture, killing, possession, sale, purchase, shipment, transportation, carriage, or export of any . . . bird, or any part, nest or egg" could be undertaken and to adopt regulations for this purpose. These determinations are to be made based on "due regard to the zones of temperature and to the distribution, abundance, economic value, breeding habits, and times of migratory flight." (16 U.S.C. 704)

A decree that domestic interstate and international transportation of migratory birds which are taken in violation of this law is unlawful, as well as importation of any migratory birds which are taken in violation of Canadian laws. (16 U.S.C. 705)

Authority for Interior officials to enforce the provisions of this law, including seizure of birds illegally taken which can be forfeited to the U.S. and disposed of as directed by the courts. (16 U.S.C. 706) Establishment of fines for violation of this law, including misdemeanor charges. (16 U.S.C. 707)

Authority for States to enact and implement laws or regulations to allow for greater protection of migratory birds, provided that such laws are consistent with the respective Conventions and that open seasons do not extend beyond those established at the national level. (16 U.S.C. 708)

A repeal of all laws inconsistent with the provisions of this Act. (16 U.S.C. 710)

Authority for the continued breeding and sale of migratory game birds on farms and preserves for the purpose of increasing the food supply. (16 U.S.C. 711)

The 1936 statute implemented the Convention between the U.S. and Mexico for the Protection of Migratory Birds and Game Mammals. Migratory bird import and export restrictions between Mexico and the U.S. were also authorized, and in issuing any regulations to implement this section, the Secretary of Agriculture was required to consider U.S. laws forbidding importation of certain mammals injurious to agricultural and horticultural interests. Monies for the Secretary of Agriculture to implement these provisions were also authorized.

The 1960 statute (P.L. 86-732) amended the MBTA by altering earlier penalty provisions. The new provisions stipulated that violations of this Act would constitute a misdemeanor and conviction would result in a fine of not more than \$500 or imprisonment of not more than six months. Activities aimed at selling migratory birds in violation of this law would be subject to fine of not more than \$2000 and imprisonment could not exceed two years. Guilty offenses would constitute a felony. Equipment used for sale purchases was authorized to be seized and held, by the Secretary of the Interior, pending prosecution, and, upon conviction, be treated as a penalty.

Section 10 of the 1969 amendments to the Lacey Act (P.L. 91-135) repealed the provisions of the MBTA prohibiting the shipment of wild game mammals or parts to and from the U.S. or Mexico unless permitted by the Secretary of the Interior. The definition of "wildlife" under these amendments does not include migratory birds, however, which are protected under the MBTA.

The 1974 statute (P.L. 93-300) amended the MBTA to include the provisions of the 1972 Convention between the U.S. and Japan for the Protection of Migratory Birds and Birds in Danger of Extinction. This law also amended the title of the MBTA to read: "An Act to give effect to the conventions between the U.S. and other nations for the protection of migratory birds, birds in danger of extinction, game mammals, and their environment." Section 3(h) of the Fish and Wildlife Improvement Act of 1978 (P.L. 95-616) amended the MBTA to authorize forfeiture to the U.S. of birds and their parts illegally taken, for disposal by the Secretary of the Interior as he deems appropriate. These amendments also authorized the Secretary to issue regulations to permit Alaskan natives to take migratory birds for their subsistence needs during established seasons. The Secretary was required to consider the related migratory bird conventions with Great Britain, Mexico, Japan, and the Soviet Union in establishing these regulations and to establish seasons to provide for the preservation and maintenance of migratory bird stocks.

Public Law 95-616 also ratified a treaty with the Soviet Union specifying that both nations will take measures to protect identified ecosystems of special importance to migratory birds against pollution, detrimental alterations, and other environmental degradations. (See entry for the Convention Between the United States of America and the Union of Soviet Socialist Republics Concerning the Conservation of Migratory Birds and Their Environment; T.I.A.S. 9073; signed on November 19, 1976, and approved by the Senate on July 12, 1978; 92 Stat. 3110.)

Public Law 99-645, the 1986 Emergency Wetlands Resources Act, amended the Act to require that felony violations under the MBTA must be "knowingly" committed. P.L. 105-312, Migratory Bird Treaty Reform Act of 1998, amended the law to make it unlawful to take migratory game birds by the aid of bait if the person knows or reasonably should know that the area is baited. This provision eliminates the "strict liability" standard that was used to enforce Federal baiting regulations and replaces it with a "know or should have known" standard. These amendments also make it unlawful to place or direct the placement of bait on or adjacent to an area for the purpose of taking or attempting to take migratory game birds, and makes these violations punishable under title 18 United States Code, (with fines up to \$100,000 for individuals and \$200,000 for organizations), imprisonment for not more than 1 year, or both. The new amendments require the Secretary of Interior to submit to the Senate Committee on Environment and Public Works and the House Committee on Resources a report analyzing the effect of these amendments and the practice of baiting on migratory bird conservation and law enforcement. The report to Congress is due no later than five years after enactment of the new law.

P.L. 105-312 also amends the law to allow the fine for misdemeanor convictions under the Migratory Bird Treaty Act to be up to \$15,000 rather than \$5000.

Re: Comments on the Whistling Ridge DEIS and too much of a good thing: Growth in wind power makes life difficult for grid

Dear EFSEC and BPA,

I forgot to include this article on wind farms creating challenges for the power grid, with my comments (submitted on 27 August 2010) in the document that I sent on Friday, entitled Comments_DEIS_BPA_Inadequate_27Aug2010. I think this article makes it quite clear that too much wind power is not good for the power grid—which brings up the question of why are so many subsidized wind farms being built if the power they produce can't actually be used on the electric power grid? And, why are we concentrating all our energy eggs in the wind power basket?

I have bulletized the article, below, for a quick summary of my concerns about wind generation and its effects on BPA's power grid:

- Fast-growing number of wind farms;
- Has created **new challenges** for those who manage the power grid;
- Almost two nuclear plants worth of extra **power was sizzling down the lines**;
- Storm caused the **largest hourly spike in wind power the Northwest has ever experienced**;
- At BPA, it was **too much of a good thing**;
- **More electricity than its customers needed**;
- More than the available power lines could export;
- **More than the grid could readily absorb**;
- The edict went out: Feather your turbine blades; **slash output**;
- It's **one likely to go out with increasing frequency**;

- The last three years have seen a **doubling of the generation capacity of wind farms** in the region;
- **By 2013, wind generation capacity expected to double again;**
- In the real world, wind development, coupled with **wild swings in its output**, are **overwhelming the region's electrical grid** and outstripping its ability to use the power or send it elsewhere;
- In theory, better coordination could help solve the problem, reducing costs, eliminating bottlenecks and solving scheduling conflicts;
- In practice, risk-averse engineers, utility managers or public utility customers **worried about rates increasing;**
- Renewables explosion forcing the **transmission issue** to center stage now;
- California, which already buys much of the Northwest's wind energy, **increasing its appetite for green power;**
- The solution to the problem is to **beef up or build new power lines**, a five to ten year proposition;
- Involves coordination on **what to build, where to put it and who pays;**
- **Only 15 percent of the electricity generated by wind farms in the Northwest goes to the public utilities that buy power directly from BPA;**
- **BPA manages three quarters of the region's high voltage transmission system**, including the sections serving most of the region's wind farms;
- BPA's job is to balance **wind farms' up-and-down power output**, blending it with other sources of power so total generation at any given time matches total demand -- **a requirement to maintain grid reliability;**
- As the region's wind fleet grows, **an ever bigger slice of the hydro pie** is being reserved to fill in when the wind doesn't blow as scheduled;
- That means **foregone sales of surplus power**, a source of revenue that reduces BPA's rates for public utility customers;
- **Dumping too much water over the spillways, to balance wind power production, harms fish;**
- Another option is to **cut generation at the wind farms;**
- Too many curtailments **undermines the economics of wind;**
- **"It's not fair to have a cost shift,"** said Elliott Mainzer, BPA's director of strategic planning;
- BPA proposed quadrupling its **"integration" rate**, Oregon's congressional delegation took up the wind developers' fight, accusing the agency of dragging its feet on renewables and focusing solely on **maintaining low rates for its public utility customers**. Sen. Ron Wyden was highly critical of the agency's attitude problem, and Rep. Earl Blumenauer even suggested it might be time for new leadership at the agency;
- **In extreme situations, however, the agency continues to dump wind;**
- At the current rate of wind development the region's system of dams and power lines will start running into consistent operational problems around 2013;
- In 2013, wind in BPA's territory will reach a total capacity of some 6,000 megawatts;
- The 6000 MW capacity ceiling will require major structural changes;

- The solution lies in **better coordination of power plants** across the west, **more efficient use of existing power lines** and **some expansion of the grid**;
- **New lines often require new rights of way through sensitive habitat and private property, are phenomenally expensive**, raising the show-stopping question of **who pays**;
- The piece that is not doing well is **planning for moving wind out of the region**;
- Changes won't come quickly, easily or cheaply.
- **"We can't pay for everything at once, and we don't want to pay for everything on the table,"** said Jeff Bissonnette, a lobbyist for the Citizen's Utility Board of Oregon. **"We have to figure out what makes sense to pay for first, second and third, and what makes sense for consumers and the environment."**

In conclusion, it appears that wind may not be the end all answer to our concerns about carbon footprints and going green. More wind farms will mean more cries for more and bigger transmission lines. None of this was addressed in the Whistling Ridge DEIS in terms of cumulative impacts and effects on our region from the proposals to build more and more transmission lines. Why not? This is a real and vital deficiency of information, an information gap, in the DEIS, and these concerns about the effects of wind power on our power grid must be addressed. They have not been adequately addressed in the DEIS. This is a fatal flaw in the DEIS.

Too much of a good thing: Growth in wind power makes life difficult for grid managers

Published: Saturday, July 17, 2010, 10:00 AM Updated: Saturday, July 17, 2010, 8:45 PM

Ted Sickinger, The Oregonian

Benjamin Brink/The Oregonian The fast-growing number of wind farms in the Northwest, such as the Biglow Canyon Wind Farm near Rufus, has created new challenges for those who manage the power grid.

On the afternoon of May 19, in a single chaotic hour, more than a thousand wind turbines in the Columbia River Gorge went from spinning lazily in the breeze to full throttle as a storm rolled east out of Hood River.

Suddenly, **almost two nuclear plants worth of extra power was sizzling down the lines** -- the largest hourly spike in wind power the Northwest has ever experienced.

At the Bonneville Power Administration's control room in Vancouver, **it was too much of a good thing**. More electricity than its customers needed. **More than the available power lines could export** from the region. And more than the grid could readily absorb by ramping down generation at the region's network of federal dams.

So the edict went out: **Feather your turbine blades; slash output.**

It was an unwelcome instruction for wind farm owners, whose economics depend on generating electricity whenever possible. **Yet it's one likely to go out with increasing frequency.**

During the **last three years**, the building boom spawned by green energy mandates in Oregon, Washington and California **doubled the generation capacity of wind farms** in the region. **By 2013, it's expected to double again.**

That seems like great news. Plenty of carbon-free energy with no fuel costs. Jobs. Property taxes.

In the real world, however, the pace and geographic concentration of **wind development**, coupled with **wild swings in its output**, are overwhelming the region's electrical grid and outstripping its ability to use the power or send it elsewhere.

In theory, better coordination of the balkanized grid operations around the west could help solve the problem, reducing costs, eliminating bottlenecks and solving scheduling conflicts that plague the system today.

In practice, however, those efforts have often stalled at the planning stage -- the victim of risk-averse engineers, utility managers or public utility customers worried about seeing their rates increase.

It's not a new problem. But the renewables explosion, and pressure to reduce carbon emissions, is forcing the transmission issue to center stage now.

"There's a sweet spot to talk about these issues, and everyone's attention is on this at the moment," said Rachel Shimshak, executive director of the Renewables Northwest Project. "Maybe the benefits didn't look so obvious before, but now we have a lot more people with skin in the game."

The most significant player in that crowd is **California, which already buys much of**

the Northwest's wind energy, but has trouble getting it delivered over clogged interstate power lines. The state has just increased its already aggressive renewable energy standards, **increasing its appetite for green power.**

Ultimately, the solution to the problem is to beef up or build new power lines, said Randy Hardy, a Seattle-based energy consultant. But that's a five to ten year proposition, involving even more coordination on **what to build, where to put it and who pays.**

"We have a next-year problem," Hardy said, "or maybe a this-year problem."

Only 15 percent of the electricity generated by wind farms in the Northwest goes to the public utilities that buy power directly from BPA, which sells power from federal dams in the Columbia Basin. But the federal power marketing agency manages three quarters of the region's high voltage transmission system, including the sections serving most of the region's wind farms.

That makes it **BPA's job to balance their up-and-down output**, blending it with other sources of power so total generation at any given time matches total demand -- a **requirement to maintain grid reliability.**

The dams are great for the job -- operators can adjust water flows through the turbines to help offset variable wind output.

But only within limits.

As the region's wind fleet grows, an ever bigger slice of the hydro pie is being reserved to fill in when the wind doesn't blow as scheduled. That means foregone sales of surplus power, a source of revenue that reduces BPA's rates for public utility customers.

When the wind blows harder than forecast, particularly during periods of high spring runoff at the dams, operators face the opposite problem. They can't bypass the dam turbines to lower hydro generation, because dumping too much water over the spillways harms fish.

So the other option is to cut generation at the wind farms.

Too many **curtailments**, however, **undermines the economics of wind**, not only because turbines generate less power to sell but because valuable tax and renewable energy credits are only generated when their blades are spinning.

"We are committed to trying to find ways to get as much wind into the system as possible, but we're going to be real sticklers about reliability, and we think it's not fair to have a cost shift," said Elliott Mainzer, BPA's director of strategic planning

BPA does charge wind farms to offset the additional costs they bring to the system. But

those charges have been highly contentious.

Last year, when **the agency proposed quadrupling its "integration" rate**, Oregon's congressional delegation took up the wind developers' fight, accusing the agency of dragging its feet on renewables and focusing solely on maintaining low rates for its public utility customers. Sen. Ron Wyden was highly critical of the agency's attitude problem, and Rep. Earl Blumenauer even suggested it might be time for new leadership at the agency.

BPA ultimately backed away from the big rate increase. But it is coming up again this year as the agency kicks off a new rate-setting process.

Meanwhile, it has pushed ahead with a variety of efforts to accommodate more variable resources, from better wind forecasting to more flexible scheduling of transmission.

In extreme situations, however, the agency continues to dump wind.

At the current rate of wind development, says the BPA's Mainzer, the region's system of dams and power lines will start running into consistent operational problems around 2013, when wind in the agency's territory reaches total capacity of some 6,000 megawatts.

Above and beyond that, he said, **will require major structural changes.**

"If it's done right, he said, "it's a huge opportunity for the Northwest."

The solution, most experts believe, lies in **better coordination of power plants across the west, more efficient use of existing power lines and some expansion of the grid.**

"We believe there's more space on the lines if we get smarter about how we use them," said John Audley, deputy director at the Renewables Northwest Project. "But there isn't anyone out there who feels we have enough transmission in place to get what we need done."

Building new transmission, though, is an uphill battle. **New lines often require new rights of way through sensitive habitat and private property.** And they are phenomenally expensive, raising the show-stopping question of who pays.

BPA has had **some success** convincing wind developers and other transmission customers **to commit to helping fund new power lines and upgrades within the region.**

"The piece that is not doing well is planning for moving wind out of the region," said Brian Silverstein, senior vice president of transmission services for BPA. Ultimately, he said, "we can plan all we want. The challenge is getting people to commit to the investment."

There's a broad-based effort to get more out of the existing lines, too.

The capacity of power lines linking Oregon and California, for instance, is completely booked long term. But on a day-to-day basis, utilization can be lower than 50 percent.

Part of the problem is that utilities buy more capacity than they need, and hoard it for emergencies. **If that capacity can be freed up, BPA estimates the lines could transfer 10 to 15 percent more power.**

Another issue is that utilities are required to reserve line capacity an hour ahead of time. By allowing them to adjust their orders more frequently, utilities could accommodate unanticipated ebbs and flows in wind generation and maybe free up another 25 to 30 percent of capacity on the power lines.

But none of those changes come quickly, easily or cheaply. Utility managers, renewable developers, customer advocates and environmentalists met last week in Portland for a day-long seminar on expanding and modernizing the grid to accommodate renewables.

There was a definite sense of urgency in the air. But also determination.

"We can't pay for everything at once, and we don't want to pay for everything on the table," said Jeff Bissonette, a lobbyist for the Citizen's Utility Board of Oregon. **"We have to figure out what makes sense to pay for first, second and third, and what makes sense for consumers and the environment."**

Re: Comments on the Whistling Ridge DEIS, Chapter 3, Affected Environment, Impacts, and Mitigation; and, lack of cumulative impacts and effects analyses in the DEIS.

Dear EFSEC and BPA,

In this section, I am commenting upon the lack of any real, science-based cumulative impacts analyses done by either BPA or SDS Lumber, in Chapter 3 (p.3-1 to 3-289), Affected Environment, Impacts and Mitigation as presented in the Draft Environmental Impact Statement (DEIS). My *Comments are italicized and bolded after each section that I commented upon*, for the entirety of Chapter 3. (I saved Chapter 3 in text format so the tables and other pictures are not displayed properly). In order to preserve my sanity during my perambulations through 1500+ pages of the DEIS, I have had to also write a few separate memos, which I will also e-mail, upon certain specific areas that I had to research more thoroughly.

3.0 AFFECTED ENVIRONMENT, IMPACTS AND MITIGATION

This chapter describes the existing environmental resources in the vicinity of the proposed project and the potential impacts that the Proposed Action and the No Action Alternative would have on those resources. The potential impacts described were determined through research and field observation by environmental specialists and information provided by agency and public comments. More specific information on methodology for each resource is provided as appropriate. Each resource lists the mitigation measures that would lessen impacts and the impacts that would be unavoidable.

Toward the end of the chapter, cumulative impacts are described, followed by discussions of intentional destructive acts, relationship between short-term uses of the environment and long-term productivity, and irreversible or irretrievable commitments of resources.

3.1 EARTH

This section discusses the existing setting and potential project impacts related to geology, soils and topography. This analysis includes potential impacts of the Proposed Action on resources, and potential impacts of geologic hazards such as earthquakes or landslides on the project. This section includes information submitted as part of the Application for Site Certification (Appendix A) and the background data to that document (Appendix B Geotechnical Report).

3.1.1 AFFECTED ENVIRONMENT

3.1.1.1 Topography

The 1,152-acre proposed wind project site is situated on a series of north-trending ridges that range in elevation from approximately 2,100 to 2,300 feet above mean sea level (msl). The land west of the proposed project site drops sharply to a narrow river terrace and then to an elevation of less than 800 feet above msl in the Little White Salmon River valley. The topography northeast of the site drops gradually toward the White Salmon River or climbs gently up the northeast flank of Underwood Mountain at 2,728 feet above msl. To the south, the topography drops to a terrace of largely agricultural use and then toward the Columbia River. Figure 3.1-1 shows the site topography.

3.1.1.2 Regional Geology

The White Salmon, Washington area is located within the Cascade Range and the Columbia Intermontane Physiographic Province. The project area is located just within the western boundary of the Columbia Plateau, which is located at the western edge of the Columbia Intermontane Physiographic Province. This lowland province is surrounded on all sides by mountain ranges and highlands, and covers a vast area of eastern Washington and parts of northeastern Oregon and western Idaho.

3-1

33758687_115.cdr

Figure 3.1-1

Source: GeoDataScape. Site Topography

The Columbia Plateau is underlain by a series of layered basalt flows extruded from vents (located mainly in southeastern Washington and northeastern Oregon) during the Miocene epoch (between 5.3 and 23.8 million years before present [BP]). Individual basalt flows ranged in thickness from a few millimeters to as much as 300 feet. Where significant time elapsed between successive flows, interflow zones developed. The interflow zones are characterized by the presence of highly weathered basalt and paleosols. These interflow zones are generally significantly weaker than the surrounding basalt and sometimes form basal failure surfaces for large landslide complexes.

Above the basalts are a variety of younger volcanic rocks and sedimentary materials that range from Pliocene (1.8 to 5.3 million years BP) to Holocene (less than 10,000 years BP). Sedimentary rocks are generally thought to underlie the basalts.

Individual geologic units in the general area are primarily Underwood Mountain Basalt., as described in Section 3.1 of the Application for Site Certification (Appendix A). Near-surface rock consists of yellow-gray volcanoclastic rocks, medium to dark gray, fine-grained to medium-grained basalt and andesite, which is fractured into angular gravels, cobbles, and boulders.

Regional geologic maps indicate the presence of Quaternary-age mass wasting landslide deposits located north of Underwood Mountain (Figure 3.1-2). These deposits are mapped as a large landslide, estimated to be approximately 1/3 square mile in area and almost a mile long. However, based on field work conducted in 2007, there is no obvious evidence to suggest the presence of a landslide as mapped on the 1:100,000 scale geologic map. If landslide deposits are present, they have been exposed long enough that most or all of the geomorphic evidence has been removed by erosion.

Comment: Just because there is “no obvious evidence to suggest the presence of landslides” does not mean that the landslide does not exist or that mass wasting is not a definite possibility. What is mass wasting? A Wisconsin geology class syllabus defines mass wasting as follows: “Mass-wasting processes: Mass-wasting processes such as creep, landslides, and debris flows are distinguished from each other in part by whether they occur rapidly or slowly. Landslides are capable of transporting massive amounts of rock and soil downslope for miles in very short periods (e.g. minutes). Creep can also transport much material, but at rates of only millimeters per year. Both are important erosional processes. Rapid mass wasting events such as massive landslides or debris flows are typically triggered by events that destabilize material that resides on steep slopes. Such events include earthquakes, volcanic eruptions, rain or melting snow, and poorly planned landscape alterations by humans (e.g. road cuts or developments that require the removal of material at the bases of slopes).” [Source:http://www.geology.wisc.edu/courses/g112/mass_wasting.html] Hmm, “landscape alterations”? I’m thinking that putting hundreds of tons of whirling propellers on top of impermeable surfaces in a steep-sloped area subject to wind and water erosion is probably not a well-thought out proposal.

3.1.1.3 Local Geology and Soils Geology

The proposed project site is located within the northern boundary of the Hood River Valley, which extends a few miles into southern Washington. In general, the geology of the area consists of basalt flows extruded from local vents, layered with conglomerate, tuff, tuff breccias, and other volcanoclastic deposits (Figure 3.1-2).

The bedrock underlying the proposed project site consists of Grande Ronde Basalt of the

Columbia River Basalt Group and Quaternary basalt of Underwood Mountain—a shield volcano that lies approximately midway between the lower reaches of the Little White Salmon and White Salmon Rivers. Its southern slopes drain to the Columbia River.

In the project area, these basalt formations are typically overlain by silt and clay soil of varying thickness. Unconsolidated deposits are thin to absent with surface materials consisting primarily of a veneer of brown, silty topsoil that is likely derived from forest duff and wind-blown deposits. The thickness of this material varies across the site from a few inches to three feet. In several areas, bedrock and talus can be observed at the ground surface.

3-3

Site Geology Source: Korosec, 1987.
Figure 3.1-2

Soils

Soil Types. Figure 3.1-3 shows soils in the project area. The Natural Resources Conservation Service (NRCS) describes the soils in the project vicinity as follows (USDA NRCS 2003):

- **McElroy Series.** The McElroy series consists of very deep soils (up to 5 feet) formed in colluvium and residuum from basalt with a mantle of volcanic ash that influences soils in the top 9 to 13 inches. The soils exist on the footslopes and backslopes of mountains on slopes from 5 to 90 percent at elevations from 400 to 2,600 feet in eastern Skamania County and western Klickitat County. McElroy Soils are well drained with medium to rapid runoff and moderate permeability. The series was established in 1981 following the introduction of volcanic ash from the eruption of Mt. St. Helens.
- **Timberhead Series.** The Timberhead series consists of very deep soils (up to 5 feet) formed in residuum and colluvium from basalt mixed with volcanic ash. The soils exist on mountain ridges between 5 and 30 percent at elevations from 2,000 to 3,600 feet in Skamania County and western Klickitat County. Timberhead Series soils are well drained with medium to rapid runoff and moderately high to high permeability.
- **Underwood Series.** The Underwood series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 2 and 50 percent at elevations between 500 and 2,700 feet in southeast Skamania County and west Klickitat County. Underwood Series soils are well drained with slow to medium runoff and moderately high permeability.
- **Undusk Series.** The Undusk series consists of very deep soils (5 feet or more) formed in residuum and colluvium from basalt and andesite with a thin mantle of volcanic ash. The soils exist on benches, backslopes, and footslopes of mountains with slopes between 5 and 65 percent

at elevations between 2,000 and 2,800 feet in southeast Skamania County and west Klickitat County. Undusk Series soils are well drained with slow to medium runoff and moderately high permeability. Based on the current test pits and field observations, the site soil is best represented as Soil Site Class D (stiff soils). Rock with varying strength and weathering characteristics was encountered at depths ranging from 3 to 12 feet bgs.

Soil Erosion Potential. Erosion is the breakdown and transport of soils and bedrock by natural processes, including water, wind, and glaciation. The susceptibility of any material to erosion depends on chemical and physical characteristics; topography; the amount and intensity of precipitation and surface water; the intensity of wind; and the type and density of vegetative ground cover, if present.

Erosion potential was assessed for the Application for Site Certification, principally based on the erosion potential specified for surficial soils by the NRCS. These erosion factors indicate that the Underwood loam has a high potential for erosion by water and the McElroy, Timberhead, and Undusk units have a medium potential, with the remaining soil types having a low potential. Most soils found in the site vicinity are classified as having a low susceptibility to wind erosion.

3.1.1.4 Geologic Hazards

Earthquakes

Earthquakes are the result of sudden releases of built-up stress within the tectonic plates that make up the earth's surface. Stress accumulates where movement between plates or on faults produces friction. No faults are mapped within the footprint of the proposed project area. However, faults are mapped approximately 1.5 miles to the southwest and northeast. (Pezzopane 1993 and Geomatrix 1995) Many of these faults are inferred, and shown as dotted lines buried by younger surficial deposits. While the activity of the area faults is unknown, a review of aerial photography showed no indication of recent movement along the trace of the inferred faults.

Comment: "A review of aerial photography is NOT doing geology!! This is a totally inadequate geologic analysis. "Inferred" faults shown as dotted lines (!!) does not mean that there are NOT buried, sub-surface, wide-ranging faults. Ridges have fault lines. I will comment further on the soils issue in a separate memo.

There have been no surface-rupture earthquakes on any fault within northwestern Oregon or southwestern Washington in historic times, and investigations of the regional faults have been limited.

According to the updated National Seismic Hazard Maps published by the US Geological Survey (USGS) in 2008 (Petersen et al. 2008 and USGS 2009), the peak ground acceleration estimated for the area of the Whistling Ridge site is 0.18g for a 475-year return period earthquake (i.e., ground motion with a 10 percent chance of being exceeded in 50 years) and 0.40g for a 2,475-year return period earthquake (i.e., ground motion with a 2 percent chance of being exceeded in 50 years).

Large earthquakes at more distant faults could cause prolonged ground movement at the project site. Information on historic large earthquakes can be found in the Application for Site Certification Section 3.1 (Appendix A).

Comment: What does “large earthquakes at more distant faults could cause prolonged ground movement at the project site” actually mean? Does that mean that there will be earth movement downhill? Mass wasting? Does this mean that people and wildlife will be affected? How will they be affected? Does this mean that people would have to leave their homes? Are there evacuation routes? Would there be loss of life and property involved in “prolonged ground movement”? These questions are not answered in the DEIS.

Landslides

As part of the Application for Site Certification, a preliminary landslide hazard evaluation of the project site was conducted by a licensed geologist pursuant to Skamania County Code (SCC) Title 21A, Chapter 21A.06 - Landslide Hazard Areas (LHAs), which are shown on Figure 3.1-4. Skamania County recognizes three classes of LHAs.

- Class I (Severe) LHAs are considered to present a severe landslide hazard and are distinguished as areas of known mappable landslide deposits that have been designated by the local legislative body.
- Class II (High) LHAs are areas with slopes between 20 and 30 percent that are underlain by soils that consist largely of silt, clay or bedrock, and all areas with slopes greater than 30 percent.
- Class III (Moderate) LHAs are areas with slopes between 20 percent and 30 percent not included in Class II.

3-7

33758687_110.cdr

Approximate Turbine

Locations

Figure 3.1-4

Job No. 33758687 Landslide Hazard Areas

The preliminary landslide hazard evaluation concluded that there do not appear to be any areas in the site that meet Skamania County’s criteria for a Class I LHA. Figure 3.1-4 shows Class II LHAs in green. The Class II LHAs at the site are predominantly associated with the steep slopes

west of proposed Tower Lines A and B. There are also steep slopes to the east of the seven southernmost Tower Lines A towers, and on both sides of Tower Line C. The Class II areas are generally bordered by smaller areas of Class III.

Volcanic Eruption

The Cascade Mountains of the Pacific Northwest region contain sixteen major volcanoes, which extend from Mount Garibaldi in British Columbia to Lassen Peak in California (Harris 1988). Four of the volcanoes within Washington and Oregon have experienced activity within historic time: Mount Baker, Mount Rainier, Mount Hood, and Mount St. Helens. Mount Adams is the closest volcano to the project site, situated approximately 30 miles due north, but is not historically active. Mount St. Helens is the closest historically active volcano to the project site, situated approximately 42 miles to the northwest.

3.1.2 IMPACTS

3.1.2.1 Proposed Action Construction

Construction would involve approximately 108 acres of earth-disturbing activities (56 acres of permanent disturbance and 52 acres of temporary disturbance). Activities that would involve earth disturbance include tree harvesting in areas not already cleared; constructing roads and turbine crane pads; constructing foundations for turbine and meteorological towers; trenching for underground utilities; clearing and grading for the substation placement; and clearing and excavating for the foundation for the Operations and Maintenance facility at either of the two alternative locations. Approximately 50 percent of excavated soils are anticipated to be too large for re-use as backfill at foundations. Based on preliminary calculations and depending on the type of foundation design used, approximately 20 cubic yards of excavated soil would remain from each turbine foundation excavation.

Comment: How many truckloads of haul material does all this excavation involve? What will be the impacts on our roads and byways? Will public money have to be used to re-pave or re-construct these roads after all this heavy traffic? Where will all the haul material go?

Roadway improvements would be necessary to accommodate the heavy and long loads associated with the turbine towers. Improvements would be made to approximately 7.9 miles of existing roads, and 2.4 miles of new road would be built. Most of these improvements would be made on the project site, with the exception of off-site improvements to West Pit Road. For areas with steep slopes, it may be necessary to flatten and rebuild the slopes to allow access for the long loads required. Some steep sections of existing or new roads may be graded to create shallower grades, and some tight-radius turns may require localized rerouting of existing roads. West Pit Road would require permanent widening to accommodate long loads. Widening could include removal of trees and other vegetation, along with engineered cut and fill sections (cut and fill volumes will be calculated during final design). The road would not require paving, but would require an all-weather driving surface.

The primary impacts during construction would be potential for erosion, landslides, soil compaction and changes to topography.

Comment: "The primary impacts during construction would be potential for erosion, landslides, soil compaction and changes to topography." IS THAT ALL?!? As the WA State Department of Transportation learned during its rock removal along Highway 14 during the summer of 2010, in Skamania County, when they started an unintended landslide, there is always the very high potential that once you start moving earth, earth does what it wants to and moves where it wills!

3-9

Soils

Because some surface soils on the project site are moderately susceptible to erosion, there is some potential for adverse impacts on the site soil in areas of steep topography during grading and foundation construction, as shown on Figure 2.15-1, Landslide Hazard Classifications, in Section 2.15 of the Application for Site Certification (Appendix A).

Topography

Changes to the topography would include grading turbine foundations and access roads. The changes to topography would be minor to moderate depending on location.

Erosion

The potential for erosion or aggradation would be greatest during the construction process. The NRCS classifies surficial soils at the site as generally having medium erosion potential. During the dry season, soils that are disturbed and stripped of vegetative cover may be susceptible to wind erosion. The potential for erosion by wind and water would be minimized through the use of best management practices (BMPs).

Comment: As far as I could find, the DEIS does not list what these Best Management Practices (BMPS) are. They should be listed, so we could evaluate if they are adequate for this project which proposes to move a lot of earth and has a high potential for erosion and land movement.

Operation

Once the project is constructed, the primary risks would be associated with earthquakes, volcanic activity, and landslides.

Earthquakes

Liquefaction. Liquefaction is a phenomenon whereby soils undergo significant loss of strength and stiffness when they are subjected to vibration or large cyclic ground motions produced by

earthquakes. Saturated soils without cohesive fines (i.e., gravels, sands, and silts) are most susceptible to liquefaction. Other factors affecting the potential for liquefaction in soils are density, amplitude of loading, confining pressure, past stress history, age of soil deposit, the size, shape and gradation of particles, and the soil fabric structure. In earthquakes, liquefaction-induced ground settlement and lateral spreading have been the primary cause for extensive damage to aboveground structures, foundations, and pipelines.

Field investigation concluded that the potential for liquefaction is very low at this site. Test pits excavated at the project site encountered shallow bedrock covered with a combination of cohesive and cohesionless soil. No groundwater was observed in any of the test pits.

Structure failure could occur with enough ground shaking even without liquefaction. However, this hazard would be mitigated by adhering to seismic building codes.

Settlement. Field investigation concluded that settlement and lateral spread induced by a seismic event would be minimal, due to the low liquefaction potential.

Surface Rupture. Surface rupture occurs when a fault breaks to the land surface during an earthquake. Surface rupture is usually associated with moderate to large earthquakes (Mw 6.5 or greater) or rarely during smaller, very shallow events. There are no mapped faults crossing the site. Therefore, the potential for primary surface rupture at the proposed project site is small.

3-10

Volcanic Activity

Effects of volcanic activity may include lava flows, mudflows, pyroclastic flows, and ash-fall. Volcanic flows are typically limited to the flanks of the volcano and major drainage channels extending from the volcano, which for all known volcanoes in the area are located outside the project area. The largest potential impact to the site from volcanic activity would be ash carried aloft that subsequently falls to the land surface. Based on prevailing wind patterns, the USGS (Wolfe and Pierson 1995) estimates that there is between a 0.02 and 0.1 percent annual probability that there would be 4 inches (10 cm) or more of ash deposited at the site from eruptions throughout the Cascade Range (Figure 2.15-2 in the Application for Site Certification).

Landslides

The landslide evaluation conducted for the Application for Site Certification concluded that the project could be constructed and operated without danger to human life or the surrounding environment due to landslide hazards.

Although none of the proposed turbines are located within Class II LHAs, several of the towers along the western side of the project site (Tower Lines A and B) are located along ridgelines with descending slopes that are locally greater than 35 degrees (70 percent). Based on studies conducted for the Application for Site Certification, it appears that the primary concern for towers located adjacent to the Class II LHAs is the potential for headward erosion of the steep

drainages by debris or earth flow processes. Erosion rates of these drainages are unknown, but no obvious recent mass wasting features were observed in the aerial photos or during the site reconnaissance. Further subsurface investigation in support of final tower foundation design would help determine if there are weak rock or soil layers that could contribute to more deep-seated failure of the ridges and provide information on the quality of the rock underlying the ridgelines.

Comment: So, we are to gather from the above statement that “further subsurface investigation” has NOT been done, there is NOT a “final tower foundation design that would help determine if there are weak rock or soil layers that could contribute to deep-seated failure of the ridges”?! And, that this LACK of a final tower foundation design could “provide information on the quality of rock underlying the ridgelines”? Well, I’m confused. Isn’t this DEIS supposed to provide all this information so that a thoughtful, science-based decision can be made by EFSEC and the involved public as to whether this project should even go on? This LACK of information is critical and should be provided in the DEIS.

Class III LHAs were delineated adjacent to proposed wind turbines along the southern Tower Line A and along Tower Line C. Class III LHAs are not anticipated to have any impact on the proposed facilities due to the robust nature of the proposed foundation designs.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project’s operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

Comment: The initial site restoration plan and the decommissioning plan SHOULD be part of the DEIS and SHOULD also be included in the FEIS. We should all be able to evaluate all of SDS’s and the BPA’s plans for this proposal, NOW not later, especially if “the initial site restoration plan will...identify, evaluate, and resolve all major environmental and public health and safety issues...including potential changes to soils, topography, or erosion...impacts to earth...mitigation measure...”. All of these issues should be addressed in the DEIS and these plans should be available for public comment and input NOW.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to soils, topography, or erosion. If impacts to earth are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

3-11

3.1.2.2 No Action Alternative

Under the No Action Alternative, no structures would be built and there would be no road construction or improvement. Potential impacts to the site from geologic hazards would continue as under present conditions. Some potential for erosion could continue from ongoing logging activity, as mitigated by Washington State requirements and BMPs.

3.1.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts of the proposed project related to geology, soils, topography, and geologic hazards.

- Prior to project construction, confirm subsurface soil and rock types and strength properties through a detailed geotechnical investigation of the specific locations of all wind project elements, including wind turbines, access roads, underground trenching corridors, electrical grounding systems, and the substation and Operations and Maintenance facility locations.
- If detailed geotechnical investigations indicate potential for slope instability at project facilities, ensure that design of these facilities included proper engineering to account for this risk or relocate the facilities on-site to avoid this risk.
- Prepare and implement a Stormwater Pollution Prevention Plan (SWPPP), Erosion and Sedimentation Control Plan, and Environmental Protection Control Plan to lessen soil erosion and improve water quality of stormwater run-off through stabilization practices, structural practices, and stormwater management. These Plans would be developed and approved by EFSEC prior to construction or modification of any roads or facilities.
- Build all structures on the site in accordance with the seismic design provisions of the 2006 version of the International Building Code, and the American Society of Civil Engineers 07-05 standard. Foundations and buildings would be designed for Seismic Zone 2, and the values listed in Table 3.1-1 would be used for seismic design of the project in accordance with Section 1613.5.3 of the 2006 International Building Code. The occupancy category of the proposed structure is assumed III as per Section 1613.5.6 of the 2006 International Building Code.

Comment: All of the above should be part of the DEIS now, not later. These are all valid questions that should be answered PRIOR to the start of any construction or earth movement. Once a proposal is approved, then the proponent can almost do anything to make sure that it gets done. We should use the PRECAUTIONARY PRINCIPLE and know all the details and facts that it is possible to know PRIOR to any construction and excavation. The detailed geotechnical investigation; ensuring that design of these facilities includes proper engineering; [possible] relocation of the facilities; the Stormwater Pollution Prevention Plan (SWPPP), Erosion and Sedimentation Control Plan, and Environmental Protection Control Plan; and, the seismic design provisions should all be part and parcel of the DEIS, not done after the fact when the public has no recourse for further input and comment.

a. Assumes Seismic Use Group III

- Conduct a visual inspection of project facilities following any abnormal seismic activity. These inspections would look for signs of incipient mass movement in areas identified as potentially susceptible to such failures.
- Implement all stormwater pollution prevention activities prior to any clearing and site preparation. Measures would include installation of a stabilized construction entrance, wheel wash, silt fences, hay bales, temporary and/or permanent water conveyance systems, and installation of temporary and/or permanent retention ponds. Dust would be controlled as needed by spraying water on dry, exposed soil.
- Limit clearing, excavation and grading to those areas of the project site absolutely necessary for construction of the project. Areas outside the construction limits would be marked in the field and equipment would not be allowed to enter these areas or to disturb existing vegetation.
- Inspect any installed run-off and erosion control structures at a frequency sufficient to provide adequate environmental protection. Such inspections would increase in frequency during rainfall periods.
- Store additional erosion control supplies, including sandbags and channel-lining materials, on site for emergency use.
- Divert surface runoff around and away from cut and fill slopes using pipes and/or protected channels. If the runoff is from disturbed areas, it would be directed to a sediment trap prior to discharge.
- Construct all project roads to be gravel surfaced with a low profile. Road construction would be performed in multiple passes starting with the rough grading and leveling of the roadway areas,

if necessary. Once rough grade is achieved, a fabric layer would be installed, base rock would be trucked in, spread and compacted to create a road base. A capping rock would then be spread over the road base and roll-compacted to finished grade.

3-13

- Spread soil and rock that is excavated through grading across the site to the natural grade and reseed with native grasses or seeds to control erosion by water and wind.
- Crush larger cobbles into smaller rock for use as backfill or road material or dispose of off site. Those materials that cannot be reused on site would be disposed of in accordance with Skamania County and Ecology regulations for clean fill materials.

3.1.4 UNAVOIDABLE ADVERSE IMPACTS

The primary unavoidable impacts are the potential for landslide and erosion. Both can be mitigated through appropriate design and the application of mitigation measures, but some erosion would nonetheless occur.

3.2 AIR QUALITY

This section describes the existing air quality conditions in the project area, the potential for impacts to air quality from the proposed project, and mitigation measures designed to avoid or minimize those impacts.

3-14

3.2.1 AFFECTED ENVIRONMENT

Regulatory Overview

The Clean Air Act (CAA) is the primary federal statute governing air quality. The CAA establishes National Ambient Air Quality Standards for six “criteria pollutants,” and local agencies may establish Ambient Air Quality Standards themselves, provided that these are at least as strict as federal standards. Local air quality is measured against these national and state standards, and areas that do not meet the standards are designated as “non-attainment” areas. Skamania County does not have any non-attainment areas for air quality¹.

Comment: Just because the DEIS states that “Skamania County does not have any non-attainment areas for air quality” does not mean that the air quality in the Columbia River Gorge is good. The OR Department of Environmental Quality and the SW Clean Air Agency have been working for many years on the issue of increasing haze and air quality in the Gorge; they have written very large documents about this issue. Neither agency has had the political will or incentive to actually do anything about the issue. There are air pollution issues in the Gorge and the surrounding environments. Most people who reside in the area or swim in the Columbia River will tell you that they have noticed a degradation of the air and water quality. These issues have not been adequately addressed by any government agency, to date. Which does not mean that air [or water] quality of the Gorge is good or bad, from a science viewpoint. It means that it needs to be thoroughly investigated and analyzed. The DEIS fails to do any adequate air [or water] cumulative impacts analyses.

New stationary sources of air emissions in nonattainment areas must undergo more rigorous permitting than equivalently sized sources in attainment areas, in an effort to bring the nonattainment area back into compliance with the air quality standards. The state of Washington has established rules through Ecology for permitting new sources in both attainment and nonattainment areas of the state, and additional requirements may be imposed by local air authorities. EFSEC issues authorizations for air emissions for sources under its jurisdiction. In general, if potential emissions from stationary sources exceed certain thresholds, approval from the appropriate permitting authority is required before beginning construction.

Under the CAA, new industrial sources of air pollution must receive an air quality permit prior to operation. The two most common permits associated with industrial activity emitting regulated air pollutants are Notice of Construction (NOC)/New Source Review approvals and Prevention of Significant Deterioration (PSD) permits. WAC Chapters 463-39 and 173-400 establish the requirements for review and issuance of NOC approvals for new sources of air emissions under

EFSEC jurisdiction. PSD regulations apply to proposed new or modified “major” sources located in an attainment area that have the potential to emit criteria pollutants in excess of predetermined de minimus values (40 Code of Federal Regulations [CFR] Part 51). For new generation facilities, these values are 100 tons per year of criteria pollutants for 28 specific source categories, or 250 tons per year for sources not included in the 28 categories.

The Project is not required to go through these permitting processes. A NOC is not required for the proposed project because there would be no permanent sources of regulated air emissions, and no backup generation or spinning reserves would be required as part of the proposed project. A PSD permit would not be required; the generation of electricity with wind turbines does not produce air emissions because no fuel is being burned to produce energy.

Comment: Although this proposed wind farm project itself does not, allegedly, have any “permanent sources of regulated air emission, and no backup generation,” it does not mean that there are no cumulative impacts on air emissions, because this project is included in BPA’s energy production grid and BPA’s energy production DOES have CUMULATIVE IMPACTS on REGIONAL AIR QUALITY. It is widely known that X amount of wind energy production requires Y amount of gas plant back-up capability because wind energy is notoriously unreliable and BPA cannot have unreliable sources of energy in the grid. It creates havoc among users and I’m pretty sure it negatively affects BPA’s machinery. The effects of wind power on the grid and on the actual BPA hard infrastructure is not addressed in the DEIS and it should be. The public should be aware if there are any dangers associated with the influx of large amounts of energy from wind farms into the energy grid and if the grid can reliably balance this energy influx without hardware meltdowns. BPA should have addressed these issues in the DEIS and their failure to do so is just another fatal flaw in this fatally flawed DEIS.

Although construction emissions are not included in permitting of stationary sources, mobile sources (such as construction equipment and maintenance pickups) are regulated separately under the federal CAA. In addition, Washington State also regulates emissions generated by various construction activities. According to WAC 173-400-300, fugitive air emissions are emissions that “do not and which could not reasonably pass through a stack, chimney, vent or other functionally equivalent opening.” These emissions include fugitive dust from unpaved roads, construction sites, and tilled land. Fugitive emissions are considered in determining the level of air permitting required only for a certain subset of sources, not including wind power

1 See: http://www.ecy.wa.gov/programs/air/other/namaps/web_map_intro.htm.

3-15

projects. However, pursuant to WAC 173-400-040(8)(a), “The owner or operator of a source of fugitive dust shall take reasonable precautions to prevent fugitive dust from becoming airborne and shall maintain and operate the source to minimize emissions.”

Other Washington state regulations that apply to nuisance emissions, including fugitive dust, and various equipment used during construction include the following:

- WAC 173-400-040(2) Fallout states that no person shall cause or allow the emission of particulate matter from any source to be deposited beyond the property under direct control of the owner or operator of the source in sufficient quantity to interfere unreasonably with the use and enjoyment of the property upon which the material is deposited.
- WAC 173-400-040(3-3a) Fugitive emissions states that the owner or operator of any emissions unit engaging in materials handling, construction, demolition, or other operation which is a source of fugitive emissions, if located in an attainment area and not impacting any non-attainment area, shall take reasonable precautions to prevent the release of air contaminants from the operation.
- WAC 173-400-040(4) Odors states that any person who shall cause or allow the generation of any odor from any source that may unreasonably interfere with any other property owner's use and enjoyment of his property must use recognized good practice and procedures to reduce these odors to a reasonable minimum.
- WAC 173-400-040(8a) Fugitive dust states that the owner or operator of a source of fugitive dust shall take reasonable precautions to prevent fugitive dust from becoming airborne and shall maintain and operate the source to minimize emissions.
- WAC 173-400-035 Portable and Temporary Sources states that for portable sources that locate temporarily at particular sites, such as rock crushers and batch plants, the owner(s) or operator(s) shall be allowed to operate at the temporary location providing that the owner(s) or operator(s) notifies Ecology or the local air quality authority of the intent to operate at the new location at least 30 days prior to starting the operation, and supplies sufficient information to enable Ecology or the local air quality authority to determine that the operation will comply with the emissions standards for a new source, and will not cause a violation of applicable Ambient Air Quality Standards and, if in a non-attainment area, will not interfere with scheduled attainment of ambient standards. The permission to operate shall be for a limited period of time (one year or less) and Ecology or the local air quality authority may set specific conditions for operation during that period. A temporary source shall be required to comply with all applicable emission standards.

Greenhouse Gases

Greenhouse gases are gases that trap heat in the atmosphere, and are implicated in potential global climate change. Some greenhouse gases such as carbon dioxide occur through both natural processes and human activities. Other greenhouse gases (e.g., fluorinated gases) are created and emitted solely through human activities. The most abundant greenhouse gasses are

3-16

water vapor, carbon dioxide, methane, nitrous oxide, ozone and chlorofluorocarbons². However, because different gasses have different heat-trapping effects, the most abundant greenhouse gasses are not necessarily the largest contributors to potential climate change.

Greenhouse gases are discussed in this section because in the United States, energy-related activities account for 75 percent of human-generated greenhouse gas emissions, mostly in the form of carbon dioxide emissions from burning fossil fuels. Half of all emissions from energy-related activities come from large stationary sources such as power plants (USEPA 2009).

Largely because of the contribution of hydropower, energy generation in the Pacific Northwest, including the Federal Columbia River Power System, produces less carbon dioxide per MW-hour than any other region in the United States. The Federal Columbia River Power System alone produces about 7,000 average MW of hydro-electricity even in a dry water year, enabling the region to sustain its relatively small carbon footprint.

Comment: "Half of all emissions from energy-related activities come from large stationary sources such as power plants" is not a reassuring statement. Half means 50 per cent, that is 50%. This is not a small amount. The DEIS does not state, as far as I was able to ascertain, how much BPA contributes to greenhouse gases through its entire energy production process. How many power plants back up BPA's hydro-energy production when there is not enough water, or fish protections prohibit BPA from dumping water over the dam? What is BPA's calculated carbon footprint? Why didn't BPA calculate its total carbon footprint for the DEIS? This is another fatal flaw in this document. The statement that hydropower "produces less carbon dioxide per MW-hour than any other region in the United States" is NOT a conclusive statement about BPA's or the wind farms' total cumulative contribution to greenhouse gases! LESS does not mean that BPA and Whistling Ridge and all the other energy production facilities in the region do not contribute CO2 to the total footprint. BPA needs to calculate its cumulative carbon footprint from ALL its energy production facilities and processes. Then we can start to talk about carbon footprints.

Like hydropower, production of electricity from wind produces no direct emissions of greenhouse gasses or other air pollutants. The generation of wind energy also displaces generation from individual fossil-fuel-fired power plants or units, thereby reducing fuel consumption and the resulting air emissions that would have otherwise occurred.

Comment: The statement "production of electricity from wind produces no direct emissions of greenhouse gasses or other air pollutant" is specious. The DEIS does not provide any details on what huge propeller-like blades do to the air and what, if any, gasses are produced by the machinery that is used to run the wind towers. The DEIS does not provide any details on how many gas plants are used by BPA to manage the flexibility and balance of the influx of unreliable wind power generated by all the wind farms producing energy and trying to get it onto our energy grid. If the capability of the hydro system to incorporate wind power will be fully utilized in a couple of years, as the NW Energy Council has stated, then the option to use existing gas-fired power plants, unidentified in the DEIS, would be used to integrate wind more fully into the energy grid. Where are these plants located? How much CO2 do they produce? What is their carbon footprint? What if global climate change negatively affects the winds that are now powering some of these wind farms, will more and more gas-fired plants have to be brought online, thus eliminating any benefits that may accrue to wind power? Where is BPA's Wind Integration documentation? If, as the NW Energy Council states, we

can achieve 85% of load growth can be met, through the use of technologically proven efficiencies in our homes, commercial spaces, lighting, etc., then why do we need so many wind farms and gas plants that degrade our environment and our quality of life? These questions need to be answered in the DEIS. The NW Energy Council sees conservation and “improved efficiency of electric use” as the best choice for the region. See the Sixth NW Electric Power and Conservation Plan Overview, below, put out by the NW Energy Council:

Sixth Northwest Conservation and Electric Power Plan

Sixth Power Plan Overview

Summary.....1
Future Regional Electricity Needs.....2
Resource strategy.....3
Efficiency.....4
Generation Alternatives5
Climate Change Policy6
Capacity, Flexibility, and Wind Integration7
Fish and Wildlife Program and the Power Plan.....8

SUMMARY

The Pacific Northwest power system is faced with significant uncertainties about the direction and form of climate change policy, future fuel prices, salmon recovery actions, economic growth, and integrating rapidly growing amounts of variable wind generation. And yet the focus of the Council’s power plan is clear, especially with regard to the important near-term actions.

The Council’s power plan addresses the risks these uncertainties pose for the region’s electricity future and seeks an electrical resource strategy that minimizes the expected cost of, and risks to, the regional power system over the next 20 years. Across multiple scenarios considered in the development of the plan, one conclusion was constant: the most cost-effective and least risky resource for the region is improved efficiency of electricity use.

In each of its power plans, the Council has found substantial amounts of conservation to be cheaper and more sustainable than most other types of generation. In this Sixth Power Plan, because of the higher costs of alternative generation sources, rapidly developing technology, and heightened concerns about global climate change, conservation holds an even larger potential for the region.

The plan finds enough conservation to be available and cost-effective to meet 85 percent of the region’s load growth for the next 20 years. If developed aggressively, this conservation, combined with the region’s past successful development of energy efficiency could constitute a resource comparable in size to the Northwest federal hydroelectric system. This efficiency resource will complement and protect the Northwest’s heritage of clean and affordable power.

Aggressive pursuit of this conservation is the primary focus of the power plan's actions for the next five years. Combined with investments in renewable generation as required by state renewable portfolio standards, improved efficiency will help delay investments in more expensive and less clean forms of electricity until the direction and form of future climate change legislation becomes clearer, and alternative low-carbon energy technologies become cost-effective.

At the same time, the region cannot stand still in maintaining and improving the reliability of its power system. Investments to add transmission capability and improve operational agreements are important for the region, both to access growing site-based renewable energy and to better integrate it into the power system. The Council also expects that there are small-scale resources available at the local level in the form of cogeneration or renewable energy opportunities. The plan encourages investment in these resources when cost-effective.

The power plan recognizes that meeting capacity needs and providing the flexibility reserves necessary to successfully integrate growing variable generation sources may require near-term investments in generation resources to provide reliable electricity supplies in specific utility balancing areas. In addition, individual utilities have varying degrees of access to electricity markets and varying resource needs. The Council's regional power plan is not necessarily a plan for every individual utility in the region, but is intended to provide guidance to the region on the types of resources that should be considered and their priority of development.

The near-term actions recommended in the Council's Sixth Power Plan are important, but the region cannot neglect longer-term needs. The plan encourages research in advanced technologies for the long-term development of the power system. For example, emerging smart-grid technologies could make it possible for consumers to help balance supply and demand. By providing information and tools to consumers to adjust electricity use in response to available supplies and costs, the capacity and flexibility of the power system would be enhanced. Smart-grid development also may facilitate the deployment of plug-in hybrid electric vehicles that work in concert with the power system to improve the use of available generating capacity and help reduce carbon emissions in the transportation sector. In general, these technologies offer the potential to fundamentally change the power system while improving its efficiency and reliability. Developing these technologies is a long-term process that will require many years to reach full potential, but the region can facilitate progress through research, development, and demonstration of the technologies.

Along with the smart grid, other technologies may be able to provide power when it is needed with low cost, low risk, and low emissions. In the future, the region may find greater value in power generated by geothermal resources, ocean waves, tides, gasified coal with carbon sequestration, advanced nuclear, or currently unknown technologies. New methods to store electric power, such as pumped storage or advanced battery technologies may enhance the value of existing variable generation like wind. Given the uncertainties of the future, the region should not concentrate on any one potential future solution to its power supply, but should explore a diversity of potential sources of future energy generation and conservation.

FUTURE REGIONAL ELECTRICITY NEEDS

The Pacific Northwest is expected to develop and expand over the next 20 years. Regional population is likely to increase from 12.7 million in 2007 to 16.7 million by 2030. This four million increase compares to a 3.8 million increase between 1985 and 2007. The population growth will be focused on older age categories as the baby boom generation reaches retirement age. While the total regional population is projected to increase by over 28 percent, the population over age 65 is expected to nearly double. Such a large shift in the age distribution of the population will change consumption patterns and electricity uses. Some possible effects could include increased health care, more retirement and elder care facilities, more leisure activities and travel, and smaller-sized homes.

The cost of energy (natural gas, oil, electricity) is expected to be significantly higher than during the 1980s and 1990s. Although these prices have decreased significantly since the summer of

P. 2

2008, a significant portion of the reductions are likely due to the effects of the current economic recession. Natural gas prices have also been affected by the recent growth of production from nonconventional natural gas supplies. The technology to retrieve these supplies cost-effectively has only developed recently and has improved expectations of adequate future supplies. Nevertheless, the cost of finding and producing these supplies is higher than for conventional supplies, which increases the estimated future price trend for natural gas.

If carbon emissions taxes or cap-and-trade policies are implemented, energy costs are likely to increase. Some of the planning scenarios used to develop this plan include a wide range of possible carbon mitigation costs from zero to \$100 per ton. The expected average prices in this range start at zero and increase over time to \$47 per ton of CO₂ emissions by 2030. Carbon costs can have a significant impact on electricity costs and prices to consumers. While higher prices reduce demand, they also stimulate new sources of supply and efficiency and make more efficiency measures cost-effective.

Electricity load (before accounting for new conservation) is expected to grow by about 7,000 average megawatts between 2009 and 2030, growing at about 335 average megawatts, or 1.4 percent, per year. Residential and commercial sector electricity use account for much of the growth in demand. Contributing to the growth in the residential sector is an anticipated increase in air conditioning and consumer electronics. Also, summer peak electricity use is expected to grow more rapidly than annual energy. All of this growth in energy demand must be met by a combination of existing resources, more efficient use of electricity, and new generation. An important change for the Sixth Power Plan is that electricity needs in the future can no longer be adequately addressed by evaluating only average annual energy requirements. In the future, resource needs must also consider capacity to meet peak load and the flexibility to provide within-hour, load-following, and regulation services. The requirements for within-hour flexibility reserves have increased because of the growing amount of variable wind generation located in the region.

RESOURCE STRATEGY

The Council's resource strategy for the Sixth Power Plan provides guidance for the Bonneville Power Administration and the region's utilities on choices that will help meet the region's growing electricity needs while also reducing the risk associated with uncertain future conditions. The strategy minimizes the cost of, and risks to, the future power system. The timing of specific resource acquisitions is not the essence of the strategy because the timing of resource needs will vary for every utility. Rather, the important message of the resource strategy lies in the nature of the resources and their priorities.

The resource strategy can be summarized in five specific recommendations:

1. Improved efficiency of electricity use is by far the lowest-cost and lowest-risk resource available to the region. Cost-effective efficiency should be developed aggressively and on a consistent basis for the foreseeable future. The Council's plan demonstrates that cost-effective efficiency improvements could on average meet 85 percent of the region's growth in energy needs over the next 20 years.

P. 3

2. Renewable resource development is required by resource portfolio standards in three of the four Northwest states. The most readily available and cost-effective renewable resource is wind power and it is being developed rapidly. Wind requires additional strategies to integrate its variable output into the power system and, in addition, it provides little capacity value for the region. The region needs to devote significant effort to expanding the supply of cost-effective renewable resources, many of which may be small scale and local in nature.

3. Remaining needs for new energy and capacity should be based on natural gas-fired generation until more attractive technologies become available. The resource strategy does not include any additional coal-fired generation to serve the region's needs. Further, the Council's plan demonstrates that meeting the Northwest power system's share of carbon reductions called for in some state, regional, and federal carbon-reduction goals will require reduced reliance on the region's existing coal plants.

4. The challenges of wind integration and the need for additional within-hour reserves initially should be addressed through improvements in system operating procedures and business practices. Changes in wind forecasting, reserve sharing among control areas, scheduling the system on a shorter time scale, and advancing dynamic scheduling can all help address wind integration and contribute to a more efficient use of existing system flexibility. The region is already making significant progress in these areas.

5. Finally, the Council's resource strategy calls for efforts to expand long-term resource alternatives. The region should demonstrate the potential of smart-grid applications to improve the operation and reliability of the regional power system and to access the

potential of consumers to provide demand response for the capacity and flexibility of the power system. The region should continue to assess new efficiency opportunities, expand the availability of cost-effective renewable energy technologies, and monitor development of carbon capture and sequestration, advanced nuclear technologies, and other low-carbon or no-carbon resources.

Efficiency

The Council's power plan includes a detailed analysis of efficiency potential in hundreds of applications. The achievable technical potential of efficiency improvements increased from the Fifth Power Plan levels due to advancing technology, reduced cost, and estimates in new areas such as efficiency in electricity distribution systems, consumer electronics, and street, parking, and exterior building lighting. In addition, the cost-effectiveness of these technologies has increased significantly because avoided costs have doubled and carbon-cost risk is several times higher than in the Fifth Power Plan. The estimated achievable potential conservation is nearly 6,000 average megawatts for measures costing under \$100 per megawatt-hour. Over 4,000 average megawatts are available at a cost of less than \$40 per megawatt-hour. These increased opportunities exclude future savings from efficiencies that have already been secured through building codes and appliance efficiency standards.

The plan shows that a substantial amount of the growth in electricity demand could be met by conservation. Portfolio model analysis shows that over 5,900 average megawatts of conservation are cost-effective, double the amount in the Council's Fifth Power Plan. The amount that can be

P. 4

achieved is constrained by the commercial availability of technologies, limits on the annual development rate, and an ultimate penetration rate limit of 85 percent. The amount of conservation found to be cost-effective changed very little in response to changing assumptions about carbon costs and policies. Conservation in the plan is projected to be responsible for reducing carbon emissions by 17 million tons per year by 2030, a 30 percent reduction in 2030 emissions. Failure to achieve the conservation included in the plan will increase both the cost of, and risks to, the power system and likely prevent Washington and Oregon from meeting legislated carbon-reduction goals.

Generation Alternatives

The Council analyzed a large number of alternative generating technologies. Each of these technologies is compared in terms of risk characteristics and cost with other generating technologies, efficiency improvements, and demand response. In addition, resource contributions need to be considered in terms of their energy, capacity, and flexibility characteristics.

Generating technologies that are technologically mature, meet restrictions on new plant

emissions, and are cost-effective are limited in the short to intermediate term. Wind remains the primary large-scale, cost-effective renewable generation source in the near term. However, the Council believes there likely are small-scale dispersed renewable generation alternatives that are local and site-specific. Cost-effective development of these is encouraged, even though the Council currently lacks enough information to include them explicitly in the plan. Natural gas-fired generation is also feasible and cost-effective. New coal-fired generation is difficult to site and permit, and prohibited in many states by new plant emissions standards. During the next 20 years, alternatives may develop such as carbon separation and sequestration, maturing renewable technologies, advanced nuclear generation, demand response, smart-grid technologies, and storage strategies to help provide flexibility reserves. When CO₂ costs are added to the direct cost of generating alternatives, the cost of most generating resource alternatives range between \$70 and \$105 per megawatt-hour or higher (levelized 2006\$).

New renewable generation (primarily wind) is required to meet renewable portfolio standards in Washington, Oregon, and Montana. Analysis shows that meeting RPS requirements uses most of the 5,300 megawatts of readily accessible wind potential in the region. In addition to the wind, some geothermal resources were found to be attractive. However, the amount of geothermal potential is considered quite limited. Given the risk that a carbon-pricing policy might be enacted in the future, some renewable generation is cost-effective even without renewable portfolio standards.

Natural gas-fired generation is anticipated toward the middle of the planning period. Natural gas is attractive for energy and capacity needs and provides an ability to displace coal plants in the event of high carbon costs or coal plant closures. Both combined-cycle turbines and simple-cycle turbines are included in most scenarios. Although these natural gas plants are sited and licensed in the plan, this does not occur until after the five-year action plan period. Preparing to add natural gas-fired generation helps protect against the risk of uncertain future conditions, but the generating plants are not actually completed in many of the simulated futures during the 20-year planning period. The Council recognizes that individual utilities' needs and access to market resources vary. Some utilities will need additional resources in the near-term even if they

P. 5

Plan Overview Sixth Power Plan

meet their renewable portfolio standards and acquire all conservation available to their service territories.

During the last 10 years of the power plan the generating resource priorities become less clear. Given current climate change policies and concerns, new coal without carbon sequestration is unlikely. Further, any significant reduction in carbon will require reduced operations of existing coal plants. Alternatives beyond greater reliance on natural gas are typically unproven commercial technologies or alternatives that require significant new transmission investments. Long-term generating resources considered include wind developed outside the region and imported on new transmission lines, advanced nuclear, gasified coal with carbon

sequestration, and development of relatively unproven renewable resources, or ones that are currently too expensive. Natural gas is used in the plan to meet long-term needs, but the Council recognizes that other alternatives are likely to become available over time. In particular, the evolution of smart-grid technologies could significantly change the nature of future power system needs and the kinds of resource alternatives required and available.

CLIMATE CHANGE POLICY

Addressing the topic of uncertain climate policies was identified as one of the most important issues for the Sixth Power Plan. The focus of climate policy, especially for the power generation sector, will be on carbon dioxide emissions. Nationwide, carbon dioxide accounts for 85 percent of greenhouse gas emissions. Nationally, about 38 percent of carbon dioxide emissions are emitted from electricity generation, but for the Pacific Northwest the power generation share is only 23 percent because of the hydroelectric system. Analysis by others has shown that substantial and inexpensive reductions in carbon emissions can come from more efficient buildings and vehicles. More expensive reductions can come from substituting non- or reduced-carbon electricity generation such as renewable resources, natural gas, and nuclear generation, or from sequestering carbon.

Reductions in carbon emissions can be encouraged through various policy approaches, including regulatory mandates (RPS or emission standards), emissions cap-and-trade systems, emissions taxation, and efficiency improvement programs. State policy responses within the region to climate change concerns have focused on renewable energy standards and new generation emission limits. In addition, Oregon and Washington have carbon reduction targets adopted by statute. National and regional proposals have focused on cap-and-trade systems intended to reduce carbon and other greenhouse gases, although none have been implemented successfully in the region. Although carbon taxes are easier to implement than cap-and-trade systems, policy discussions have focused mainly on cap-and-trade systems.

The question for the power plan is what strategies are prudent given a future where carbon pricing policies are unclear. The Council does not take a position on any particular regional carbon reduction goal or carbon price in this power plan. The plan does recognize the uncertainty about future carbon prices and that possible carbon emission reductions are important risk issues for the regional power system. Multiple carbon reduction scenarios, including a carbon risk scenario that considers a range of future carbon prices between zero and \$100 per ton provide relevant information for policy makers in the region. In general, the resource strategy in the plan will allow Washington and Oregon to meet their carbon reduction targets and constructively address the risk of uncertain future carbon policy. According to Council analysis,

P. 6

states and/or the federal government will need to take additional actions in order to achieve these targets. Potential carbon pricing plays an important role in the Council's resource strategy, with the exception of the conservation resource, which remains a key component regardless of climate change policy assumptions.

The key findings from the Council's analysis of climate change policies include the following:

- Without any carbon control policies, including existing ones, carbon emissions from the Northwest power system would continue to grow to 6 percent over 2005 levels by 2030. However, without the significant amount of conservation (which is cost-effective even without carbon policies) the growth in emissions would be far greater.*
- Without additional carbon pricing policies, current policies would stabilize carbon emissions from the Northwest power system at 2005 levels, but not meet current carbon reduction goals.*
- Assuming a risk of higher carbon prices, the Sixth Power Plan resource strategy has the potential to reduce average regional power system carbon emissions to 9 percent below 1990 levels, or 30 percent below 2005 levels, adjusted for normal hydro conditions.*
- Significant reductions of carbon emissions from the Northwest's power system require reduced reliance on coal, which currently emits more than 85 percent of the carbon dioxide from the regional power system. A carefully coordinated retirement and replacement of half the existing coal-fired generation serving the region with conservation, renewable generation, and lower carbon-emission resources could reduce average carbon emissions to 18 percent below 1990 levels.*
- To the extent that public policy raises the cost of carbon, we can expect an increase in a typical consumer's electric bill and a decrease in carbon emissions, especially when the carbon price begins to exceed \$40 per ton. A fixed carbon price of \$45 dollars per ton has a similar effect on carbon emissions as retiring half of the existing coal-fired generation. Both would meet current carbon reduction targets for 2020 on average, but coal retirement would provide more certainty in meeting the targets.*
- Preserving the capability of existing regional hydroelectric generation will help keep power system costs and carbon emissions down. In scenarios where the capability of existing resources are reduced, whether hydroelectric or coal, the energy and capacity are largely replaced with gas-fired generation to maintain the adequacy and reliability of the power system.*

CAPACITY, FLEXIBILITY, AND WIND INTEGRATION

Reliable operation of a power system requires minute-to-minute matching of electricity generation to varying electricity demand. In the Pacific Northwest, resource planners have been able to focus mostly on annual average energy requirements, leaving the minute-to-minute balancing problem to system operators. This was because, historically, the hydroelectric system had sufficient peaking capacity and flexibility to provide the needed operations as long as there was sufficient energy capability. This is changing for several reasons: growing regional

P. 7

electricity needs are reducing the share of hydroelectricity in total demand, peak load has grown faster than annual energy, the capacity and flexibility of the hydro system has been

reduced over time for fish operations, and growing amounts of variable wind generation have added to the balancing requirements of the system.

As a result, planners must now consider potential resources in terms of their energy, capacity, and flexibility contributions. The rapid growth of wind generation (which has little capacity value and increases the need for flexibility reserves) means that meeting growing peak load and flexibility reserves will require adding these capabilities to the power system. Changes can be made to the operation of the power and transmission system that will reduce flexibility reserve needs. These operational changes are expected to cost less than adding peaking generation, demand response, or flexibility storage, and they can be implemented more quickly.

FISH AND WILDLIFE PROGRAM AND THE POWER PLAN

The Columbia River Basin Fish and Wildlife Program is by statute incorporated into the Council's power plan. The fish and wildlife program guides Bonneville's efforts to mitigate the adverse effects of the Columbia River hydroelectric system on fish and wildlife. One of the roles of the power plan is to help assure reliable implementation of fish and wildlife hydrosystem operations. The Columbia River power system operators have reliably provided hydrosystem actions specified to benefit fish and wildlife (and Bonneville ratepayers have absorbed the cost of those actions) while maintaining an adequate, efficient, economic, and reliable energy supply. This is so even though the hydroelectric operations for fish and wildlife have a sizeable impact on power generation. On average, hydroelectric generation is reduced by about 1,200 average megawatts, relative to operation without any constraints for fish and wildlife. Since 1980, the power plan and the Bonneville Power Administration have addressed this impact through changes in secondary power sales and purchases, by acquiring conservation and some generating resources, by developing resource adequacy standards, and by implementing other strategies to minimize power system emergencies and events that might compromise fish operations.

In addition to operational changes, most of the direct cost and capital costs of fish and wildlife programs have been recovered through Bonneville revenues and Bonneville has absorbed the financial effects of lost generation, resulting in higher electricity prices. Bonneville estimates that the total financial effect of replacing lost hydropower capability and funding direct fish and wildlife program expenditures totals from \$750 million to \$900 million per year (a range affected by, among other things, water conditions and electric prices). The power system is less economical as a result of fish and wildlife program costs, but still economical in a broad affordability sense when compared to the costs of other reliable and available power supplies.

The future presents a host of uncertain changes that are sure to pose challenges for the successful integration of power system and fish and wildlife needs. These include possible new fish and wildlife requirements, increasing wind generation and other variable renewable integration needs that could require more flexibility in power system operations, conflicts between climate change policies and fish and wildlife operations, possible changes to the water supply from climate change that might make it more difficult to deliver flows for fish and meet

power needs, and possible revisions to Columbia River Treaty operations to match 21st century power, flood control, and fish needs.

P. 8

To address current operations and prepare for these additional challenges, the Council has adopted a regional adequacy standard to help ensure that events like the 2000-01 energy crisis, in which fish operations and power costs were affected, do not happen again. In addition, the Wind Integration Forum is addressing issues with integration of wind into the power system. Large swings in wind output have sometimes adversely affected hydropower and fish operations. Addressing adequacy and flexibility issues in the Sixth Power Plan will improve electricity reliability and help ensure reliable fish operations.

P. 9 /End

Comment continued: The DEIS should have addressed the issue of Wind Integration into the power system and the aforementioned Wind Integration Forum. The statement "Large swings in wind output have sometimes adversely affected hydropower and fish operations" should be further explained in the DEIS. How large are these swings in output? Just how big is the issue of wind integration into the power grid? How much wind is too much wind? Does wind inconsistency mean more gas plant back-ups (or other types of back-ups) being used by BPA? Frankly, just because there are now some state and federal requirements to meet some made up greenhouse gas emissions number. does not mean that new technologies or other methods (energy efficiencies and conservation, for example) might not change these requirements. In the rush to go "green" perhaps common sense has fallen by the wayside. Wind energy production is subsidized by taxpayer monies. It is not cheap green energy. The full cost of wind energy production should be added up and should be included in the DEIS.

State Regulation of Greenhouse Gasses

In Washington State, greenhouse gasses are regulated by RCW Chapter 80.80, which establishes goals for statewide reduction of greenhouse gas emissions. The statute aims to reduce overall greenhouse gas emissions to 1990 levels by 2020, and to 25 percent below 1990 levels by 2035. By 2050, the state intends to reduce overall emissions to fifty percent below 1990 levels. Goals also include fostering a clean energy economy by increasing the number of jobs in the clean energy sector to 25,000 by 2020, from just over 8,000 jobs in 2004. Ecology has proposed regulation (Chapter 173-441 WAC)³, which would establish an inventory of greenhouse gas emission through a mandatory greenhouse reporting rule for owners or operators of:

- A fleet of on-road motor vehicles that as a fleet emit at least 2,500 metric tons of greenhouse gases annually in the state
- A source or combination of sources that emit at least 10,000 metric tons of greenhouse gases annually in the state

Comment: The state initiative to lower greenhouse gases by 2020 through the use of renewable energy sources, while admirable, is perhaps not the only and best way to achieve reduction of greenhouse gases. Going green is not a concept carved in cement. Our ideas can evolve and we can change our minds if a better and safer ideas and technology comes along. See previous comment.

Since wind power projects would not emit greenhouse gasses during operations, these regulations are unlikely to apply to the Project.

Bonneville Power Administration Greenhouse Gas Initiatives

In 2008, BPA adopted new initiatives related to climate change, and included the issue in their strategic objectives and key agency performance targets. One of BPA's first steps was to prepare an initial climate change roadmap (BPA 2008) intended as a step toward subsequent, more

2 See: http://en.wikipedia.org/wiki/Greenhouse_gas#cite_note-kiehl197-6; accessed December 2009.

3 See: <http://www.ecy.wa.gov/laws-rules/activity/wac173441.html>; accessed December 2009.

3-17

robust plans for managing greenhouse gas emissions. This document identifies near-term and long-term potential actions to meet agency targets and contribute to national and regional greenhouse gas reduction goals. As a first step in managing greenhouse gas emissions, BPA will collect data in 2009 to inventory BPA's greenhouse gas footprint, which will be reported in 2010.

Comment: Where is this document in the DEIS? I was not able to find it. This should be part of the DEIS and if it isn't then the DEIS is not adequate and should not have been rushed out for public comment. This is a crucial report on BPA's carbon footprint. One rationale for all of these regional wind farms is that they produce less CO2 than other types of energy production facilities and therefore have less of a carbon footprint. Well, we don't really know that, do we? There is nothing in the DEIS that would lead to this conclusion, at least nothing based on facts and figures. All of BPA's greenhouse gas-causing activities SHOULD be in the DEIS, so that a comparison can be made based on facts and figures.

Background Air Quality

The Dalles, Oregon is the closest city with an air monitoring station. The Oregon Department of Environmental Quality (ODEQ) reports air quality data using an air quality index based on particulate matter 2.5 micrometers diameter and smaller (PM2.5). ODEQ's 2008 report for The Dalles shows 339 days with good air quality, 25 days with moderate air quality, and no days with unhealthy air quality (ODEQ 2009).

While air quality in the project area is generally good, haze is a well-documented problem in the

Columbia Gorge and the causes are being studied by the Southwest Clean Air Agency. In a 2008 Report, the agency found that haze was largely caused by winter stagnations that trap pollutants and fog (SWCAA 2008). In the summer, winds flow predominantly from the west, transporting emissions from the Portland metropolitan area into the Gorge. Wildfires also contribute to the haze when smoke is blown into the Gorge. There is no single source that is primarily responsible for haze; however, man-made sources are important contributors (ODEQ 2008). The most significant man-made sources contributing to haze in the Gorge include:

- Power plant emissions
- Woodstoves
- Motor vehicles
- Non-road emissions (e.g. ships, trains, trucks)
- Agricultural sources of ammonia

The Skamania Fish Hatchery, located west of the project site, collected climatological data in the project site area for 1965–2005. Average temperatures ranged from a minimum of 38.2 degrees Fahrenheit to a maximum of 61.8 degrees Fahrenheit. Average precipitation was 84.06 inches, and there was an average of 9 inches of snow per year.⁴

3.2.2 IMPACTS

3.2.2.1 Proposed Action

The potential environmental consequences of the proposed project include those from construction and operation. Impacts to air quality would not differ between the two alternative

⁴ Columbia Gorge Economic Development Association,
<http://www.cgeda.com/environment/quclimat.shtml>.

3-18

locations for the Operations and Maintenance Facility. Potential impacts include emissions, odors and dust.

Construction

Emissions

Construction of the project would result in temporary air emissions from the following sources:

- Exhaust from the diesel construction equipment used for project site preparation (including logging), grading, excavation, and construction of on-site structures
- Exhaust from water trucks used to control construction dust emissions
- Exhaust from diesel trucks used to deliver equipment, concrete, fuel, and construction supplies to the construction site
- Exhaust from pickup trucks and diesel trucks used to transport workers and materials around the construction site and from vehicles used by workers to commute to the construction site

- Exhaust from diesel-powered welding machines, electric generators, air compressors, etc.
- Emissions from one or more portable rock crushers and one or more portable concrete batch plants, which will be used as necessary to supply the large amounts of gravel and concrete needed for the project

The primary air pollutants from diesel-powered equipment would be nitrogen oxides, hydrocarbons, carbon dioxide, particulate matter (PM) and sulfur dioxide. In addition to these, the rock crusher and batch plant(s) would produce additional PM. These emissions would be similar in nature to those produced by any construction project that involves heavy equipment and transportation of materials to the project site. These construction emissions would be temporary and would be limited to the areas adjacent to the construction site. They would not affect a substantial number of persons or persist for an extended period of time and would not result in exceedance of any air quality standards.

Comment: So, nitrogen oxides, hydrocarbons, carbon dioxide, particulate matter, and sulfur dioxide would be the primary air pollutants, plus more particulate matter produced by the rock crusher and batch plants! What quantity of each of these would be produced? How much particulate matter would go into our air and affect air quality? Where is the data and some hard numbers so that we can see what quantity of these "primary air pollutants" will be produced! Where are the cumulative impacts analyses on our regional air and water quality to see how much air and water pollution this project would contribute to our region? There is nothing here to compare, assess, and analyze. This is a DEIS deficiency.

Odors

Project construction would produce limited odors associated with exhaust from diesel equipment and vehicles, and painting the Operations and Maintenance facility, turbine towers, and other structures. The effect of odors would be temporary, and would be limited to the areas adjacent to the construction site and along haul routes to the batch plant(s) and rock crusher. Odors would not affect a substantial number of persons or persist for an extended period of time. An occasional small amount of diesel exhaust may be noted from trucks entering or leaving the site from public roadways.

Dust

Project construction would create fugitive dust from construction and re-construction of gravel roads, including from rock crushing and/or a concrete batch plant. Small amounts of dust would

3-19

be created by construction-related traffic and additional wind-blown dust as a result of ground disturbance. The presence and impact of dust would be temporary, and would be limited to areas adjacent to the construction site and along haul routes. Dust would not affect a substantial number of persons or persist for an extended period of time. A small amount of dust may be noted from trucks entering or leaving the site from public roadways.

Operation

Emissions

Since the fuel source for the proposed project would be wind, there would be no emissions from the operation of the turbines. Project operation would not produce visible plumes, fogging, misting, icing, or impairment of visibility, or changes in ambient levels of pollutants. Emissions would occur from Operations and Maintenance vehicles. Travel on the project access roads would produce minor exhaust emissions.

Avoided Emissions

Project operation would avoid the use of fossil fuel to meet the energy needs of the region. The project's annual electricity production is estimated at 197,000 megawatt hours (MWh). This energy is equivalent to 114,000 barrels of crude oil or 654 million cubic feet of natural gas. Total electricity production can be used to estimate the emission displaced by a fossil-fuel alternative. Table 3.2-1 shows emission rates for carbon dioxide and sulfur dioxide for fossil-fuel-based power plants in the Northwest Power Pool, along with estimated emissions avoided from the operation of the wind power plant. This table also shows the displaced emissions from the project as a percentage of Washington State emissions for 2004.

Table 3.2-1
Air Pollutant Emissions Displaced by the Project

Air Pollutant	Emission Rates a (lb/MWh)	Tons Displaced by Projectb	Washington State Emissions 2005	Project as % of Washington Emissions
Carbon dioxide	1334c	131,466	16,882,540c	0.7
Sulfur dioxide	1.573	155,452	3.4	

a. Non-baseload output emission rates for Northwest Power Pool Western Electric Coordinating Council Northwest Region. A non-baseload emission factor was used to calculate the avoided emissions from the project, based on guidance from the US Environmental Protection Agency that "Annual non-baseload output emission rates ... can be used to estimate GHG emissions reductions from reductions in electricity use. These output emission rates, called annual nonbaseload emission rates, are the annual output emission rates for plants that combust fuel and have capacity factors less than 0.8. These new data values are derived from plant level data and supplement, rather than replace, the fossil fuel output emissions rates, which are sometimes used

as a rough estimate to determine how much emissions could be avoided if energy efficiency and/or renewable energy displaces fossil fuel generation. These non-baseload output emission rates would somewhat improve this rough estimate by factoring out baseload generation, which is generally unaffected by measures that affect marginal generation” (USEPA 2007).

b. Estimated annual electricity production multiplied by emission rate, for example, for carbon dioxide $(1,334) \times [(75 \text{ MW}) \times (0.30 \text{ capacity factor}) \times 24 \times 365]/2000 = 131,465.7 \text{ tons}$

c. 2005 value; values for 2005 were not available for the other pollutants listed. By avoiding the need for fossil-fuel-powered plants, the project would contribute to air quality by avoiding emissions associated with burning fossil fuels, including greenhouse gasses. Using wind power also likely would have a beneficial effect on visibility, since the same pollutants that affect visibility also affect air quality (ODEQ 2008).

Comment: Cumulative Impact Analyses are NOT done on a project by project basis. They are done on a regional, inclusive basis. Therefore, any and all fossil fuel-powered plants and other types of backup energy production that is used to back up BPA's hydro power generation have to be accounted for in the DEIS. They are not. Just because Whistling Ridge doesn't have a gas power plant onsite does not mean that a gas power plant will not be used to balance its wind energy production on the grid. The statement "Using wind power also likely would have a beneficial effect on visibility" is patently inaccurate. If visibility in the Gorge and along the Columbia River has been deteriorating for 20 or more years when there wasn't any wind power to speak of, then it is pretty specious to make the correlation that using wind power today would have "beneficial" effects on visibility! The two things are not mutually inclusive.

3-20

Greenhouse Gas Emissions from the Project

Greenhouse gasses would be emitted during construction of the project, as a result of burning fossil fuels in the construction equipment and vehicles. The amount of these emissions has not been quantified, but would be directly proportional to the number of workers and vehicles on the site. Some emissions of greenhouse gases will take place during the design, manufacture, transport of the wind turbines. During operation, greenhouse gas emissions would be the result of vehicles used for regular maintenance activities and would be much lower than during construction. Production of electricity itself would not release greenhouse gasses or other pollutants. The American Wind Energy Association estimates that including generation from all sources, wind energy's carbon dioxide emissions are on the order of 1 percent of coal or 2 percent of natural gas per unit of electricity generated (AWEA 2009).

Comment: So what does "wind energy's carbon dioxide emissions are on the order of 1 percent of coal or 2 percent of natural gas per unit of electricity generated" actually mean? This statement doesn't mean anything without data to compare. Where are the comparison charts for wind, gas, and coal CO2 emissions? I could not find them in the DEIS.

While greenhouse gas emissions from the project will be low, several of the mitigation measures mentioned in Section 3.2.3 will reduce such emissions. These include limiting idling times of equipment and encouraging carpooling among construction workers.

Odor

Operation of the turbines would create no odors, as no combustion is involved and no odor-producing materials would be used in project operations. Travel on the project access roads would produce insignificant amounts of odor from exhaust. Maintenance of the substation and Operations and Maintenance building would produce occasional minor odors from painting.

Dust

Operation of the project would result in minor increases in dust during regular maintenance of gravel access roads. Project-related increases to traffic on these gravel roads would generate small amounts of additional fugitive dust. This increased traffic would consist largely of weekly or less frequent trips to turbines in service vehicles for maintenance and repair activities.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan would address site restoration that would occur at the conclusion of the project's operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan would include or parallel a decommissioning plan for the project.

The initial site restoration plan would be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential emissions or impacts to air quality. If impacts to air quality are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures would be proposed as part of the plan.

3.2.2.2 No Action Alternative

Under the No Action Alternative, the project would not be built. The project site would continue to be used primarily for timber harvests. If the No Action Alternative is selected, the growing

3-21

electricity needs of the region would continue to be met through a combination of other renewable development and combustion of additional fossil fuels. In recent years, several of the new power plants proposed and constructed in the Pacific Northwest have been fossil fuel powered plants, primarily using natural gas as fuel.

Comments: If Whistling Ridge is NOT built, this does not necessarily mean that gas plants will take its place. Conservation and energy efficiencies in our homes, businesses, and

infrastructure could fill the energy gap. Whistling Ridge and other wind farms are not necessarily the best way to meet our energy needs. What must be addressed, and it is NOT addressed in the DEIS, is that most of the energy produced in the NW is sucked down to California and parts South and they will continue to demand more and more energy and we will never be able to satisfy their energy thirst because they will want more and more. With global climate change upon us and temperatures rising, people will want more energy for air conditioning. Why should our environment and ecosystems be degraded just to satisfy this insatiable energy thirst? If California wants more energy let them put wind turbines on their beaches. Like that's going to happen any time soon!!

Fossil fuel power plants, in contrast to wind power projects, emit significant quantities of carbon dioxide, an important greenhouse gas linked to potential climate change. Natural-gas-powered plants also emit sulfur oxides and nitrogen oxides, which contribute to both ground-level air quality problems and acid rain. According to the Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2006 (USEPA 2008), air emissions from fossil fuel combustion for electricity production are a leading source of air pollution nationally, accounting for:

- 67 percent of sulfur dioxide emissions
- 28 percent of nitrogen oxide emissions
- 36 percent of carbon dioxide
- 3 percent of mercury

3.2.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential construction-related air emissions and dust impacts:

- Ensure that all vehicles used during construction comply with applicable Federal and state air quality regulations.
- Implement operational measures, such as limiting engine idling time and shutting down equipment when not in use, to reduce air emissions.
- Implement active dust suppression on unpaved construction access roads, parking areas and staging areas, using water-based dust suppression materials in compliance with state and local regulations.
- Implement a dust control program to minimize any potential disturbance from construction-related dust. Dust suppression would be accomplished through application of either water or a water-based, environmentally safe dust palliative such as lignin. The use of a dust palliative such as lignin (a non-toxic, non-hazardous compound derived from trees) would result in the use of substantially less water for dust suppression and therefore less traffic from water trucks to the construction site. The final decision regarding dust suppression techniques would be made by the Construction Contractor in consultation with local authorities.
- Limit traffic speeds on unpaved project roads to 25 mph to minimize dust.

- Encourage carpooling among construction workers to minimize construction-related traffic and associated emissions.

3-22

- Replant or gravel disturbed areas to reduce wind-blown dust.
- Implement erosion control measures to limit deposition of silt to roadways.

3.2.4 UNAVOIDABLE ADVERSE IMPACTS

The proposed project would produce minor and temporary impacts to air quality during construction activities, similar to existing logging operations.

3.3 WATER RESOURCES

This section describes the existing water resources in the project area, the potential for impacts to water resources from the proposed project, and mitigation measures designed to minimize or avoid those impacts. Information in this section is taken primarily from the Application for Site Certification and the visual assessment completed for that document.

Comment: In 2007, Underwood had a really dangerous water situation, as reported in The Columbian newspaper: "Underwood water deemed safe to drink"

The Columbian

State health officials Wednesday lifted a boil-water advisory issued Friday for the Underwood area after tests showed the water is now safe to drink.

Major firefighting efforts in the Columbia River Gorge last week drained local water supplies, causing Underwood's water system to lose pressure in some areas. The pressure loss could have allowed contaminants to enter the water, so the state Department of Health and the Skamania County Public Utility District issued the boil- water advisory as a precaution. The Underwood system serves 876 residents.

Water supplies have returned to normal, officials said, and excess air has been flushed from the system. Water samples sent for bacterial analysis came back indicating the water is safe.

Originally published by KATHIE DURBIN Columbian staff writer, 9/27/2007.

Source: Columbian

The DEIS has no data on the watershed in this area and from which or what type of source, in actuality, the residents get their water. This is a fatal flaw in data gathering and analysis. What would be the cumulative effects, on the water resources that these 876 Underwood residents use, of all the impermeable surfaces—wind turbine pads, substation, maintenance roads, etc.-- that would result from the construction of this proposed wind farm? This is a critical question for fire fighters and the residents. We all know that there will be future fires. What if one of the turbines causes a fire in the woods? Where is the water going to come from to combat this type of fire? Would the Underwood reservoir be depleted thus affecting the residents and their health and safety?

3-23

3.3.1 AFFECTED ENVIRONMENT

3.3.1.1 Surface Water

The Columbia River flows south of the project site and receives runoff via the White Salmon

Basin from the east portion of the project site and via the Little White Salmon Basin from the west portion of the project site. Surface water resources in and near the project site are shown on Figure 3.3-1 and include the following:

One wetland labeled “Cedar Swamp” on Figure 3.3-1 and described in Section 3.4.

- Several drainages located within the project site boundaries, which are typed as seasonal, non-fish habitat streams or perennial, non-fish habitat streams (Figure 3.3-1). Some drainages extend upstream from these typed reaches, but lack defined channel features. Most of the drainages within the project site boundary would be classified as Class V streams under Skamania County’s critical areas ordinance. Class V streams are small perennials streams or seasonal streams with short periods of spring or storm runoff (SCC 21A Appendix C). The tributary to Little Buck Creek may be classified as a Class IV stream as it nears the eastern project site boundary. The stream information has been updated from the information contained in the Application for Site Certification with additional data from field visits.

Comment: LIDAR reconnaissance would be useful to determine drainages and streambeds. It could also be used for the geologic survey. Why isn’t LIDAR a requirement for this DEIS?

- One unnamed perennial stream crossed by West Pit Road, the proposed access road. This stream occurs in the Little White Salmon watershed. Flow was observed through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to any other stream or waterbody.

3.3.1.2 Stormwater Runoff Water runoff from the northeast portion of the project site drains southeast via Cedar Swamp and its tributaries to Little Buck Creek before flowing south to the White Salmon River, and ultimately to the Columbia River. Water runoff from the southwest area of the project drains west and southwest to a flat area east of the project, ultimately draining to the Little White Salmon River and then the Columbia River.

Project site soils are classified as well-drained, with slow to moderate runoff, and slight to moderate hazard of water erosion. The presence of scour, sedimentation, steep slopes, ephemeral and perennial streams, and the soil classifications suggest that surface water runoff and infiltration within the project are moderate (Haagen 1990).

3-24

33758687_154.cdr

Figure 3.3-1
Job No. 33758687 Waterways in the Project Vicinity

3.3.1.3 Groundwater

A subsurface investigation was conducted in September 2007 to assess near-surface soil and rock characteristics (Appendix B). The investigation included twelve test pits excavated from seven to 16 feet in depth. Groundwater was not encountered in any of the test pits. However, these observations reflect groundwater levels at the time of the field investigation and actual groundwater levels may fluctuate significantly in response to seasonal effects, regional rainfall, and other factors not observed during this investigation. Regional or perched water tables may be present at a greater depth.

Comment: Why weren't the field investigations done during the rainy season? How does one find perched water tables and if they "may be present at greater depth" shouldn't they be found since SDS and BPA are proposing to put structures that weigh quite a few tons onto unstable ground that is subject to mass wasting? The groundwater issue needs to be addressed with further field studies and deeper coring. Where is the watershed map for this area? What is the extent of the watershed for this area? The 50+ turbine pads are 50 X 50 feet and this would introduce a large quantity of impermeable surface area to unstable ridges. How would these impermeable surfaces affect water saturation and water flow in the watershed? Is this area included in the Water Resource Inventory Area (WRIA) 29?

3.3.1.4 Floodplains

The project site is located on a series of north-trending ridges that range in elevation from approximately 2,100 to 2,300 feet, outside the 100-year floodplain for the White Salmon, Little White Salmon, and Columbia Rivers (FEMA 1986).

3.3.1.5 Public and Private Water Supplies

There are no public water supplies within the project site. Private water supplies are limited to water supply wells serving adjacent residences and agricultural operations.

Comment: Well, where do these "private water supplies" come from? From perched water tables? Other types of groundwater? Are these wells interconnected? Could the construction and excavation from Whistling Ridge affect these wells?

3.3.2 IMPACTS

3.3.2.1 Proposed Action

Construction

Surface Water

On site, project construction would involve roadway improvements on approximately 7.9 miles of existing private, gravel logging roads, construction of approximately 2.4 miles of new gravel access roads, the project substation, an Operations and Maintenance building at one of two alternative sites, the collector system pad, a pad for each turbine tower, and underground electric cables buried in trenches along the access roads. Temporary roadways would be built to provide additional access for heavy machinery during construction. Of these improvements, only the planned improvement to West Pit Road may directly affect water resources.

The planned improvements to West Pit Road would cross one unnamed drainage that currently flows under West Pit Road through a culvert. This drainage would be classified by Skamania County as a Class V stream. The Skamania County Code establishes buffers for Class V streams; however, expansion of existing uses is allowed within these buffers. The culvert under West Pit Road was upsized during road improvements in summer 2009. Depending on the amount of additional roadway widening that may be required, this new culvert may need to be lengthened to extend beyond the width of the improved access road. This would be determined in during final design.

Comment: "Additional roadway widening"? What does this mean? Doesn't SDS know now how much roads would have to be widened? And which roads would actually have to be widened? Determining this during "final design" does not work for me. I want to know now, before this project is approved or not whether and which roads would have to be widened or reinforced since hauling those heavy turbines up narrow roads would require widening and perhaps repaving. SDS should provide information on roads now, not later.

Small portions of stream and stream buffer are located with the 650-foot turbine corridors used for permitting this project. However, all streams and stream buffers would be avoided during the micro-siting process.

3-26

No wetlands or other surface water bodies would be filled or otherwise affected as a result of the project. Wetlands are discussed in further detail in Section 3.4.

Stormwater Runoff

Construction would result in approximately 108 acres of disturbed surface, of which approximately 52 acres will be restored. Use of standard construction BMPs would mitigate surface runoff and erosion from these surfaces to a minor level.

Comment: What are these "standard construction BMPs" and where are they located in the DEIS?

Groundwater

No impacts to groundwater are anticipated from construction. Construction water would be obtained from a supplier with valid water rights and no construction water would be withdrawn on site. Potential spills to groundwater during construction would be controlled through standard construction BMPs. A Spill Prevention, Control and Countermeasure (SPCC) Plan will be prepared.

Floodplains

The project site is located outside of floodplain areas. No construction impacts to floodplains would occur.

Public and Private Water Supplies

During construction, approximately 1.7 million gallons of water would be used for road construction, wetting of concrete, dust control, and other activities. Water consumed during construction would be purchased by the contractor from an off-site vendor with a valid water right and transported to the project site in tanker trucks. No water would be withdrawn from the project site during construction. There would be no water treatment requirements or methods on site. Environmentally benign dust palliatives such as lignin may be added to water used for dust suppression to improve efficiency and reduce water use.

Operation

Surface Water

No impacts to surface water are anticipated from project operation.

Stormwater Runoff

The total project site area is approximately 1,152 acres; however, permanently improved areas would cover approximately 56 acres, less than 5 percent of the total project site. Stormwater impacts from disturbed areas would be generated from this permanently improved area.

The increase in surface water runoff from this additional impervious surface is expected to be minimal. Stormwater would continue to be routed off-site via culverts and some stormwater would continue to infiltrate in the way it does currently. Based on site conditions and assuming implementation of appropriate BMPs, the net impact to absorption on the project site is considered negligible and there would be negligible impacts to surface water.

3-27

Approximately 22 acres would be converted from forested to non-forested habitat in the areas surrounding the turbines where re-growth of trees would be prevented. This conversion would result in minimal impacts to precipitation interception and runoff.

Groundwater

Operation of the project would have minimal or no impacts to groundwater. The well serving the Operations and Maintenance building would use less than 5,000 gallons of water per day, and would thus be exempt from permit requirements of RCW 90.44.040. The size of the aquifer is not known; however, this would be the only well on the project site, which is approximately 1,152 acres in size. The well would be installed by a well contractor licensed pursuant to Chapter 173-162 WAC, and in compliance with the requirements and standards of Chapter 173160 WAC. The well would be installed consistent with Skamania County Community Development Department and Ecology requirements for new wells.

Although the amount of impervious surface would increase by approximately 52 acres with the construction of the project, impacts to groundwater recharge during operation would be negligible.

Floodplains

The project site is located outside of floodplain areas. No impacts to floodplains would occur from operation of the project.

Public and Private Water Supplies

Project operation would require water use primarily for the bathrooms, showers, and kitchen in the Operations and Maintenance building. When the project is operational, there would be eight to nine permanent full-time and/or part-time employees on the Operations and Maintenance staff. The average total water supply needs would be less than 5,000 gallons per day.

Water supply for the Operations and Maintenance staff would be provided through a well drilled on the project site. All water would be discharged to a septic tank installed on site, and thus most of the water used would be returned to the aquifer. There would be no process water generated on site, and no water associated with plant operations would be discharged to surface waters.

Comment: So there is an aquifer. If there is an aquifer then there is groundwater. What is this aquifer, what is its extent? Do the other wells in the area use this aquifer for their water?

The project would not require the use of any water for cooling or any other industrial use, and there would be no industrial wastewater stream from the project. The project would require and obtain approval for the new well from EFSEC, in consultation with Skamania County Environmental Health Department and Ecology.

The project would not require any new water rights or authorizations beyond the well for the Operations and Maintenance building.

Due to the low volume of water that would be required for operational use, no alternatives to reclaim water or other water reuse projects would be required.

3-28

Project water use is not expected to affect water levels in private wells in the vicinity of the project. There are no public water supplies within the project site; therefore, no impacts are anticipated to public water supplies.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least 90 days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the

project's operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

Comment: These plans should not be left for later. They should be in the DEIS now so that we can all comment on them. I think it is very important to know HOW a project will be decommissioned and who will be responsible for removal and costs. Is there some type of bond that the project proponents have to put up so that we the taxpayers don't get stuck with having to decommission wind farms??

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to surface water flow, water quality, stormwater runoff, groundwater quality, or water supply. If impacts to water resources are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

Comment: What are these "mitigation measures" that will be proposed if there are water impacts? What kind of impacts to water resources is SDS anticipating? Why not list these mitigation measures now so that we can all see if they would be adequate? The DEIS should include information on impacts to water resources.

3.3.2.2 No Action Alternative

Under the No Action Alternative the project would not be built, and there would be no well drilled to support the Operations and Maintenance building. No impacts to surface or ground water would occur.

3.3.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts of the proposed project related to water resources during pre-construction, construction, and operation.

- Prepare and implement a Stormwater Pollution Prevention Plan (SWPP) prior to construction of the proposed project to lessen soil erosion and improve water quality of stormwater run-off. The SWPP will be developed to prevent movement of sediment off-site to adjacent water bodies during short term or temporary soil disturbance at construction sites. The plan addresses stabilization practices, structural practices and stormwater management (as outlined by Section 402(p) of the Federal Clean Water Act and Chapter 90.48 RCW of the State of Washington's Water Pollution Control Act).
- Identify all areas of potential chemical storage during construction, including any herbicides, and provide appropriate control measures within the SWPP.

Comment: Is Whistling Ridge proposing to use herbicides over the life of the proposed wind farm to control vegetation? What kind of herbicides and/or pesticides is SDS proposing to use? What is the chemical makeup of any proposed chemicals that might be used on this project? Are there any potential health hazards to human beings and wildlife?

- Control the sequence and methods of construction activities to limit erosion. Clearing, excavation, and grading would be limited to the minimum areas necessary for construction of the project, and would not be performed far in advance of facility construction.

3-29

- Design slopes to be graded no steeper than 3 feet horizontal (H) to 1 foot vertical (V).

- Protect slopes less than 3H:1V with silt fencing as appropriate. Silt fences would be installed in locations where they would trap silt eroded from slopes during construction and prior to reestablishing vegetation. The maximum flow path to each silt fence would be approximately 100 feet. No concentrated flows greater than 1 cubic foot per second would be directed toward any fence for the 25-year storm. Silt fences would be maintained throughout the construction period and beyond, until disturbed surfaces had been stabilized with vegetation. Silt fence construction would be determined by local construction conditions during final design of the facilities.

- Design sediment control measures used during construction based on 10-year design storm specifications. Water quality measures (other than sediment removal) would be based on the 6-month, 24-hour design storm.

- Utilize sediment traps to intercept stormwater runoff and allow sediment to settle, thereby minimizing the amount of sediment flowing off site. Sediment traps would be sized for the specific disturbed area, for bare soil conditions, and typically for 75 percent sediment removal efficiency.

- Implement and emphasize erosion controls over sediment controls through non-quantitative construction activities such as:

- Straw mulching and vegetating disturbed surfaces

- Retaining original vegetation wherever possible

- Timing grading operations to dry seasons

- Directing surface runoff away from denuded areas

- Keeping runoff velocities low through minimization of slope steepness and length

- Providing and maintaining stabilized construction entrances

- Grade control structures such as rock check dams, hay bale check dams, dikes, and swales would be used where appropriate to reduce runoff velocity, as well as to direct surface runoff around and away from cut-and-fill slopes. Swales and dikes also would be used to direct surface water on top of the filled pad toward sediment traps and away from flowing over the bank.
- Utilize the appropriate erosion control blankets designed for various weather conditions during the construction period, such as straw or jute matting or other suitable erosion control blankets, on any disturbed slopes to prevent erosion and control sediment migration.
- Use quarry spall construction entrances to reduce migration of construction dirt to public roads. Placing the construction entrances is one of the first activities required at the site, but the rock bed also must be periodically replenished as it becomes dirty or migrates into the subgrade. All construction traffic would be directed to use the construction entrances.

3-30

- Restore ground surfaces within fourteen days of the area's final disturbance. Interim surface protection measures, such as erosion control blankets or straw matting, also may be required prior to final disturbance and restoration if warranted by the potential for erosion.
- Reduce potential for chemical pollution of surface waters during construction. Since source control is the most effective method of preventing chemical water pollution, careful control must be exercised over potentially polluting chemicals used on site during construction. Under the SPCC Plan, the general contractor would be responsible for planning, implementing, and maintaining BMPs for:
 - Neat and orderly storage of construction chemicals and spent containers in lined, bermed areas
 - Prompt cleanup of construction phase spills
 - Regular disposal of construction garbage and debris
- Train employees to utilize methods outlined by the SWPP.
- Dispose and contain garbage generated during construction properly.
- Design and incorporate BMPs into final construction plans and specifications so that operational impacts to water resources will be minor.
- Construct appropriate stormwater hydraulic and treatment facilities making sure that routine maintenance and chemical pollution prevention through source control are utilized for permanent stormwater management.
- Utilize the following constructed permanent stormwater BMPs:
 - Vegetated drainage ditches
 - Culverts with stabilized inlets and outlets

-Permanent erosion and sedimentation control through site landscaping, grass, and other vegetative cover

-Runoff treatment BMPs facilities would be designed to conform to the applicable Stormwater Management Manual

- Adopt operational BMPs to implement good housekeeping, preventive and corrective maintenance procedures, steps for spill prevention and emergency cleanup, employee training programs, and inspection and record keeping practices as necessary to prevent stormwater pollution. Examples include:

- Neat and orderly storage of chemicals under cover in the Operations and Maintenance facilities

Comment: What are these chemicals that are in storage? What is their chemical makeup? Are they hazardous? Are they dangerous to humans and wildlife?

3-31

- Prompt cleanup and removal of spillage

- Regular pickup and disposal of garbage and rubbish

- Prevention of accumulations of liquid or solid chemicals on the ground or the floor

- Train facility operators annually to in spill response and in the applicable pollution control laws and regulations.

- Train additional staff to recognize areas that may be affected by a spill and potential drainage routes.

- Train additional staff to report spills to appropriate individuals.

- Train additional staff on the appropriate material handling and storage procedures.

- Train additional staff to implement spill response procedures.

- Summarize in-house compliance inspections to be kept with the SWPP, along with any notifications of non-compliance and reports on incidents such as spills. If the SWPP has been followed but still proves inadequate to prevent stormwater pollution, project staff would amend the SWPP and seek EFSEC concurrence with the improvements.

- Utilize BMPs to include vegetated ditches or swales which will increase infiltration to protect groundwater.

- Utilize a site development plan to protect groundwater from the on-site storage of chemicals (if any).

3.3.4 UNAVOIDABLE ADVERSE IMPACTS

Construction and operation of the project would only result in negligible to minor impacts to water resources because the impacts are localized and the disturbance is short-term.

Comment: Now see, this is why this DEIS is so frustrating. Since there is no watershed map and the proponents don't know whether there is an aquifer or perched water tables or other sources of groundwater, they cannot make such a blatantly inaccurate statement. There is no data in this DEIS that could be used to conclude "negligible to minor impacts to water resources." The proponents don't have any way of knowing whether "impacts are localized and the disturbance short term" because they have NOT done a CUMULATIVE IMPACTS ANALYSIS for impacts and effects of this project and all other such projects in the region.

3-32

3.4 BIOLOGICAL RESOURCES

This section describes the existing biological resources on the project site, including vegetation, habitat, wetlands, special status species, fish and other wildlife. It also considers the potential for impacts to biological resources as a result of construction and operation of the project, and mitigation measures designed to minimize those impacts. Information in this section is taken from the following background studies and reports:

- Vegetation Technical Report: Saddleback Wind Project (CH2MHill, no date) (Appendix C-1)
- Wetland Delineation Report, Saddleback Wind Energy Project (CH2MHill 2007) (Appendix C-2)
- Rare Plant Survey Report: Saddleback Wind Project (CH2MHill 2003) (Appendix C-3)
- Baseline Avian Use Surveys of the Project in Fall 2004, Summer 2006, and winter-spring 2008-2009 (West Inc. 2009a) (Appendix C-4)
- Final Report, Northern spotted owl, western gray squirrel and northern goshawk surveys conducted for the Whistling Ridge Wind Energy Project (Turnstone 2004) (Appendix C5)
- 2008 Final Report, Results of northern spotted owl, western gray squirrel and northern goshawk surveys conducted for the Whistling Ridge Wind Energy Project. (Turnstone 2008) (Appendix C-6)
- 2009 Report, Results of northern spotted owl, western gray squirrel and northern goshawk surveys conducted for the Whistling Ridge Wind Energy Project. (Turnstone 2009) (Appendix C-7)

- Bat Acoustic Studies for the Whistling Ridge Wind Resource Area in 2007 (West Inc. 2008; Appendix C-8), 2008 (West Inc. 2009b; Appendix C-9), and 2009 (West Inc. 2009c; Appendix C-10)
- Washington Natural Heritage Program (WNHP 2003a, 2003b, 2009)
- Discussions with representatives of Washington Department of Fish and Wildlife and USFWS
- Supplemental wetland reconnaissance and special status plant surveys in May and July 2009

Comment: I am not an expert on the spotted owl issue, but wasn't there a lawsuit filed in Washington, D.C., by the American Forest Resource Council, in 2009, challenging the Department of Interior's (DoI) U.S. Fish and Wildlife Service (USFS) 2008 Northern Spotted Owl critical habitat designation? The U.S. DoI had made a court motion asking the court judge to remand and vacate the owl's critical habitat designation and to remand the recovery plan on which the designation was made. The government's action was basically seeking to set aside the 2008 critical habitat designation. It was DoI Secretary of Interior Ken Salazar who announced the withdrawal of the Western Oregon Plan Revisions (WOPR) Records of Decision (RODs) on July 16 2009; at this same time he also announced the government would also seek to have the critical habitat designation vacated. What is the status of this lawsuit as it regards to the spotted owl critical habitat in this region? BPA must do cumulative impact analyses on the effects of its regional infrastructure and energy production facilities on the critical habitats of the spotted owl (and other species). The DEIS, as far as I was able to see, does not address BPA's impacts on critical spotted habitat. This needs to be remedied.

3-33

3.4.1 AFFECTED ENVIRONMENT

3.4.1.1 Regional Environment

The project site is located in the Southern Washington Cascades Province, within the grand fir (*Abies grandis*) and Douglas-fir (*Pseudotsuga menziesii*) major vegetation zones (Franklin and Dyrness 1988). Topography in the area is characterized by generally accordant ridge crests, separated by steep, deeply dissected valleys. The prevailing climate is cool and wet. The majority of precipitation falls as snow, which may accumulate one to three meters during the winter season. The site is located on Underwood Mountain. Major drainages in the vicinity of the project site include the White Salmon Basin to the east and the Little White Salmon River Basins to the west, both of which drain to the Columbia River, which is located south of the project site.

Comment: In section 3.17, there is this statement about snow: average of 9 inches of snow per year. Footnote 4. Which is the true statement "...snow, which may accumulate one to three meters during the winter season" or "average of 9 inches of snow per year"?? This does not compute. Three to nine feet of snow is a lot different than 9 inches of snow. Meters of snow mean more water erosion. Meters of snow mean more snow removal traffic. Meters of snow could also mean lack of access to the wind turbines when they have to be tied down due

to high winds. What happens if the technicians can't get to the wind turbines and the blades are subjected to high winds? Will they rip off? Will they go flying into neighboring properties? What happens during high winds and snow season? What's the standard operating procedure to be followed? The DEIS should answer these questions and address the issue of snow.

Historically, the project site was dominated by grand fir and Douglas-fir. The relative abundance of each of these coniferous species was driven by elevation, aspect, underlying soil, and previous disturbance history (Franklin and Dyrness 1988). Mixed conifer and deciduous forest stands were present, typically following natural disturbance events. Deciduous forests also were present, composed mainly of alder (*Alnus rubra*, *A. viridis* ssp. *sinuata*), Pacific dogwood (*Cornus nuttallii*), and big-leaf maple (*Acer macrophyllum*).

For the last century, the predominant land use in the area located between Underwood Mountain and the Little White Salmon River has been commercial forest production. Lands within the project site are privately owned, and have been actively-managed for timber for the last century. As a result of ongoing timber harvest, forests within the project site are now characterized by a mosaic of stand ages; however, average stand age has declined as a result of relatively short stand rotations.

Changes in stand structure and complexity, patch size, and species distribution also have occurred. Forest management practices have resulted in a shift in species dominance to the commercially valuable Douglas-fir. Changes in stand structure and complexity, patch size, and species distribution also have occurred. Few large, old-growth conifers exist in the project vicinity, and there are no late-successional stands or old forest habitats (using Washington Forest Practices habitat definition) within or adjacent to the site.⁵ Canopy species within the corridor areas have been removed, and areas are managed to be devoid of shrub and tree species.

Comment: If SDS is such a poor steward of their lands so that there is a mosaic of stand ages, few large, old growth conifers, and no late successional stands or old forest habitats, then I'm not quite sure why we would trust SDS to take care of and protect the 1000+ acres on the proposed wind farm site from further fragmentation and degradation! SDS's purported reason for proposing this wind farm is to help reduce the CO2 footprint of the Pacific NW. Then wouldn't it be better if they were growing more older and bigger trees which have been scientifically proven to store more CO2 than younger trees? Instead they have an area which has been under commercial forest production for the last century and "average stand age has declined as a result of relatively short stand rotations" and probably the practice of clear-cutting, a practice that should be prohibited in active forest management, has not helped the stands, either.

The proposed turbine corridors have been forested recently in general conformance with established timber harvest schedules, and are connected by a network of existing forest roads. Four major BPA high voltage transmission lines, located in two corridors, cross the site. Canopy species within these two corridors have been removed, and areas are managed to be devoid of shrub and tree species. The project site contains a network of roads ranging in width from

approximately 8 to 20 feet. These roads are currently used to support logging activity and to access BPA transmission lines.

5 “Adjacent” refers to defined as non-SDS lands that were within 1.8 mile of the proposed turbine strings and/or the two known northern spotted owl management areas (Mill and Moss Creek) north of the project site.

3-34

A Williams Northwest natural gas pipeline is located on the northern edge, their natural compressor station is located to the west, and cellular towers and communications facilities are located nearby. Resource mining in the area has left rock pits in places. As a result, the project area includes no native habitat and is permanently committed to use by commercial forestry operations and utility infrastructure.

Comment: SO, where are the cumulative impact analyses for this apparently industrialized area? If all of this man-made infrastructure exists in this area, surely there are cumulative impacts and they must be considered in the broader context of cumulative regional impacts and effects of further industrialization—and a wind farm is an industry.

Initial habitat, vegetation, and special status plant surveys were conducted within the Project site in 2003. Environmental assessments included a pre-field information review and field surveys designed to classify habitats and identify special status plants that may occur within the project site. Supplemental habitat, vegetation, and special status plant surveys were conducted in 2009.

3.4.1.2 Habitats

Habitat maps were created using DNR orthophotos from January 2002 and classified using the USFS Classification System (USFS 1985). Habitat maps were field-verified during the 2003 survey season. These data were entered into a GIS database and used to calculate the total acres of each habitat type that would be crossed by the proposed project elements. The results of the habitat survey are provided in the Vegetation Technical Report (Appendix C-1).

Five vegetation communities and wildlife habitats were identified within the project site:

- Grass-forb stand (recent clearcuts)
- Brushfield/shrub stand
- Conifer-hardwood forest
- Conifer forest
- Riparian-deciduous forest

All five of the vegetation communities are part of a mosaic of habitat that comprises a commercial forest operation, as discussed in Section 3.4.1.1. Because of these man-made conditions, which result in frequent and repeated disturbance, the quality and value of the forest is generally considered low. Native tree species are used in timber production; however, they are not allowed to become mature forests prior to harvesting. Stand structure also is considered to be

low quality with limited undergrowth of a few species. Weeds are present, especially in clear cuts, which are eventually cleared for regeneration. Patch size of forests are generally small, and bisected by numerous roads, transmission lines and other facilities for logging. Timber harvest rotations are ongoing; therefore, future quality of the habitat on the project site is also considered low.

Grass-Forb Stand

Grass-forb stands are defined as habitats where shrubs comprise less than 40 percent crown cover and are less than 5 feet tall (USFS 1985). This stand type typically occurs when a natural or anthropogenic disturbance such as a wildfire, wind, or timber harvest results in the removal or death of the majority of large trees, or when brushfields are cleared for planting. These habitats

3-35

may be devoid of vegetation, or covered by herbaceous grasses and forbs. Tree regeneration in grass-forb stands is typically less than 5 feet tall and 40 percent crown cover. Grass-forb stands within the project site are located primarily in recently clearcut harvest areas. Vegetation in these areas is minimal and consists predominantly of weedy herbaceous species, including bull thistle (*Cirsium vulgare*), Canada thistle (*Cirsium arvense*), and dandelion (*Taraxacum officinale*). Coarse woody material, occasional slash piles, and large areas of bare ground are common in these areas.

Brushfield/Shrub Stand

Brushfields are defined as the shrub-dominated habitats (USFS 1985). These habitats typically develop following clearcut harvest, or natural disturbance that may result in removal of vegetation.

The majority of brushfields are young plantations that have been planted with Douglas-fir. The plantations typically have not reached the closed-canopy stage. Vegetation consists of remnant forest understory species, such as vine maple (*Acer circinatum*), Sitka alder, beaked hazelnut (*Corylus cornuta* var. *californica*), serviceberry (*Amelanchier alnifolia*), oceanspray (*Holodiscus discolor*), bracken fern (*Pteridium aquilinum*), sword fern (*Polystichum munitum*), and early successional species such as Himalayan blackberry (*Rubus armeniacus*), fireweed (*Epilobium angustifolium*), common yarrow (*Achillea millefolium*), pearly everlasting (*Anaphalis margaritacea*), and grasses. Large amounts of bare soil, slash and other logging debris are common.

Vegetation control has occurred in some areas as part of existing forest management practices. Control methods include herbicide application and/or mechanical control. Areas where vegetation management has occurred are visually and functionally different from areas where control has not been implemented. In areas where vegetation control has not occurred, dense vine maple thickets with occasional alder or Douglas-fir frequently occur. Patches of alder saplings, salmonberry (*Rubus spectabilis*), vine maple, red elderberry (*Sambucus racemosa*),

oceanspray, lupine (*Lupinus* spp.), Oregon oxalis (*Oxalis oregana*), and grass also may be present in these areas. Small diameter coarse woody material is common.

Conifer-Hardwood Forest

Conifer-hardwood forests within the project site are predominantly characterized by the presence of bigleaf maple and Douglas-fir, with some red alder. The forest stand condition is characterized as a multi-layer, closed sapling-pole forest (USFS 1985). Canopy height ranges from 40 to 60 feet, and canopy closure is between 60 and 80 percent. The majority (~70 percent) of canopy cover results from the presence of Douglas-fir. The shrub layer is characterized by vine maple, salmonberry, thimbleberry (*Rubus parviflorus*), red elderberry, beaked hazelnut, and Pacific dogwood. Density of the shrub layer is variable. The herbaceous layer is characterized by sword fern, trailing blackberry (*Rubus ursinus*), oxalis, grasses, and moss. Coarse woody material is generally low to moderate. Deciduous snags are more common than conifer snags; however, short well-decayed conifer snags may be present.

3-36

Conifer Forest

Coniferous forests located within the project site are dominated by grand fir and Douglas-fir. Forest stand condition is primarily closed sapling-pole-sawtimber and large sawtimber. The diameter at breast height of pole-size conifers measures 8–12 inches. The diameter at breast height of sawtimber measures 12 to 23 inches. Closed sapling-pole-sawtimber stands are characterized by closed canopy, relative short live crowns, and exclusion of shrub species and many forb species. Coarse woody material in these stands is typically low, consisting mainly of remnants from historic forests. Snags are rare; however, small diameter snags become more common in the pole and sawtimber stages, as smaller individuals are out-competed.

Large sawtimber is considered to be at least 21 inches diameter at breast height. Large sawtimber stands are characterized by within-stand differentiation of canopy species, the emergence of dominant trees, and a more diverse and multilayer understory composed of shrubs and forbs. Snags and coarse woody material are generally rare; however, this may vary depending on past harvest practices, stand management, and actual stand age. The majority of coniferous forests within the project site is managed for commercial timber production, and is replanted following harvest. Commercial timber lands are widespread throughout the vicinity of the project site.

Riparian Deciduous Forest

Riparian deciduous forests may develop in near-stream areas as a result of natural or anthropogenic disturbance. Riparian deciduous forest habitats are present within the project site in an area known as “Cedar Swamp.” Historically this area was dominated by large, old-growth western redcedar (*Thuja plicata*); however, these trees have since been harvested. Cedar Swamp is now dominated by willow (*Salix* sp.) and cottonwood (*Populus balsamifera*), with scattered occurrences of young western redcedar. Cedar Swamp is discussed further in Section 3.4.1.3.

The vegetation communities described above are common throughout the Southern Washington Cascades Province. In the proposed project site, these communities are maintained primarily through forest management. Because the project is located within private commercial timber lands, existing forest management practices are expected to continue for the foreseeable future. The total acreage of each habitat type was calculated during the 2003 surveys; however, because of active forest rotation schedules, some of these areas have been harvested. Aerial photos from 2009 were used to update the habitat maps from 2003 with recent timber harvests (Figure 3.4-1). The updated acreages of each habitat type can be found in Table 3.4-1.

Grass-forb, brushfield/shrub, and conifer forest habitat types are present along West Pit Road. However, the band along the road that is within the project bounds is too narrow to map on Figure 3.4-1.

Table 3.4-1
Habitat Types within the Project Site

Habitat Type
Area
(acres)
Grass-Forb Stand 522
Brushfield/Shrub Stand 103
Conifer-Hardwood Forest 310
Conifer Forest 209
Riparian Deciduous Forest 8
Total 1,152

In addition, the Washington Department of Fish and Wildlife (WDFW) Priority Habitats and Species database was searched for the area in and around the project site. No sensitive habitat features such as snags, talus, or Oregon white oak were identified in or within one mile of the project site. The project site is not located within any known wildlife corridor, flyway, foraging area, or migratory route.

Comment: Just because “the project site is not located within any known wildlife corridor, flyway, foraging area, or migratory route” does not mean that these do not exist on site. The whole Columbia Gorge region is a well known bird migration route so why would this area be exempt. Flying predators love ridges and ridges are where SDS proposes to put whirling death

blades which probably won't do the predators much good. I'm sure the Audobon Society will be glad to provide SDS and BPA with facts and figures on migrating birds.

3.4.1.3 Wetlands

No wetlands or wetland indicators were identified within the project site study area (the turbine corridors and proposed access roadways). One wetland was identified outside the study area perimeter west of turbines C1-C4 (Figure 3.4-2). This wetland is labeled as "Cedar Swamp" on the USGS map and is listed as palustrine unconsolidated bottom, semi-permanently flooded, impounded (PUBFh) on the National Wetland Inventory (NWI) (Appendix C-2).

Cedar Swamp is classified as a Category II wetland according to the Washington State Wetland Rating System for Eastern Washington (Ecology 2004). The standard wetland buffer for Category II wetlands enforced by Skamania County is 100 feet. The Cedar Swamp wetland is over 150 feet from the nearest proposed turbine string or proposed road.

A preliminary review of the NWI was conducted for the area encompassing the construction access. Results indicate that wetlands occur along SR 14 near White Salmon, Washington (Figures 3.4-3a and 3.4-3b). The NWI does not show the presence of wetlands along any of the local secondary and forest roads proposed to be used by the project. As the NWI is based on historic aerial photography interpretations, field investigations were conducted in May and July 2009. These investigations confirmed that wetlands do not occur along the local secondary and forest roads. See Section 3.3 for a discussion of surface water features such as streams.

3.4.1.4 Special Status Plant Species

Several sources were used to identify special-status plants that have been documented or have the potential to occur within the vicinity of the proposed project, including:

- Listed and Proposed Endangered and Threatened Species and Critical Habitat; Candidate Species; and Species of Concern in Skamania County (USFWS 2009a)
- A Washington Natural Heritage Program (WNHP) record search of known special status plant locations in the vicinity of the project site (WNHP 2003a and 2009)
- Rare Plant List for Skamania County (WNHP 2003b and 2009)

These data indicated that no federal-listed plant species are known to occur in the vicinity of the project site. However, four WNHP sensitive plants occur within 2 miles of the project site, including branching montia (*Montia diffusa*), Suksdorf's desert parsley (*Lomatium suksdorfii*), Siskiyou false hellebore (*Veratrum insolitum*), and golden chinquapin (*Chrysopsis chrysophylla*). Two additional special status plant species are reported as historically occurring in the vicinity of the project site, including bolandra (*Bolandra oregana*) and white-top aster (*Sericocarpus rigidus*). Three occurrences of the Oregon white oak/Idaho fescue (*Quercus garryana*/*Festuca idahoensis*) vegetation community, a WNHP high-quality plant community, are documented within 2 miles of the project site (WNHP 2003a and 2009). These are located along the Columbia and White Salmon Rivers.

Initial surveys were conducted in May and June 2003, and followed methods described in the US Bureau of Land Management Survey Protocols for Survey and Manage Strategy 2 Vascular Plants (Whiteaker et al. 1998). Survey dates were selected to encompass all or a portion of the blooming times of all special status plants potentially occurring in the project site. Surveys were conducted within a 300-foot corridor centered on proposed turbine strings and associated access roads, and a 100-foot corridor centered on existing roadways that were identified as needing improvement (Figure 3-4-4). Special status plant surveys also were conducted in proposed locations for the Operations and Maintenance facility, substation, and staging areas. During the 2003 surveys, no special status plant species or plant communities were detected on the project site. A detailed account of survey methods and results, as well as a list of plant species observed during vegetation surveys, can be found in Appendix C-3.

Because turbine locations were changed from the initial alignment, field surveys conducted prior to the March 2009 Application submittal did not cover 100 percent of the proposed project area. Additional surveys were conducted in May and July 2009 to supplement the previous studies and included West Pit Road and underground cable routes where potential special status plant habitat could exist (Figure 3.4-4). During this survey, two WNHP Watch List species were observed within the project area: phantom orchid (*Cephalanthera austiniiae*) and gnome plant (*Hemitomes congestum*). Watch List species are afforded no protection by any agency. Most species on the Watch List are no longer actively tracked because they were found to be more abundant than previously thought.

Figure 3.4-4

Job No. 33758687 2003-2006, 2009 Rare Plant Survey Areas

3.4.1.5 Special Status Wildlife Species

Seven special-status wildlife species are known to occur within the vicinity of the proposed project: bald eagle (*Haliaeetus leucocephalus*) golden eagle (*Aquila chrysaetos*), northern goshawk (*Accipiter gentilis*), pileated woodpecker (*Dryocopus pileatus*), Vaux's swift (*Chaetura vauxi*), olive-sided flycatcher (*Contopus cooperi*) and western gray squirrel (*Sciurus griseus*). One species, the northern spotted owl (*Strix occidentalis caurina*), has been surveyed extensively within the project area and never detected and is therefore considered not to occur. Two additional special status species, Keen's myotis (*Myotis keenii*) and Townsend's big-eared bat (*Corynorhinus townsendii*), may occur but have not been identified in prior surveys. These species are summarized in Table 3.4-2. This section provides a detailed account of each species, their status within the project area, and a summary of surveys conducted within the project area.

Bald Eagle

The bald eagle is a state and federal species of concern, and also protected under the Bald Eagle Protection Act of 1940 (16 United States Code [USC] 668-668d, 54 Stat. 250) which prohibits the taking, possession and commerce of such eagles. In Washington, bald eagles are year-round residents. In addition, many bald eagles from northern areas migrate south to Washington during the winter. In Washington they occur generally in coastal waters or near large inland lakes or

ivers. They are considered “fairly common” during the winter near the project site, but likely occur nearby year round (BirdWeb 2009). The Columbia River is approximately two miles south of the project site, and the White Salmon River is approximately three miles east of the project site. These are the two nearest likely foraging locations for bald eagles. One bald eagle was recorded on the project site in 2009 during surveys for northern goshawk. In addition, three

3-45

bald eagles were observed during the winter of 2008–2009 during baseline avian surveys. Two were observed flying within the rotor-swept area, and one below.

Golden Eagle

The golden eagle is a Candidate under the Endangered Species Act and also protected under the Bald Eagle Protection Act of 1940 (16 USC 668-668d, 54 Stat. 250) which prohibits the taking, possession and commerce of such eagles. In Washington, golden eagles are year-round residents, primarily in the eastern part of the state. The project area is at the westernmost edge of their year-round distribution, where they are considered “uncommon” (BirdWeb 2009). Golden eagles require open areas with large, rocky cliffs or large trees. They are often found in alpine parkland and mid-elevation clear-cuts, as well as shrub-steppe area and open forests. Although they soar at high altitudes, they drop down to the ground to capture prey. They prey on mid-sized mammals such as marmots, rabbits, ground squirrels, and birds.

Two golden eagles were recorded during the fall of 2004. The timing of this observation was consistent with localized or longer distance migration of this species in the fall. One was observed flying at a height within the rotor-swept area, and one was observed flying above the rotor-swept area. None were recorded during the summer of 2006 during baseline avian studies in the project area, which is consistent with the project site being outside of the species breeding distribution.

Comment: So, bald eagles and golden eagles, both under protection from the Federal government, were observed in the project area. They could be subject to lethal harm from the whirling blades of the turbines. Where is the de minimis analysis of any “taking” that would result from this project?

There is a troubling attitude among some of the public and among some officials that it’s okay if birds get killed because energy is being produced and we humans need energy. Well, it’s not okay if birds get killed. There are cumulative impacts to the entire food chain when predators are killed off. Trophic cascade effect anyone? We humans do not exist on this planet in a vacuum. Everything and all life and life’s processes are interconnected.

Northern Goshawk

The northern goshawk is categorized as a “species of concern” by the USFWS, and as a “listing candidate” for sensitive, threatened or endangered species by the State of Washington. Goshawks inhabit a wide variety of forest habitats, including true fir (red fir, white fir, and subalpine fir), mixed conifer, lodgepole pine, ponderosa pine, Jeffrey pine, montane riparian

deciduous forest and Douglas-fir. Goshawk nest sites tend to be associated with patches of relatively large, dense forest; however, home ranges often consist of a wide range of forest age classes and conditions. Nest sites tend to be positively correlated with proximity to water or meadow habitat, forest openings, level terrain or “benches,” northerly aspects and patches of larger, denser trees, although variation in habitat associations does occur (USFS 2002). Although they inhabit and hunt dense forest sites, they also hunt in open areas. They hunt on the wing, and by swooping down on ground-dwelling prey.

In Washington State, goshawks occur year-round and in some areas only during the non-breeding seasons. The project site is located in an area where either may occur, and the eastern slope of the Cascades is considered the most common place to find this “uncommon” species (BirdWeb 2009). This species is generally non-migratory. Some birds move to lower elevations in the winter.

Northern goshawks were recorded during avian surveys during the fall of 2004 and the summer of 2006. A total of five individuals were sighted; two during the fall and three during the summer (Figure 3.4-5). They were observed flying both within and above the rotor-swept height during surveys. Results of these surveys are detailed in Appendix C-4.

3-46

In response to the baseline data, and in order to better understand these sightings, the Applicant commenced multi-year, species- and season-specific biological surveys for Northern Goshawk. These surveys were developed based on best available survey protocols described below, and in consultation with WDFW. Northern goshawk surveys were conducted during the spring and summer seasons in 2004, 2008, and 2009, which are the time of year when goshawks would be most expected to occur. Surveys occurred on properties managed by SDS, Broughton Lumber and adjacent private land.

In 2004, protocol-level surveys were conducted in suitable habitat located in four core project sections, including the provincial home range radius of 0.5 mile around the core area (see Map 7, Appendix C-5). Suitable habitat was identified using topographic maps and aerial photography. Survey stations were established at 0.2-mile intervals on roads and trails located in suitable habitat within 0.5 mile of a proposed wind turbine location. Potential goshawk habitat was surveyed in accordance with “Survey Methodology for Northern Goshawks in the Pacific Southwest Region” (USFS 2002). Two rounds of surveys were completed, including 185 calling stations each time. All raptor species responses detected during surveys also were recorded. No Northern Goshawks were recorded during the 2004 surveys. Detailed methodology and results for northern goshawk surveys can be found in Appendix C-5.

In 2008, the potential survey area for the northern goshawk was determined by protocol parameters outlined in the Northern Goshawk Inventory and Monitoring Technical Guide (USFS 2006), consultation with WDFW biologists, and GIS analysis. The survey area was established by placing a 150-foot buffer around the turbine string layout, and then adding an additional 2,624 foot buffer per protocol (see map in Appendix C-6). Forest stands with greatest potential to contain suitable habitat structure and composition to support northern goshawk were identified

using GIS data and aerial photographs. Criteria for selecting stands included stand age greater than 25 years, and an average tree diameter at breast height of at least 12 inches. Based on these criteria, 1,100 acres was identified for surveys (Figure 3.4-5).

It was determined that the "Broadcast Acoustical Survey" methodology would be used for a two-year survey effort (2008 and 2009). Biologists completed two protocol surveys at 136 calling stations during the 2008 goshawk survey season. The first survey was conducted during the nesting period, and the second during the fledgling period. No northern goshawk responses were documented during either of the two site visits in 2008. In 2009, in addition to the two rounds of Broadcast Acoustical Surveys, two rounds of "Intensive Search" surveys were completed. These surveys were conducted where the turbine alignment extended north from prior project design. No goshawks were recorded during either type of surveys in 2009. Detailed methodology and results for 2008 can be found in Appendix C-6. The full methods and results for the 2009 surveys can be found in Appendix C-7.

3-47

Figure 3.4-5

Job No. 33758687 2008-2009 Northern Goshawk Survey Locations

Northern Spotted Owl

The Applicant conducted surveys and analysis to confirm the absence of northern spotted owls or spotted owl activity centers in the vicinity of the proposed project. Additionally, the Applicant coordinated and met with USFWS regarding its surveys and analysis for the northern spotted owl.

On April 9, 2009, the Applicant met with the USFWS to discuss the proposed project. On May 14, 2009, the USFWS met the Applicant at the site for a site visit. On July 13, 2009 and September 14, 2009, the Applicant met with USFWS to further discuss the studies that have been performed for northern spotted owl. This section documents all the information that Whistling Ridge Energy LLC obtained from its discussions with USFWS and the surveys and analysis conducted by SDS.

As detailed below, extensive surveys indicate that neither northern spotted owls nor northern spotted owl activity centers are present in or around the proposed project area. In addition, the project would not be located within a habitat area designated as critical or identified as essential to owl recovery. Given the extensive survey record confirming the absence of northern spotted owls, the proposed the Project will not pose a risk of taking northern spotted owls under the Endangered Species Act Section 9 and its regulations (50 CFR § 17.3).

Northern Spotted Owl Distribution and Status

The northern spotted owl is one of three spotted owl subspecies, and the only one found in

Washington State. They are distributed from extreme southwestern British Columbia to northern California. In Washington State, they inhabit the Eastern and Western Cascades, Western Lowlands and Olympic Peninsula Provinces. Within these regions, northern spotted owls are associated with a variety of areas containing suitable habitat for nesting, roosting, foraging and dispersal. They prefer forest habitats characterized by multi-layered canopy and a high incidence of large trees that provide suitable structure for nesting and roosting. They have large home ranges and use large tracts of land containing late successional forests. Fragmented forest habitats may be used for dispersal and foraging. They will nest in stick nests of northern goshawks, on clumps of mistletoe, in large tree cavities, on broken tops of large trees, or on large branches or cavities in bands and rock faces.

Northern spotted owls are designated as threatened under the Endangered Species Act (16 USC §§ 1531-1544), as well as under Washington State law (WAC 232-12-297). Because they are listed under the Endangered Species Act, USFWS has designated northern spotted owl critical habitat and issued a northern spotted owl recovery plan (USFWS 2008). In addition, the Endangered Species Act prohibits the “take” of northern spotted owls, which includes modifying habitat in a manner that impairs significant behavioral patterns and results in actually killing or injuring an animal (50 CFR § 17.3).

As described in detail below, the project is not located within habitat designated as critical or identified as essential to northern spotted owl recovery. In addition, the owls prefer forest habitats characterized by multi-layered canopy, and a high incidence of large trees that provide suitable structure for nesting and roosting. No such forests are present within the project site. Most importantly, however, extensive surveys following USFWS protocol indicate that the

3-49

project is not sited in or near northern spotted owls or spotted owl activity centers. Two historical nesting sites on public lands near the property have not been used in over six and eight years, respectively, and are therefore no longer considered occupied site centers pursuant to USFWS protocol and state law. Based on these facts, this analysis concludes that northern spotted owls will not be “taken” by the proposed project.

Survey History and Description

The Applicant contracted with Turnstone Environmental Consultants (Turnstone) to conduct wildlife investigations on the proposed project site. Surveys were conducted in 2003, 2004, 2008 and 2009, and all surveys followed the Protocol for Surveying Proposed Management Activities that May Impact Northern Spotted Owls (USFWS 1992). In addition, the National Council for Air and Stream Improvement (NCASI) surveyed historical activity centers near the project site each year since 1994, the last six years of which were under contract with the DNR. These surveys were conducted in support of an ongoing owl demography monitoring study and, while focused on the same activity centers, placed more emphasis on the nest cores. Table 3.4-3 summarizes the survey results.

Table 3.4-3

Whistling Ridge Energy Project Site Survey Results for
Northern Spotted Owl at the Mill Creek Core Areas

Year	Mill Creek Core Survey Results	Moss Creek Core Survey Results
	Spotted Owl	Barred Owl

2008	no response male & female observed	observed
	no response pair observed	
2004	no response present*	no response present*
2003	no response present*	no response no response

* = Surveyor unable to determine sex of barred owl detected.

Project Area Surveys. Surveys were conducted in suitable habitat located in and adjacent to the proposed project site, and included two historical spotted owl activity centers, discussed in further detail below. Suitable habitat was conservatively defined as stands with 12-inch diameter at breast height and greater with a canopy cover of 60 percent or greater⁶. Suitable habitat was identified using topographic maps, aerial photography, and stand classification data from Whistling Ridge Energy LLC. Figure 3.4-6 indicates the location of survey calling stations.

⁶ Features that support nesting and roosting typically include a moderate to high canopy closure (60 to 90 percent); a multilayered, multi-species canopy with large overstory trees (with diameter at breast height greater than 30 inches); a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections, and other evidence of decadence); large snags; large accumulations of fallen trees and other woody debris on the ground; and sufficient open space below the canopy for spotted owls to fly (Thomas et al. 1990.)

3-50

33758687_159.cdr

Figure 3.4-6

Job No. 33758687 2008-2009 Spotted Owl Calling Points

During the 2003–2004 survey periods, the project site was surveyed from March–July 2003 using the one-year survey methodology, and from March–August 2004 using the two-year survey methodology. USFWS protocol allows a six-visit survey followed by three-visit survey over two years to rule out northern spotted owls for the following two years (USFWS 1992). No northern spotted owls were detected during the 2003–2004 surveys. See Maps 1 through 5 in Appendix C-5 for 2004 survey locations.

More recent northern spotted owl surveys were conducted from May–July 2008 and May–August 2009 (Appendices C-6 and C-7). Surveys were conducted using the USFWS protocol two-year survey methodology, which requires a minimum of three visits for two consecutive

years in order to determine presence or absence (USFWS 1992). Surveys were implemented in all potentially suitable habitat located within a 1.8-mile radius of the corridor. This area totaled 14,901 acres. The survey area also included the historical activity centers discussed below, which expanded the survey area by 7,222 acres. No northern spotted owls were detected in either the survey area or historical activity centers in the 2008–2009 surveys.

The project's proposed layout was finalized in October 2008 and included additions to proposed turbine strings, removal of previously proposed turbines, and identification of areas requiring improved roadways. Changes to the project layout resulted in lands added to the project area that, in some cases, were not included in wildlife surveys conducted prior to October 2008. The final turbine alignment did expand the area requiring owl surveys; however, because the survey area had included spotted owl activity centers located at the northern reach of the proposed project site, the area was accounted for in the 2008 and 2009 surveys.

Historical Activity Centers. Two historical northern spotted owl activity centers, Mill Creek (master site no. 0991) and Moss Creek (master site no. 1003), are located near the project site (Figure 3.4-6). The nest cores of both activity centers are located on public lands managed by DNR and USFS. The Mill Creek activity center is composed of contiguous but scattered northern spotted owl habitat located on private and DNR lands. This site was designated in 1992, and the last known spotted owls were a non-nesting pair seen in 2000 (Table 3.4-4 and T. Flemming, personal communication.). Since 2000, neither the surveys conducted by Whistling Ridge Energy LLC nor DNR/NCASI have found northern spotted owls.

The Moss Creek activity center is composed of patchily distributed northern spotted owl habitat and a mix of rural residential lands, industrial timberland, and lands administered by DNR and USFS. This activity center was established in 1994 and the last known spotted owl was a male detected in 2002 (Table 3.4-4). Since that time, the Turnstone and DNR surveys have not resulted in any detections.

The longstanding absence of any northern spotted owls at these locations suggests that these historic site centers likely no longer qualify for special protection. As of January 1, 2009, a site center is defined under WAC as the location of status 1, 2 or 3 northern spotted owls, where status 1 means a male and female owl pair (i.e., observed in proximity to each other, a female detected on a nest, or one or both adults observed with young); status 2 means a male and female owl where pair status cannot be determined; and status 3 means either (a) "the presence or response of a single owl within the same general area on three or more occasions within a breeding season" where there is no response by an owl of the opposite sex after a complete

3-52

survey, or (b) three or more responses over several years (WAC 222-16-010). Only sites documented in substantial compliance with WDFW protocols and quality control methods will be considered site centers (WAC 222-16-010).

Source: Washington Department of Natural Resources (T. Flemming, personal communication).
2003-2008 surveys conducted by
NCASI pursuant to DNR contract; 2000-2002 survey data provided to DNR by NCASI.

No surveys—whether in substantial compliance with WDFW protocols or otherwise—have documented status 1, 2 or 3 owls on the Mill Creek or Moss Creek sites since January 1, 2009, when the new rule became effective. Furthermore, the Turnstone and DNR/NCASI surveys affirmatively documented the absence of northern spotted owl site centers at these locations. Therefore, the Mill Creek and Moss Creek locations do not meet the definition of a site center under Washington regulations. Even if they did, they should qualify for decertification under the interim decertification rules passed by the Washington Forest Practices Board⁷.

Similarly, the USFWS protocol allows a historical activity center to be considered unoccupied if no owl responses are obtained after three years of surveys using protocol guidelines (USFWS 1992). These surveys do not need to be consecutive; the protocol anticipates that surveys will be conducted in one- or two-year increments (not three). In any case, however, the DNR/NCASI surveys of the Moss Creek and Mill Creek centers were conducted annually and obtained no responses over six and eight years, respectively. Based on the collective Turnstone and DNR/NCASI surveys, these centers should therefore be considered unoccupied pursuant to the USFWS protocol.

Barred Owl Concerns. During the 2003–2004 and 2008–2009 project area surveys described above, only barred owls were detected. In addition, Whistling Ridge Energy LLC learned that the USFWS is in the process of revising its protocol for 2010 to include special guidance for conducting surveys where barred owls are detected. After the 2008 surveys, the Applicant consulted with USFWS, and was instructed to follow existing survey protocol (K. Berg, personal communication). The Applicant did so, but also incorporated USFWS’s suggestion that

⁷ See Washington State Register 09-02-202 (amending WAC 222-16-080(6)(b) (re-promulgated in Washington State Register 09-10-012 [April 24, 2009]) (emergency rule effective for 2009 calendar year establishing “spotted owl conservation advisory group” to determine whether

northern spotted owl site center need be maintained based on surveys demonstrating absence of the owls).

3-53

biologists visit core areas during the day to look for northern spotted owls, which might not respond in the presence of barred owls. Biologists conducted three day-time site visits over the seasonal breeding window in 2009 but did not detect any northern spotted owls.

NSO Habitat Designations

Federal and state habitat designations can be useful in characterizing the importance of certain areas to spotted owl life cycles and recovery. In this case, as described in the subsections below, the project would not be located in the areas designated as most critical to northern spotted owls or identified as essential to their recovery. The project would be located within a state-delineated management area, but the absence of a site center means that management restrictions would not be applicable to the project site.

Managed Owl Conservation Area and Designated Critical Habitat Area. The USFWS released its Final Recovery Plan for the Northern Spotted Owl in 2008 (USFWS 2008), which recommends a network of habitat blocks, or managed owl conservation areas (MOCAs), on federal lands in the west-side provinces in the northern spotted owl range. MOCAs were designated to correspond to the owl's full geographic distribution. The recovery plan's strategy focuses on managing MOCAs to support self-sustaining populations of 15 to 20 spotted owl pairs, as well as spacing and managing areas between MOCAs to permit owl movement between and among MOCAs (USFWS 2008). The revised critical habitat designation, also issued in 2008, concluded that the MOCA network is "sufficient to achieve the recovery" of northern spotted owls and designated only those lands as critical (73 Federal Register page 47,328). The project site is not located within, adjacent to, or between federally designated MOCAs or, therefore, corresponding designated northern spotted owl critical habitat (Figure 3.4-7).

Conservation Support Area. In the final recovery plan, USFWS delineated Conservation Support Areas (CSAs) to support designated MOCAs. CSAs are areas between or adjacent to MOCAs where habitat contributions made by private, state or federal land managers "are expected to increase the likelihood that [spotted owl] recovery is achieved, shorten the time needed to achieve recovery, and/or reduce management risks..." (USFWS 2008). In Washington State alone, the USFWS delineated 2,163,453 acres as CSA habitat.

The proposed project site is located within the Klickitat CSA, a 425,114-acre mix of private, state and federal lands (Figure 3.4-7). The project site's location within a CSA does not mean that spotted owls are present in the project area, or that modification of the area will compromise owl recovery. As the USFWS explained in excluding CSAs from designated critical habitat, "although recognized as potentially helpful in achieving recovery plan goals, these areas were not considered essential to the conservation of the species" (73 Federal Register page 47,331). Although CSAs are not unimportant, the recovery criteria for northern spotted owl populations "do not require the contributions of [CSAs] as an essential component of recovery" (USFWS

2008). Moreover, to the extent CSA lands provide an important function in supporting the MOCA network, it is worth noting that the project site constitutes just 0.27 percent of Klickitat CSA lands and 0.053 percent of Washington CSA lands.

3-54

Project Area

Figure 3.4-7

Source: 2008 Final Spotted Owl Recovery Plan (USFWS 2008). Map of Spotted Owl MOCAs and CSAs

Spotted Owl Special Emphasis Area. In 1996, Washington State finalized a rule identifying ten spotted owl special emphasis areas (SOSEAs) to complement protections provided by the Northwest Forest Plan. The proposed project is located in the southernmost portion of the White Salmon SOSEA which, like the Klickitat CSA, was delineated with the goal of providing demographic support (WAC 222-16-086[10]). In such areas, any suitable spotted owl habitat should be maintained (WAC 222-10-041[1]). More specifically, all suitable habitat within 0.7 mile of a site center plus 2,605 acres (approximately 40 percent) of suitable habitat within the median home range circle (a 1.8 mile radius) is assumed necessary to maintain the site center's viability (WAC 222.10.041[4]). This 40 percent suitable habitat level corresponds with USFWS research on the level of habitat necessary to avoid take and support recovery⁸. According to DNR, both the Mill Creek and Moss Creek site centers exceed 40 percent of the suitable habitat⁹.

The proposed project will not alter that fact. Therefore, the SOSEA limitations on habitat use or modifications do not restrict use of the project site as a wind turbine energy facility (WAC 222.10.041[4]). Forest practices within a SOSEA are therefore allowed to proceed so long as they do not affect the 40 percent suitable habitat threshold.

Habitat Conservation Plans. A review of USFWS habitat conservation plans issued in the Pacific region indicates that there are no spotted owl-related habitat conservation plans applicable in or near the project area (USFWS 2009b).

The Applicant has sited the proposed project to avoid habitat areas deemed critical to northern spotted owls or essential to their recovery. Surveys conducted pursuant to USFWS protocol indicate that spotted owls are not present in or near the project, and that nearby historical sites are no longer occupied pursuant to USFWS protocol or state law. Because there are no spotted owls or activity centers present in the project area, no project impacts to northern spotted owls are expected. Finally, the project would not affect the White Salmon SOSEA's 40 percent suitable habitat level and therefore is not restricted by Washington's forest practice regulations. Given the extensive record and review, this project does not pose a risk of taking northern spotted owls under The Endangered Species Act Section 9.

Olive-Sided Flycatcher

The olive-sided flycatcher is considered a federal species of concern. This species occurs in forest habitat and adjacent cleared areas such as burned areas or clear cuts. They perch high in treetops and catches insect prey on the wing in cleared areas. They breed in Washington State and also migrate through during August to areas in South America. The olive-sided flycatcher is considered a fairly common breeder in the area encompassed by the project site (BirdWeb 2009). There were 21 birds observed during summer 2006 avian surveys, and six recorded during the spring of 2009. All 21 observed in 2006 were within the rotor-swept area; it is not reported in 2009 how many were in the rotor-swept area. None were recorded during the fall of 2004 or the winter of 2008–2009 (Appendix C-4).

8 See 61 Federal Register 21,426, 21,428 (May 10, 1996) (proposed 4(d) rule for northern spotted owls setting 40 percent target); USFWS (2008) Appendix C at 77 (targeting 35–40 percent).

9 Data provided by DNR which shows Mill Creek at 48 percent and Moss Creek at 55 percent (J. Herman, personal communication)

3-56

Pileated Woodpecker

The pileated woodpecker is considered a Washington State Candidate for listing. This species occurs in all forest types as long as large trees exist for nesting and foraging. Old-growth and mature forest therefore are a common association. In Washington, pileated woodpeckers occur year round but are uncommon in the vicinity of the project site. They are more common west of the Cascades. During avian surveys in the project area, six pileated woodpeckers were recorded in the fall, two during the winter, seven during the spring, and none in the summer. None occurred within the rotor-swept area (Appendix C-4).

Vaux's Swift

Vaux's swift is considered a Washington State Candidate for listing. It typically occurs in coniferous or mixed forest of mature age where snags are available for roosting and nesting. They forage for insects in flight in open sky, typically above woodlands or bodies of water. In Washington, Vaux's swift breeds widely, and the project site is considered within the range of common occurrence for the species. They migrate south during the fall. During fall 2004 avian surveys, 15 Vaux's swifts were recorded in three groups, 87 percent of which occurred within the rotor-swept area. Four were recorded in two groups during the summer of 2006, all of which occurred within the rotor-swept area. Eleven were recorded during the summer of 2009; the number within the rotor-swept area was not reported in this study (Appendix C-4).

Western Gray Squirrel

The western gray squirrel is listed as a “threatened” species by WDFW. In Washington, western gray squirrel distribution has been reduced to three geographically isolated populations: the “Puget Trough” population, centered in Thurston and Pierce counties, the “South Cascades” population, located in eastern Skamania County, Klickitat and Yakima Counties, and the “North Cascades” population, located in Chelan and Okanogan Counties. Western gray squirrels are arboreal species. Although they forage on the ground, this species rarely strays far from trees. They use tree canopies for cover and nesting. Western gray squirrels prefer areas where contiguous tree canopy allows arboreal travel in a minimum of a 198 feet (60 meters) radius around the nest (Ryan and Carey 1995). Western gray squirrels are diurnal species, with most activity occurring during morning hours. This species is most active during August and September, when this species is collecting and storing food for winter (Ryan and Carey 1995). The principal food source for the gray squirrel is acorns; however, conifer seeds are also eaten (Dalquest 1948). While pine nuts and acorns are considered essential foods for accumulating body fat in preparation for winter, green vegetation, seeds, nuts, fleshy fruits, and mushrooms also are consumed (WDW 1993, Carraway and Verts 1994, Ryan and Carey 1995).

Western gray squirrel surveys were implemented by Whistling Ridge Energy LLC on lands located in and adjacent to the project site in 2004, 2008, and 2009 (Figure 3.4-8). Surveys conducted in 2004 included a general search for western gray squirrels and nests while conducting northern goshawk station placement and surveys. Two adult western gray squirrels were identified during that effort.

3-57

33758687_160.cdr

Figure 3.4-8
Job No. 33758687 Western Gray Squirrel Survey Areas

An additional protocol survey was completed following methods described in Surveys for western gray squirrel nests on sites harvested under approved forest practice guidelines: analysis of nest use and operator compliance (Van der Haegen et al. 2004). No western gray squirrels were detected during protocol surveys. Detailed methodology and results for western gray squirrel surveys in 2004 can be found in Appendix C-5.

Additional western gray squirrel surveys were completed by Whistling Ridge Energy LLC in 2008 and 2009. Prior to implementing field surveys, the Applicant consulted with a WDFW biologist to identify survey criteria and methodology. It was determined that gray squirrel surveys should be performed in areas where project activities would result in the removal of potential western gray squirrel habitat or structural modification (i.e., stand thinning), and these surveys should include unaltered habitat within 400 feet of potential disturbance.

An area consisting of a 1,050-foot buffer around the proposed turbine layout to account for lands that may be affected by the project, and also the 400-foot buffer of undisturbed lands, was identified for potential survey. This area included 1,420 acres; however, only 738 acres were identified as potentially suitable to support western gray squirrel (Figure 3.4-8). Surveys were

conducted following methods described by Van der Haegen, Van Leuven, and Anderson (2004). Surveyors searched for individuals and nests, focusing mainly on gray squirrels, but also noting other species. When possible, historical use by western gray squirrels was determined. No gray squirrels or nests were detected during these surveys in 2008 or 2009. Detailed methodology and results can be found in Appendices C-6 and C-7.

Keen's Myotis

Keen's bat is considered a Washington State Candidate for listing. In Washington, this species is recorded as occurring on the Olympic Peninsula and Cascade Mountains (BCI 2009). The project site is likely on the very edge of the distribution range for Keen's myotis. Although little is known about this species, it is believed to rely on old-growth forests. Keen's myotis likely roosts in tree cavities and forages in dense coniferous forests. Bat surveys conducted during 2007, 2008, and 2009 (Appendices C-8, C-9, and C-10) did not have the ability to detect individual species of bats. Instead, bats are grouped into species with either "high-frequency" calls or "low-frequency" calls. Keen's myotis is considered part of the "high-frequency" group. Based on the lack of detailed information of this species life history and habitat requirements and nature of the bat surveys conducted it is difficult to conclude with certainty what the likelihood of Keen's bats occurring on the project site. However, due to the lack of old-growth or mature forest types within the project area and the predominant commercial forestry use of the property, the likelihood of occurrence on the site is considered to be low.

Townsend's Big-Eared Bat

Townsend's big-eared bat is a federal species of concern and a Washington state candidate for listing. Its distribution spans the western US, and occurs primarily in desert scrub and pine forest regions (BCI 2009). In the spring and summer, females form maternity colonies in mines, caves or buildings. In winter they hibernate in caves and abandoned mines. These maternity and roosting locations are sensitive to disturbance. It forages after dark in upland areas. Bat surveys conducted on the project site during 2007, 2008, and 2009 (Appendices C-8, C-9, and C-10) did not have the ability to detect individual species of bats. Instead, bats are grouped into species

Comment: This is inadequate data and analysis and should be redone using the best available science techniques to gather enough data on this particular species so that a thorough analysis of its habitat and numbers can be made.

3-59

with either "high-frequency" calls or "low-frequency" calls. Townsend's big-eared bat is considered part of the "low-frequency" group. Based on lack of detailed information on this species distribution and the nature of the bat surveys conducted on the site, it is difficult to conclude with certainty the likelihood of Townsend's big-eared bats occurring on the project site. There are no known roosting structures or maternity colonies occurring in the vicinity of the project area. Consequently, the likelihood of occurrence on the site is considered to be low.

3.4.1.6 Other Wildlife Species

In addition to studies of special status species, other studies of birds and bats at the Project site have been ongoing since 2004. Birds were surveyed during all seasons of the year in the fall of 2004, summer of 2006, winter 2008–2009 and spring of 2009. Results are summarized in Appendix C-4.

Bats were surveyed during the fall of 2007, summer–fall of 2008 and summer–fall of 2009. Results of those studies are presented in Appendices C-8, C-9 and C-10. The timing of these surveys is expected to capture the peak of bat use during the breeding season (summer) and migration (fall). Information on the potential for other taxonomic groups to occur on the project site is based on general distribution and habitat requirements for individual species.

Birds

Avian surveys were conducted on the project site across all seasons in multiple years. There were: 53 surveys during the fall migration period (September 11 to November 4, 2004), 45 surveys during the breeding/nesting season (May 15 to July 14, 2006), 47 surveys during winter and 116 surveys during spring (December 4, 2008 to May 29, 2009).¹⁰

Study protocol followed methods described by Reynolds et al. (1980). An 800-meter circular plot was centered on each observation point (Figure 3.4-9). All observations, behavior, and flight patterns of birds in and near plots were recorded. Flight patterns, such as direction of travel and flight altitude also were recorded.

Observations of birds beyond the 800-meter radius were recorded; however, these data were analyzed separately from data collected from survey plots. The location of raptors, other large birds, or species of concern observed during counts was recorded on field map. A list of all birds recorded on the project site (including those during special status species surveys) is provided in Table 3.4-5. Appendix C-4 contains full results of fall 2004, summer 2006, winter 2008-09 and summer 2009 surveys.

¹⁰ In its 2003 Energy Overlay Environmental Impact Statement, Klickitat County also included two survey locations at or in proximity to the Project site. These included surveys during the spring and summer 2003 seasons. See Appendix B to the Klickitat County Energy Overlay Draft Environmental Impact Statement (Kennedy/Jenks Consultants 2003).

A total of 87 species were recorded during avian surveys. Passerines (songbirds) were the most abundant avian group overall. American robin, dark-eyed junco and white-crowned sparrow were the three most frequently observed birds across all seasons. Mean overall bird use in the study area was low compared to these other wind resource areas studied; ranking 19th compared to 24 other wind resource areas (Figure 9 in Appendix C-4). Eleven species of raptors were observed: American kestrel, bald eagle, Cooper's hawk, golden eagle, northern harrier, northern goshawk, osprey, prairie falcon, red-tailed hawk, sharp-shinned hawk, and turkey vulture. Red-tailed hawk was by far the most observed raptor, followed by Cooper's hawk and sharp-shinned hawk. Mean annual raptor use was 0.28 raptors per plot per 20-minute survey, which is a standardized way to measure use in order to compare results to avian use at other sites. This

3-63

annual rate is low relative to raptor use at 36 other wind-energy facilities that implemented similar protocols and had three or four season surveys. Mean raptor use in the study area was low compared to these other wind resource areas; ranking 29th compared to 36 other wind energy facilities (Figure 7 in Appendix C-4).

Fall Migration Surveys (2004)

General avian surveys identified 39 species of bird in the survey area (Figure 3.4-9). Passerines (songbirds) were the most abundant avian group, constituting 87.4 percent of observations. This group was observed with the greatest frequency (94.4 percent of surveys). Raptors were the second most abundant group observed; however, this group represented only 4.9 percent of observations. Raptors were observed during 38.5 percent of the surveys, followed by woodpeckers (22.6 percent of surveys) and doves/pigeons (9.3 percent of surveys).

The most common species at the project site included dark-eyed junco, American goldfinch, Steller's jay, common raven, and white-crowned sparrow. The species of birds most frequently observed during fall surveys were common raven, Steller's jay, dark-eyed junco, red-breasted nuthatch, and golden-crowned kinglet. Eight species of raptor were observed during the survey. Those with the highest use of the site were sharp-shinned hawk, Cooper's hawk, and red-tailed hawk. The highest raptor use observed at the site during 2004 surveys occurred between September 11 and October 12, 2004. These data do not indicate that any areas within the proposed site have substantially higher raptor use than others.

No federal or state listed endangered or threatened avian species were observed during the survey period. Four state candidate species were observed: golden eagle, northern goshawk, pileated woodpecker, and Vaux's swift. Two State Monitor species were observed, including four single turkey vultures and four groups totaling 27 western bluebirds. Detailed results and summary tables can be found in Appendix C-4.

Summer Surveys (2006)

Fifty-five species of birds were observed during summer breeding and nesting surveys in 2006 (Figure 3.4-9). Passerines were the most abundant group (88.5 percent), followed by raptors and woodpeckers (3.3 percent each), and doves/pigeons (3.2 percent). The most frequently observed groups were passerines (100 percent of surveys), woodpeckers (35.6 percent of surveys), and raptors (31.1 percent of surveys). Species with the highest use of the project site included white-crowned sparrow, red crossbill, western tanager, spotted towhee, and MacGillivray's warbler. The most frequently observed species included white-crowned sparrow (77.8 percent of the surveys), western tanager (75.6 percent of surveys), spotted towhee (64.4 percent of surveys), MacGillivray's warbler (48.9 percent), and dark-eyed junco (48.9 percent). Three species of raptors were observed, including red-tailed hawk, northern goshawk, and sharp-shinned hawk. Raptor use in the fall was only slightly higher than during the summer breeding season. The data do not indicate that any portions of the project site have substantially higher raptor use than other areas. For all bird species combined, use of the project site by avian species was slightly higher during the summer breeding season than during the fall migration period. Detailed results and summary tables can be found in Appendix C-4.

3-64

Winter/Spring Surveys (2008-2009)

Fifteen species of birds were observed during winter surveys in 2008–2009, and 65 species during the spring of 2009. In winter, observations were dominated by common raven, American robin, and unidentified finches. The number of species and number of individuals observed in the spring were the highest across all seasons. Similar to other seasons, passerines were the most abundant group, followed by woodpeckers and then raptors. Individual species with the highest use included American robin, dark-eyed junco and yellow-rumped warbler. The data do not indicate that any portions of the project site have substantially higher raptor use than other areas. Detailed results and summary tables can be found in Appendix C-4.

The WDFW Priority Habitats and Species database was searched for known occurrences of raptor nests. The only recorded nest was for an osprey, more than one mile east of the project site.

Bats

Bat acoustic studies were conducted for the Project in 2007, 2008 and 2009. Detailed information on these investigations can be found in Appendices C-8 (2007), C-9 (2008) and C10 (2009).

Bat acoustic studies conducted from 2007 through 2009 were implemented at various locations on the project site. The goal of the studies were to: (1) characterize the local bat populations in a variety of habitats, (2) identify areas of high usage by bats, and (3) characterize the frequency of bat usage of areas representative of where turbine strings would be located. Studies were done across several seasons to estimate annual variation during breeding and periods of migration.

For all studies, passive Anabat® II echolocation detectors coupled with Zero Crossing Analysis Interface Modules (ZCAIM; Titled Electronics Pty Ltd., NSW, Australia) were used in all survey years. Anabat detectors record bat echolocation calls using a broadband microphone. Bat species are generally grouped into those that emit low frequency (<35 kHz) or high frequency (= 35 kHz) calls. The units of activity equaled the number of bat passes, and were used to calculate the number of bat passes per detector night (Hayes 1997). The data thus indicate the level of bat activity rather than absolute abundance.

In 2007, detectors were placed at two locations from August 20 through October 21 (Figure 1 in Appendix C-8). The 2007 studies were intended to provide a general census of bat activity in recently reforested or young forest areas. This type of habitat is similar to what would be found in the areas within 150 feet of the proposed turbines, on the two sides of the turbines. The northernmost detector was located just outside the proposed turbine corridor. This detector was initially placed at ground level; however, it was raised to a height of 130 feet (40 meters) on September 7. The southernmost detector was located outside the project site; however, it was placed in habitat believed to be representative of that found on the project site. The southernmost detector was placed at ground level, and remained at that location for the duration of the study.

Due to equipment failures in 2007, both Anabat detectors were only operable for 24 percent of the sampling period, amounting to 45 detector-nights. Bat activity was similar between north and south ground level Anabat units (mean = 11.67 ± 2.0 and 9.6 ± 4.1 , respectively). Bat

3-65

activity recorded after the northern Anabat detector was elevated was much lower (mean = 2.47 ± 1.1) than that recorded at ground level. A list of bat species with potential to occur on the project site based on range maps, divided between high-frequency and low-frequency species, can be found in Table 3.4-6.

Status Codes:

FCo – Federal Species of Concern
SC – State Candidate
SM – State Monitor

The bat acoustic survey effort was increased to four locations during the 2008 survey period, and the survey period covered July 3 to October 7, 2008. This period corresponded with summer breeding and fall bat migration. Four survey locations were used, all on the ground (Figure 1 in Appendix C-9). Two were located in clear cuts (SB1 and SB4), one immediately adjacent to a wetland (SB2) and one in a road corridor (SB3). Sampling at the wetland was intended to characterize bat occurrence a location known to have a high level of usage, because wetlands are frequently used as foraging and drinking habitat for bats. Similarly, sampling in the road corridor was intended to capture the highest levels of use within the project site, because road corridors are frequently used by bats to travel between roosting and foraging locations. The two clear cut sites were most representative of the types of habitat where turbines would be located for the proposed project. However, because all detectors were located on the ground, sampling did not entirely capture the potential bat use of the rotor-swept area.

Table 3.4-7 summarizes bat activity at all survey locations. During the 2007 and 2008 surveys, the two clear cut sites (SB1 and SB4) had an average of 14.30 and 73.76 bat passes per night, respectively. The wetland (SB2) and road corridor (SB3), recorded much higher levels of use, at

178.03 and 327.25 bat passes per night, respectively. Seasonal activity patterns were similar for the two clear cut survey locations, with the highest bat activity occurring during the months of July and August. Bat activity in the wetland area was highest during the month of July. In comparison to 2007, bat numbers were on average higher because in 2007 this peak use period was not captured during the sampling period (in 2007 sampling did not begin until August 20).
3-66

Table 3.4-7

Average Bat Detections Per Night During Three Survey Years

Year	Location	Habitat	Ground or Elevated	Average per Detector Night
2007	North Young forest	G	11.67	
	North Young forest	E	2.47	
	South Young forest	G	9.60	
2008	SB1	Clear cut	G	14.30
	SB2	Wetland	G	178.03
	SB3	Road corridor	G	327.25
	SB4	Clear cut	G	73.76

2009 WR1 Clear cut G 17.28
WR2 Clear cut E 10.59
WR3 Young forest G 11.04
WR4 Young forest E 1.53
WR5 Clear cut G 6.43
WR6 Clear cut E 1.64

In 2009, the bat survey efforts were further refined to focus specifically on the types of locations where turbines would be sited. Three locations were selected (Figure 3.4-10), two in clear cuts and one in a recently reforested area (young forest). In addition, each sampling location had a pair of Anabat detectors; one on the ground and one elevated on a meteorological tower. The elevated detectors were intended capture bat use in what would likely be the rotor-swept area, which is where potential bat-turbine collisions would occur. The ground level detectors were intended to provide some comparison to prior year studies, most of which were done at ground level. The numbers of bat detections in 2009 are summarized in Table 3.4-7.

In general, elevated detectors recorded fewer bats than their ground level counterparts, indicating that bat occurrence within the rotor-swept area is lower than those at lower flight elevations. For all years (2007–2009), elevated bat detections were the lowest numbers recorded, between 1.53 and 10.50 bat passes per night. All bat detections in 2009 were collected by Anabat equipment installed in locations most representative of potential turbine locations. The detections were notably lower than some of the other records in 2008 taken from equipment placed in areas of known high bat use.

Amphibians and Reptiles

Amphibians and reptiles likely to occur on the project site are those species that can tolerate disturbance associated with managed timber activities and drier-than-average conditions for at least part of their life cycle. This includes such common species as Long-toed salamander (*Ambystoma macrodactylum*), Rough-skinned newt (*Taricha granulose*), Ensatina (*Ensatina eschscholtzii*), Pacific treefrog (*Pseudacris (=Hyla) regilla*), and northwestern garter snake (*Thamnophis ordinoides*). Breeding may occur within the intermittent drainages located in the northeast corner of the site, within cedar swamp, or substantial roadside drainage ditches. These species may stray further from water sources during heavy rains or during winter conditions.

Figure 3.4-10

33758687_162.cdr

Figure 3.4-10

Job No. 33758687 2009 Bat Survey Locations

Mammals

Several large mammals have the potential to occur within the project site. Known priority

wildlife habitats, including mule deer and black-tailed deer (*Odocoileus hemionus*) winter range, are present east of Underwood Mountain, extending to lands to the north/northeast. Winter range for Columbia black-tailed deer is present in lands west of Underwood Mountain, and extends north and south from the project site. Elk (*Cervus elaphus*) winter range is present throughout the project site. Other species likely to occur throughout the region include cougar (*Puma concolor*), bobcat (*Lynx rufus*), coyote (*Canis latrans*), and black bear (*Ursus americanus*). Douglas squirrels (*Tamiasciurus douglasii*) were recorded during surveys for the western gray squirrel.

Fish

No fish have been documented within the project site. The project is on a ridgeline between Underwood Mountain and the White Salmon River, approximately 3 miles north of the Columbia River. The ridgeline is oriented in a north-south direction. The Columbia River receives runoff via the White Salmon drainage area east of the site and via the Little White Salmon River west of the site. The White Salmon River contains evolutionarily significant units and designated critical habitat for three species listed as threatened under the Endangered Species Act: (1) Lower Columbia River Chinook, (2) Middle Columbia River Steelhead, and (3) Columbia River Chum (Figure 3.4-11).

A tributary to Little Buck Creek is located in the northeast portion of the project site. This tributary is typed as a non-fish-bearing stream. No special status fish species are present in Little Buck Creek. However, Buck Creeks drains into Northwestern Lake, which in turn drains into the White Salmon River.

West Pit Road crosses an unnamed drainage. This stream had observed flow through the existing culvert under West Pit Road at the time of the July 2009 field visit. However, the surface flow and the channel disappear downstream of the culvert. There is no surface water connection to Lapham Creek or the Little White Salmon River. Fish are not present in this stream.

3.4.1.7 Noxious Weeds

The project site contains several noxious weed species, which are nonnative, invasive plants. The weed species observed during field visits to date are listed in Table 3.4-8.

The Washington Noxious Weed Control Board identifies lists of noxious weed species that require control, eradication, or monitoring. Class A noxious weeds are nonnative species with a limited distribution within a state and require eradication to reduce the potential of becoming more widespread.

3-69

33758687_163.cdr

Figure 3.4-11

Job No. 33758687 Designated Critical Fish Habitat

Table 3.4-8
Noxious Weed Observations

Scientific Name	Common Name	Status
<i>Centaurea stoebe</i>	Spotted knapweed	Class B - Designate
<i>Cirsium arvense</i>	Canada thistle	Class C - Designate
<i>Cirsium vulgare</i>	Bull thistle	Class C
<i>Cytisus scoparius</i>	Scot's broom	Class B - Designate
<i>Daucus carota</i>	Queen Anne's lace	Class B
<i>Hypericum perforatum</i>	Common St. John's-wort	Class C
<i>Leucanthemum vulgare</i>	Ox-eye daisy	Class B
<i>Linaria dalmatica</i>	Dalmatian toadflax	Class B - Designate
<i>Rubus armeniacus</i>	Himalayan blackberry	Class C
<i>Senecio vulgaris</i>	Common groundsel	Class C

Class B noxious weeds are regionally abundant, but may have limited distribution in some counties. In Washington, in regions where a Class B noxious weed is unrecorded or of limited distribution, prevention of seed production is required. In these areas the weed is a "Class B designate." However, in regions where a Class B species is already abundant or widespread, control is a local option. In these areas the weed is a "Class B non-designate."

Class C noxious weeds are already widely established, but placement on the state list allows counties to enforce local control if desired. Skamania County has designated a few Class C weeds. Within the project boundary, only Canada thistle (*Cirsium arvense*) is a designated Class C weed.

3.4.2 IMPACTS

This section identifies the potential impacts to biological resources as the result of both construction and operation of the proposed project.

3.4.2.1 Proposed Action

Skamania County Critical Areas Ordinance Regulation

The Skamania County Critical Areas Ordinance recognizes the following as critical areas: watershed protection areas (including wetlands, streams, creeks, rivers, ponds and lakes); critical aquifer recharge areas; fish and wildlife habitat; frequently flooded areas; and geologically hazardous areas (including landslide hazards, erosion hazards and volcanic hazards). All critical areas have a required no-touch buffer setback based on the classification of the critical area, as set forth in Skamania County Critical Areas Ordinance Title 21A. All buffers are undisturbed buffers and must be free of any logging, road building, or other development activities including, but not limited to, vegetation removal, grading, filling, mowing, or placement of structures. The project would not affect any critical areas or buffers.

Comment: Skamania County has failed to update its Title 21A Critical Areas Ordinance, to date. They began the process in 2006 and have not managed to get an updated Critical Areas Ordinance done, and this is 2010. There are new, updated Best Available Science and Best Management Practices that are not in Skamania County's Title 21A. Skamania County has also not updated its Title 21 Zoning, having failed to ram through a version that would have industrialized Skamania County. The version supported by the Skamania County commission was soundly rejected after appeals to the Hearings Examiner, who issued a 37-page decision (see attachment) stating that the county could not implement the commissioners' zoning unless they did an Environmental Impact Statement. The county declined—that is the reason they punted (and circumvented the public) Whistling Ridge a.k.a. Saddleback to EFSEC.

3-71

Construction

Habitat Types

Construction and operation of the project would require the removal of vegetation in some areas to accommodate roadway construction and improvement, turbine siting, staging, and construction. The impacts of project construction would not differ substantially from customary forestry activities on the site. Each turbine footing and foundation would measure approximately 3,100 square feet. Vegetation surrounding each turbine would be managed according to the following specifications:

- A circular area extending 50 feet from each turbine tower base would be harvested and graveled
- From 50 feet to 150 feet from the base of the turbine towers, tree heights would be limited to 15 feet above the elevation of the base of the turbine
- From 150 feet to 500 feet from the base of the turbine towers, tree height would be limited to 50 feet above the turbine base within an area formed by a 90 degree arc centered on the ordinary downwind direction (Figure 2-4 in Chapter 2)

The A and F turbine strings and parts of the B and C turbine strings would be accessed by existing roads. Modifications to these roads are anticipated in order to support the long and heavy loads required for delivery of the wind turbine systems. An estimated 5.1 miles of roads within the project site would require improvements as a result of the proposed project. The majority of new roads would be constructed to access parts of the B and C turbine strings, and all of the D and E turbine strings. Access to these turbines would require 2.4 miles of new roadway. All roads used to access turbines would be maintained throughout the life of the project.

All vegetation clearing would be completed using crawler tractors, rubber-tired skidders, mobile feller-bunchers, or cable yarding equipment. This equipment is typically used in timber harvest, and is currently used to harvest other stands located on SDS property. Logs would be transported by truck to SDS facilities in Bingen, Washington. Except for permanently cleared areas, cleared areas would be replanted with trees within one year following completion of construction (typically the following spring). Areas where trees are permanently removed would

be replanted with appropriate native grasses and low-growing shrubs. Because trees would be cleared for the purpose of the project, cleared areas would be considered “forest conversion” under the Washington Forest Practices Act. However, cleared areas would still be reforested in accordance with typical commercial forestry management practices when feasible. Permanent and temporary impacts to habitat types within the project site can be found in Tables 3.4-9 and 3.4-10.

West Pit Road was widened in the summer of 2009. Additional road improvements would be required during the construction phase of the project. However, the loss and modifications of habitat types from these modifications are anticipated to be minor. Tables 3.4-9 and 3.4-10 show that temporary and permanent impacts of the project to the habitat types found on the site and along the portion of West Pit Road that would be improved.

- a. Total permanent impact area of proposed development within the 650-foot corridor measured on either side of an imaginary line connecting each turbine string.
- b. The permanent impact area of proposed roadway modifications within the project site area encompassed by a 100-foot corridor along all roads. Does not include overlap of transmissioncorridor or turbine corridor. Also excludes existing roadway.
- c. The permanent impact area of proposed development within the area encompassed by a 100-foot corridor along all project transmission lines. Does not include overlap of road corridor or turbine corridor.

d. The permanent impact area is based on the assumption that the existing roadway is 20 feet wide, the new roadway would be 25 feet wide, and that an additional 5 feet on each side of the roadway would be permanently cleared.

3-73

Wetlands

No wetlands or wetland buffers are located within the project footprint. Therefore, no wetlands or buffers are expected to be affected by construction of the project.

A review of the National Wetland Inventory indicates that wetlands may occur along SR 14 but not along County or private roads proposed for the project's construction access and turbine delivery routes. No improvements to SR 14 are anticipated to be required, and therefore no wetland-related impacts would occur. Roadway improvements to the County or private logging roads are not expected to affect wetlands. This information was confirmed through field investigations performed in May and July 2009.

See Section 3.3 for a discussion of impacts to other surface water features such as streams.

Special Status Plant Species

No federal- or Washington State-listed plant species have been documented at the site during multiple field surveys. Therefore, no project-related impacts are anticipated from construction of the proposed project. Two plant species on the WNHP Watch List, gnome plant and phantom orchid, were observed within areas that may be cleared for construction of the project. Both species are growing in areas that have been previously clearcut and were able to re-establish. In addition, there are no regulatory requirements to protect these species.

Special Status Wildlife Species

Potential construction related impacts to bald eagle, golden eagle, northern goshawk, northern spotted owl, olive-sided flycatcher, pileated woodpecker, Vaux's swift, western gray squirrel, Keen's myotis, and Townsend's big-eared bat are discussed in this section.

Bald Eagle. Four bald eagles were recorded on the project site. The project site is over two miles away from the nearest known bald eagle foraging habitat, which is the Columbia or White Salmon Rivers. Therefore bald eagle use of the project site is considered infrequent and sporadic. The removal of coniferous forest as a result of project construction that far away from suitable foraging habitat would not impact bald eagles. No breeding habitat would be affected.

Golden Eagle. Golden eagles have been recorded on the project site; however they are considered an uncommon visitor to this region of Washington State. They are known to forage in mid-elevation clear cut habitat. The permanent removal of 21.31 acres of grass-forb stand or shrub habitat for construction of turbine strings and transmission line corridors would decrease the amount of foraging habitat available to golden eagles within the project site. Any golden

eagles potentially using the project site for foraging would likely be temporarily deterred from using the site by construction vehicle and personnel activity.

Northern Goshawk. Northern goshawks were recorded on the project site. Although they were recorded during the summer, no evidence of nest or breeding individuals was observed during multiple years of surveys. A breeding goshawk may have a wide area of home range spanning multiple age classes of forest. They also may forage in open areas. Construction of the proposed project would result in the permanent loss of 21.86 acres of managed coniferous or mixed deciduous-coniferous forest. This would represent a loss of habitat generally suitable for goshawks, though unlikely to support breeding pairs. Goshawks also forage in open area, where

3-74

they swoop to the ground to capture prey. Approximately 17.13 acres of grass-forb habitat would be permanently lost during construction of the project.

Northern Spotted Owl. Whistling Ridge Energy LLC has sited its proposed project to avoid habitat areas deemed critical to the northern spotted owl or essential to its recovery. Surveys conducted pursuant to the USFWS protocol indicate that spotted owls are not present in or near the project, and that nearby historical sites are no longer occupied pursuant to USFWS Protocol and state law. Because there are no northern spotted owls or activity centers present in the project area, no project construction impacts are expected. Finally, the project would not impact the White Salmon SOSEA's 40 percent suitable habitat level and therefore is not restricted by Washington's forest practice regulations. Given the extensive record and review, this project does not pose a risk of taking northern spotted owls under Endangered Species Act Section 9.

Olive-sided Flycatcher, Pileated Woodpecker, and Vaux's Swift. These three avian species are all passerines with known occurrence within the project area. All three use coniferous forest for nesting. Construction of the proposed project would result in loss of 21.86 acres of forest habitat. Construction during the breeding season would likely result in disturbance of any individuals occurring in the vicinity, thereby temporarily reducing the use of further areas of habitat. Vaux's swift and olive-sided flycatchers forage on the wing over cleared areas, so it is likely that no additional habitat loss would occur for these species as the result of conversion of forested area to clearing (grass-forb stand).

Western Gray Squirrel. The construction of the proposed project would result in the permanent removal of 21.86 acres of managed coniferous or mixed deciduous-coniferous forest. The gray squirrel prefers habitat where contiguous tree canopy allows arboreal travel in a minimum of a 198-foot (60-meter) radius around the nest (Ryan and Carey 1995). Current forest management practices on forest within the proposed project site has created habitat not generally suitable for this species, due to fragmentation of mature forest stands. Contiguous forest habitat located on the project site will not develop in the future. The project site also contains very few oak trees, and those that were observed were of small stature (less than 20 feet tall), stunted, and growing in openings on exposed rocky slopes in shallow soils. Acorn crops from oak trees are an important food source for western gray squirrels, and the lack of this primary food source may deter use of the project site by gray squirrels. Because habitat for this species is considered rare

or of moderate/poor quality on the project site, impacts to western gray squirrel due to loss of coniferous forest habitat are expected to be negligible.

Keen's Myotis and Townsend's Big-Eared Bat. The special status bat species may occur in the project site, based on their documented distribution. Surveys for bats were not able to identify all bats to species level. Both species may utilize mature or old-growth forested habitats within the project area, if suitable nest sites were available. Permanent loss of 21.86 acres of forest habitat and 21.31 acres of shrub/grass/forb habitat may result in a small reduction of suitable habitat for these species. No known roosting or breeding locations would be impacted.

Other Wildlife Species

In general, wildlife in the project area could be affected by the construction of the Project through the loss of suitable habitat, potential fatalities during clearing or grading of the construction area, and disturbance/displacement from construction activity and personnel

3-75

occupying the site. Fragmentation of the remaining habitat also could occur, although current land management practices result in an existing source of ongoing fragmentation on the site. Therefore, permanent vegetation removal and temporary construction disturbance are the primary impacts as a result of the proposed project.

Birds. Direct mortality to birds and/or bird nests could occur during the initial clearing or grading of the construction areas. Additional disturbance could occur indirectly to birds or bird nests occurring adjacent to construction areas. This may occur if a nest or a primary foraging area is nearby. In areas where temporary disturbance would occur, it is anticipated that birds would generally reoccupy restored habitats with time. Some habitat would be permanently converted from one type (forest) to another (clear cut or grass forb). This would result in a temporary disturbance, likely followed by recolonization of the area by a different suite of birds.

Bats. Impact to bats as a result of construction would be minimal unless known nesting or roosting sites were removed. Disturbance or displacements to bats as a result of construction activities would be minimal because bats are primarily active during the night, when construction would not occur.

Amphibians/Reptiles. No wetlands or other surface water bodies are proposed to be filled as a result of the project. Therefore, no amphibian breeding habitat would be directly impacted. Amphibians and reptiles would potentially experience direct loss of non-breeding habitat and further fragmentation of the remaining habitats.

Mammals. No direct mortality of large mammals is anticipated as a result of construction because these species are able to relocate away from heavy equipment used in clearing and grading. Some avoidance of the area due to disturbance would likely occur on a temporary basis. Permanent removal of vegetation would result in the loss of some habitat for these species. The

conversion of one habitat type to another would likely not reduce the amount of area available to the more commonly-occurring species, which utilize multiple habitat types during their life cycle.

Fish. No impacts are anticipated from construction of the project. No perennial streams or fish are located within the construction areas within the project boundaries. In addition, the construction will occur when the ephemeral drainages that cross the access roads are dry. This will eliminate any potential impacts from sediment. The unnamed drainage on West Pit Road may be temporarily impacted if this segment of the road needs to be widened. However, no fish are present in this stream.

Comment: See my separate memo on the inadequacy of BPA's input into this DEIS and the most definite impacts on fish and their habitats.

Noxious Weeds

While no Class A weeds have been observed in the project area, several Class B and C weeds are present. Noxious weeds can threaten the general ecological health and diversity of native ecosystems. Noxious weed infestations are the second leading cause of wildlife habitat degradation.

Because many weeds are adapted to disturbed conditions and can establish immediately after construction, constructing the project could foster the spread of noxious weeds throughout the project area. Noxious weeds would be managed within the project site. By implementing BMPs, weeds are not anticipated to spread further as a result of the development of the project.

3-76

Operation

Habitats

Operation of the project would result in no further impacts to habitats on the project site.

Wetlands

No wetlands or wetland buffers are located within the project operation area. Therefore, no wetlands or buffers are expected to be impacted by operation of the project.

Special Status Plant Species

No impacts to special status plant species are anticipated from the operation of the project.

Special Status Wildlife Species

In order to determine which species (including special status species) are most at risk for turbine

fatalities, a relative index to collision risk (R) was calculated for bird species observed in the survey area using the following formula:

$$R = A * P_f * P_t$$

Where A = mean use for species i averaged across all surveys, P_f = proportion of all observations of species i where activity was recorded as flying (an index to the approximate percentage of time species i spends flying during the daylight period), and P_t = proportion of all flight height observations of species i within the rotor-swept height. This is a relative index, which only illustrates which species may be the most susceptible to turbine fatalities. For the Project, the exposure index ranges from 0.29 on the high end (red crossbill) to 0 for many species (indicating that they were recorded on the site but not flying within the rotor swept area. If a species was recorded on the site, but never flying at all, then the exposure index would not be applicable. Exposure indices for all species across all years of survey can be found in Appendix C-4.

This index does not account for differences in behavior other than flight characteristics (i.e., flight height and proportion of time spent flying). In this impacts section, point count data were used to establish diurnal indices of avian use, and how these indices compare to other wind resource areas in the United States.

Bald Eagle. Bald eagles, although now fairly common in Washington State, are likely uncommon visitors to the project site. They are unlikely to nest or forage within the project site because there is no suitable habitat. An exposure index of 0.02 was calculated for the bald eagle (Appendix C-4). The potential for ongoing occurrence of bald eagle on the project site is very low. The potential for bald eagle fatalities as a result of turbine strike is also considered to be extremely low.

Golden Eagle. Two golden eagles were recorded on the project site during the fall of 2004. One occurred within the rotor-swept area and one was above. The golden eagle's exposure index at Whistling Ridge is reported to be less than 0.01 (Appendix C-4). Therefore, golden eagles are considered to be at relatively low risk for collision with turbines at this site.

3-77

Golden eagles typically soar at a height within the rotor-swept area of most modern turbines, and swoop to the ground to capture prey. Golden eagles have recently experienced their first mortality at a wind turbine site in Washington State (Durbin 2009). Numerous golden eagles have been killed at the Altamont wind turbine project in California, indicating that this species is susceptible to turbine collision. Golden eagles have experienced mortality greater than would be anticipated based on their level of occurrence at Altamont Pass (Appendix C-4).

The creation of cleared areas re-vegetated with low growing herbaceous species around turbines may increase the risk of golden eagles entering the rotor-swept area if they forage for prey located beneath turbines. However, given their rare occurrence on the project site, the potential for golden eagles to experience a turbine collision is extremely low.

Northern Goshawk. Extensive surveys over four years recorded no goshawks on the project site, indicating that if they do occur, it would be extremely rare. Based on these years of species specific surveys using multiple methodologies, they were recorded more than would be expected during baseline surveys in 2004 and 2006. Based on those records, the exposure index for northern goshawk at the project site is reported to be 0.02. This includes the occurrence of five individuals, four of which were flying within the rotor swept area. Similar to the golden eagle, this species may be at risk of increased foraging activity in open areas around turbines because they hunt for prey that occurs on the ground in cleared areas. However, given their rare occurrence on the project site, the potential for turbine related fatalities for this species is extremely low.

Northern Spotted Owl. Whistling Ridge Energy LLC has sited its proposed project to avoid habitat areas deemed critical to the northern spotted owl or essential to its recovery. Surveys conducted pursuant to the USFWS protocol indicate that spotted owls are not present in or near the project, and that nearby historical sites are no longer occupied pursuant to USFWS Protocol and state law. Because there are no northern spotted owls or activity centers present in the project area, no project construction impacts are expected. Finally, the project would not impact the White Salmon SOSEA's 40 percent suitable habitat level and therefore is not restricted by Washington's forest practice regulations. Given the extensive record and review, this project does not pose a risk of taking northern spotted owls under Endangered Species Act Section 9.

Western Gray Squirrel. No impacts to western gray squirrels are anticipated from operation of the proposed project.

Olive-sided Flycatcher, Pileated Woodpecker, and Vaux's Swift. These three species are encompassed in the bird discussion under "Other Wildlife."

Keen's Myotis and Townsend's Big-Eared Myotis. These two bat species are encompassed in the bat discussion under "Other Wildlife."

Other Wildlife Species

Birds. Potential operation-related impacts to avian species include turbine collision and displacement. Based on the exposure index derived from abundance and flight behavior, the species most likely to collide with wind turbines located at the project are red crossbills ($R = 0.29$), American robin ($R = 0.14$), common raven ($R = 0.23$), and western bluebird ($R = 0.11$). The full list of species and their exposure index can be found in Appendix C-4.

3-78

The highest index for any raptor was 0.05 for red-tailed hawk, indicating a risk approximately six times lower than for the red crossbill. A regression analysis using data collected from the Whistling Ridge site and 13 other new-generation wind turbine projects found a significant correlation between raptor use and raptor mortality. Based on this analysis and surveys on the project site, the estimated a raptor/vulture fatality rate is zero per MW/year, which is an

extremely low estimate compared to many wind projects (Appendix C-4). Further, data collected from the project site indicate that the area is not within a major migratory pathway, at least during fall migration.

Comment: "...the area is not within a major migratory pathway, at least during fall migration."?!? What is this supposed to mean? That it might be a migratory pathway during other seasons. The entire Columbia River Gorge and its environs is recognized by Audobon and other reasoning people as a migration corridor for a large number of species. Ridges attract raptors. Turbines are sited on ridges. Turbines kill raptors. Not good. This contradictory DEIS statement should be clarified.

Vaux's swifts, western bluebirds (a State Monitor species), and olive-sided flycatchers were commonly observed flying at rotor-swept heights, and some turbine-related mortality may occur for these species over the life of the project. One prairie falcon and multiple turkey vultures (both State Monitor species) were observed at rotor-swept heights. Turkey vultures are known to have very low susceptibility to turbine collisions (Orloff and Flannery 1992). Pileated woodpeckers were recorded on the site, but not flying. Osprey (a State Monitor species) was recorded during northern goshawk surveys, which was separate from the baseline avian studies and therefore not included in the exposure index calculations.

These collisions would likely be rare, and it is unlikely that the Project would have any negative impacts on population levels on and near the project site. Higher numbers of Vaux's swifts and western bluebirds were recorded during fall migration, whereas olive-sided flycatcher appears to primarily use the project site for breeding.

Waterfowl, waterbirds, and shorebirds were not observed using lands within the project site during this study, and mortality involving this group is expected to be rare. Based on abundance, passerines are expected to make up the largest proportion of fatalities at the project. Post-construction mortality data collected at other wind projects in Washington and Oregon indicate that less correlation between pre-construction surveys and turbine-related mortality is observed in non-raptor species. The lack of correlation may be because most fatalities are among nocturnal migrants that are not accounted for during surveys.

The avian use information for the project site is based on detections of birds seen and/or heard calling. Because songbirds are less vocal during fall, this information may be skewed toward summer use. Similarly, the level of night migration for species associated with the project site is also not known. Risk analyses presented above provide some insight into which species are most vulnerable to turbine collision; however, estimates are based on abundance, proportion of daily activity budget spent flying, and flight height of each species. Observations were made during daylight hours, and do not take into consideration flight behavior or abundance of nocturnal migrants. Further, the analysis does not account for varying ability among species to detect and avoid turbines, habitat selection, or other factors that may influence exposure to turbine collision. As a result, actual risk may be lower or higher than indicated by these estimates (Orloff and Flannery 1992).

Bats. It is likely that some bat mortality would occur during operation; however, mortality

estimates are difficult due to our lack of understanding of why bats collide with wind turbines (Kunz et al. 2007, Baerwald et al. 2008). Several factors may aid in the assessment of potential impacts to bats, including site-specific habitat and topography, species composition, and activity

3-79

patterns. The following impact assessment was completed by examining site-specific habitat features and bat acoustic data collected to date. Additional insight from investigations conducted at other wind projects is presented where relevant.

The number of bat detections varied greatly between the three survey years. This is based on variation in habitat surveyed and the height of detector placement. Overall, the majority of detected species were low-frequency species, such as big brown and silver-haired bats. Hoary bats made up 8.2 percent of all passes by low-frequency species. Based on studies from other wind energy projects in the Pacific Northwest, turbine fatalities would be most expected from hoary bats and silver haired bats. Big brown bats are relatively uncommon at wind turbine fatalities. At elevated stations meant to reflect the rotor-swept area, low-frequency bats were again recorded in much higher numbers than high-frequency species. This likely reflects migration flight heights and foraging preferences.

The timing of peak bat activity on the proposed project site (portions of July and August) does not coincide with when the highest levels of bat mortality have been documented at other wind projects in the US. Fatality studies have shown a peak in mortality in August and September and generally lower mortality earlier in the summer (Johnson 2005, Arnett et al. 2008). While the survey effort varies among the different studies, the studies that combine Anabat surveys and fatality surveys show a general association between the timing of increased bat call rates and timing of mortality, with both call rates and mortality peaking during the fall (Kunz et al. 2007). The highest use of the project site occurred in July and August, prior to the time that most bat mortality occurs at wind resource areas in the Pacific Northwest as well as throughout the US.

High bat activity in July and August is likely due to use of the project site by local bats during the reproductive season, when pups are being weaned and foraging rates are high. Activity beyond mid-August likely represents movement of migrating bats through the area. Activity by hoary bats also was substantially higher in July, and dropped off significantly beginning in early August. After August 31, activity for all bats was very low relative to earlier dates, indicating that most bats had left the area for winter hibernacula or warmer climates. These data indicate higher use of the project site by resident populations of bats, rather than by migrants passing through the area. Further, high bat activity levels during the breeding season, as seen on the project site, do not equate to high bat fatality rates. Low mortality has been documented during the breeding season at several wind projects, even when relatively large bat populations were present in the area (Fiedler 2004, Gruver 2002, Howe et al. 2002, Johnson et al. 2004, Schmidt et al. 2003).

Finally, no known large bat colonies are present near the proposed the Project. The nearest known hibernaculum is located near the town of Trout Lake, nearly 20 miles north of the proposed project (B. Weiler, personal communication). The project site does not contain topographic

features, such as canyons, that may funnel migrating bats toward corridors where turbines would be placed. No turbines would be constructed near wetlands or ponds, and cleared areas surrounding turbine strings would closely mimic clearcuts or young reforested areas, where to date, recorded bat activity levels on the project site were the lowest.

3-80

Some bat fatalities are anticipated as a result of the operation of the proposed project. Variable levels of recorded use by bats across years, habitats and recording height above ground indicate that the extent of impacts is difficult to predict at this time.

Amphibians/Reptiles. No impacts are anticipated to amphibians or reptiles as a result of project operation.

Mammals. Because data on impacts to big game as a result of wind project operation is limited, it is difficult to predict the impact of the proposed project on wildlife using priority habitats on the proposed project site. Additional coordination with WDFW is ongoing, and would continue to address this resource.

Fish. No impacts are anticipated to fish as a result of project operation.

Noxious Weeds

The spread of noxious weeds is not anticipated to occur as a result of project operation with BMPs in place.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least 90 days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project's operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential changes to wetlands, vegetation, wildlife habitat, and noxious weeds. If impacts to biological resources are anticipated as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

3.4.2.2 No Action Alternative

Under the No Action Alternative the project would not be built. Timber harvest would still occur within the proposed project boundary, which would continue to affect habitats and potentially increase the spread of weeds. However, there would be no increased avian or bat

fatalities from turbine operations.

Other power generation facilities could be constructed and operated in the region to meet long-term needs for power, including other wind projects or generation using fossil fuels. Fossil fuel combustion would affect vegetation, wetlands, wildlife, and threatened and endangered species, including impacts related to carbon dioxide emissions. The significance of such impacts would depend on the site-specific locations and design of such facilities.

Comment: This is a totally inadequate (how many times will I have to use this word when referencing this very inadequate DEIS!) "No Action Alternative" analysis. SDS doesn't know that other generation facilities would be constructed and operated in the region—based on this DEIS, which might be a Waterloo moment for wind generation and wind farms in the region—it is also likely that wind power and its unpredictability might be reassesses and other methods of conservation found and used. There would be not "increased avian or bat fatalities from turbine operations, but there would also be less pesticide use, less impermeable surfaces built on erosion-prone ridges, less fragmentation of the environment, less impact on wildlife, less impact on humans, etc. There would be many more LESSES if this project wasn't built!!

3-81

3.4.3 MITIGATION MEASURES

- The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts to biological resources during construction and operation to the extent feasible.
- Avoid and minimize the use of overhead collector lines, which create areas where birds may congregate and perch, thus decreasing the potential for turbine collisions.
- Use of tubular turbine towers, avoiding the lattice type towers which creates areas where birds may congregate and perch, thus decreasing the potential for turbine collisions.
- Use of un-guyed meteorological towers, reducing the potential for bird collision with wires.
- Minimize the use of turbine lighting on the project site, thereby reducing the potential for birds and bats to be disoriented by lights or attracted to turbines.
- Install newer generation up-wind turbines.
- Utilize certified "weed free" straw bales during construction to avoid introduction of noxious weeds.
- Re-seed all temporarily disturbed areas with an appropriate mix of native plant species as soon as possible after construction is completed to accelerate the re-vegetation of these areas and to avoid the establishment and spread of noxious weed species.
- Implement a noxious weed control program, in coordination with the Skamania County Noxious Weed Control Board, to control the spread and prevent the introduction of noxious weed species.
- Conduct raptor nest surveys prior to construction during the breeding season (approximately April to July) in order to avoid or minimize impacts to any raptors potentially nesting on or near the project site. Construction activities requiring the surveys would include those that would remove forested areas and/or require the use of heavy equipment substantial enough to potentially disturb nesting activities.
- Implement a two year minimum post-construction avian mortality study.

- Convene a Technical Advisory Committee to evaluate the mitigation and monitoring program and determine the need for further studies or mitigation measures. The Technical Advisory Committee would be composed of representatives from WDFW, USFWS, Skamania County, and the Applicant. The role of the Technical Advisory Committee would be to coordinate appropriate mitigation measures, monitor impacts to wildlife and habitat, and address issues that arise regarding wildlife impacts during construction and operation of the project, including potential adaptive management

3-82

opportunities. The post-construction monitoring plan would be developed in coordination with the Technical Advisory Committee.

- Coordinate with WDFW for potential impacts to big game species (deer and elk), if appropriate.
- Prepare a SWPP for both the construction and operation phases of the project and submit to EFSEC for approval.

3.4.4 UNAVOIDABLE ADVERSE IMPACTS

The proposed project would result in permanent loss, temporary disturbance and fragmentation of existing habitat for a number of wildlife species. These impacts, while unavoidable, would take place in landscape of managed timber lands which has for many years and will continue to be a fragmented environment with ongoing disturbance. There are no impacts to wetlands, and any particularly sensitive areas would be avoided during micro-siting of the turbines.

The proposed project would cause mortality to birds and bats through turbine collisions. However, the level of mortality is not anticipated to be sufficient to negatively affect the population viability of any single species.

Comment: This is a really insufferably dataless, inane statement! "Anticipation" is not science. SDS doesn't know what level of mortality would be sufficient to affect or not affect any single species. Until they gather more data and do a thorough analysis of the regional effects of wind farms on species mortality, the DEIS is incomplete and flawed in regard to bird and bat mortality rates; and, the stated non-effects of turbine collisions on species viability is totally unfounded and unsupported by any data.

It appears unlikely that the project would cause any mortality to a threatened or endangered species. Extensive surveys for northern spotted owl and northern goshawk have been conducted throughout the project area and both species are considered either completely absent or extremely rare. Golden eagles were recorded during surveys in 2004, but not in more recent surveys. Bald eagles were recorded in the winter of 2008 and summer of 2009. The potential for ongoing occurrence of either golden or bald eagles is considered extremely rare.

3.5 ENERGY AND NATURAL RESOURCES

This section describes potential impacts to energy resources.

3.5.1 AFFECTED ENVIRONMENT

3.5.1.1 Region

Regional Demand

In September 2009, the Northwest Power and Conservation Council released the Draft Sixth Northwest Power Plan (NWPPCC 2009), which contains projections for regional power demand. The plan notes that regional population is likely to increase from 12.7 million in 2007 to 16.3 million by 2030. Demand for electricity is expected to grow, in part as a result of this population growth. The Draft Sixth Northwest Power Plan states:

The Pacific Northwest consumed 19,000 average megawatts or 166 million megawatt-hours of electricity in 2007. That demand is expected to grow to 25,000 average megawatts by 2030 in the Council's medium forecast. Between 2007 and 2030, demand is expected to increase by a total of 6,500 average megawatts, growing on average by 270 average megawatts, or 1.2 percent, per year.

The cost of energy of all types is expected to be significantly higher over the next twenty years than during the 1980s and 1990s. Cost increases will be driven by increasing demand and the fact that the cost of finding and producing new energy sources is higher than for existing supplies. Carbon emission taxes or cap-and-trade policies are likely to further raise energy costs. The Northwest Power and Conservation Council predicts that wholesale electricity prices are expected to increase from about \$45 per megawatt-hour in 2010 to \$85 by 2030 (2006\$).

Pacific Northwest Markets for Renewable Energy Resources

According to the Northwest Power and Conservation Council, much of the future demand for electricity in the region could be met through conservation. However, markets for renewable or "green" energy are still growing in the Pacific Northwest, and the Project can help to meet this growing demand. One driver for this shift is the establishment of RPS at the state level, which requires that utilities obtain a percentage of their power from renewable sources. For example, in 2006, voters in the Washington passed Initiative 937, which requires that by 2020 large public and private utilities must obtain 15 percent of their electricity from renewable resources, and undertake cost-effective energy conservation. In 2008, California increased its RPS goal from 20 percent to 33 percent renewable energy by 2020.

In addition to the RPS requirements, Washington law requires larger utilities in Washington to offer a voluntary "qualified alternative energy product," essentially an electricity product powered by green resources, beginning in January 2012 (RCW 19.29A.090). State law defines a qualified alternative energy resource as electricity fueled by wind, solar energy, geothermal energy, landfill gas, wave or tidal action, gas produced during the treatment of wastewater, qualified hydropower, or biomass. As of 2008, 15 of the 16 utilities covered by the report had an active green power program with customers participating, and five additional utilities not

covered by the law reported to the state that they were operating green power programs. Estimated sales of green power for 2008 were up 17 percent over 2007. Wind powered electricity represented 83.3 percent of green power sales (WUTC 2008).

Bonneville Power Administration Transmission System

BPA owns and operates 15,000 miles of power lines that carry power from the dams and other power plants to utility customers throughout the Pacific Northwest. The BPA service area includes Oregon, Washington, Idaho, Western Montana, and small portions of Wyoming, Nevada, Utah, California, and Eastern Montana.

Electric power plants require an interconnection with a high-voltage electrical transmission system for delivery to purchasing retail utilities. BPA owns and operates the FCRTS, which comprises more than three-fourths of the high-voltage transmission grid in the Pacific Northwest, and extra regional transmission facilities. BPA considers and grants interconnection requests to the FCRTS in accordance with its Open Access Transmission Tariff. Under BPA's tariff, BPA offers transmission interconnections to the FCRTS to all eligible customers on a first-come, first-served basis, with a decision on whether or not to make this offer subject to environmental review under NEPA.

Comment: If BPA owns and operates 15,000 miles of power lines, and BPA is concurrently proposing building bigger power lines throughout the NW, where is the cumulative impacts analysis on the environmental effects of 15,000 miles of power lines? Where is the human health cumulative analysis? Where is the cumulative impact analysis on wildlife—habitat fragmentation, habitat destruction, herbicide effects, etc.? From the DEIS we learn that BPA provides energy to a “service area includes Oregon, Washington, Idaho, Western Montana, and small portions of Wyoming, Nevada, Utah, California, and Eastern Montana” but this regional area is not included in any cumulative impacts analysis in this DEIS. Why not? BPA's energy production has cumulative effects on the environment, on ecosystems throughout their service area but there is no cumulative impact analysis reporting in this DEIS. This is another fatal flaw in this DEIS.

3.5.1.2 Project Area

The project would be located north of the Columbia River. The Columbia River corridor is an area of good wind energy potential that currently supports several successful wind power projects. The Columbia River Gorge provides a low-elevation connection between continental air masses in the interior of the Columbia Basin east of the Cascade Range and the maritime air of the Pacific Coast. Especially strong pressure gradients develop along the Cascades and force the air to flow rapidly eastward or westward through the Gorge.

Electric service for the project area is provided by Skamania County Public Utility District #1, which obtains electricity from the Federal Columbia River Power System (FCRPS), the series of hydroelectric projects along the Columbia River, through BPA. Backup power is obtained from Condit Dam, which is scheduled to be decommissioned in 2010. In July 2009 the Public Utility District sought intervener status with EFSEC to argue in favor of the Project, based on the ability

of the project to provide backup power to the Public Utility District once Condit Dam is removed (EFSEC 2009). There is currently no utility service of any kind at the proposed project site.

The proposed project area and the project site are already heavily used by energy and other utilities. Two BPA high-voltage transmission lines cross the project site, a natural gas pipeline runs near the north border of the project site, and there are two communications towers within one mile of the site.

3-88

3.5.2 IMPACTS

3.5.2.1 Proposed Action

Construction

The project would consume limited amounts of energy and natural resources, primarily during construction. The electrical substation would be built immediately adjacent to the BPA lines, reducing the need to build new long-distance high-voltage transmission lines.

Estimated types and quantities of energy and natural resources consumed during construction are as follows:

- 19,250 gallons of fuel (diesel and gasoline) for construction equipment
- 3,700 tons of steel for turbine towers
- 1,000 tons of steel for tower foundation reinforcement
- 100,000 yards of gravel (aggregate) for roads and crane pads
- 10,000 cubic yards of concrete for turbine foundations
- 1.7 million gallons of water for road compaction, dust control, wetting concrete, etc., assuming plain water is used for dust control (this amount could be reduced through the use of lignin or other dust palliative if permitted by EFSEC)

The source of fuel for construction equipment and vehicles would be licensed fuel distributors or gas stations. Petroleum products, including vehicle and equipment gasoline and diesel fuels, and machinery lubricants are available and would be purchased from numerous commercial outlets in the project vicinity. Water for construction would be obtained from a local source with valid water rights, as described in Section 3.3 Water Resources. Concrete would be purchased from existing suppliers located near the project site. Electricity for construction equipment would be provided from portable generators.

Bulk materials such as aggregate gravel and sand, in addition to soils, would be supplied locally from existing quarries. Other building materials, equipment, and other operational commodities would be purchased from equipment and material suppliers. The largest resource use would be steel and concrete. Diesel fuel and electricity also would be consumed during construction. The amounts of all of these resources would be small compared to existing supplies, and none are expected to affect availability or market supply.

Nonrenewable resources in the project vicinity are primarily gravel extracted from local sources

and used locally. Primary consumption of these resources is related to construction projects (sand, gravel, and other mineral resources as used in steel, aluminum, concrete, and other building products). Several gravel pits and quarries are located near the project site. These would be adequate to supply the needs of the project.

3-89

Renewable resources are materials that can be regenerated, such as wood, other fibers, wind, and sunlight. The primary renewable resources in the project area are timber and wind. The project area, including the project site, has been used for the renewable production of forest products for many years. The addition of the Project would diversify this renewable resource-based business by using a second, compatible renewable resource, the wind energy of the site. The project would shift approximately 56 acres of commercial forest land to non-forest uses for the project area roads and the turbine corridors. In the context of the 1,152-acre site and the large areas of surrounding area in private and Washington State timber management, this reduction would not affect the availability of timber as a renewable resource.

Operation

Operation of the project would consume limited amounts of energy and nonrenewable natural resources. During operations, electrical energy from Skamania County Public Utility District #1 would be consumed on a limited basis during times when the wind generated on site is insufficient to power warning lights required by the Federal Aviation Administration and security lights. Some electricity would be used at the Operations and Maintenance and substation facilities. In addition, turbines require electrical energy to run lubrication pumps and cooling systems, electrical monitoring systems, and position motors when wind speeds are below generation levels.

- Types and quantities of energy and natural resources consumed during operations are as follows:
- Fuel for operations and maintenance vehicles (approximately 8,500 gallons annually)
- Minor quantities of lubricating oils, greases and hydraulic fluids for the wind turbine generators
- Electricity for project operations (less than approximately 600 kilowatt hours per wind turbine generator per month)
- Water for use at the Operations and Maintenance facility and periodic maintenance of turbine blades (less than 5,000 gallons per day) Electricity for project operations would mostly be generated by the approximately 75 MW of electricity created by the project itself. Wind farms have a very high “energy payback” (ratio of energy produced compared to energy expended in construction and operation), and wind’s energy payback time is one of the shortest of any electrical generation technology. It takes approximately three to eight months, depending on the wind speed at the site, for a wind farm to produce the total amount of energy used to construct the equipment and build the project (AWEA 2007). The Project Proponent expects this to be true for the Project as well.

During periods when the wind turbines are not generating power, electricity would be purchased

from the Skamania County Public Utility District #1.

The impact of this proposed project to the regional electric demands can best be seen by a recent Northwest Power and Conservation Council evaluation of projected electrical demand in the

3-90

region. The NPCC found that a medium forecast predicts a demand of about 5,300 MW by 2025 with a range of about minus 2,500 MW to a high of about plus 7,000 MW. The medium forecast represents a growth of about 1 percent per year. Given the regional energy needs and the unique convergence of gas pipelines, wind energy, and transmission lines in Klickitat County, it is reasonable to estimate that the County could produce a portion of the projected increased energy demand. Currently, the regional power resources come from the following energy technologies:

- Hydroelectric, 55 %
- Coal fired thermal, 19 %
- Nuclear power, 5 %
- Imports, 8 %
- Gas fired combustion turbines, 3 %
- Non-Utility generation, 6 %
- Miscellaneous, including wind power, 4 %

The Klickitat County Energy Overlay Zone Final EIS11, released by the Klickitat County Planning Department, also recently evaluated the projected energy demand in Klickitat County, Washington, the county immediately adjacent to Skamania County. The Klickitat County Planning Department found that the technologies that are currently being used within Klickitat County include hydroelectric, gas fired combustion turbines, biomass fired turbines, and wind energy. These energy technologies are expected to continue to be developed in the County (through the year 2024) and include:

- Seven 250 MW or five 350 MW natural gas thermal projects
- Two 50 MW biomass projects
- Four wind power projects with total generating capacity of 1,000 MW
- Solar projects are anticipated to be small in size and number.

Comment: If Klickitat County evaluated projected energy demand, then where is their cumulative impacts analysis for environmental impacts? Klickitat is in BPA's service area and any cumulative impacts from their energy production should be part of this DEIS. Cumulative impacts are just not calculated for past and present actions—they must also be calculated for FUTURE actions, such as the" seven 250MW or five 350MW natural gas thermal projects, and the two 50MW biomass projects, and the four wind power projects, and the solar projects" mentioned above. Where are the FUTURE cumulative impacts analyses for these FUTURE actions?

The proposed project, although in a small way, would help meet the project demand outlined by the NPCC as mentioned above through its wind power generation. Additionally, the proposed

project would be consistent with the types of projects that have been outlined within the Klickitat County Energy Overlay Zone Final EIS.

11 See: <http://www.klickitatcounty.org/default.asp>

3-91

Studies of the projected impact of this proposed project to the FCRTS have found that the North Bonneville-Midway 230-kV line interconnection provides sufficient capacity for the proposed 70 MW request. From the proposed BPA substation interconnection, the power flow will be directed 80% towards North Bonneville and 20% towards Midway. The contingency analysis for this interconnection request indicates that no overloads are anticipated to occur, and this proposed project would not be expected to affect the operation of BPA's transmission system.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least 90 days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project's operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated, including potential uses of energy and natural resources. If impacts to energy or natural resources are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

3.5.2.2 No Action Alternative

Under the No Action Alternative, the wind energy project would not be built. The energy and water use for the Operations and Maintenance building would not take place. It is likely that the region's power needs would be met through energy efficiency and conservation measures, existing power generation, or the development of new power generation. Base load demand would likely be filled through expansion of existing, or development of new thermal generation such as gas-fired combustion turbine technology. Other wind sources also could be developed. Such development could occur at appropriate locations throughout Washington State. The impacts on energy and natural resources would depend on the type, location, and size of the facility proposed.

3.5.3 MITIGATION MEASURES

Adverse impacts to energy and natural resources are identified to be minimal and therefore no mitigation measures would be required.

3.5.4 UNAVOIDABLE ADVERSE IMPACTS

The project would have minor unavoidable adverse impacts to energy and natural resources. The overall impact of the project to energy and natural resources would be positive, since it would provide the region with low-cost, clean, renewable energy, in accordance with state and national policies and priorities.

Comment: Just “minor unavoidable adverse impacts to energy and natural resources”? What exactly does minor mean? How many cumulative “unavoidable adverse impacts” are there? “Overall impact...would be positive”? Do we now sing Kumbaya and call it good?!? This is not analysis. This is a proponent making a subjective, wishful statement unsupported by data and factual information. Where is the data to support the assertions in the adverse impact statement?

3.6 PUBLIC HEALTH AND SAFETY

This section describes existing health and safety hazards at the project site and identifies potential health and safety risks from project construction and operation. Risks discussed include fire or explosion, release of hazardous materials, vandalism, traffic accidents, turbine structural failure, ice throw, electric and magnetic fields, and shadow-flicker. Mitigation measures are identified for potential impacts.

3.6.1 AFFECTED ENVIRONMENT

3.6.1.1 Existing Health and Safety Risks

Existing health and safety hazards at the project site include those associated with the current commercial forestry operations on the site. Commercial forestry operations include some risks of fire and explosion from equipment operation, especially during dry summer months.

Commercial forestry entails a small risk of leaks or spills of fuel, oil, or hydraulic fluid. There is also a small health and safety hazard related to logging trucks currently traveling to and from the site. During the dry summer months, there is some risk of fire from lightning.

Resources for responding to risks to environmental health and safety include fire prevention, law enforcement, and emergency medical response.

3.6.1.2 Fire Prevention

The project site is currently used for commercial forestry and there are no structures on the site.

Two city fire departments (North Bonneville and Stevenson) and seven Skamania County fire districts provide fire protection to Skamania County residents. DNR also provides fire suppression services to forested areas in Skamania County, and would be the first responder to a fire emergency at the project site (J. Weeks, personal communication). Skamania County Fire

3-93

District No. 3 (SCFD3) (also known as Underwood Fire District) provides fire protection and emergency response to a 20-square mile service area immediately south of the project site (D. Cox, personal communication). Although the project site is not formally within SCFD3's service area (T. Skinner, personal communication), SCFD3 would likely respond to a fire at the project site, along with and in coordination with DNR (R. Hovey, personal communication). The Mill A Fire Department is also near the project site, and has a staff that includes less than six volunteer firefighters and no paid personnel (J. Carlson, personal communication).

The project site is located in DNR's West Klickitat Area. The DNR work center closest to the project site is the Husum work center, which is staffed by one fire manager officer and one assistant fire manager (J. Weeks, personal communication). Other staff and equipment at the Husum work center includes six firefighters and two Type 6 wildfire engines (Fullerton and Helgerson 2008). The DNR response time to the project site would vary depending on the location of the engines and the type of fire emergency at the project site, but would range from 45 minutes to one hour (R. Hovey and J. Weeks, personal communications). The engines are usually assigned to work projects in the field.

SCFD3 is located in the unincorporated community of Underwood and is staffed by 17 volunteer firefighters. The SCFD3 service area is 20 square miles. Equipment at SCFD3 includes one each of the following: Type 1 engine, Type 2 engine, Type 3 engine, Type 7 engine, Type 2 tender, and Type 3 tender (Fullerton and Helgerson 2008). The Washington State Ratings Bureau rating for SCFD3 at the project site is "Unprotected – 10," because the site is not located

within the SCFD3 boundaries (T. Skinner, personal communication).

The project site is located outside of the Columbia River Gorge National Scenic Area. If an incident at or near the site, i.e., a wildland fire, threatens the area, the Columbia River Gorge National Scenic Area fire agency could respond. The fire agency is equipped with three Type 6 wildfire engines, one fire prevention module, two command vehicles, two cooperative engines (with the DNR), and one cooperative engine (with the Oregon Department of Forestry). The Columbia River Gorge National Scenic Area fire agency has nine employees and is staffed seven days per week, July through September (Fullerton and Helgerson 2008).

Skamania and Klickitat Counties have jointly prepared a Community Wildfire Protection Plan through a Title III grant from the Secure Rural Schools and Self Determination Act (Klickitat and Skamania Counties 2006). This is a plan developed by a community in an area at risk from wildfire, with the goal of reducing the risk of catastrophic wildfire within the region. .

Table 3.6-1 lists the fire departments that serve the site and surrounding area, along with the departments' staff and equipment. These fire districts have mutual aid agreements with each other (J. Carlson, personal communication).

a. T. Skinner (personal communication): As rated by the Washington Surveying and Rating Bureau. The Bureau rates the level of fire protection provided by fire departments against four main elements: available water supply; logistical characteristics and makeup of the district fire department; available communications systems; and fire control and safety measures taken and ordinances in effect in the particular fire district. Ratings are used to evaluate fire protection availability for insurance purposes. Ratings range from 1 to 10, with class 1 representing the highest level of fire protection and class 10 the lowest level. Ratings were not available for the DNR or the Columbia River Gorge National Scenic Area Fire Agency.

b. Not available.

3.6.1.3 Law Enforcement

The Skamania County Sheriff's Office provides law enforcement services in the project vicinity. Sheriff's Office headquarters are located in Stevenson, approximately 15 miles southwest of the project site. The response time from Sheriff's Office headquarters to the project site is approximately 20 minutes.

The Washington State Patrol patrols SR 14 south of the site. Roads extending north of SR 14 are county roads, and are patrolled by the Sheriff's Office. Table 3.6-2 provides information on the police departments serving the site area, including service area and number of officers.

3.6.1.4 Emergency Medical Services

Two ambulance companies provide emergency response services for the Project site: Skamania County Emergency Medical Service and Skyline Ambulance. Skamania County Emergency Medical Services is the functioning entity of Skamania County Hospital District No. 1, which provides ambulance service to the residents of Skamania County. Skyline Ambulance is based at Skyline Hospital in White Salmon, and is equipped with three ambulance vehicles. Table 3.6-3 lists characteristics of the first response ambulance service providers for the Project site.

Ambulance Service Providers in the Whistling Ridge Energy Project Vicinity

Name	Ownership	Level of Care
Skyline Ambulance	Public	Advanced Life Support
Skamania County Emergency Medical Services	Public	Advanced Life Support

Sources: Skyline Hospital (2008), Skamania County EMS (2008).

The two hospitals closest to the project site are Skyline Hospital in White Salmon (7 miles southeast of the project) and Providence Hood River Memorial Hospital, directly across the Columbia River from White Salmon in the City of Hood River (8 miles southeast of the project). Skyline Hospital is a 32-bed acute care hospital with a Trauma Level IV designation, serving western Klickitat County and eastern Skamania County. Services at Skyline Hospital include acute care, obstetrics, surgery, cardiopulmonary care, radiology and laboratory services, physical therapy, a pharmacy, and emergency services. Skyline Hospital owns and operates a three-vehicle ambulance service (Skyline Hospital 2008).

Providence Hood River Memorial Hospital is a 25-bed facility that provides cardio conditioning, counseling, diabetes treatment, a dialysis center, emergency services, obstetrics, radiology, laboratory services, nutrition, occupational medicine, a sleep center, and surgery¹².

3.6.2 IMPACTS

3.6.2.1 Proposed Action

Potential impacts to environmental health may occur during construction or operation.

Construction

Construction impacts include the typical risks to health associated with the construction of an industrial facility, including fire or explosion, release of hazardous materials, vandalism, and accidents.

12 See: <http://www.providence.org/hoodriver/>

3-96

Fire or Explosion

The only structures proposed on the site are the turbine towers, associated transformers and substation, and the Operations and Maintenance facility. Project construction could temporarily increase the risk of fire at the project site and in the broader project area, as a result of the operation of vehicles and power equipment, which may cause fires through contact with dried plants during dry summer weather. Blasting may be used where solid rock is encountered during construction of turbine foundations or trenches for the underground electrical collection system. Blasting could create a fire hazard during dry weather.

As the landowner and a long-term commercial forestry business, SDS has maintained the ability to respond to fires on their forest land with dozers and water trucks, and will continue to do so. Fire response by SDS will be supplemented by DNR, which provides fire protection on forest lands. DNR has resources in the area and responds to all wildland fires. DNR would likely respond to a structure fire in the woods, as would Underwood Fire District #3 and Mill A Volunteers. SCFD3 is the nearest local fire district. Eric Ziegler, District Chief, submitted a letter to EFSEC during the EIS scoping period stating that SCFD3 can provide service coverage to the project area to respond to fires without any reduction in service to their constituency. Mill A Volunteers is not a recognized fire district with a tax base but a volunteer fire company. Mill A Volunteers has joint responder agreements with Underwood Fire District and the DNR.

There are two locations being considered for the Operations and Maintenance facility site, one site next to the substation and the other at the bottom of West Pit Road. The West Pit Road site would have a lower fire risk and shorter response times for emergency services, since the facility would be along a county road.

Releases of Hazardous Materials

The risk of releases to the environment that would affect health would be similar to any large construction project. The primary potentially hazardous materials used during construction would be diesel fuel for construction equipment, lubricating oils and hydraulic fluids for the turbines, and mineral oil for the transformer at each turbine and the substation. Approximately 19,250 gallons of diesel fuel would be used during construction. Most trucks would fuel up off-site; some fuel would be transported to the site.

Each turbine would contain a small amount of hydraulic fluid, and would have a pad-mounted transformer containing approximately 500 gallons of mineral oil for cooling. The BPA substation would have either one or two transformers, each containing up to 12,000 gallons of mineral oil. These transformers would be filled during construction.

Comment: How dangerous is mineral oil to the environment, in case of leaks? Is there combustion danger? How much of the mineral oil is stored onsite for use? Over the life of each turbine transformer, how much mineral oil is used? How much mineral oil is used over the lifetime of the BPA substations? What is the chemical makeup of the mineral oil?

Vandalism

During construction, the presence of out-of-area workers could create a negligible increase the risk of vandalism in the community. Vandalism of project facilities and theft of equipment during construction also is a potential area of concern. Security provisions could include temporary fencing with a locked gate around the construction site; the use of site trailers for the temporary storage of special equipment or materials; and the use of outdoor lighting and motion-sensor lighting. Access to the project site would be controlled, and site visitors including vendors, equipment personnel, maintenance contractors, material suppliers, and all other third

3-97

parties would require permission for access from authorized project staff prior to entrance. These measures would help to reduce the potential for vandalism and other incidents at the project site that would require a response by local law enforcement agencies. Whistling Ridge Energy LLC may contract for on-site security to supplement coverage by the Skamania County Sheriff.

Traffic Accidents

Project construction could lead to a slight increase in the chance of traffic accidents, due to the presence of a peak of 265 construction workers traveling to the site, along with the transport of construction materials and the turbine components. This impact would last a maximum of one year, with peak impacts limited to a several-month period in the summer. This risk would be minimal and similar to any construction project involving the use of heavy equipment and large structural components on the roadways. The Skamania County Sheriff or the Washington State Patrol would respond to traffic accidents. Medical response would be provided by the local ambulance services (Skamania County Emergency Medical Service and Skyline Ambulance) and the two local hospitals (Skyline Hospital in White Salmon and Providence Hood River Memorial Hospital in Hood River), which have capacity for additional patients.

Turbine Structural Failure

The risk of turbine structural failure during construction would be very small, and would be due primarily to problems in the assembly process, should a failure occur. The turbine supplier will be required to document and provide the quality assurance/quality control procedures used

during manufacturing and assembly to minimize or eliminate the risk of failure.

Ice Throw

Ice storms, both mild and occasionally severe, may occur in the project area. During periods of ice build-up, the exposed parts of the turbine may be coated with ice. When a stationary blade accumulates ice followed by an increase in temperature, the ice on the blade can thaw. If the blades are stationary, the ice will fall near the turbine base, but once the blades begin to rotate, ice fragments may be thrown. Ice throw would not be a risk during construction because the turbines would not be operating.

Shadow Flicker

Shadow flicker caused by wind turbines is defined as alternating changes in light intensity as the moving blade casts shadows on the ground and objects, including windows at residences. Some health concerns have been raised about the effects of shadow flicker. Shadow flicker can only occur if the location of the turbine is close to a receptor that is in a position where the blades interfere with very low-angle sunlight. Shadow flicker would not be a risk during construction because the turbines would not be operational.

Comment: Duh. "Shadow flicker would not be a risk during construction because turbines would not be operational." I really dislike it when people think I'm stupid... SO, what happens after the turbines are constructed? How much shadow flicker is there? How are people and wildlife affected by shadow flicker? Shadow flicker is VERY ANNOYING, as anyone who has had light flickering on their peripheral vision can attest! This is not an analysis of shadow flicker, its effects on humans and wildlife, and its location relative to human habitation in the area.

Electromagnetic Fields

Electrical transmission lines, distribution lines, and substations create electromagnetic fields. Electromagnetic fields also exist in nature and around all types of electrical devices and appliances. They are produced by the presence of differences in electrical potential (voltage) and the movement of charges because of the potential (current). This movement produces magnetic fields. The electrical and magnetic fields around electrical appliances and utility facilities are

3-98

extremely low frequency. They have a significantly lower frequency (60 cycles per second, or Hz), than radio broadcast waves (0.5 to 100 million cycles per second) or electromagnetic energy from sunshine (1,000 trillion cycles per second). Electrical and magnetic fields would not be generated prior to completion of the project other than by electrical generators used for temporary site power.

Comment: SO, what happens after construction. What strength electrical and magnetic fields would be generated? What effects do electromagnetic fields have on humans and wildlife? Are there any genetic effects? Cancer-causing effects?

Operation

Potential health and safety concerns from operation of a wind energy facility include ongoing risks of fire or explosion, releases to the environment, vandalism or traffic accidents, along with concerns regarding turbine structural failure, tower failure, blade throw ice throw from the turbine blades, shadow flicker from the moving blades, and electrical and magnetic fields.

Fire or Explosion

Wild fires in the project area are relatively rare, and fire conditions are monitored continually by the DNR. During project operation, fire protection would continue to be provided by SDS, DNR, Underwood Fire District, and Mill A Volunteers. Potential for fire would be lower once construction is completed, and would relate primarily to lightning and vehicle use during the dry summer months. These risks would be mitigated through appropriate operational practices. DNR has stated that resources for fire protection and suppression services are adequate to serve the project during construction and operation (J. Weeks, personal communication).

Turbine fires are possible; however, with the types of modern wind turbines proposed for the project, turbine malfunctions leading to fires in the nacelle are extremely rare. The turbine control system detects overheating in turbine machinery, and internal fires would be detected by these sensors, causing the machine to shut down immediately and send an alarm signal to the central supervisory control and data acquisition system, which would notify operators of the alarm by cell phone or pager.

Releases to the Environment

Operation of the project would not result in the generation of regulated quantities of hazardous wastes. Since no fuel would be burned to power the wind turbine generators, there would be no spent fuel, ash, sludge or other process wastes generated. The only materials used during project operations that present any potential for accidental spills are lubricating oils and hydraulic fluids used in the wind turbine generators and transformers.

- **Turbine Fluids.** The fluids within the turbines are checked by staff periodically and must be replenished or replaced on an infrequent basis (generally less than once per year and sometimes only once every five years). When replacing these fluids, the industry standard practice is for staff to climb up to the nacelle and remove the fluids in small (typically five-gallon) containers and lower them to the ground using a small maintenance crane built into the nacelle itself. The containers would then be transferred to a pickup truck for transport to the Operations and Maintenance facility for temporary storage (typically less than one month) before being picked up by a licensed transporter for recycling. Replacement fluids are added in the same method, only in reverse.

- **Replacement Fluids.** Small quantities of replacement fluids, typically no more than a few 50-gallon drums of lubricating oil and hydraulic oil, may be stored at the Operations and Maintenance facility for replenishing and replacing spent fluids. These fluids would be stored in appropriate containers. All operations staff would be trained in appropriate handling and spill prevention techniques to avoid any accidental spills. Because only small quantities of fluids are transported, added, or removed at any one time and are stored for short periods of time, the potential for an accidental spill during routine maintenance is extremely limited.
- **Pad Mounted Transformers.** Each wind turbine generator has a pad mounted transformer located at its base. These transformers contain mineral oil, which acts as a coolant. Each pad mounted transformer contains up to 500 gallons of mineral oil. The transformer is designed to meet stringent electrical industry standards, including containment tank welds and corrosion protection specifications. Regular maintenance is performed on the transformers, including checking the condition of the coolant.
- **Substation Transformer(s).** The BPA substation would be equipped with either one or two transformers. Each substation transformer would contain up to 12,000 gallons of mineral oil for cooling. These transformers are designed to meet stringent electrical industry standards, including containment tank welds and corrosion protection specifications. The substation transformers are equipped with an oil level sensor that detects any sudden drop in the oil levels and send an alarm message to the central supervisory control and data acquisition system. Finally, the substation transformers are supported by a concrete vault to ensure that any accidental fluid leak does not result in any discharge to the environment. It is anticipated that an Operation SPCC Plan would be submitted and approved by EFSEC prior to operation.

Vandalism

Vandalism of project facilities and theft of equipment during operation is similar to that expected during construction. As with the construction period, the project design will include site security measures including fencing and outdoor lighting, and Whistling Ridge Energy LLC may contract for on-site security to supplement coverage by the Skamania County Sheriff.

Traffic Accidents

The risk of traffic accidents during operation would be low. The project would employ between eight and nine operations staff; this number would not generate sufficient additional traffic to increase accident rates. Traffic accident response would continue to be provided by the Skamania County Sheriff and Washington State Patrol, with support by local ambulance services and hospitals as needed.

Tower Failure

Structural failure of the turbine tower is very rare, though some instances of turbine failure have been documented in older turbine models. A review performed for the Kittitas Valley Wind Project EIS located five reported instances of tower failure worldwide. There are at least 55,000

wind turbines installed world-wide (EFSEC 2007). One insurance company representative whose company insured over 12,000 turbines reported that he was not aware of any instances of the failure of tubular turbine towers (EFSEC 2007).

Tower failure can be attributed to improper design, manufacturing defects, extreme weather events, or the wrong application of technology. Reasons for tower collapse can vary depending on conditions and tower type, but may include blade strikes, very strong winds, and improper maintenance. While structural failure is more damaging than blade failure, the consequences and risks to human health are far lower since risks are confined to within a relatively short distance from the turbine (Caithness 2006). There is only one recorded death from a tower collapse, which occurred in Sherman County, Oregon (a construction worker who died during the testing phase and not during operation). A six-month investigation found that the operating company “failed to properly instruct and supervise workers in the safe operation of tools and equipment. It also found that company procedures for working under potentially dangerous conditions fell short of OSHA [Occupational Safety and Health regulations]” (Hill 2008). The investigation did not find any structural problems with the tower itself.

Comment: This is the Gorge. There are strong winds in the Gorge. There is extreme weather in the Gorge. Why is SDS proposing to build huge, dangerous propellers in an area known for gusting, strong, winds?

Blade Throw

Cases of blade throw are rare and have generally been linked to improper assembly or exceedance of design limits (AWEA 2008). In those rare instances where towers or blades have failed, the failure typically results in components crumpling or falling straight down to the ground, although in a small number of cases blades or parts of blades have been thrown from the nacelle. There is limited data available on how far blade components would be thrown since blade throw is extremely rare. In testimony for the Kittitas Valley Wind Project, a representative from Vestas Wind Systems in Denmark stated that there are approximately 10,000 Vestas turbines installed and operating worldwide. There has been only one noted occurrence of blade throw, with a Vestas V39-500kW turbine in Denmark in 1992 where a blade was thrown 50 to 75 meters (approximately 165 to 245 feet) (EFSEC 2007). Based on this information, the Applicant determined that using a minimum of turbine tip height to define the minimum safety setback distance is sufficient to protect against blade throw.

For the Project, members of the public would not have access to the project site, and signs would be used to discourage unauthorized access. The tip height of the turbines would be approximately 426 feet. The property boundaries of the project site would be greater than 426 feet in distance to the nearest turbine in all but a few isolated cases. Exact distances from the turbines to the property boundary would depend on the final design and placement of the turbines; however, it is possible that the nearest turbine would be within this distance of the project boundary for small parts of turbine strings A and B (on the west of side of the project area), F and D (on the south side) and B and C (on the north side). However, most of this area is

under control of the Applicant or in large-scale agriculture, and there are no residences within this buffer area:

- On the west side of the project area, there are six properties, of which only two are owned by a person or entity other than the Applicant. These two are owned by the State and managed by DNR. All these neighboring properties are managed as commercial forest land with no residential structures.

3-101

- On the south side, there are five adjacent off-project properties, located within the Scenic Area. Of these five properties, only one, totaling 29 acres, is owned by someone other than the Applicant. The 29-acre parcel is primarily managed as forest and orchard lands, with 1 acre used for residential purposes. The owner has received approval from Skamania County to relocate their existing home to within 50 feet of their north property line. This new location would bring the residence to within 2,000 feet of the closest proposed turbine corridor. Except for this parcel, all adjacent lands to the south are in commercial timber production.
- On the north side, the land is owned by the State and managed for commercial timber harvest by the DNR.

The wind turbines for the project would be equipped with sophisticated computer control systems to monitor variables such as wind speed and direction, air and machine temperatures, electrical voltages, currents, vibrations, blade pitch and yaw angles, etc. Each turbine would be connected to a central data control system. The system will allow for remote control and monitoring of individual turbines and the wind plant as a whole from both the central host computer or from a remote computer.

Comment: I did not see any wind studies, long-term wind direction distribution curves, data on maximum and minimum temperatures onsite, the different altitude locations for the wind turbines (altitude above sea level affects wind production? Where are the air density tables for the proposed location, etc. Where are the wind studies for this area? What are the environmental issues associated with micro-siting?

All turbines are designed with several levels of built-in safety and comply with the codes set forth by Occupational Safety and Health Administration and American National Standards Institute standards. The turbines would be equipped with two fully independent braking systems that could stop the rotor either acting together or independently. The braking system is designed to bring the rotor to a halt under all foreseeable conditions. The system would include aerodynamic braking by the rotor blades and by a separate hydraulic disc brake system. Both braking systems would operate independently such that if there is a fault with one system, the other could still bring the turbine to a halt. Remote restarting of the turbine would not be possible following an emergency stop. The turbine would be inspected in-person and the stop-fault reset manually to re-activate automatic operation. The turbines also would be equipped with a parking brake used to “park” the rotor while maintenance routines or stationary rotor inspections are performed.

Ice Throw

As noted above, during periods of ice build-up, the exposed parts of the turbine may be coated with ice. When a stationary blade accumulates ice followed by an increase in temperature, the ice on the blade can thaw. If the blades are stationary, the ice would fall near the turbine base, but once the blades begin to rotate, ice fragments may be thrown. The risk of impacts from ice throw is minimal. Most modern turbines include sensors that would shut down the turbine when ice build-up is detected. A 1998 study reported that there had been no injury from ice thrown from wind turbines (Morgan et al. 1998). A 2009 study reported one human injury due to ice-throw, although the specifics of the incident were not provided (Caithness 2009). As stated above, there are at least 55,000 wind turbines in operation world-wide.

Reported data on ice throws at other projects indicate that ice fragments were found on the ground from 50 to 328 feet from turbines (<33 to 197 feet blade diameter) and were in the range of 0.2 to 2.2 pounds in mass (Morgan et al. 1998, EFSEC 2007). When more than a few meters from the turbine, the risk of ice landing at a specific location was found to reduce quite quickly

3-102

with the distance of the location from the turbine. It was also found that ice falls predominantly downwind of the rotor plane. Seifert et al. (2003) conducted risk analyses on ice throw primarily in Europe. The general conclusion was that wind turbines would not cause ice throw risks as they are normally set back from residences and roadways and that the hypothetical risk of being struck by ice is small. However, the actual throwing distance of the ice fragments would vary based on many variables not included in this calculation, including rotor azimuth, rotor speed, local radius, ice fragment size and weight, and the wind speed.

Thus, a buffer based on tip height (approximately 426 feet) would provide adequate protection from ice throw. As discussed in the Blade Throw section above, the project area boundaries are usually farther than this distance from the nearest turbine, and where this is not the case the surrounding area is either under the control of the Applicant, managed for commercial timber harvest by Washington State, or managed for large-scale agriculture. The nearest residence is approximately 2,000 feet from the nearest proposed turbine string.

Shadow Flicker

Shadow flicker is the alternating change in light intensity when moving turbine blades cast shadows on the ground and objects, such as windows in residences. Shadow flicker is not caused by viewing the sun through rotating wind turbines blades or moving through the shadows of a wind energy facility, or sunlight reflected from turbine blades. Shadow flicker occurs when a turbine is located near a receptor (e.g., residence) with an unobstructed line of sight to the turbine, the sun is behind and perpendicular to the turning turbine blades and the receptor is located close enough to the turbine to be in its shadow.

The existence and intensity of shadow flicker are affected by a number of factors including:

- The strength of the sun as affected by cloud cover.
- The line of sight of the observer relative to the sun and the turbine. This is related to the sun's height in the sky, which varies with latitude and longitude, time of day, and time of year
- The distance between the observer and the turbine, which affects the distinctness of the shadows.
- The presence of obstructions such as buildings or vegetation.
- The orientation of the turbine depending on wind conditions. When the turbine is facing the sun, shadow flicker is greater behind the turbine; when the turbine is rotating in line with the sun, there is much less flicker (Committee for Renewable Energy 2008).

Potential shadow flicker from wind turbines can only occur when (1) the sun is very low in the sky; (2) a receptor is very close to the turbine; (3) the receptor is oriented toward a turbine; (4) the receptor has an unobstructed line of sight; and (5) the weather conditions include bright sun. When all these factors exist, they may produce a pulsating shadow which may or may not be perceptible. Shadow flicker frequency is related to the rotor speed and number of blades on the rotor, which can be translated into a "blade pass frequency" measured in alternations per second,

3-103

or hertz (Hz). Although in some instances the flickering of light can induce epileptic seizures in people who are photosensitive (about 3- 5 percent of the 1 percent of Americans who are epileptic are photosensitive), shadow flicker from wind turbines is too slow to induce epileptic seizures. Whether light flicker will provoke a reaction depends on its frequency, light intensity, visual area, image pattern, and color (Epilepsy Foundation 2009). Flicker frequency due to a turbine is on the order of the rotor frequency, i.e., 0.6–1.0 Hz (NRC/NAS 2007). The flicker frequency that provokes seizures in photosensitive individuals is 5–30 Hz, well above the maximum of approximately 1 Hz for wind turbines. There is no scientific data or peer-reviewed studies that suggest a link between epileptic seizures and rotor blade alternatives.

Analyses conducted at other wind energy facilities approved by EFSEC (Kittitas Valley Wind Power Project and the Wild Horse Wind Power Project) examined the potential effects of shadow flicker for residents near the proposed projects and recommended certain measures for minimizing these effects. EFSEC found that as the distance between the wind turbine generators and residences increases, the perception of shadow flicker decreases or attenuates. At a distance beyond 2,500 feet, shadow flicker is considered to be imperceptible. Even if shadow flicker were a proven impact (as the Council found in the Kittitas Valley Wind Power Project case), none of the planned turbines are within 2,500 feet of existing residences (Figure 3.7-1 Noise Level Contours in Section 3.7 shows the locations of the closest residences.). If shadow flicker were found to occur, operational controls could be implemented to completely eliminate this perceived impact. For instance, turbine speed or orientation could be controlled during specific periods.

Electromagnetic Fields

The project will include 34.5-kV collector lines and systems, primarily located underground. There will be a new collector substation located adjacent to BPA's existing North Bonneville to

Midway 230-kV transmission line and a new interconnection from the proposed BPA substation to the 230-kV transmission line.

Electrical transmission lines, distribution lines, and substations create electromagnetic fields, which also exists in nature and around all types of electrical devices and appliances. As shown in Table 3.6-4, much of typical daily exposure to electromagnetic fields from human-made sources is a result of using electric home appliances. Electromagnetic field strength is expressed with a unit of measure called a milligauss (mG), and is measured using a special monitoring device. The strength of electromagnetic fields falls rapidly as one moves away from the source.

3-104

Table 3.6-4
Electromagnetic Field Readings for Common Equipment

Source Readings (mG)

Video Display Terminals (VDTs)(distance 6 inches) 14 mG

Portable Heaters (distance 6 inches) 100 mG

Vacuum Cleaners (distance 6 inches) 300 mG

Can Opener (distance 6 inches) 600 mG

Hair Dryer (distance 6 inches) 300 mG

Distribution Line 37.5-kV (distance 100 feet) <1-2 mG

Transmission Line 115-kV (distance 100 feet) 1.7 mG

Transmission Line 230-kV (distance 100 feet) 7.1 mG

a. National Institute of Environmental Health Sciences (2002). , EMF: Questions and Answers, 2002.

b. Gauger, J.R. (1985), Silva et al. (1988)

Electromagnetic fields from the project will be lower than those of many common household appliances and will not have health and safety impacts. Electromagnetic field readings for items commonly found in homes compared to electrical transmission lines are shown on Table 3.6-4.

Given the low strength of electromagnetic fields from the project and the distance to the nearest residences and the Operations and Maintenance facility, the project would have no impacts from electromagnetic fields.

Other Potential Impacts

Other potential adverse impacts to environmental health during operation could occur from the following:

- Weather. Weather emergency includes hail, high winds, thunderstorms, extreme cold weather, and any other naturally occurring weather situation that may endanger equipment, or require adjustments to the normal operations of the facility. Risks to personnel at the project would be minimized through preparation of and implementation of an Emergency Plan that includes planning for weather contingencies.

- Geological. This type of emergency deals with seismic activity and related geological phenomena. As discussed in Section 3.1 Earth, the likelihood of earthquake at the site is very low.
- Security. This type of emergency includes bomb threats, civil unrest, sabotage, or any other man made threats to the facility or personnel. The risk of a security emergency in this location and to this type of facility is considered very low.

Comment: So this wind farm would be operating in an area that gets up to 3 meters of snow in the Winter? There would be hail, high winds, thunderstorms, and extreme cold weather? Personnel would have operate in this environment? What does OSHA have to say about this?

Project Decommissioning

The health and safety risks associated with decommissioning will be similar to those during the construction process. In compliance with WAC 463-72 Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project's operating life (estimated to be 30 years), and restoration in the event

3-105

the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major environmental health issues presently anticipated. If impacts to environmental health are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

3.6.2.2 No Action Alternative

Under the No Action Alternative, the wind energy project would not be built. The risk of fire due to lightning strikes or human activity in the general area would continue at their present levels, as would the risk of hazardous waste release, vandalism, and traffic accidents. The electrical energy that would otherwise be produced by the project would need to be obtained from another generating source.

3.6.3 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential impacts to public health and safety to the extent feasible.

- Prepare Emergency Plans for the project containing the following components:
 - Fire Protection and Prevention Plan. A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented, in coordination with the Skamania County Fire Marshall and appropriate agencies. As part of the plan, the construction manager would be responsible for

staying abreast of fire conditions in the project area by contacting DNR and implementing any necessary fire precautions.

-Personal Injury Response Plan. Procedures will be developed for construction, operation and maintenance of the project to describe procedures to be followed in the event of a personal injury, including who is to be alerted, contacting 911, how to alert others in the immediate vicinity, remaining with the employee, and administering first aid until medical assistance arrives.

-Safety Plan. Prior to the commencement of any construction work, the construction contractor would be required to prepare a Safety Plan that would apply to all contractor and subcontractor personnel working at the site. The plan would be designed to ensure compliance with all laws, ordinances, regulations, and standards concerning health and safety. The contractor would assign a safety manager with the authority to issue a "stop work" notice when health and safety issues arise.

-SPCC Plan. While storage of chemicals on site would be minimal, the project could require an SPCC Plan that would protect groundwater. The SPCC Plan would apply to both construction and operation if hazardous materials were stored on site in quantities sufficient to trigger the plan requirement.

3-106

-Hazardous Waste Management Plan. Hazardous materials to be used or stored on site would be limited to small quantities of materials used for maintenance (cleaning and painting), lubrication of equipment, and possibly fuel. During construction, the construction contractor would be required to prepare a Hazardous Waste Management Plan that complies with state and federal hazardous waste management laws for handling, storage, and disposal. A similar plan would be prepared and implemented for operation.

- Report conditions affecting the safety of the project to EFSEC, including any condition, event, or action that might compromise the safety, stability, or integrity of any facility or the ability of any equipment to function safely; or that might otherwise adversely affect life, health, or property.

- Develop agreements related to emergency planning with Skamania County Department of Emergency Management prior to project construction. This agreement would be provided to EFSEC and attached to the Emergency Plan prior to implementation.

- Comply with all applicable local, state, and federal safety, health, and environmental laws, ordinances, regulations, and standards. Some of the main laws, ordinances, regulations and standards that would be reflected in the design, construction, and operation of the project are as follows:

- Occupational Safety And Health Act of 1970 (29 USC 651, et seq.) and 29 CFR 1910, Occupational Safety and Health Standards

- Uniform Fire Code

- Americans with Disabilities Act

- Uniform Fire Code Standards

- Uniform Building Code

- National Fire Protection Association design standards for the requirements of fire protection systems
- National Institute For Occupational Safety And Health requirements that safety equipment carry markings, numbers, or certificates of approval for stated standards
- American Society of Mechanical Engineers plant design standards
- American National Standards Institute plant design standards
- National Electric Safety Code
- American Concrete Institute Standards
- American Institute of Steel Construction Standards
- National Electric Code

3-107

- Utilize the following measures to mitigate the risk of fire or explosion:
 - The construction manager would be responsible for staying abreast of fire conditions in the project area by contacting DNR and implementing any necessary fire precautions
 - A Fire Protection and Prevention Plan would be developed for EFSEC approval and implemented by the Applicant, in coordination with the Skamania County Fire Marshall and appropriate agencies
 - Both the wind turbine generators and the substation would be equipped with lightning protection systems

Table 3.6-5 lists sources of potential fire and explosion along with measures to mitigate the risk of either occurring.

3-108

Table 3.6-5
Fire and Explosion Risk Mitigation

- Construction or Potential Fire or
Operation Explosion Source Mitigation Measures
- Construction and
Operation
- General Fire Protection • All on-site service vehicles fitted with fire extinguishers
- Fire station boxes with shovels, water tank sprayers, etc. installed at multiple locations on site along roadways during summer fire season
 - Minimum of one water truck with sprayers must be present on each turbine string road with construction activities during fire season
- Construction and
Operation
- Dry vegetation in contact
with hot exhaust catalytic
converters under vehicles
- No gas powered vehicles allowed outside of graveled areas
 - Mainly diesel vehicles (i.e. w/o catalytic converters) used on site

- Use of high clearance vehicles on site if used off-road Construction and Operation

Smoking • Restricted to designated areas (outdoor gravel covered areas)

Construction and Operation

- Explosives used during excavation
- Only state-licensed explosive specialist contractors are allowed to perform this work—explosives require special detonation equipment with safety lockouts

- Clear vegetation from the general footprint area surrounding the excavation zone to be blasted
- Standby water spray trucks and fire suppression equipment to be present during blasting activities

Construction and Operation

Electrical fires • Use generally high clearance vehicles on site

- No gas powered vehicles allowed outside of graveled areas
- All major construction equipment used is to be diesel powered (i.e., without catalytic converters)

Construction and Operation

Lightning • Specially engineered lightning protection and grounding systems used at wind turbines and at substation

- Footprint areas around turbines and substation are graveled with no vegetation

Construction Portable generators – hot exhaust

- Generators not allowed to operate on open grass areas
- All portable generators to be fitted with spark arrestors on exhaust system

Construction Torches or field welding equipment

- Immediate surrounding area would be wetted with water sprayer
- Fire suppression equipment to be present at location of welder/torch activity

Construction and Operation

Electrical arcing • Electrical designs and construction specifications meet or exceed requirements of the National Electric Code and National Fire Protection Agency

3-109

- Require that all on-site operations employees would be responsible for contributing to ongoing fire prevention in the project area through the following programs:

- Operational Safety Program
- Operations Written Safety Program
- Emergency Action Plan
- Fire Prevention Plan

- Develop on-site emergency plans would be prepared for the project in case of a major natural disaster or accident relating to or affecting the project. The plans would describe the emergency response procedures to be implemented during various emergency situations that may affect the project or surrounding community or environment. In addition to the above measures, Whistling Ridge Energy LLC would:

- Provide detailed maps that show all access roads to the project
- Provide keys to a master lock system that would enable emergency personnel to unlock gates that would otherwise limit access to the project
- Use spark arresters on all power equipment, e.g., cutting torches and cutting tools

- Inform workers at the project site of emergency contact phone numbers and train them in emergency response procedures
- Carry fire extinguishers in all maintenance vehicles
- Coordinate with DNR when the fire danger is high
- Comply with equipment rules and regulations required by DNR for work conducted in wildland/forested lands
- Prepare in advance to reduce the potential for traffic accidents. Mitigation for lowering the risk potential of traffic accidents includes:
 - A Transportation Management Plan (TMP) that would direct and obligate the contractor to implement procedures to minimize traffic impacts would be prepared in consultation with both WSDOT and Skamania County and submitted to EFSEC for approval. The TMP would include requirements for coordination of project-related construction traffic and WSDOT planned construction projects, along with requirements for coordination of project-related construction traffic and Skamania County, City of Bingen, and City of White Salmon summer recreational traffic.
 - Whistling Ridge Energy LLC and its contractors would be required to comply with State and County permitting requirements for over-size and over-weight vehicles.

Comment: There are no designated haul routes for Whistling Ridge, as far as the public is aware. I have gone to our Skamania County Road Department and talked with our Larry Douglas, the department head and he stated that they were working on a draft but that it is not available for public disclosure. They are using Klickitat County's Haul Route Agreement as a go-by; this was for the Windy Ridge project in Klickitat. However, Mr. Douglas stated that Klickitat's engineer had expressed that if they had to do it again, they would put in more restrictions on road usage, in the Haul Route Agreement. Since Skamania County is not giving out the draft Haul Route Agreement that they would be implementing for Whistling Ridge, the public doesn't really know which roads are going to be widened, straightened, re-constructed, etc. The public doesn't really know anything specific about the stresses that will be put on the roads, if roads will have to be rebuilt. This is a serious inadequacy of the DEIS and should be addressed prior to any decision on the proposed project.

3-110

- Whistling Ridge Energy LLC would be required to notify land owners in the project vicinity prior to construction of transportation routes that would be used for construction equipment and labor.
- Approved State and/or County advanced warning construction signs would be placed prior to and during construction.
- Certified flaggers would be used when necessary to direct traffic when over-size and over-weight trucks either enter or exit public roads, to minimize risk of accidents.
- Pilot cars would be used both in front of and behind all trucks transporting over-size or over-weight loads on all public roadways.

-Traffic flow would not be restricted for more than 20 minutes during the construction phase.

-All loads over 10 feet wide traveling on SR 14 from east of the proposed project site between MP 76.77 and 76.91 would require three pilot cars, two in front and one in the rear. The two front pilot cars would be required to maintain a minimum 500-foot separation. The lead pilot car in front of the load would warn oncoming traffic of the over-size load, and the pilot car immediately in front of the over-size load would be responsible to stop all oncoming traffic.

3.6.4 UNAVOIDABLE ADVERSE IMPACTS

Unavoidable adverse impacts to environmental health are anticipated to be minimal.

Because there would be no need to transport, store, or combust fuel to generate power, the risk of unintentional or accidental fire or explosion or discharge to the environment during both construction and operations would be minimal. The risk of accident during construction would be no higher than for any large construction project and would be minimized through standard construction safety requirements and procedures. The risk of accident during operation would be minimal.

3.7 NOISE

This section describes the existing noise levels in the vicinity of the Project and the potential noise impacts from construction and operation of the proposed project.

3.7.1 AFFECTED ENVIRONMENT

3.7.1.1 Analysis of Environmental Noise

Noise is generally defined as loud, unpleasant, unexpected, or undesired sound that is typically associated with human activity and that interferes with or disrupts normal activities. Although exposure to high noise levels has been demonstrated to cause hearing loss, the principal human response to environmental noise is annoyance. The response of individuals to similar noise events is diverse and influenced by the type of noise, the perceived importance of the noise and its appropriateness in the setting, the time of day and the type of activity during which the noise occurs, and the sensitivity of the individual.

Sound is a physical phenomenon consisting of minute vibrations that travel through a medium, such as air, and are sensed by the human ear. Sound is generally characterized by several variables, including frequency and intensity. Frequency describes the pitch of the sound and is measured in Hz, while intensity describes the sound's loudness and is measured in decibels (dB). Decibels are measured using a logarithmic scale. A sound level of 0 dB is approximately the threshold of human hearing and is barely audible under extremely quiet listening conditions. Normal speech has a sound level of approximately 60 dB. Sound levels above approximately 110 dB begin to be felt inside the human ear as discomfort and eventually pain at 120 dB and higher levels. The minimum change in the sound level of individual events that an average human ear can detect is about 1 to 2 dB. A 3 to 5 dB change is readily perceived. A change in sound level of about 10 dB is usually perceived by the average person as a doubling (or if minus 10 dB, halving) of the sound's loudness.

Due to the logarithmic nature of the decibel unit, sound levels cannot be added or subtracted directly and are somewhat cumbersome to handle mathematically; however, some simple rules are useful in dealing with sound levels. First, if the intensity of a sound is doubled, the sound

level increases by 3 dB, regardless of the initial sound level. For example: 60 dB + 60 dB = 63 dB, and 80 dB + 80 dB = 83 dB.

Sound level is usually expressed by reference to a known standard. This report refers to sound pressure level (SPL). In expressing sound pressure on a logarithmic scale, the sound pressure is compared to a reference value of 20 micropascals (μPa). SPL depends not only on the acoustic power of the source, but also on the distance from the source and on the acoustic characteristics of the space surrounding the source, the receiver, and the path between them. A sound power level, on the other hand, is analogous to the wattage of a light bulb: it describes a source's rate of emitted acoustical energy and is not distance dependent. Using the same light analogy, SPL would be the brightness or intensity of light that can be measured at a specific distance from a source. To clarify the distinction between sound power level and SPL, the latter should always be specified with a location or distance from the noise source.

The distance value associated with SPL is an important metric, as the decrease in measurable sound level due to increasing distance from any single sound source normally follows the inverse square law. In other words, SPL changes in inverse proportion to the square of the distance from the sound source. As a general rule, at distances greater than 50 feet from a noise generator such as a wind turbine, SPL drops at a rate of 6 dB with each doubling of distance. Additionally, some sound energy is absorbed in the medium (e.g., air) through which it travels as a function of temperature, humidity, and the frequency of the sound. This attenuation can be up to 2 dB over 1,000 feet. The overall sound propagation drop-off rate will vary based on other conditions such as natural terrain and intervening obstructions.

Sound frequency (Hz) is a measure of how many times each second the crest of a sound pressure wave passes a fixed point. For example, when a drummer beats a drum, the skin of the drum vibrates a number of times per second. When the drum skin vibrates 100 times per second it generates a sound pressure wave that is oscillating at 100 Hz, and this pressure oscillation is perceived—by way of the inner ear organs and their connection to the brain—as a tonal pitch of 100 Hz. Sound frequencies between 20 and 20,000 Hz are within the range of sensitivity of the best human ear.

Sound from a tuning fork contains a single frequency (a pure tone), but most sounds one hears in the environment do not consist of a single frequency but rather a broad band of frequencies differing in sound level. The method commonly used to quantify environmental sounds consists of evaluating frequencies of sound according to a weighting system that reflects that human hearing sensitivity: less sensitive at low frequencies and extremely high frequencies than at the mid-range (e.g., speech) frequencies. This is called “A-weighting,” and the measured decibel level adjusted by the A-weighting constants is called the A-weighted sound level (dBA). In practice, the level of a noise source is conveniently measured using a sound level meter that includes a filter corresponding to the dBA curve of adjustment constants across the audible spectrum.

C-weighting is another type of filter, with adjustments that help expose low-frequency sound sources that the ear does not detect well, such as compressors, pumps, and diesel engines. For

the same measured sound, it is not uncommon for corresponding dBC and dBA levels to vary. As an example, the difference between dBC and dBA levels within an office building may be 20

3-114

dB (i.e., 40 dBA and 60 dBC). These wind turbines are not a source of substantial low-frequency noise. Because low frequency sound is less audible to human hearing, C-weighting is often used to assess potential annoyance from rattling due to low frequency noise that may excite vibration in structures.

Although the dBA may adequately indicate the level of environmental noise at any instant in time, community noise levels vary continuously. Most environmental noise includes a mixture of noise from distant sources that creates a relatively steady background noise in which no particular source is identifiable. A single descriptor called the equivalent sound level (Leq) may be used to describe sound that is changing in level. Leq is the energy-mean dBA during a measured time interval. It is the “equivalent” constant sound level that would have to be produced by a given source to equal the acoustic energy contained in the fluctuating sound level measured. In addition to the energy-average level, it is often desirable to know the acoustic range of the noise source being measured. This is accomplished through the maximum Leq (Lmax) and minimum Leq (Lmin) indicators that represent the root-mean-square maximum and minimum noise levels measured during the monitoring interval. The Lmin value obtained for a particular monitoring location is often called the acoustic floor for that location.

To describe the time-varying character of environmental noise, the statistical noise descriptors L10, L50, and L90 are commonly used. They are the noise levels equaled or exceeded 10 percent, 50 percent, and 90 percent of the measured time interval, respectively. Sound levels associated with L10 typically describe transient or short-term events. For the L50 descriptor, half of the sounds during the measurement interval are softer than L50 and half are louder. Levels associated with L90 often describe background noise conditions and/or sound sources that exhibit continuous, “steady-state” characteristics.

Finally, another sound descriptor known as the day-night average sound level (Ldn) represents the average sound level for a 24-hour day and is calculated by adding a 10 dB penalty only to sound levels during the night period (10:00 PM to 7:00 AM). The Ldn is typically used to define acceptable land use compatibility with respect to noise. Because of the night-time penalty associated with the Ldn descriptor, the Leq for a continuously operating sound source during a 24-hour period will be numerically less than the day-night level. Thus, and by way of example, for a power plant operating continuously for periods of 24 hours, the Leq will be 6 dB lower than the Ldn value.

Table 3.7-1 provides sound levels of typical noise sources and environments to provide a frame of reference.

Aside from industrial and other settings where workers may be exposed to very high noise levels and the risk of hearing loss, environmental noise effects are typically limited to subjective impacts (e.g., annoyance, nuisance, dissatisfaction) and activity interference (i.e., impacts to

sleep, speech, and learning). Despite attempts by prominent acousticians to satisfactorily quantify the association between measurable sound levels and corresponding reactions of annoyance and dissatisfaction, there is no way to measure the subjective impacts of noise. Further, the aforementioned variability of individual human sensitivity and/or tolerance to noise defies creation of a common standard.

3-115

Table 3.7-1

3.7.1.2 Regulatory Overview

Washington State and Skamania County Noise Limits

WAC 463-62-030 states that energy facilities shall meet the noise standards established in Chapter 70.107 RCW, also known, in short, as the “Noise Control Act of 1974”, as implemented in the requirements of WAC 173-60. SCC Title 8 Chapter 22: Noise Regulations identifies limits and exceptions specific to noise in Skamania County. SCC 8.22 was adopted pursuant to, and is consistent with, WAC 173-60. Environmental designations for noise abatement (EDNA) are established in SCC Section 8.22.080 and WAC 173-60-030. These rules establish maximum permissible environmental noise levels and are based on the EDNA, which is defined as an area

3-116

or zone (environment) within which maximum permissible noise levels are established. There are three EDNA classes:

- Class A. Lands where people reside and sleep (such as residential)
- Class B. Lands requiring protection against noise interference with speech (such as commercial/recreational)
- Class C. Lands where economic activities are of such a nature that higher noise levels are anticipated (such as industrial/agricultural).

The noise limits that a new source can impose for each land use classification are presented in Table 3.7-2.

Table 3.7-2
Washington Maximum Permissible Sound Levels
(Leq(1) in dBA)

EDNA of Noise Source	EDNA of Receiving Property
Class Aa (Residential)	Class B
Class B (Commercial)	Class C
Class C (Agricultural, Industrial)	Class A 55/45 57 60
	Class B 57/47 60 65
	Class C 60/50 65 70

aSound limits shall be reduced by 10 dBA between the hours of 10 PM and 7 AM at Class A EDNAs

Source: WAC Chapter 173-60. Standard applies at property line of receiving property.

The project is sited on land zoned as Forest Land 20 (FL 20) and Unmapped (UNM) zones. Approximately 0.9 mile west of the project site, the alternative Operations and Maintenance facility site would be located in the R-5 zone. Both the project site and the alternative Operations and Maintenance facility site are used for commercial timber harvest. Based on current zoning and land use, a reasonable interpretation would classify the project site as a noise source having an environmental designation of Class C EDNA, and the alternative Operations and Maintenance site as having an environmental designation of Class A EDNA. With respect to the receiving land uses, this noise analysis has identified some receiver locations being within agriculturally zoned lands that could normally be classified as Class C EDNA. Since the WAC does not specifically address the situation of an occupied residential structure located on an agricultural parcel, one might assess the residence as Class A EDNA and the outlying property

line as Class C EDNA. EFSEC has accepted such an interpretation for other wind energy projects such as Wild Horse and Kittitas Valley, the latter of which had approval upheld by the Washington Supreme Court. While other interpretations may be feasible, Table 3.7-3 illustrates the Class A (Residential) receiver noise level limitations for noise generated from a Class C (Commercial) EDNA (SCC 8.88.090, 100) source, including adjustments based on the duration of noise exposure time.

3-117

Table 3.7-3
Class A EDNA Receiver Noise Limits

5 minutes / L16.7 70 60
1.5 minutes / L2.5 75 65

Levels shown are at the property line of the receiving property and indicative of a source that is located in a Class C EDNA

Notwithstanding the above and per 173-60-050 WAC, there are exemptions to the limits for certain noise-producing activities or source types as follows:

- Construction noise (including blasting) between the hours of 7 AM and 10 PM
- Motor vehicles when regulated by 173-62 WAC (“Motor Vehicle Noise Performance Standards” for vehicles operated on public highways)
- Motor vehicles operated off public highways, except when such noise affects residential receivers
- Noise from electrical substations (WAC 173-60-050[2][a])

Despite these exemptions, 173-60-50(6) WAC states, “Nothing in these exemptions is intended to preclude the Department from requiring installation of the best available noise abatement technology consistent with economic feasibility.”

US Environmental Protection Agency and Occupational Safety and Health Administration

While the US Environmental Protection Agency (EPA) has no regulations governing environmental noise, the EPA has conducted extensive studies to identify the effects of certain sound levels on public health and welfare. An EPA document (USEPA 1974) identifies sound

levels “requisite to protect the public health and welfare with an adequate margin of safety.” The EPA specifies a day-night sound level (Ldn) of 55 dBA for outdoor areas, where quiet is a basis for use. The Ldn is similar to the 24-hour Leq except that a 10-decibel penalty is added to sound levels between 10 PM and 7 AM to account for sleep interference. For a potentially continuous source of noise such as operation of the project, the 55 dBA Ldn effectively translates to a 49 dBA hourly Leq, which is generally consistent with the 50 dBA Leq(1) required by Skamania County and the State of Washington. However, this EPA finding is guidance, not regulation.

The EPA’s 49–50 dBA Leq(1) sound level is far less than what is usually associated with hearing loss. The federal Occupational Safety and Health Administration (OSHA) has developed noise standards designed to address worker health and safety risks associated with noise exposure and

3-118

the potential for noise-induced hearing loss. The action level under these OSHA standards is an 8-hour time-weighted average of 85 dBA. Exposure to sound in excess of this standard requires the employer to initiate a hearing conservation program to evaluate the exposure, its duration, possible engineering controls to reduce noise and the provision of hearing protection to employees. The decibel levels covered by the state standards in WAC 173-60-110 are well below OSHA hearing impact standards.

Low Frequency Noise

Low frequency sound typically ranges from 100 Hz to 20 Hz, the latter of which is the generally understood limit audible to the human ear. WAC 173-60-110 uses the A-weighting scale because it is a standard that characterizes sound frequencies that are more sensitive to the human ear. Local jurisdictions within the State of Washington that have a C-weighted scale standard do not apply it to wind turbines. There is no Washington State standard associated with the C-weighted scale for low-frequency noise because the C-weighted scale is primarily used as an indicator of low frequency induced noise vibrations.

3.7.1.3 Affected Environment

Noise Receivers

Although Figure 3.7-1 shows that there are many potential noise-sensitive receivers surrounding the project vicinity, the three receivers closest to the project wind turbine tower locations are the two closest residences, which are approximately 0.48 mile (2,560 feet) southeast of Tower A1 (R1 on Figure 3.7-1) and 0.8 mile (4,265 feet) southwest of Tower B16 (R2 on Figure 3.7-1). A potential future residence (R3 on Figure 3.7-1) is approximately 0.38 mile (2,000 feet) from Tower A1.

Job No. 33758687 Noise Level Contours

Existing Sound Levels

While some reference materials such as the Federal Transit Administration's Transit Noise and Vibration Impact Assessment Guide (FTA 2006) offer techniques to make a coarse estimate of existing noise levels for an area based on parameters such as population density, the reality is that at residences in or near any project proposed for development, there is no such single and consistent background noise level. The background noise level can vary at a given location or across different locations on a project area due to factors such as changing climate conditions and the presence of contributing noise sources (including flows of water associated with creeks or canals, agricultural equipment operations, irrigation pumps and equipment, livestock, road, rail and air traffic, wildlife such as birds or insects, dogs, and routine human activities). Hence, a field survey that includes documentation of observed or perceived noise events and monitoring of ambient sound at different times of day at different locations helps to accurately depict actual conditions that influence pre-project ambient sound level. These conditions and their influence on ambient sound level offer clues as to how the increase in noise level resulting from the operation of any project, including those that emit a constant level, will likely vary with location and time of day.

To help establish representative baseline ambient sound levels for the project vicinity and characterize the existing noise environment in the areas occupied by the receivers shown in Figure 3.7-1, a set of long and short-term sound level measurements were conducted from January 20 to 22, 2009. The locations of the short-term and long-term measurement sites were selected to approximate the existing ambient sound in the vicinity of Ausplund Road (and hence, Receiver 1). Likewise, the location of ST2 was chosen to generally represent the ambient sound level for the Mill A community and its surroundings west of the project, on which Receiver 2 is located.

The measurement locations included a position near the intersection of Ausplund Road and Kollack-Knapp Road (ST1), and a position near the intersection of Jessup Road and Manzanola Road (ST2). For purposes of the impact analysis described in this document, these measurement locations are considered reasonably representative for each general area, and more specifically R1 and R2, respectively, on the basis of similar expected ambient sound sources, despite the dissimilarity of locations. For instance, the ambient sound environment measured at ST1 likely contains the same typically identifiable sound components (e.g., distant bird song, dog barks, roadway traffic) and a generally unidentifiable "background" that one might measure at the precise geographic location of R1.

A Bruel+Kjaer 2250 (SN: 2653963) ANSI Type-1 real-time sound analyzer, fitted with a standard microphone windscreen and mounted on a five-foot tall tripod, was used for the short-term measurements. The instrument was field calibrated before and after each measurement period with an acoustic calibrator. All sound level measurements were performed in accordance with International Organization for Standardization guidelines (ISO 1996a, b, and c). Weather conditions during the survey period were seasonably cold with overcast skies, but there was no

precipitation during the measurement periods. The air temperature varied from 30 to 44 degrees Fahrenheit, with 33 to 53 percent relative humidity. Measured ground wind speeds in the vicinity of the measurement positions were low, with averages ranging from 0 to 1 mph, and

3-121

directed toward the north for all measurements. Detailed weather conditions for individual noise measurements and a summary of the short-term measurement data are included in Table 3.7-4.

A long-term measurement (LT1) was conducted at a position near the corner of Ausplund Road and Kollock-Knapp Road using a Larson Davis 720 (SN: 0436) ANSI Type 2 Integrating sound level meter. With only the windscreen-covered microphone exposed to the outdoor environment, the sound level meter was placed in a locked, weather-resistant case and secured to a nearby tree. The long-term measurement consisted of consecutive 15 or 30 minute averages conducted over an uninterrupted 24-hour period. The instrument was field calibrated before and after the measurement period with an acoustic calibrator (CAL 200 s/n: 5789). Data from the long-term measurement is presented in Table 3.7-5.

Field observations associated with the short and long-term measurements are as follows:

ST1. This measurement location was at the corner of Ausplund Road and Kollock-Knapp Road. There are several residential receivers located in this general area. The first short-term measurement at this location was conducted between 11:52 AM and 12:12 PM on January 21, 2009. The first measurement noise sources included distant aircraft, distant roadway traffic, dogs barking in the distance, and birds vocalizing. The second short-term measurement was conducted between 6:00 PM and 6:20 PM on January 21, 2009. The second measurement noise sources included distant aircraft, distant roadway traffic, and dogs barking in the distance. The third short-term measurement at this location was conducted between 11:32 PM and 11:52 PM on January 21, 2009. Noise sources during the third measurement included distant roadway traffic and dogs barking in the distance. The first measurement Leq one-minute interval values ranged from 34 to 59 dBA, the second measurement 1-minute Leq values ranged from 27 to 66 dBA, and the third measurement 1-minute Leq values ranged from 25 to 49 dBA. Leq for the entire duration of each of these three measurement periods appears in Table 3.7-4.

ST2. This measurement location was in front of the John Schwab Memorial Tennis Courts on the corner of Jessup Road and Manzanola Road. The sound level meter was approximately 15 feet from Jessup Road. The first short-term measurement at this location was conducted between 12:48 PM and 1:08 PM on January 21, 2009. The first measurement noise sources included distant aircraft, distant roadway traffic, children playing in the distance, and birds vocalizing. The second short-term measurement was conducted between 6:36 PM and 6:56 PM on January 21, 2009. The noise sources for the second short-term measurement included distant aircraft and distant roadway traffic. The third short-term measurement was conducted between

12:08 AM and 12:28 AM on January 22, 2009. Noise sources present during the third short-term measurement included distant roadway traffic. The first measurement Leq one-minute values ranged from 35 to 52 dBA, the second measurement 1-minute Leq values ranged from 34 to

54 dBA, and the third measurement 1-minute Leq values ranged from 31 to 39 dBA. Leq for the entire duration of each of these three measurement periods appears in Table 3.7-4.

LT1. This measurement location was at the corner of Ausplund Road and Kollock-Knapp Road,

on the north side of the roadway. The sound level meter was placed in a locked, weather-resistant case and secured to a tree near the side of the road. The windscreen-covered microphone, connected to the meter by cable, was attached to the tree trunk at approximately 3 to 4 feet above the ground. Concurrent with these short and long-term ambient sound measurements, S.D.S. Co., LLC meteorological stations 320, 321, and 323 collected data on wind speed, direction, and temperature at various elevations above grade. Average reported wind velocities from the station NRG Type 40 anemometers were quite low, and while apparently consistent with the low average wind velocities measured on the ground at the sound measurement positions, were considered potentially compromised by icy conditions due to the low recorded temperatures and high moisture content of the air.

Table 3.7-4 shows the considerable decibel differences between the Leq measurements and the adjusted values when intervals containing documented automotive pass-by events were removed from the short-term measurement data sets (i.e., “without cars”). This change is unsurprising due to the proximity of the real-time sound analyzer to the roadway at ST1 and ST2. Upon removing these intervals, the remaining collected data more accurately depicts the background or a measurement position that is considerably distant from passing road traffic.

Table 3.7-6 presents the arithmetic average Leq of ST1 and LT1.

Average Ambient for ST1/LT1 Measurement Area

Daytime (Leq, dBA)	Evening (Leq, dBA)	Nighttime (Leq, dBA)
Average Leq without cars $(39+38)/2 = 38$	$(39+32)/2 = 35$	$(38+30)/2 = 34$
Average Leq with cars $(44+46)/2 = 45$	$(42+49)/2 = 45$	$(38+35)/2 = 36$

3.7.2 IMPACTS

3.7.2.1 Methodology

Construction

Project construction would take place over a period of 12 months between the hours of 7:00 AM and 7:00 PM Monday through Friday. During construction activities, a varying number of construction equipment and personnel would occupy the project area, which would result in varying levels of construction noise. The project would use conventional construction techniques and equipment, including excavators, bulldozers, heavy trucks (e.g., water truck, dump truck), and similar heavy construction equipment. Specialized construction equipment for logging, foundation building and other tasks using special equipment (e.g., heavy duty cranes) may be needed.

Conventional construction activities would result in a short-term temporary increase in the ambient noise level resulting from the operation of construction equipment. The increase in noise level would be experienced primarily close to the noise source. The magnitude of the

noise effects would depend on the type of construction activity, noise level generated by construction equipment, duration of the construction phase(s), and the distance between the noise source and receiver.

Construction noise impacts associated with the project were assessed with spreadsheet-based noise calculations. User inputs include:

- Distance from source—the distance between the edge of the construction site and the considered receiver
- Duty cycle—the portion of an hour, in aggregate, that a piece of equipment is energized (stationary or mobile) and creating noise
- Quantity—the number of equipment pieces or noise-producing events over a specific time period (e.g., equipment utilization per month)
- Hours—the number of daytime hours (up to 12) that represent a typical daily work shift

These inputs allow sound propagation prediction using the following formula:

$$Leq = \text{Source SPL} + 10 * \log_{10} (\text{Duty Cycle}) + 10 * \log_{10} (\text{Quantity}) + 10 * \log_{10} (\text{Hours}/12) - 20 * \log_{10} (\text{Distance from Source} / \text{Reference Distance})$$

where source SPL and reference distance describe the typical noise, associated with a single piece of equipment, measured at a pre-defined distance. For instance, a chainsaw may have a source SPL of 78 dBA measured at a distance of 50 feet from its operator. Values for source SPL and reference distance have either been reproduced from available manufacturers' data or calculated from industry-accepted formulas linking sound generation to the rated engine horsepower of the equipment. Note that for purposes of model conservatism, air and ground absorption effects are not included.

Operation

Once the project is commissioned and operating normally, the new ambient sound level that can be perceived will be a logarithmic sum of background and project noise. For a wind project, and aside from non-dominant sources such as electrical substations, operation noise level varies with wind speed at the turbines. When available winds are relatively calm, the turbines emit very little noise compared to what occurs when stronger wind conditions have turbines operating at their highest power generation and, concurrently, highest noise levels. Thus, a wind project's noise level at a particular receptor is primarily determined by the wind speed occurring at the turbine and the distance to the closest turbines.

The Cadna/A® Noise Prediction Model (Version 3.71.125) was used to estimate the project-generated sound pressure levels at the property lines and noise-sensitive receivers. Cadna/A® is a Windows® based software program that predicts and assesses noise levels near industrial noise sources based on International Organization for Standardization (ISO) 9613-2 standards for noise propagation calculations. Routinely used by acoustical professionals to develop sound level

predictions from a variety of complex industrial sources, including wind turbines, the model uses these industry-accepted propagation algorithms and accepts sound power levels (in dB re: 1 picowatt) for the nine standard octave bands ranging from 31.5 Hz to 8,000 Hz, as typically provided by the equipment manufacturer and other sources. The calculations account for classical sound wave divergence, plus attenuation factors resulting from air absorption, basic ground effects, and barrier/shielding. Intervening natural and man-made topographical barrier effects were considered as appropriate, including those from structures such as major buildings, tanks, and large equipment.

Table 3.7-7 summarizes octave band sound power level inputs from each type of pre-defined noise source. Given that the exact turbine model to be used for the project has not yet been determined at the time of this report, conservative but realistic and representative values for the type of equipment being considered for this project have been used. For example, the model currently uses data from an industry leading 1.8 MW 50/60 Hz wind turbine, at wind speeds of about six meters per second and nine meters per second at 33 feet (10 meters), in accordance with the protocol established in International Electrotechnical Commission Standard 6140011: 200213. The decibel values shown for the two wind turbine generator wind speeds in Table 3.7-7 at each octave band center frequency include a +2 dB margin, which produces an A-weighted overall level that represents the top end of a range associated with the manufacturer's warranty values.

Source: URS internal information and Thomas Mills, personal communication

13 As noted, the modeling is based using conservative and representative values for the type of equipment being considered. The noise model currently uses data from an industry leading 1.8 MW 50/60 Hz wind turbine. The project may use larger wind turbines, up to 2.5 MW, and these could have a different noise profile. However, total project noise would be limited by the 75 MW EFSEC certification. If 1.8 MW turbines were selected, the project could use up to 42 turbines, however if 2.5 MW turbines were selected, only 30 turbines could be built, and overall project noise could be lower.

3-126

The project layout configuration (i.e., the arrangement of wind turbine generators and ancillary equipment on the site) was imported into Cadna/A® from project files provided by the client. The Cadna/A model consequently predicts hourly sound levels, which would be equal at all times of the day in this case. The formula used to derive the overall SPL (in dBA) from sound power level (PWL) is as follows:

$$\text{SPL} = \text{PWL} - 20 \text{ Log } (r) - 10.9 + C$$

where r is in meters and C is a dimensionless absorption constant (Harris 1998).

At each studied receptor, the model calculates the acoustical contribution from each input source, which in this exercise using Cadna/A includes all expected wind turbines associated with the project at locations depicted in Figure 3.7-1. When project micrositing occurs and final turbine layout and turbine model are arrived at, additional noise modeling can be performed to re-predict operation noise level and re-evaluate anticipated project compliance with the standards discussed in this Draft EIS.

3.7.2.2 Proposed Action General Construction Noise

Table 3.7-8 shows the predicted construction noise levels experienced at the closest residences to the project. As per 173-60-050 WAC, construction noise between the hours of 7:00 AM and

10:00 PM are exempt from the receiver noise limit guidelines. Consequently, the calculated values at the three closest receivers comply with the applicable noise standard.

Table 3.7-8

Receiver 3 Residence 0.38 mile (2000')
SE of Tower A1 Class A Exempt 72 Yes

If it is determined to be necessary, blasting would occur during the turbine foundation portion of the construction schedule and only during daytime hours. Blasting noise could possibly be audible at a considerable distance from the construction site and noticeable at residences near the project area. Sound levels from blasting at a receiver would not be extreme, however, and the occurrence would be low in frequency, intermittent, and confined to a period of one to two months. The WAC 173.60.050 exemption for temporary construction noise includes noise from blasting activity, from the aforesaid state noise limits between the hours of 7 AM and 10 PM.

3-127

The large distances between much of the project area and potentially affected residences, the temporary nature of construction, and the restriction of construction activities to daytime hours would serve to minimize potential noise impacts from construction activities. Based on the anticipated noise levels and the timing aspects of these impacts, construction noise impacts are expected to be low.

If project construction occurred in phases, the effect on the level of noise impacts would be to extend the total duration of temporary disturbance from project construction, but to reduce the intensity or magnitude of impacts for any individual phase. Construction noise impacts would still be temporary, localized, and low in magnitude, and overall project impacts during construction would remain low in a phased-construction scenario.

General Operation Noise

The predicted operational noise levels at the three closest residences to the project are supplied in Tables 3.7-9 and 3.7-10. This analysis evaluates the existing noise levels at the closest receptors,

and evaluates increases in dBA at these locations. The Washington noise regulations do not require this information; however, the Applicant supplied this information to fully inform EFSEC during the Application for Site Certificate process.

Table 3.7-9
Nighttime Operational Noise Impact Assessment

Receiver ID	EDNA Class	Sound Level Limit (dBA)	Existing (dBA)	Project (dBA)	Overall (dBA)	Increase (dBA)	Complies with Regulation
6 m/sec at 10m height							
1	Class A	50	34	36	38	4	Yes
2	Class A	50	35	38	40	5	Yes
3	Class A	50	35	40	41	6	Yes
9 m/sec at 10m height

Under certain conditions, there is the potential for one or more of the following phenomena to occur that may temporarily cause a variance in the predicted sound levels:

- In the Cadna/A prediction model, all studied wind turbine generators were assumed to operate at the same speed. In reality, very slight differences in operating rotor speeds due to non-uniformities in the passing wind profile can result in intermittent constructive and destructive interference—or what one might call “beats,” that can have a perceptible frequency as current research suggests (van den Berg 2006).
- The atmosphere can either be “stable” or “unstable,” which in summary are descriptors for how layers of air mass interact. The latter of these two is usually associated with cold air near the ground that is not well coupled to higher air masses. This effect can explain why high wind speeds at wind turbine generator hub height can be substantially greater than those near ground level (van den Berg 2006).
- The relative humidity and ambient temperature have a substantial effect on the attenuation of outdoor sound at high frequencies and long distances through air absorption. Relative humidity and temperature effects can produce a variance of approximately +/- 2 dBA.
- The uncertainty range for the PWL of each wind turbine generator is +/- 2 dBA.
- Due to the very low ground wind speeds recorded during the short-term measurements, actual ambient noise levels at any receiver in the project vicinity may be higher as a result of noise generated by turbulence from wind streaming through vegetative ground cover (i.e., trees and grasses). Further, since wind-generated noise tends to rise at a rate of 2.5

dBA per 1 m/s increase in wind speed, and generally turbine aerodynamic noise rises at a rate of only 1 dBA per 1 m/s increase in wind speed, high wind speeds near the ground may cause background sound (i.e., not project operation) to dominate the perceptible and even measurable ambient sound environment (BLM 2005).

3-129

Because predicted project operation sound pressure levels at the nearest noise-sensitive receivers are at least 7 dBA lower than the 50 dBA Leq compliance threshold, none of these above conditions is expected to result in the project operation exceeding noise regulations.

Low Frequency Sound

Low frequency noise produced by a wind turbine generator can include tonal components produced by the generator and gearbox within the nacelle downstream of the rotor hub, atop the tower mast. The source sound power levels in Table 3.7-7 already include these noise contributors. Modern wind turbine design typically includes sound attenuation features in the nacelle to help reduce the magnitude of these electro-mechanical noise components to the aggregate, so that the spectrum of sound levels at the octave band center frequencies shown in Table 3.7-7 largely describes the aerodynamic effects of the rotor blades interacting with the passing wind profile. Even though there are no relevant regulations and standards related to dBC, the turbine sound power level manufacturer ratings show that C-weighted levels are within 2 dB of A-weighted levels. Therefore, low frequency noise is not anticipated to be an issue for this project.

In earlier generations of wind turbine design, the practice of using downwind rotors allowed turbulence from the tower mast to disrupt favorable aerodynamic conditions for the passing blades, causing considerable low frequency noise. This practice has been abandoned by the contemporary upwind rotor design of virtually all wind turbine generators built in the past five years, including the models contemplated for this project.

The noise produced by air interaction with the rotor blades tends to be broadband noise, but is amplitude-modulated as the upstream blades pass the tower, resulting in what some call a characteristic “swoosh.” The blade passage frequency of this “swoosh” is only a temporal modulation of sound and should not be confused with low frequency sounds. Research studies of low-frequency noise emissions from wind turbines have determined that low frequency noise is a function of the wind itself, and that the “swoosh” of the turbines is actually in the readily audible range of frequencies (500 to 1 kiloHertz) (Leventhall 2006). Virtually any sound can be time-modulated without changing its pitch. Thus, low frequency modulation of audible sound does not imply the presence of actual low frequency sound or infrasound, which is discussed in the following subsection.

Information regarding potential impacts from exposure to low frequency noise is inconclusive. Scientific articles suggest that low frequency noise does not pose a health risk (Leventhall 2006). There may, however, be some correlation between an individual receptor’s psychological sensitivity to the noise source (like or dislike for the noise source) and complaints regarding discomfort from that noise source. These are sometimes associated with complaints regarding

sleep disturbance. Because sensitivity to noise can be influenced by such psychological factors and can subjectively be deemed significant by an affected individual, regardless of measurable frequency or amplitude level, it is difficult to quantify these impacts or to impose mitigation.

3-130

However, modern turbine designs have been modified to reduce or eliminate low frequency sound.¹⁴

Infrasound

The term infrasound describes sound with frequencies of 20 Hz or less that are generally considered below the threshold of human hearing. Such sound, if sufficiently high in magnitude, can still be perceived or even heard as induced by vibration. Natural sources of infrasound include waves, thunder, wind, and even certain species of wildlife.

A review of wind turbine noise measurement studies conducted by Jakobsen (2005) concluded that operation of contemporary wind turbine generators featuring rotors “upwind” of tubular tower masts generated infrasound in the range of 70 G-weighted decibels (dBG) at a distance of one hundred meters. (The G-weighting scale, like the oft-used A-weighting scale for audible sound spectra, is a filter applied to low-frequency sound as described in ISO 7196:1995E.) Jakobsen also notes that this infrasound, usually associated with aerodynamic effects of blade passage past the tower mast, tends to ignore atmospheric sound absorption and ground attenuating effects due its very large wavelength. Hence, one could reasonably expect infrasound to attenuate only with increasing propagation distance.

Recent studies performed for the Canadian Wind Energy Association have described usage of 85–90 dBG as a criterion for human perception of infrasound and, by reasonable extension, the likely threshold for infrasound complaint (HGC Engineering 2006).

The horizontal distances of the project wind turbines to the nearest noise-sensitive receivers are at least 615 meters, which provides sufficient attenuation to offset the amount of decibels that one might add to account for the quantity of wind turbines of the project. Thus, the expected infrasound at the nearest existing receivers (i.e., R1 and R2) would remain under an estimated value of 70 dBG, which is 15 dBG less than the previously stated criteria. This estimated project aggregate wind turbine generator infrasound level also is far below what NASA studies determined (125 dB, linear) as a threshold for potential health impacts (HGC Engineering 2006).

Project Decommissioning

In compliance with WAC 463-72 Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project’s operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major noise issues presently anticipated, including noise impacts from construction activities related to removal of the wind generation equipment and site restoration. If impacts to

14 See, for instance, <http://www.bwea.com/ref/lowfrequencynoise.html>.

3-131

noise are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

3.7.2.3 No Action Alternative

Under the No Action Alternative, the project would not be constructed. Existing sound levels would be expected to remain largely the same. Although the generally quiet ambient noise levels in the project area would continue, occasionally elevated noise levels in the immediate project vicinity would be expected from ongoing timber harvest activities at the project site.

3.7.3 MITIGATION

The following mitigation measures are identified to avoid, minimize, and compensate for potential noise-related impacts during construction and operation of the propose project to the extent feasible.

- Equip all noise-producing project equipment and vehicles using internal combustion engines with mufflers, air-inlet silencers where appropriate, and any other shrouds, shields, or other noise-reducing features in good operating condition that meet or exceed original factory specification. Mobile or fixed “package” equipment (e.g., arc-welders, air compressors) would be equipped with shrouds and noise control features that are readily available for that type of equipment.
- Regulate all mobile or fixed noise-producing equipment used on the project for noise output governed by local, state, or federal agency regulations, to comply with such regulations while in the course of project activity.
- Designate that the use of noise-producing signals, including horns, whistles, electronic alarms, sirens, and bells, would be for safety warning purposes only. Unless required for such safety purposes, and as allowable by applicable regulations, no construction-related public address, loudspeaker, or music system would be audible at any adjacent noise-sensitive land use.
- Implement a noise complaint process and hotline number for the surrounding community. The Applicant would have the responsibility and authority to receive and resolve noise complaints.

3.7.4 UNAVOIDABLE ADVERSE IMPACTS

Construction noise is exempt so long as it occurs during daytime hours, and operation noise is

predicted to be less than the nighttime threshold of 50 dBA Leq per Washington State and Skamania County regulations.

The analysis of noise impacts presented here was based on specific design features of the proposed project that were current as of the date of this Draft EIS. These features, such as the turbine manufacturer and model selection, the layout of the turbines on the project site and their corresponding distances to identified closest noise-sensitive receivers, can greatly influence the

3-132

analysis results. However, assuming that final turbine selections and siting locations are comparable to those features used in this analysis, no substantial adverse construction or operation noise impacts are anticipated for the project.

3.8 LAND USE AND RECREATION

This section describes the existing land uses and recreation areas at the project site and in surrounding areas, and identifies potentially applicable land use policies and zoning ordinances. This section also discusses potential project impacts on land use and recreation, as well as the consistency of the proposed project with local land use plans and zoning ordinances.

3.8.1 AFFECTED ENVIRONMENT

3.8.1.1 Existing Land Use

Project Site

The project site is located in an unincorporated portion of southeastern Skamania County, Washington, about two miles north of the Columbia River (see Figure 1-1). The primary use at the project site is commercial forestry. The site has been used for this purpose for the last century. During this time, the owners and operators have logged the property over a series of approximately 50-year logging rotations. Ongoing tree farming activities include regular clearing, replanting, and harvesting.

Portions of the project site are also used for utility corridors. A natural gas pipeline, owned and operated by Williams Gas, runs from east to west across the project site near the north boundary of the site. Two existing transmission line corridors also cross the project. These approximately 250-foot wide corridors, which generally run in an east-to-west direction, are owned and maintained by BPA. Each corridor is occupied by a high-voltage transmission line and its associated support towers and access roads. The corridors are routinely maintained to remove all tall growing vegetation, as well as any adjacent "danger trees" (i.e., those trees with the potential to fall into the existing lines) in order to avoid interference with these lines.

Surrounding Areas

Land use in the project vicinity is predominately commercial forestry with other typical rural uses and both incorporated and unincorporated communities dispersed throughout (see Figure

3.8-1). The incorporated cities of White Salmon and Bingen, Washington are located adjacent to each other approximately 7 miles southeast of the project site, along the north side of the Columbia River. Directly south and across the Columbia River from Bingen is the City of Hood River, in Hood River County, Oregon. The city of Stevenson, the Skamania County seat, is located approximately 15 miles southwest of the project site along the Columbia River. These incorporated cities have mixed urban uses typical of small communities.

In the more immediate vicinity of the project site, the unincorporated community of Willard is located approximately 2.25 miles northwest of the project site, and the unincorporated community of Mill A is located approximately 1.5 miles west of the site. Other residential uses in the immediate vicinity of the project site are generally rural, low- to medium-density single-family homes between 30 and 50 years old. There are approximately 400 residences and businesses within three miles of the project site (see Figure 3.8-2). A new homesite location has

3-134

been approved approximately 2,000 feet (0.38 mile) from the south property line of the project site.

Commercial forestry areas and the Gifford Pinchot National Forest are generally located to the north of the project site. East of the Little White Salmon River, lands are currently being used for commercial timber production under ownership by S.D.S. Co., LLC, Broughton Lumber Company, and Washington State. The Washington State lands are managed by DNR for commercial harvest to support the State's schools.

To the south of the project site is the Columbia River Gorge National Scenic Area (see Figure 3.8-3). The Scenic Area extends along the Columbia River for about 85 miles and includes 292,500 acres in parts of three Oregon and three Washington counties. In addition to forested areas, land uses within the Scenic Area near the project site on the Washington side of the Columbia River include limited agriculture, mostly pear and apple orchards recently augmented with some wine grape vineyards. On the Oregon side of the Columbia River, land use within the Scenic Area is predominantly commercial timber production and residential. Further south of the Scenic Area in Oregon, land uses include commercial forestry, agriculture (primarily pears, apples, and cherries), and some residential.

SR 14 and the Burlington Northern Santa Fe Railway are located between the project site and the Columbia River, within the Scenic Area. I-84 is located on the Oregon side of the Columbia River, within the Scenic Area.

33758687_166.cdr

Figure 3.8-3

Job No. 33758687 Recreation Facilities within Five Miles of the Project Site

3.8.1.2 Recreation

The primary recreation activities within Skamania County are camping, hiking and fishing. Major recreation locations include the Gifford Pinchot National Forest; the Mount St. Helens National Volcanic Monument; the Lewis and Clark Trail Highway, which follows the Columbia River through Skamania County; and the Columbia River Gorge National Scenic Area south of the project area. Informal recreational activities such as hunting, hiking, and mountain biking also take place on private land, subject to landowner approval. There are no formally designated recreational areas within the project site; however, SDS does allow informal recreational use of their land with approval.

Summer recreational activities include water sports such as fishing, swimming, boating, river rafting, kayaking, water skiing, and wind surfing; as well as camping, biking, hiking, horseback riding, hunting, picnicking, and other outdoor sports. Some of these activities continue into the winter, weather permitting. Sightseeing is a popular year-round activity in the Columbia River Gorge. Recreational facilities within a 25-mile radius of the project site are shown on Figure 3.8-3 and listed in Table 3.8-1.

The closest recreational facility is the Underwood Park and Community Center, located near Underwood just off of Cook-Underwood Road, approximately 1.5 miles east of the project site. The community center has a large gymnasium, stage, kitchen, and meeting room; while the park has soccer fields, a pavilion, and a playground. Recreational facilities or activities available closest to the project site include hiking and horseback riding along Buck Creek Trail, Husum Hills Golf Course, BZ Corners Boat Launch, Underwood Park/Community Center, and Drano Lake Boat Ramp.

There are no Skamania County recreation facilities within five miles of the proposed project. However, two national trails, the Lewis and Clark National Historical Trail and the Oregon National Historic Trail, are located within 5 miles of the project site. These trails roughly follow SR 14 and I-84, respectively. Also within 5 miles of the site, the White Salmon River is designated as a Wild and Scenic River, and within 25 miles, the Klickitat River is also so designated.

There are no new parks or recreation facilities planned within a 5-mile radius of the site, either as part of the Skamania County Parks and Recreation Master Plan or the Columbia River Gorge National Scenic Area Management Plan. No federal recreation regulations apply to the site, nor

are there federal or state plans for recreation facilities on or near the site.

3.8.2 APPLICABLE LAND USE REGULATIONS

Skamania County has two independent sets of land use regulations. The first is a stand-alone

zoning code (SCC Title 22) that regulates uses and development within the General Management Area (GMA) and Special Management Area (SMA) of the Columbia River Gorge National Scenic Area). The Scenic Area Code is based on the Management Plan for the Scenic Area, which is overseen by the USFS and Columbia River Gorge Commission, as directed by the National Scenic Area Act.

3-140

The remainder of unincorporated Skamania County, as well as those portions of the Scenic Area classified as Urban Areas (such as White Salmon, Bingen, and Hood River), is governed by the Skamania County Comprehensive Plan, zoning regulations in SCC Title 21, and Titles 20, Shorelines, and 21A, Critical Areas.

Because the project site is located outside of the National Scenic Area, land use at the site is regulated by the Skamania County Comprehensive Plan and SCC Titles 21, 20, and 21A. In addition, although the project site is immediately adjacent to the National Scenic Area, the National Scenic Area Act expressly provides that land use regulations developed for the National Scenic Area do not apply to adjacent area. Section 544O(a)(10) of the Act states:

Nothing in Sections 544 to 544p of this title shall establish protective perimeters or buffer zones around the scenic area or each special management area. The fact that activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas.

16 USC §544O(a)(10). The remainder of this section therefore focuses on describing potentially applicable provisions of the Skamania County Comprehensive Plan and SCC Titles 21, 20, and 21A. For additional information of the provisions of the National Scenic Area Act, see Section 4.11 of this EIS.

3.8.2.1 Skamania County Comprehensive Land Use Plan

On July 10, 2007, Skamania County adopted its current Comprehensive Plan, which includes three Subarea Plans. The project site is not located in one of these subareas. There are three land use designations outside of the specific subarea plans: Rural I, Rural II, and Conservancy (see Figure 3.8-4). The project site is designated as Conservancy. The Comprehensive Plan identifies zoning that is consistent with the Conservancy designation, including: Residential 10 (R-10), Rural Estates 20 (RES-20), Resource Protection (FOR/AG 10 and 20), Commercial Resource Land 40 (CRL 40), Natural (NAT), and Unmapped Classification (UNM).

The alternative location of the Operations and Maintenance facility is in the Rural II designation of the Comprehensive Plan. Most residential zoning classifications are consistent with the Rural II designation, as are the FOR/AG 10 and 20, NAT, and UNM zoning classifications.

The overall Comprehensive Plan vision statement is:

Skamania County is strongly committed to protecting our rural character and natural resource based industries while allowing for planned future development that is balanced with the protection of critical resources and ecologically sensitive areas, while preserving the community's high quality of life.

primary data and information sources to ascertain the usability of the information.

Forest Resource

Figure 3.8-4

Skamania and Klickitat Counties

Source: Skamania County. Comprehensive Plan Designations

Natural resources-based industry is further encouraged in the Comprehensive Plan's description of the intent of the Conservancy designation:

The Conservancy land use area is intended to provide for the conservation and management of existing natural resources in order to achieve a sustained yield of these resources, and to conserve wildlife resources and habitats. Much of the Conservancy land use area is characterized by rugged terrain, steep in slope, and unsuitable for development of any kind. Logging, timber management, agricultural and mineral extraction are main use activities that take place in this area. Recreational activities of an informal nature such as fishing, hunting, and hiking occur in this area, although formal recreational developments may occur from time to time. Conservancy areas are intended to conserve and manage existing natural resources in order to maintain a sustained resource yield and/or utilization.

Among the uses identified as appropriate in the Conservancy designation are: public facilities, utilities, utility substations, forest management (including temporary logging and mining camps), and surface mining (by conditional use).

The Rural II designation is described in the Comprehensive Plan as follows:

“The Rural II land use area is intended to provide for rural living without significant encroachment upon lands used for agriculture and timber. This land use area is the middle developmental range level suggested by this plan. The lower density will help to protect agricultural and timber lands from dense residential type development, and should maintain the rural character of this designation.”

Among the non-residential uses identified in the Comprehensive Plan as appropriate in the Rural II designation are public facilities, utilities, utility substations, telecommunication facilities, hospitals, meeting halls, agriculture, forest management including temporary logging and mining camps, and surface mining.

The following identifies potentially applicable goals and policies in the Comprehensive Plan.

Goal LU.1: To integrate long-range considerations (comprehensive planning) into the determinations of short-term action (individual development applications).

Policy LU.1.2: The plan is created on the premise that the land use areas designated are each best suited for the uses proposed therein. However, it is not the intention of this plan to foreclose on future opportunities that may be made possible by technical innovations, new ideas and changing attitudes. Therefore, other uses that are similar to the uses listed here should be allowable uses, review uses or conditional uses, only if the use is specifically listed in the official controls of Skamania County for that particular land use designation.

3-143

Goal LU.2: To provide for orderly future physical development of Skamania County.

Policy LU.2.4: Encourage new commercial enterprises to locate within or near existing commercial areas to avoid further scattering and to better serve the public.

Goal LU.3: To coordinate public and private interests in land development.

Policy LU.3.3: Encourage industry that would have minimal adverse environmental or aesthetic effects.

Goal LU.4: To promote interagency cooperation and effective planning and scheduling of improvements and activities so as to avoid conflicts, duplication and waste.

Policy LU.4.3: Land use patterns, which minimize the cost of providing adequate levels of public services and infrastructure, should be encouraged.

Goal LU.5: To promote improvements which make our communities more livable, healthy, safe and efficient.

Policy LU.5.5: Promote compatibility of industry with the surrounding area or community by fostering good quality site planning, landscaping, architectural design, and a high level of environmental standards.

Policy LU.5.6: Encourage commercial development that is convenient, safe and pleasant to the general public by: requiring that new establishments provide off-street parking adequate for its needs. Encourage pooled or joint use parking areas for adjacent developments may be utilized; Regulate access points for vehicular traffic for commercial areas to prevent unsafe conditions; the design of commercial sites, buildings, and signs should be compatible with surrounding areas; and, landscaping may be required as a buffer when commercial use adjoins residential or farm property.

Goal E.1: To ensure the proper management of the natural environment to protect critical areas and conserve land, air, water, and energy resources.

Goal T.1: Transportation – Encourage an efficient multi-modal transportation network that is based on regional priorities and coordinated with county and city comprehensive plans.

Goal T.2: Continue the priority of increasing safety of the Skamania County rural 2-lane road system. The majority of the Public Works Department's future efforts will be to reduce the accident rate with Skamania County.

3-144

Goal T.3: Public Facilities and Services – Ensure that those public facilities and services necessary to support development should be adequate to serve the development at the time the development is available for occupancy and use without decreasing current service levels below locally established minimum standards.

Goal AHP.1: Identify and encourage the preservation of lands, sites, and structures that have historical or archaeological significance.

Goal AHP.2: Increase recognition of historic, archaeological, and cultural resources.

Goal AHP.3: Protect historic, archaeological and cultural resources through a comprehensive planning approach.

3.8.2.2 Skamania County Zoning Ordinance SCC Title 21

Title 21 of the Skamania County Zoning Ordinance is the county zoning that applies to the project site. Although extensive updates of SCC Title 21 have been proposed for adoption, the last-adopted version is still in effect because the proposed updates are currently under appeal by local interest groups.

Under SCC Title 21, the project site is located primarily in the UNM zone, with the southern tip of the project site in the FOR/AG 20 zone (see Figure 3.8-5). Both of these zoning classifications are consistent with the Comprehensive Plan's Conservancy designation for this area. None of the project site is designated as farmland.

Approximately 7,152 acres of the 1,152-acre project site are located in the UNM zone. UNM zones are those areas of the county where no formal adoption of any zoning map has taken place. The Skamania County Code provides:

In the UNM zone all uses which have not been declared a nuisance by statute, resolution, ordinance or court of jurisdiction are allowable. The standards, provisions, and conditions of this title [SCC Title 21] shall not apply to unmapped areas.

SCC 21.64.020. Nuisances established by the Board of County Commissioners by resolution and ordinance are identified in SCC 8.30.010; this provision of the County Code does not identify wind energy facilities as a nuisance. In addition, neither the RCW nor the WAC designate wind energy facilities as a nuisance.

In July 2007, the County adopted a moratorium on unincorporated UNM-zoned lands outside the Swift Subarea. The moratorium does not prohibit all development in UNM lands. Rather, it restricts three types of land uses: (1) issuance of building permits on lands created by deed since January 2006 that are 20 acres or larger; (2) land divisions (short plat and subdivision); and (3) acceptance of SEPA checklists in support of converting land to non-forestry uses.

3-145

33758687_167.cdr

Figure 3.8-5

Job No. 33758687 Skamania County Zoning

The remainder (approximately 400 acres) of the project site is located within the FOR/AG 20 zoning classification (see Figure 3.8-5). Pursuant to SCC 21.56.010[A]), the purpose of this zone is:

To provide land for present and future commercial farm and forest operations in areas that have been and are currently suitable for such operations, and to prevent conflicts between forestry and farm practices and nonresource production uses by not allowing inappropriate development of land within this zone classification.

Uses allowed outright in the FOR/AG 20 zone include the following:

- A. Forestry practices and associated management activities of any forest crop in accordance with Washington Forest Practices Act of 1974 including timber, Christmas trees, nursery stock, and surface mining.
- B. Commercial and domestic agriculture.
- C. Orchards and vineyards.
- D. Horticulture.
- E. Cottage occupation (in accordance with Chapter 21.70).
- F. Light home industry (in accordance with Chapter 21.70).
- G. Management of unique biological areas.
- H. Management and propagation of fish and wildlife.
- I. Water resources management facilities.
- J. Storage of explosives, fuels and chemicals.
- K. Accessory uses normally associated with an allowable use.
- L. Public and private conservation areas or structures for retention of water, soil, open space, forest, or wildlife resources.
- M. Log sorting and storage areas, scaling stations, temporary crew quarters, forest industry storage and maintenance facilities.
- N. Family day care home (in accordance with Section 21.86.020).
- O. Residential care facilities (in accordance with Chapter 21.85).
- P. Farm labor housing.
- Q. Accessory equipment structures.
- R. Attached communication facilities not located on BPA towers (in accordance with Section 21.70.160).

Uses allowed by Conditional Use Permit in the FOR/AG 20 zone include:

- A. Individual single-family residences not provided in conjunction with forest or farm management, including residential and resource related development may be permitted conditionally, provided they meet (...additional listed conditions).

3-147

- B. Recreational facilities.
- C. Semi-public facilities and utilities.
- D. Sawmills, shake and shingle mills, chippers, pole and log yards.
- E. Geothermal energy facilities.
- F. Aircraft landing fields.
- G. Cluster developments.

H. Child mini-day care center (in accordance with Section 21.86.030).

I. Child day care center (in accordance with Section 21.86.040).

The alternative Operations and Maintenance facility site is located approximately 0.9 mile west of the project site in the R-5 zoning classification (see Figure 3.8-5). This zoning classification is consistent with the Comprehensive Plan's Rural II designation for this area. Pursuant to SCC 21.36.010, the purpose of the R-5 zone is:

To provide a transition zone of medium to low density residential development which will maintain a rural character of the area in the Rural II Land Use Area of the County Comprehensive Plan A.

Comment: The industrialization of Skamania County and other counties in the region is NOT preserving the rural character of the area! The Futurewise article, Planning for Sustainable Rural Areas, written in March 21, 2005 has a definition for rural character: 'The rural area is the land located outside the urban growth area and outside resource lands. Resource lands are agricultural, forest, and mineral lands of long-time commercial significance.

"Rural character" refers to the patterns of land use and development established by a county in the rural element of its comprehensive plan:

(a) In which open space, the natural landscape, and vegetation predominate over the built environment;

(b) That foster traditional rural lifestyles, rural-based economies, and opportunities to both live and work in rural areas;

(c) That provide visual landscapes that are traditionally found in rural areas and communities;

(d) That are compatible with the use of the land by wildlife and for fish and wildlife habitat;

(e) That reduce the inappropriate conversion of undeveloped land into sprawling, low-density development;

(f) That generally do not require the extension of urban governmental services; and,

(g) That are consistent with the protection of natural surface water flows and ground water and surface water recharge and discharge areas.

"Rural development" refers to development outside the urban growth area and outside agricultural, forest, and mineral resource lands designated pursuant to RCW 36.70A.170. Rural development can consist of a variety of uses and residential densities, including clustered residential development, at levels that are consistent with the preservation of rural character and the requirements of the rural element. Rural development does not refer to agriculture or forestry activities that may be conducted in rural areas.' I don't think that putting up 50+ industrial wind turbines and constructing maintenance roads throughout the

landscape conforms to the definition of rural character “ (a) In which open space, the natural landscape, and vegetation predominate over the built environment”!!

Uses allowed outright in the R-5 zone include the following:

- A. Single-family dwellings
- B. Commercial and Domestic agriculture
- C. Forestry
- D. Public facilities and utilities
- E. Cottage occupation (In accordance with Chapter 21.70)
- F. Light home industry (In accordance with Chapter 21.70)
- G. Residential care facilities (In accordance with Chapter 21.85)
- H. Family day care home (In accordance with Chapter 21.86.020)
- I. Safe home
- J. Accessory equipment structures
- K. Attached communication facilities located on BPA towers. (in accordance with Section 21.70.160)

Uses allowed by Conditional Use Permit in the R-5 zone include:

- A. Surface mining
- B. Recreational facilities
- C. Professional services

3-148

- D. Geothermal energy facilities
- E. Public displays
- F. Cluster developments
- G. Semi-public facilities
- H. Small and Large-Scale Recreational Vehicle Parks.
- I. Child day center (In accordance with Chapter 21.86.040)

3.8.2.3 Skamania County Code, Title 20, Shorelines

Because the project site is not located near or on any shorelines of State, County or other significance, there are no applicable provisions of this county code.

3.8.2.4 Skamania County Code, Title 21A, Critical Areas

The Washington State Growth Management Act, RCW 36.70A.060, requires counties to identify and regulate critical areas.¹⁵ Critical areas include:

- Fish and wildlife habitat conservation areas
- Frequently flooded areas
- Geologically hazardous areas
- Ponds and lakes
- Streams, creeks, and rivers

In Skamania County, critical areas regulations are found in SCC Title 21A. The project site is not located within any critical recharge areas, frequently flooded areas, ponds and lakes, or rivers. Portions of the project site are located near geologically hazardous areas due to steep slopes classified as Class II and III LHAs. There are wetlands, fish and wildlife habitat areas, streams, and creeks on the site.

3.8.3 IMPACTS

Adverse impacts to land use can be defined two ways:

- Changes to existing land use activities and development patterns. The project could cause adverse impacts if it were to preclude the continuance of existing land uses or cause major changes to the existing patterns of land use activities or development. See: http://www.commerce.wa.gov/_CTED/documents/ID_892_Publications.pdf

3-149

- Inconsistency of a proposed project with existing land use regulations. The project could cause adverse impacts if it was found to be inconsistent with the Skamania County Comprehensive Plan, Zoning Code, or Critical Areas regulations.

3.8.3.1 Proposed Action

Changes to Existing Land Use Patterns and Recreation

Project Construction

During construction, earth movement and construction-related traffic would generate noise and dust that could temporarily affect nearby homes and businesses located along the site access route (described in Section 3.11, Transportation). Cook-Underwood Road would be the primary access route for construction materials and workers. However, construction impacts would not be sufficient to cause changes to existing land use patterns.

Land clearing for the construction of the alternative Operations and Maintenance facility site would occur concurrently with roadway improvements to West Pit Road. The additional earth movement and construction-related traffic would generate slightly more noise and dust in that area along West Pit Road over anticipated levels for roadway construction without the facility. The additional noise and dust could temporarily affect nearby homes along Willard Road. Construction impacts would not be sufficient to cause changes to existing land use patterns.

Construction would not directly affect local recreational facilities beyond the potential for construction workers to use local recreational facilities during the one year construction period. Existing limits on the length of stay in public camping areas would minimize any potential impacts on park users from construction workers staying in parks, and a majority of the construction workers are expected to be within daily commuting distance of the site. Additionally, workers who did stay at local parks would most likely do so on weekdays and would thus not be there on the days with the highest levels of use.

Construction activities could affect some recreation users such as users of the Underwood Park and Community Center located along Cook-Underwood Road, through temporary increases to traffic, and from construction-related dust and noise. These impacts would be temporary and are expected to be minor.

Construction of the Operations and Maintenance facility at the West Pit Road location would not impact local recreational facilities. Existing limits on the length of stay in public camping areas would minimize any potential impacts on park users from construction workers staying in parks, and a majority of the construction workers are expected to be within daily commuting distance of the site. Additionally, workers who did stay at local parks would most likely do so on weekdays and would thus not be there on the days with the highest levels of use.

Construction of the Operations and Maintenance facility at the West Pit Road could affect some recreation users through temporary increases to traffic, and from construction-related dust and noise. Impacts would be primarily limited to recreational users traveling on Cook-Underwood Road. This impact would not be noticeably different from the construction of the on-site location. Construction impacts would be temporary and are expected to be minor.

3-150

Project Operation

Project operation also would not cause changes to existing land uses or land use activities or development patterns. The surrounding land uses are predominantly commercial forestry, agriculture and residential, and these uses would not be directly negatively affected by the project (Figure 3.8-5). The majority of the project site itself would remain in commercial forest production, with a maximum of approximately 56 acres of land (under 5 percent) converted to non-forestry uses related to new and widened roads, the turbine strings, the Operations and Maintenance facility, and the substation. At decommissioning, all of these facilities would be removed and the area returned to commercial forest.

Project operation would not force any changes in forestry operations or activities on the rest of the project area or on surrounding properties. The project would not generate sufficient amounts of noise, traffic, visual changes, energy use, air emissions or water use to cause changes to these existing land use patterns.

Comment: Since there is no watershed data, the proponent cannot say that the project would or would not cause changes in water use. The proponent does NOT know how this project would affect any aquifer(s), water tables, or wells, in the area.

Concern was expressed during scoping that the visibility of the turbines would cause a negative impact on agricultural tourism, specifically visits to area wineries. Wind power and winery tourism already co-exist in the Columbia River area. For example, four wind power facilities are located between Walla Walla and Kennewick (Canyon, Stateline, Vansycle, and Combine Hills). This area is home to a thriving wine industry with over 60 wineries. Section 3.9 Visual

Resources discusses visual impacts.

Project operation would not result in a sufficient increase in population or traffic to impact local recreational facilities. The only potential impact to recreation users would be the minor to moderate visual impacts discussed in Section 3.9 Visual Resources.

Operation of the alternative Operations and Maintenance facility would not change existing land use patterns. The surrounding land uses are predominantly commercial forestry, agriculture and residential, with the nearest home approximately 0.25 mile away. The site is adjacent to West Pit Road, which will be used for access to the project site during both construction and operation. Use of the alternative site for the Operations and Maintenance facility would generate noise, traffic, new lighting, energy use, air emissions, and water use, but not at levels sufficient to cause changes to the existing surrounding land uses. The Operations and Maintenance facility thus would be compatible with surrounding land use and would not hinder the development of permitted land uses on neighboring properties.

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project's operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major environmental and public health and safety issues presently anticipated,

3-151

including potential changes to land use, recreation or recreational access. If impacts to land use or recreation are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

Consistency with Applicable Land Use Regulations

Overall, the proposed project would be consistent with applicable land use regulations. The project would not involve subdividing any land parcels nor applying for changes to zoning or Comprehensive Plan designations. In a letter to EFSEC dated May 4, 2009, Skamania County found that the proposed project is consistent with the Skamania County Comprehensive Plan, SCC Title 21 Zoning Code, SCC 21A Critical Areas, Title 24 Clearing and Grading, and resource maps. On December 22, 2009, the Skamania County Board of County Commissioners passed Resolution 2009-54, resolving that the revised project, including the use of the alternative location of the Operations and Maintenance facility and the use of the West Pit Road as an access route, is consistent with Skamania County Land Use Plans and applicable zoning ordinances (see Appendix D Land Use Consistency Determination). When a county certifies

consistency with its local land use plans and ordinances, pursuant to WAC 463-26-090, the plan states that “such certificates will be regarded as prima facie proof of consistency and compliance with such land use plans and zoning ordinances absent contrary demonstration by anyone present at the hearing.”

The following further evaluates the consistency of the proposed project with applicable land use regulations.

Skamania County Comprehensive Land Use Plan

The project would be consistent with the Comprehensive Plan vision and the Conservancy designation in that it would conserve and manage existing natural forest and wind resources to maintain a sustained yield and utilization of both. Within the Conservancy designation, public facilities, utilities, and utility substations are allowed. Wind energy facilities are consistent with the Conservancy designation because they are utilities. The project would provide an alternative source of electrical energy generation that is not reliant on either fossil fuels or hydropower, while allowing forest management activities to continue around the turbine corridors. In addition, the staff report attached to Skamania County Resolution 2009-54 documents the County’s determination that the proposed project would be a semi-public facility under SCC Title 21 (see Appendix D). Semi-public facilities are defined in SCC 21.08.010 as “facilities intended for public use which may be owned and operated by a private entity.” The project thus would be a utility consistent with the Conservancy designation’s appropriate uses.

The alternative location for the Operations and Maintenance facility on West Pit Road would include an approximately 3,000-square-foot building, located on a 5-acre parcel in an area designated as Rural II in the Comprehensive Plan. The facility would be similar in size to a larger single family home. The project would be a utility that is consistent with the Rural II designation and would not conflict with any of the goals or policies expressed in the Comprehensive Plan.

3-152

Skamania County Zoning Ordinances

The portion of the proposed project that would be located in the UNM zoning classification would be considered consistent with this zoning. There is no conflict from siting wind energy facilities in the UNM zone, and these facilities have not been identified as a nuisance by statute, resolution, ordinance, or court order. Concerning the County’s moratorium on unincorporated UNM-zoned lands, the project is not sited on lands created by deed since January 2006 and does not involve any land division. Because of Washington EFSEC’s preemptive role in permitting wind energy facilities, including acting as Lead Agency for associated SEPA review, the County’s moratorium on acceptance of SEPA checklists for forest practices conversions does not affect the project.

Turbine Corridor A1–A7, with approximately seven turbines, would be located in the small portion at the southern tip of the project site that is within the FOR/AG 20 zone. If the proposed

project were being permitted through Skamania County rather than through Washington EFSEC, it is probable that a Conditional Use Permit from the County would be required for siting these turbines. Since Washington EFSEC is the permitting authority in this case, no such permit is required. Nonetheless, this portion of the proposed project would be consistent with the purpose and intent of the FOR/AG 20 zone in which it would be located, and while not an outright allowed use, this project is considered to be semi-public facility that would be a conditional use in this zone. As discussed above, the project also would provide renewable energy generation while allowing forest management activities to continue around the turbine corridors. The portion of the proposed project that would be located in the FOR/AG 20 zone thus would be considered consistent with this zoning.

The proposed alternative Operations and Maintenance facility located along West Pit Road would be within an area zoned R-5. Like turbine Corridor A1–A7, if the County was the permitting authority for the alternative Operations and Maintenance facility, a Conditional Use Permit likely would be required. However, Washington EFSEC is the permitting authority and no such permit is required. Nonetheless, the alternative Operations and Maintenance facility would be consistent with the purpose and intent of the zone in which it would be located. The Operations and Maintenance building would be located on a 5-acre site, and, at 3,000 square feet, would be similar in size to a larger single-family residence. The building would meet all applicable setback requirements, and would not pose a hazard to the health, safety or welfare of the surrounding community. Traffic associated with the facility would be similar to traffic from staff currently involved in ongoing timber management in the area. A well and on-site septic system would be installed to provide potable water for the Operations and Maintenance building. The anticipated demand for fire and police services would be low, and similar to other commercial operations in the project vicinity. Development of the facility would not hinder or discourage development or continuation of timber management activities on nearby properties, or of residential properties in the area. Finally, the facility would not conflict with the goals and policies expressed in the current version of the County’s Comprehensive Plan. Accordingly, location of the alternative Operations and Maintenance facility in the R-5 zone would be considered consistent with this zoning.

The proposed project also would be consistent with the critical areas regulations found in SCC Title 21A. The project site is not located within any critical recharge areas, frequently flooded

3-153

areas, ponds and lakes, or rivers. Portions of the project site are located near geologically hazardous areas due to steep slopes classified as Class II and III LHAs. There are wetlands, fish and wildlife habitat areas, streams, and creeks on the site. The project has been designed to minimize impacts to these areas, as discussed in Section 3.8.4, Mitigation Measures, and primarily in Section 3.3 Water and 3.4 Biological Resources.

Improvements to West Pit Road to widen it in places also would be consistent with SCC Title 21A. The use of the West Pit Road would not create safety concerns. While no new construction would occur within wetlands, streams, or their buffers, West Pit Road crosses one unnamed drainage in the Lapham Creek watershed. In July 2009, the drainage had observed

flow through the existing culvert under West Pit Road, but the surface flow and the channel disappeared downstream of the culvert. The drainage is classified as a Class V stream under SCC 21A.04.020(B), Appendix C. Buffers are established for Class V streams, within which expansion of existing uses is allowed. As long as the proposed expansion or widening is 100 percent or less than the existing footprint, no development review is required under SCC 21A.05 and SCC 21A.06 in fish and wildlife protection areas or geologically hazardous areas. The road improvements in these regulated fish and wildlife protection areas do not exceed the allowed expansion threshold. For a full discussion of fish, wildlife, their habitats, and project impacts to these, please see Section 3.4 of the Application for Site Certification.

Columbia River Gorge National Scenic Area Management Plan

While the proposed project would be located entirely outside of the Columbia River Gorge National Scenic Area, concerns have been raised regarding the compatibility of the project with the objectives and policies of the National Scenic Area Management Plan. The following identifies key objectives and policies, along with a discussion of project consistency with each of these objectives and policies.

- **Protection of Resources.** The project would not decrease any resources within the Scenic Area. Neither the site nor its access roads are within the Scenic Area, and no recreation resources would be lost.
- **Scenic Appreciation and Scenic Travel Corridors.** The project would have only minor to moderate impacts on visual quality as viewed from travel corridors inside the Scenic Area. See Section 3.9 Visual Resources.
- **Resource Based Recreation.** No resource-based recreation resources are within or in proximity to the project area. The only potential impact to recreation in the Scenic Area would be incidental recreational use by construction workers during the construction period. Such use is expected to be minimal.
- **River Access and Protection of Treaty Rights.** This project is on private lands outside of the Scenic Area and would have no effect on river access or treaty rights.
- **Interpretation/Education.** An opportunity to provide alternative energy interpretation and education could be included in this project and further the goals of the Scenic Area.

3-154

- **Trails and Pathways.** The project would not affect any trails or pathways in the Scenic Area. There may be some distant views of wind turbines from trails; the impact is expected to be “low to moderate.” See Section 3.9 Visual Resources.
- **Transportation.** Portions of SR 14 and portions of Cook-Underwood Road that are within the Scenic Area would be used to access the project. Increased traffic would cause a temporary and limited impact to recreational travelers during the construction period.
- **Coordination.** The project and access road are located outside of the Scenic Area. No coordination is required.

3.8.3.2 No Action Alternative

Under the No Action Alternative, the project would not be built. The site would continue to be used for commercial forestry and timber harvest would continue on a regular rotating schedule. Accordingly, existing land uses at the project site would remain unchanged. In addition, the informal recreation activities at the project site would remain largely the same, and no effect on recreational uses in surrounding areas would occur. The current level of consistency with land use plans and regulations also would continue to exist under this alternative.

3.8.4 MITIGATION MEASURES

No substantial impacts to land use are identified and no mitigation measures are required. The only potential impact to recreation users from operation would be the minor to moderate impact to visual resources from some viewpoints. Mitigation for this potential impact is identified in Section 3.9, Visual Resources.

3.8.5 UNAVOIDABLE ADVERSE IMPACTS

The 1,152-acre project site would continue to be predominantly used for commercial forestry operations. A maximum of approximately 56 acres of forestry land (under 5 percent of the project site) would be converted to energy facility use for the life of the project. This conversion would not constitute a substantial change to area land use patterns given the area of the project retained for active forestry operations, and given the acreage surrounding the project in both private and state ownership that will be maintained in commercial forestry operations.

3.9 VISUAL RESOURCES

This section describes potential impacts to visual resources. It assesses the potential for visual impacts using accepted methods of evaluating visual landscape quality and predicts the type and degree of effects the project would likely have on those attributes. This section also identifies mitigation measures designed to minimize those impacts.

3-155

3.9.1 METHODOLOGY

This section summarizes the visual impact assessment performed for the Application for Site Certification Agreement. The visual assessment used the Scenery Management System defined in Landscape Aesthetics, A Handbook for Scenery Management (USFS 1995) and Visual Impact Assessment for Highway Projects (FHWA 1988). The study was also designed to respond to the provisions of WAC 463-42-362, Built Environment—Land and Shoreline Use, which specifies the analysis of aesthetic and light and glare issues as part of the EFSEC process.

Comment: These 400-foot turbine towers break up the horizon, are visible to the eye, and don't belong in the visual landscape of the Columbia River Gorge National Scenic Area. Klickitat County has pillaged their entire prairie landscape with turbines and maintenance roads and these turbines are intrusive to one's enjoyment of the rural environment. The view shed would be ruined by these monstrous entities.

The Federal Highway Administration (FHWA) methodology is widely used for visual assessment of private lands such as the Project area, where visual quality objectives have not been established. A visual quality objective is a resource management objective established by a district manager or contained in a plan that reflects the desired level of visual quality based on the physical characteristics and social concern for the area. Five categories of visual quality objectives commonly used are preservation, retention, partial retention, modification, and maximum modification.

The FHWA methodology has been used to evaluate other recent wind power projects, including the Desert Claim project¹⁶, Lower Snake River (FHWA and BLM) and the Kittitas Valley project (FHWA and USFS methodologies)¹⁷. The FHWA method is also used where linear features of the project such as roads or turbine strings move into differing landscapes and visual corridors with differing view groups.

Three methodologies are commonly used to analyze visual impacts in federal and state EISs: the FHWA and USFS methodologies used for this project, and the Visual Resource Management system used by the BLM¹⁸. The BLM methodology is generally used where projects are proposed on or in proximity to BLM lands, and visual resource objectives for specific planning areas are already established. Under the BLM methodology a contrast rating can be completed and compared to the established BLM visual classifications. In order to use the BLM process for projects on private lands where no visual resource objectives have been established, it would be necessary to complete a full visual management inventory to delineate all lands in question and then classify each delineated area using the BLM classifications. The FHWA process provides for establishing existing visual quality objectives at a smaller scale or project level.

The BLM analysis would then determine whether and how the project features meet the objectives of the classification using the Visual Resource Management process for contrast rating. The FHWA process also follows this process, but is more conducive to a project of this scale and complexity. Full-scale Visual Resource Management delineation and classification are more appropriate for land management planning on a large scale and for providing visual objectives for public lands with multiple management objectives and uses.

16 See: <http://www.efsec.wa.gov/Desert%20Claim/FEIS/3.10Aesthetics.pdf>

17 See: <http://www.efsec.wa.gov/Desert%20Claim/FEIS/3.10Aesthetics.pdf>

18 See: <http://www.blm.gov/nstc/VRM/>

3-156

While the FHWA process does not rely on pre-existing visual quality objectives, it does incorporate elements of the Scenery Management System, which is part of both the USFS and BLM methodologies establishing existing visual quality and process for determining visual contrast. The FHWA process incorporates Scenery Management System and Visual Resource Management components, including landscape features, ecological conditions, cultural settings,

and social needs to establish the existing visual conditions and the effects of a project on the visual environment.

The methodology used is appropriate since it provides a clear understanding of how the proposed project would affect the visual landscape as seen from the key viewing areas. This methodology portrays the differing viewer groups and their sensitivity to visual change, defines distance zones (foreground, middle ground and unseen areas) and evaluates the contrast between pre- and post-project conditions as seen from the different viewpoints, by different viewer groups, and from different distances.

This analysis of visual effects was based on field observations and review of wind energy facilities' visual effects, public perception, design measures to reduce visual impacts, and local planning documents. Project maps, drawings, technical data, and computer-generated viewshed maps were used to determine areas where the project would be visible, and visual simulations were generated (described in Section 3.9.1.3) to illustrate the change from the existing conditions if the project is implemented. The analysis included systematic documentation of the visual setting, evaluation of visual changes associated with the project, and measures designed to mitigate these visual effects. Mitigation measures include restoration or enhancement activities in areas that would be disturbed during construction.

3.9.1.1 Scenic Quality Assessment

Scenic quality ratings were developed based on observations in the field, photographs of the affected area, methods for assessing visual quality, and research on public perceptions of the environment and scenic quality ratings of landscape scenes. The final assessment of scenic quality was made based on professional judgment that took a broad spectrum of factors into consideration, including:

- Natural features, including topography, watercourses, rock outcrops, and vegetation
- The positive and negative effects of human alterations and built structures on visual quality
- Visual composition, including an assessment of the vividness, intactness, and unity of patterns in the landscape, defined as:
 - Vividness refers to the memorability of the visual impression received by the viewer from contrasting landscape elements as they combine to form a striking and distinctive visual pattern
 - Intactness is the integrity of visual order in the natural and human landscape, and the extent to which the landscape is free from visual encroachment

3-157

-Unity is the degree to which the visual resources of the landscape join together to form a coherent and harmonious visual pattern.

Each viewpoint was assigned a final rating based on the rating scale shown in Table 3.9-1. This

rating scale incorporates the landscape assessment concepts developed in the USFS and FWHA methodologies.

Table 3.9-1

Landscape Scenic Quality Scale

Visual Quality Rating Explanation

Outstanding 6

A rating reserved for landscapes with exceptionally high visual quality. These landscapes are significant nationally or regionally. They usually contain exceptional natural or cultural features that contribute to this rating. They are what we think of as “picture postcard” landscapes. People are attracted to these landscapes to view them. High Landscapes that have high quality scenic value. This may be due to cultural or natural features 5 contained in the landscape or to the arrangement of spaces contained in the landscape that causes the landscape to be visually interesting or a particularly comfortable place for people. These landscapes have high levels of vividness, unity, and intactness.

Moderately High 4

Landscapes that have above average scenic value but are not of high scenic value. The scenic value of these landscapes may be due to human or natural features contained within the landscape, to the arrangement of spaces in the landscape, or to the two-dimensional attributes of the landscape. Levels of vividness, unity, and intactness are moderate to high. Moderate Landscapes that are common or typical landscapes with average scenic value. They usually lack 3 significant human or natural features. Their scenic value primarily results from the arrangement of spaces contained in the landscape and the two-dimensional visual attributes of the landscape. Levels of vividness, unity, and intactness are average.

Moderately Low 2

Landscapes that have below average scenic value but not low scenic value. They may contain visually discordant human alterations, but these features do not dominate the landscape. They often lack spaces that people perceive as inviting and provide little interest in terms of two-dimensional visual attributes of the landscape.

Low 1

Landscapes that have below average scenic value. They may contain visually discordant human alterations, and often provide little interest in terms of two-dimensional visual attributes of the landscape. Levels of vividness, unity, and intactness are below average.

Source: Buhyoff et al. (1994), FHWA (1988), and USFS (1995)

3.9.1.2 Visual Sensitivity Assessment

The analysis also assessed visual sensitivity, which involves predicting the general impact on the

quality of views from a given viewpoint. A combination of three factors determines how sensitive a landscape scene is:

- The number and type of viewers
- The viewing conditions
- The quality of the view

Residential areas with unobstructed views of a regionally important and memorable scene would be very sensitive to objects or structures that would impede views. A view from a seldom

3-158

traveled rural road where motorists have only distant, oblique views of wind turbines in an unremarkable setting would likely qualify as an area of low sensitivity.

The principal types of viewers in the project area who have predictably high levels of sensitivity to visual impacts include:

- Resident viewers
- Roadway viewers (drivers and passengers)
- Recreating viewers such as hikers, water recreationists, and mountain bikers

This analysis defines three levels of visual sensitivity:

- Low. Viewer types representing low visual sensitivity include agricultural and industrial/warehouse workers. Compared with other viewer types, the number of viewers is generally considered small and the duration of view is short. Low levels of sensitivity are assigned to areas 5 miles or more from the closest turbine, where a wind power project would be a distant and a relatively minor element in the overall landscape.
- Moderate. Viewer types representing moderate visual sensitivity consist of highway and local travelers. The number of viewers varies depending on location; however, on average they tend to be moderately large, based on overall densities of surrounding areas and highway commuters. Viewer awareness and sensitivity are also considered moderate because destination travelers often have a focused orientation. Moderate levels of sensitivity were assigned to areas where turbines would be visible from 0.5 mile to 5 miles within the primary view of residences and roadways. The primary view refers to the central area that the eye can see clearly without moving and is surrounded by the peripheral vision. In distinguishing between moderate and low levels of sensitivity in the 0.5-mile to 5-mile zone, contextual factors were also considered, including the viewing conditions in the immediate foreground of the view.
- High. Residential, recreational, and viewers congregating in public gathering places (churches, schools, trails, designated scenic viewpoints, etc.) are considered to have comparatively high visual sensitivity. The visual setting may in part contribute to the enjoyment of the experience. Views may be of long duration and high frequency. High levels of sensitivity are generally assigned in those cases where turbines would be potentially visible within 0.5 mile or less from residential properties, heavily traveled roadways, or heavily used recreational facilities. The principal types of viewers in the project area who have predictably high levels of sensitivity to visual impacts include residential viewers, roadway viewers (drivers and passengers) and recreating viewers such as hikers, water recreationists, and mountain bikers. These criteria were

used to establish the sensitivity levels of each view using a systematic approach based on the distance of the project from the viewpoint, the number of turbines or percentage of the project area that could be viewed from this viewpoint, and the dominant viewer

3-159

types for each view. Through this analysis, an overall sensitivity rating was established for each existing landscape view.

3.9.1.3 Preparation of Visual Simulations

Visual simulations were developed using photographs taken with a 35 mm digital SLR camera. Various focal lengths from 40 to 70 mm were used with the intent to capture the maximum pixels and resolution for the simulation. Visual Nature Studio, a widely-used three-dimensional Geographic Information System (GIS) software, manufactured by 3D Nature, LLC, was used to model the turbine locations on terrain built from USGS digital elevation model data. The photo locations were camera-matched in the software to render the turbines from the same viewpoint as the photographs taken on the ground. The resulting rendered turbine images were then photocomposited into the photographs to create the simulations. Existing topographic and site data provided the basis for developing the initial digital model.

In preparing the visual simulations, the turbine model used was the 2.5-MW Clipper Liberty model C93, which was considered a likely model to be selected based on information provided by the Applicant. This model has an overall height to nacelle of 80 m (262 feet) and blade diameter of 93 m (305 feet), and a blade length of 45.2 m (153 feet). The overall height to the tip of a stationary, vertical blade is 126.5 m (415 feet). The actual turbine size has not been determined, but potential turbines are estimated to have a height to nacelle of 262 feet and blade length between 129 and 164 feet.

Simulations were prepared assuming a conservative scenario of 50 turbines. This approach to creating simulations most likely overstates the visual impacts. This is because the Applicant has applied for EFSEC certification for a maximum of 75 MW. If 2.5 MW turbines were to be used, only 30 turbines could be built, and overall visual impact would be less. If lower-power turbines were used, the turbines would be smaller and thus less visible. Further, in evaluating impacts, the turbine is considered visible if any part of a vertical turbine blade is visible. In practice, turbines with only a part of the blade visible will not be seen when the blade is moving or is stationary but not vertical.

Atmospheric haze varies by location, season, time of day, and weather patterns. In creating photo composite visual simulations, the aim is to match the haze level on the rendered turbines to the observable haze present in the photograph. This is done by comparing the haze effects on the photographed terrain near the turbines to the rendered haze effects on the rendered terrain. This is then translated into a worst-case (lower than expected) haze visibility setting for the turbine renders. The result is that the turbines would be slightly more visible in the final composites than they would actually be if an observer were standing on the ground viewing them from the exact place, date, and time that the photos were taken.

The sky depicted in some of the visual simulations includes clouds, simulating the cloudy conditions that are common at the site.

Site plans and specifications for the proposed wind turbines were used to create three-dimensional digital models of the planned turbine placements. These models were combined with the digital terrain model to produce a complete computer model of the wind farm. For each

3-160

viewpoint, a render camera was placed in the Visual Nature Studio software. The aspect ratio of each render was then matched to the corresponding photograph and the rendered terrain was visually matched to the photographed terrain to confirm scale. Finally the resulting turbine images were matched in perspective, scale, and aspect ratio, are photo-composited into the original digital photo base using Adobe Photoshop. This process produces accurate portrayals of how the given turbine models and placements would look on the given terrain and from the specified viewpoints after construction. Seasonal conditions including weather, air quality, vegetation (foreground and background) and color impact the quality of the compositions. These compositions are a representative example of the area without subjectivity.

Simulations were not developed for nighttime conditions. Night simulations are inherently inaccurate, since they do not show the periodic flashing of the air warning lights, which is the impact most often mentioned. Night simulations are not typically performed as part of the analysis of wind power projects, and have not been requested by EFSEC. The potential impact of air warning lights is discussed in Section 3.9.3.1.

3.9.2 AFFECTED ENVIRONMENT

Each landscape has a specific quality that gives a geographic area its visual and cultural image, and consists of the combination of physical, biological, and cultural attributes that make each landscape identifiable or unique. The character of an existing landscape may range from a predominantly natural landscape to landscapes that are heavily culturally influenced. The existing scenic quality of an existing landscape includes the natural scenic attributes of the landscape in combination with the existing land use patterns. The list of attributes includes naturally evolving, natural appearing, pastoral, agricultural, or even urban landscapes and generally are at the broadscape or landscape level of the analysis, but can be analyzed for each specific viewpoint at a project level.

The sensitivity of a landscape or view of that landscape is based on the scenic integrity of the landscape and the types of viewers. A landscape that has a high degree of integrity is a landscape that has a sense of wholeness, intactness, or being complete. Its scenic quality is near-perfect, with no evident discordant elements or deviations from the existing character, making it highly sensitive to most changes and to the perceptions of the viewer types.

The existing visual resources are the natural and built features open to view in the project landscape. The combination of land, water, and vegetation patterns represent the natural

landscape features that define an area's visual character, while built features such as buildings, roads, and other structures reflect human or cultural modifications to the landscape. These natural and built landscape features or visual resources contribute to the public's experience and appreciation of the environment. This section describes the broad scale regional and local landscape settings that were used to establish appropriate viewpoints from which the project would be visible.

3-161

3.9.2.1 Regional Landscape Setting

The project is set in two distinct landscapes. One landscape is the areas where the turbines would be sited along ridges located on the northern plateau of the Columbia River Gorge on Underwood Mountain (Figure 1-1). The other landscape is the Columbia River Gorge National Scenic Area, which is outside the project but within the viewshed looking into the project area. The project area is completely outside the Scenic Area, and therefore is not subject to the Columbia River Gorge Scenic Area Management Plan or related regulatory requirements. No improvements to project area roadways will take place in the Scenic Area.

Comment: Although the proposed project is located outside the Columbia River Gorge National Scenic Area (CRGNSA), the haul routes do impact the NSA. And, we really don't know what the tons and tons of material—cement trucks, semi-trucks carrying all the wind farm infrastructure materials, etc.—would do to our roads. There will be impacts to the roads but SDS appears to be minimizing any impacts in the NSA because they know that the regulatory requirements for the NSA are more stringent than outside NSA requirements. The DEIS should address the impacts to all the roads that will be used—and these roads need to be named beforehand. There should be no sleight of hand in road usage. SDS and BPA should commit on paper which haul routes they will be using, what the impacts will be to the roads, and what mitigations will take place if the roads are damaged.

The Scenic Area extends 85 miles along the Columbia River, and includes portions of three Oregon and three Washington counties. Formed by ancient volcanoes and sculpted by floods, the Columbia River Gorge carves a corridor through the Cascade Mountains in Oregon and Washington as the river journeys to the Pacific Ocean.

The National Scenic Area Act designated 292,500 acres on both sides of the Columbia River for special protection from the outskirts of Portland-Vancouver in the west to the semi-arid regions of Wasco and Klickitat counties in the east. The Scenic Area is categorized as SMAs, GMAs, and Urban Areas:

- SMAs contain the most sensitive resources. They total 114,600 acres and are managed by USFS.
- GMAs total 149,400 acres and include a mixture of historic land uses such as farming, logging, and cattle grazing. The Columbia River itself is currently designated as a GMA as well. Development on GMA lands is administered by the Gorge Counties and the Gorge Commission.

- Thirteen Urban Areas in the Gorge are exempt from any Scenic Area regulations: Cascade Locks, Hood River, Mosier, and The Dalles in Oregon, and North Bonneville, Stevenson, Carson, Home Valley, White Salmon, Bingen, Lyle, Dallesport, and Wishram in Washington. The Act's second purpose is to protect and support the economy of the Gorge by encouraging growth in existing Urban Areas and by allowing future economic development in a manner that is consistent with protection and enhancement of resources. The project area is outside of the Scenic Area Management Plan and no visual quality objectives or management designations have been established for the area. Areas south of the project within the Scenic Area are designated as Urban or GMA. The views from the Gorge into the project area were examined through viewpoint selection. This area of the Gorge, closest to the project, is considered to have a high visual quality with a moderate sensitivity based on the vividly memorable, and although the area is not free of visual encroachment, the visual resources join together with a moderate degree of unity.

3.9.2.2 Local Landscape Setting

The project site is on land managed for commercial forestry by S.D.S. Co., LLC and Broughton Lumber Company. All of the parcels on which the project is located are managed for a continual

3-162

cycle of growth, harvest, and replanting. As a longstanding commercial forestry site, no old-growth forests exist in areas where the project is proposed. Many of the stands of trees on the sections of land that would have turbines on them are recently harvested and reforested. S.D.S. Co., LLC and Broughton Lumber Company implemented timber harvest plans on approximately 50 acres during 2003. Additional harvests covering approximately 100 acres are planned as part of the ongoing commercial forestry operations (Figure 2-3).

In areas surrounding the proposed wind turbines that have not been recently harvested or that are not planned to be harvested before project construction, trees would be harvested and most of the land would be replanted with seedlings. This clearing would allow for safe construction, and would reduce the potential for tree growth to interfere with the wind resource on the site during the commercial life of the project. Low vegetation would be maintained in some areas to provide safe areas around the turbines (Figure 2-4).

Comment: It is now accepted (OSU and other universities, scientific studies, etc.) that old growth trees sequester more CO2 than younger trees. The age when young trees begin to become part of the sequestration cycle of CO2 is fifteen years. So, the harvesting of the older trees and the replanting with seedlings would actually put MORE CO2 into the atmosphere. This must be computed into the total carbon footprint of this project; it must also be considered when calculating BPA's carbon footprint.

No visual quality objectives have been established in the project area beyond the harvest size and configuration requirements of the Washington Forest Practices Act. These cleared areas are considered a "forest conversion" under the Forest Practices Act and have no established visual quality objectives. These openings, to the extent feasible, would be reforested in accordance

with typical commercial forestry management practices.

S.D.S. Co., LLC and Broughton Lumber Company own this commercial property in Skamania County, Washington. The project and the West Pit Road used for project access are not located inside the Scenic Area. In relationship to the visual quality of the area, there are views from the Scenic Area into the project area. The viewpoints and viewer types in relation to the roadway improvements within the Scenic Area have been considered in this analysis for consistency with the Scenic Area guidance and conformance. SR 14 in this area is a recognized scenic roadway. Typically, this designation means that a scenic corridor management plan would be prepared to provide policy-level guidance in the local adoption of comprehensive plan policies, zoning, and other land use regulation. There is no scenic corridor management plan for SR 14 and, therefore, no regulatory control of aesthetic impacts within the corridor. However, the scenic roadway designation carries an additional level of care and scrutiny in the review of potential aesthetic impacts based on recognition, but not regulation.

The local landscape visual appearance is of moderate visual quality with a moderate level of sensitivity. The levels of vividness (memorability), intactness (freedom from visual encroachment), and unity are average within the broader landscape. The immediate area of the project site is currently characterized by several types of visual disturbance. These include:

- BPA power transmission lines running east-west through the south and center portions of the project area
- Williams gas pipeline running through the north portion of the project area, and compressor station just to the northwest of the project site
- Two rock quarries west of the project area

3-163

Draft Environmental Impact Statement 3.0 Affected Environment, Impacts and Mitigation

- Cell towers south of the project area in the Scenic Area
- Forest openings from clear-cutting throughout and surrounding the project area
- Land clearing for agriculture especially south and east of the project area

3.9.2.3 Viewpoints

To analyze the project's effects on visual resources, viewpoints were selected to characterize the aesthetic character of the project area and the differing landscapes in or near the project. Most of the viewpoints are at publicly accessible locations which would have the largest number of viewers. Within the Columbia River Gorge National Scenic Area, Key Viewing Areas (KVAs) have been established as "those portions of important public roads, parks, or other vantage points with the scenic area from which the public views scenic area landscapes." (SCC 22.04.010). Viewpoints included KVAs from which the project could be seen, other viewpoints within the Scenic Area, and viewpoints outside the Scenic Area.

Figure 3.9-1 illustrates (with colored shading) how many of the turbines would be visible. No

turbines are visible from several of the KVAs. For example, SR 14 is a KVA; however, the section of SR 14 nearest the project area has steep hills to the north, which block views of the project area. KVAs with no turbines visible were not selected as viewpoints for visual simulations and were not further analyzed.

Individual viewpoints were chosen based on the following criteria:

- Viewpoints that are most representative of the different roads, population areas, and recreation areas where views of the wind turbines would occur
- Locations that are most accessible to the public
- Locations with the largest number of viewers (including residences)

Figure 3.9-1 shows the locations of these viewpoints and the number of turbines visible from each viewpoint. Views were not modeled from every residence from which the project would be visible; however, residences and representative businesses between one and three miles from the project site are shown on Figure 3.9-2.

Each viewpoint was assessed for its scenic quality and viewer sensitivity, and a rating was applied to provide an overall average for the area. This process established the existing conditions for each of the individual viewpoints, from which impact of the project on these parameters could be measured.

During scoping, a request was received that a visual simulation be prepared to depict views from Dog Mountain, a popular local hiking area and a Scenic Area KVA. To address this request, photos were taken from potential viewpoints located on the northeast and south side of the mountain. The photographs were used to assess views of the proposed project, and to identify potential impacts to visual resources from those locations. It was determined that views of the

3-164

project area were blocked by Cook Hill at all potential viewpoints located both on and off the trail. The project would be visible from Cook Hill; however, there is no known recreational use in this area. Because the project area is not visible from Dog Mountain, scenic quality and viewer sensitivity were not rated, and no visual simulation was prepared to further assess potential impacts to visual resources.

This section describes the existing views from representative viewpoints. The viewpoint numbering below matches the numbering used in the Application for Site Certification. Additional viewpoints, which were excluded from this EIS as duplicative, can be found in the Application for Site Certification (Appendix A). Simulated photos depicting the existing view with proposed turbines are included in Section 3.9.3.

3-165

33758687_169.cdr

Figure 3.9-1

Figure 3.9-2

Residences with Visible Turbines

Viewpoint 1: Pucker Huddle (Within Scenic Area)

Scenic Quality. Viewpoint 1 is taken from SR 141, which is approximately 4 miles from the project and is a small connector providing access to the Indian Heaven Wilderness in the Gifford Pinchot National Forest. This highway also allows access to several rural communities, including White Salmon, Husum, and Pucker Huddle. Most areas are unincorporated and several of the residences are recreational in nature with some year-round residences. As discussed in the review of the regional and local landscapes, no public roads pass through or are immediately adjacent to the project.

Viewpoint 1 is a wide panoramic view of Underwood Mountain from SR 141 adjacent to the Pucker Huddle area. The view encompasses the east side of the project area and the ridged lines of forest management areas are visible in the middle ground of the viewshed. Natural openings are prevalent from this viewpoint, with several natural appearing features of openings and vegetation that provide an interesting view. The BPA transmission lines bisecting the project area on the north and south ends can be seen from this viewpoint. The quality of the views from this viewpoint along SR 141 was rated as moderate, reflecting the fact that the visible landscape is relatively common in the region and has average scenic value. The ridge line along Underwood Mountain, which is in the area of the project, provides a degree of topographic interest when viewed with the other natural appearing features. The landscape visual scenic quality from this viewpoint is moderate.

Viewer Sensitivity. Traffic volumes along SR 141 are minimal and used for local traffic and recreational traffic in the summer months. Considering the distance of the project from this viewpoint (less than 5 miles), the minimal use of the highway, and the portion of the project that is visible from the viewpoint, the level of view sensitivity is considered low. This is based on the duration of the view from SR 141, the low level of residential viewers from this viewpoint, and the scenic quality rating.

Viewpoint 3: Husum

Scenic Quality. This viewpoint captures the view from SR 141 northeast of the project area. This viewpoint would be the first view of the project from travelers moving south into the project area. The viewpoint encompasses the northern portion of the project from the highway, which is the closest viewing area from that vantage point. The foreground of the viewpoint is pastoral with a middle ground view of the hillsides and a background view of Underwood Mountain and the project area. The view is natural appearing with moderate to high levels of vividness, unity, and intactness in the foreground, middle ground, and background of the photo. The quality of

the view from this viewpoint was rated moderately high because of the above-average quality and the unity of the man-made and natural features on the landscape.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (greater than 5 miles), the duration of the view (roadway travelers), the portion of the project that is visible from the viewpoint, the viewer types (minimal residential/recreational), and the scenic quality rating, the level of visual sensitivity is considered moderate.

3-168

Viewpoint 4: Ausplund Road and Cook-Underwood Road (Scenic Area KVA)

Scenic Quality. This viewpoint captures the view from the Ausplund Road and Cook-Underwood Road where they meet and provide residential, agricultural, and forest management access to the area. These roads are connector and feeder roads that can be accessed from SR 14. This area is elevated from the Columbia River Gorge National Scenic Area but is within its boundaries. The area has a mix of uses including agriculture, forest management, and some recreation. The foreground from the roadway is an agricultural setting with middle and background views of forest vegetation and forest management areas. The view is natural appearing with moderate levels of vividness, unity, and intactness. The quality of the view from this viewpoint was rated moderate because of the average or typical views of this type in the project area.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (0.5 to 5 miles), the viewer types (roadway travelers), the portion of the project that is visible from the viewpoint, the viewer types (residential/roadway), and the scenic quality rating, the level of visual sensitivity is considered moderate.

Viewpoint 5: Willard

Scenic Quality. This viewpoint captures the view from the small residential community of Willard. This area is accessible by a County road from SR 14 and used by residential and private forest management users. The view looks southeast into the project area and provides a panorama of the longest string of turbines. The foreground is a mixture of mixed conifer second growth stands and the middle ground is of mixed timber harvest openings and a transmission corridor. The background view is similar and the mixture of vertical and horizon lines and formations detracts from the overall vividness and unity of the view. The intactness of the views is moderated by the changes in line and form. The quality of the view from this viewpoint was rated moderately low to moderate.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (0.5 to 5 miles), the duration of the view (foreground screening), the portion of the project that is visible from the viewpoint, the viewer types (minimal residential), and the scenic quality rating, the level of sensitivity is considered moderate.

Viewpoint 7: Mill A

Scenic Quality. This viewpoint captures the view from the old mill property west of the project area. This area is accessible from Willard Road and has a mixture of uses. The view looks northeast into the southern end of the A turbine string. The foreground view is obstructed by the vertical lines of transmission towers. The middle ground view is of transmission corridors and extensive timber harvest openings. Many of the residential views are partially screened from the valley floor. There is a visual discord with the man-made alterations. The vividness, unity, and intactness appear uninviting and of moderate to low visual quality. The scenic quality rating for this viewpoint is moderately low.

3-169

Viewer Sensitivity. When considering the distance of the project from this viewpoint (0.5 to 5 miles), the duration of the view (foreground screening), the portion of the project that is visible from the viewpoint, the viewer types (minimal residential), and the scenic quality rating, the level of sensitivity is considered moderate.

Viewpoint 11: I-84 Westbound (Scenic Area KVA)

Scenic Quality. This viewpoint captures the view from I-84 traveling westbound towards the project area from the east. I-84 travels along the Columbia River Gorge National Scenic Area and views along this portion of the highway are generally directed towards the river and the distant scenery. Beyond the foreground view of the highway and other corresponding structures the view is generally intact with average or above vividness, unity, and intactness. Viewers traveling along this corridor have multiple line-of-sight transitions, and this is considered to be average within those views. The scenic quality rating for this viewpoint was rated moderate.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (8–10 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway), and the scenic quality rating, the level of sensitivity was rated moderate.

Viewpoint 12: Koberg Park (Within Scenic Area)

Scenic Quality. This viewpoint captures the view across the Columbia River from Koberg Park. The foreground view of the river is a complete composition indicative of the area and the middle and backgrounds have a high level of vividness, unity, and intactness. The railway line that bisects the view in the middle ground tends to blend into the scenery without distraction. This view is considered to be above average for the types of views that are throughout the Scenic Area. The scenic quality rating for this viewpoint was rated moderately high.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (8–10 miles), the portion of the project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated moderate.

Viewpoint 13: I-84 Eastbound (Scenic Area KVA)

Scenic Quality. This viewpoint captures the view from I-84 traveling eastbound towards the project area from the west. I-84 travels along the Scenic Area and views along this portion of the highway are generally directed towards the river and the distant scenery. Beyond the foreground view of transmission structures the view is generally intact with average or above-average vividness, unity, and intactness. Viewers traveling along this corridor have multiple line of sight transitions and this view is considered to be above average within the context of those multiple views. The scenic quality rating for this viewpoint was rated moderately high.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (3 to 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway travelers with fleeting views), and the scenic quality rating, the level of sensitivity was rated as moderately low.

3-170

Viewpoint 14: Viento State Park (Within Scenic Area)

Scenic Quality. This viewpoint captures the view from Viento State Park, a popular recreation and rest area along the Columbia River. Landscape features are diverse and intact and the contrasts of the features have a high level of unity. This view is the open waters of the Columbia River in the foreground with rock features and vegetation in the middle ground and a background of mountains that provides an overall pleasing composition that is inviting to the viewer. This view is one of the less common views along the Gorge and has an above average scenic value. The scenic quality rating for this viewpoint was rated moderately high to high.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (recreational), and the scenic quality rating, the level of sensitivity was rated as moderate to high.

Viewpoint 15: Frankton Road (Within Scenic Area)

Scenic Quality. This viewpoint represents the view from the higher-elevation residential areas west of Hood River. The view looks across the Columbia River into the project area. Frankton Road is a local access road and traffic is considered low. Residences in this area have views both north and south. Many of the views are screened to the north and take advantage of the view south into Oregon. The view has residential development in the foreground, which is common along this roadway. The middle ground is vegetation, some agriculture, and some forest management. The background is the ridge along the project area. These types of views are relatively common and of average scenic value when compared to the broader area. Vividness, unity, and intactness are moderate to high levels. The scenic quality rating for these viewpoints is moderate.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (residential), and the scenic quality rating, the level of sensitivity was rated as moderate.

Viewpoint 17: Providence Hospital Hood River (Within Scenic Area)

Scenic Quality. This viewpoint represents the north view of the project from the City of Hood River. The foreground is an urban setting with a middle ground of vegetation that screens the background to some degree, providing a diverse composition of features. The view has a somewhat vivid appeal based mostly on the man-made features; however, the unity and intactness are below average and are visually discordant. This detracts from the background view. Viewers would generally be more focused on the business of the urban environment. The scenic quality of these viewpoints was rated moderately low.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (more than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (urban/residential), and the scenic quality rating, the level of sensitivity was rated as low.

3-171

Viewpoint 19: Columbia River Highway (Within Scenic Area)

Scenic Quality. This viewpoint represents the view of the roadway traveler on the Columbia River Highway (Highway 30) southeast of the project area. This view has a higher scenic quality and is more representative of the high-quality views within the Columbia Gorge area. The foreground, middle ground, and background all have an above average arrangement of spaces in the landscape. The view appears intact and has a unity with the road and even the transmission line that is visible in the middle ground. The landscape provides diversity but not to the extent of clutter. This view is rated moderately high for scenic quality.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (greater than 5 miles), the portion of the project that is visible from the viewpoint, the viewer types (roadway travelers/sightseers), and the scenic quality rating, the level of sensitivity was rated as moderate.

Viewpoint 23: Ausplund Road End (Within Scenic Area)

Scenic Quality. This viewpoint represents the view from local area roadways at specific intersections where local area travelers might converge. These roads are old logging roads that have been upgraded to meet the local residential use. However, they are still used for logging and would be used in the construction portion of this project. This would include upgrading and in some instances widening the roads, which can affect visual quality. This view is from the end of the Ausplund Road, which would be used to access the area for construction and maintenance. Very few viewers beyond those associated with the project would see this viewshed. Without the vehicles in the foreground, the scenic quality rating assigned to this view is moderate.

Viewer Sensitivity. When considering the distance of the project from this viewpoint (less than 1 mile), the portion of the project that is visible from the viewpoint, the viewer types (local area workers and residence), and the scenic quality rating, the level of sensitivity was rated as low to moderate.

3.9.3 IMPACTS

Visual impacts are a primary consideration for wind power projects. The alteration of the landscape by the introduction of wind turbines, and the visual impacts of wind turbines on the landscape is a complex issue, and factors other than the attributes described above play a major role in the observer's reaction or perception of the visual impacts or change.

Wind turbines are relatively large, and being available to the wind requires the turbines to be in a location that is open and highly visible. Viewers' reaction to the visual impacts of wind turbines on the landscape is a complex issue, and is influenced by the generally positive perception of wind as a renewable energy alternative. However, many supporters of renewable energy projects express a desire that the projects be placed elsewhere. This message was voiced by several people in the public scoping meetings for this Draft EIS. Studies have shown that some negative opinions change once the wind projects are constructed and in operation.

3-172

3.9.3.1 Proposed Action

The appearance of the project is determined by the project facilities that may be seen by the public during operation of the project. Project facilities include turbines, a meteorological tower, the BPA substation, the Operations and Maintenance facility (at one of two alternative locations) and roads. The substation, Operations and Maintenance facility, and project area roads would be difficult to see from outside of the project area, and would be typical of development in this rural area dominated by forest management and large-scale agriculture. The meteorological tower is slender and would have no moving parts, and would not be as noticeable as a wind turbine. Consequently, the visual impact assessment focused on the potential impact of the turbines. This section describes project facilities and their visibility from outside the project area.

Comment: Speaking of moving parts—these turbines are machines. Machines make noise. How much noise does each turbine make?

The project facilities are:

- Turbines. The turbines would be the most visible project facilities. Commercial-scale turbines are similar in appearance and are composed of a tower, a nacelle, and turbine blades attached to a rotor. The tower would appear to be a steel pole, tapered from base to hub, with a base diameter of approximately 14 feet. At the top of and perpendicular to the tower, the nacelle would appear to be an elongated metal boxlike structure. Three aerodynamically shaped blades connected to a nose cone attach to the front of the nacelle. Depending on the turbine model chosen, each turbine would be up to approximately 426 feet tall (262-foot hub height and 164-foot radius blades, measured from the ground to the turbine blade tip), and would be mounted on a concrete foundation. Wind turbines would be grouped in "strings," with each turbine spaced approximately 350 to 800 feet from the next (or approximately 1.5 to 2.5 times the diameter of the turbine rotor). Typically, wind turbines are painted white to comply with FAA daytime

lighting requirements. A gravel buffer and crane pad will be maintained at each turbine site, and will not be visible from outside the project area. The tall turbines will introduce vertical lines into the viewshed. Blades will be visible when stationary and moving at low speeds, but will not be visible when moving more quickly. The visibility of the turbines would be affected by the angle of the sun and climate conditions. At low sun angles (morning and evening) sunlight will reflect off a greater surface of the turbine and result in greater visibility. Conversely, when the sun is directly overhead, a relatively small surface of the turbine will reflect. On cloudy days, visibility of the light-colored turbines will be less since the turbines will blend with the background. Available data indicates that on average, there are 145 sunny days per year in Skamania County, Washington, that is, 39.7 percent of days are sunny.¹⁹ Therefore, the majority of the time some clouds are present. The turbines will therefore blend with the background the majority of the year.

Comment: This statement "turbines will therefore blend with the background" is an opinion and is not factual. Those of us who live in the NSA and surrounding areas certainly would notice, as I can state from personal experience, 400 foot spinning turbines in the landscape! These suckers are BIG and they do impinge on one's visual area of interest.

- Electrical System. The electrical system would primarily be underground, and would connect the turbines to the BPA substation. The substation would occupy a portion of a

¹⁹ <http://www.bestplaces.net/County/Skamania-Washington.aspx#>.

3-173

fenced 5-acre area at the southwest end of the project site, immediately adjacent to the BPA 230-kV transmission line. A 50-foot cleared area would be maintained around substation. The substation would difficult to see from outside the project site.

- Operations and Maintenance Facility. The Operations and Maintenance facility would be a 3,000 square foot metal building approximately 16 feet tall, with a gravel parking lot and surrounding fence and gated entrance. The facility would be built at one of two alternative locations, either on the project site or to the west of the site on West Pit Road. In either location the visual impact of the facility would be minimal, and similar to small utility or agricultural facilities in the area.
- Roads. The project will require 7.9 miles of new permanent gravel roads, and 2.4 miles of improved existing roads. New permanent and improved roads will be visually similar to existing secondary and gravel roads in the project area and most would be difficult to see from outside of the project area.
- Meteorological Tower. The project would include one meteorological tower, approximately 221 to 262 feet tall. The tower height would be the same as the hub height for the selected wind turbine. Because meteorological towers are slender and do not have large components like turbine blades, the meteorological tower would be difficult to see from outside the project area.

The primary visual concern is the potential impacts of the proposed installation of up to 50 wind turbines on existing views and the overall aesthetic character of the project area. The specific turbine type and manufacturer have not been selected; however, it is likely that the turbines would be in the 1.2- to 2.5-MW range, and would measure approximately 426 feet in height (262-foot hub height and 164-foot radius blades). Each turbine would have three rotor blades made of laminated fiberglass. The diameter of the circle swept by each blade would be from 264 to 320 feet, depending on which turbine was selected. Turbine “strings” would include rows of from three to 21 turbines placed at approximately 350 to 500 foot intervals.

For many viewers, the location of the project would minimize visual impacts. Location effects include the limiting effect of topography, tree cover, the relatively long distance to surrounding residences, and the orientation of the project vis-à-vis viewers. Figure 3.9-2 shows the number of turbines visible from residences and a selection of local businesses. The figure does not attempt to show all businesses in the project area; the businesses added are for general reference. The figure shows that the project will not be visible from many of the residences to the southeast of the project, and will be most visible to residences to the west, in and around Mill A. This figure may overstate the visibility of the project somewhat, for two reasons:

- Turbines are judged to be visible if any part of the turbine blades would be visible. In practice, if only the tip of a blade is visible then viewers will not see it when it is not vertical or when the blade is moving.
- The visual simulation is based on topography alone, and does not take into account the masking effect of trees.

3-174

However, public input and comments during EIS scoping indicated that for some viewers, the presence of the wind turbines represents a negative impact because it alters the appearance of the rural landscape over a large area. The flashing of aviation warning lights on the tops of turbines at night would similarly be considered a negative impact.

The visual impact assessment was based on evaluating the changes to the existing visual resources that would result from construction and operation of the project. These changes were assessed, in part, by evaluating the “after” views provided by the computer-generated visual simulations and comparing them to the existing visual environment. Consideration was given to the following factors in determining the extent and implications of the visual changes:

- Changes in the affected visual environment’s composition, character, and valued qualities
- The affected visual environment’s context, including distance
- The extent to which the affected environment contains places or features that have been designated in plans and policies for protection or special consideration
- The number of viewers, their activities, and the extent to which these activities relate to the aesthetic qualities affected by the changes
- The distance factor was considered in the sensitivity rating for establishment of baseline and therefore becomes a factor in the impact assessment

Levels of impact were classified as high, moderate, and low:

- High. High levels of impact were assigned when turbines would be highly visible in areas with a high number of sensitive viewers, and would greatly alter levels of vividness, unity, and intactness, decreasing the level of visual quality. This is the largest number of viewers from that key viewpoint. The assessment accounts for the number of viewers and would add that into the discussion.
- Moderate. Moderate levels of impacts were assigned in situations when turbines would be visible in areas with moderate levels of visual sensitivity and viewers, where the presence of the turbines would moderately alter levels of landscape vividness, unity, and intactness.
- Low. Low levels of visual impact were found in situations when the project would have relatively small effects on overall landscape level attributes, where existing levels of landscape aesthetic quality are low, or where there are low levels of visual sensitivity and a low number of viewers.

Construction

During construction, large earth-moving equipment, trucks, cranes, and other heavy equipment would be visible from some nearby areas. At times, small, localized clouds of dust created by road building and other grading activities may be visible at the site. Because of construction

3-175

related grading activities, areas of exposed soil and fresh gravel that contrast with the colors of the surrounding undisturbed landscape would be visible.

In close-up views the changes associated with the construction activities would be highly visible and would have a moderate to high visual impact. Close-up views would include those seen by travelers on the segment of the local roads that pass around the project site and those seen from the closest residences. From more distant locations, the visual effects of construction would be relatively minor and would have little or no impact on the quality of views.

Construction impacts would be short-term, lasting no more than the one-year construction period.

Operation

During project operation, the turbines would be visible from some viewpoints. The potential level of visual impacts from key and representative project viewpoints is summarized in Table 3.9-2 and shown on Figures 3.9-3 through 3.9-15. Additional viewpoints are analyzed in Section 4.2-3 of the Application for Site Certification (Appendix A). A more detailed description for each viewpoint follows the summary table and figures. The visual impact analysis showed that the project has the potential to create low to moderate levels of visual impact at key viewpoints.

Viewpoint 23 - Ausplund Road End

Viewpoint 1: Pucker Huddle (Figure 3.9-3)

From Viewpoint 1, approximately 25 turbines would be visible on the ridge tops at distances of approximately 4 miles to the nearest turbines. At the distance depicted in the photo, the visual clutter of more turbines has more impact than the considerable scale of the larger turbines. The composition would be silhouetted against the sky, increasing their visual impact. However, the distance and the line of sight from the residential areas would minimize the contrast. The presence of the turbines would reduce the scene's degree of intactness by introducing a large number of highly visible engineered vertical elements.

The potential visual impact from Viewpoint 1 would range from low to moderate.

Viewpoint 3: Husum (Figure 3.9-4)

From Viewpoint 3, approximately 27 turbines would be visible on the ridge tips at a distance of approximately 4.75 miles to the nearest turbines. Figure 3.9-4 illustrates the simulated views from SR 141 traveling south into the project area. Travelers moving along this highway are generally using the road to access recreation areas or for leisurely drives. Residential viewers would be screened to some degree from the view based on vegetation, landscaping, and the line of sight from the valley floor. Introduction of these vertical structures in the background of this view would decrease the intactness of the landscape, based on the numbers of turbines that would be visible. The composition of the view would be altered with the introduction of these engineered structures and would be apparent on the horizon to the travelers and residence in the area.

Due to the low levels of viewers, duration of the views, and viewer awareness, the visual impact from Viewpoint 3 is considered moderate.

Viewpoint 4: Ausplund Road and Cook-Underwood Road (Figure 3.9-5)

From Viewpoint 4, approximately 14 turbines would be visible looking northwest from the roadway, at a distance of approximately 1.23 miles to the nearest turbines. Figure 3.9-5 illustrates the simulated view from the roadway at the intersections of Ausplund and Cook-

Underwood Roads. Because of the position of this viewpoint (direct line of sight) and its distance from the turbines, the turbines apparent scale would be visible and apparent. The presence of the turbines would likely have a moderate effect on the vividness of the existing view and a moderate impact on the overall sense of unity and intactness by the roadway and residential viewers.

The potential visual impact from Viewpoint 4 would be moderate.

Viewpoint 5: Willard (Figure 3.9-6)

From Viewpoint 5, approximately 24 turbines in turbine strings A and B would be visible from screened views from residences in the area of Willard. Figure 3.9-6 shows the simulated view from Viewpoint 5 in the northern portion of the project looking southeast. These turbines would be located in the ridge tops, with the nearest turbines approximately 1.35 miles away. Because the turbines would be seen against the sky at medium range and screened in many residential views, they would still be visible in the background. This would reduce the visual unity and

3-191

intactness minimally when compared to the existing components in the landscape. The wind turbines would be arrayed uniformly along the ridgeline and would create a moderate change in the setting's existing low to moderate visual quality.

The potential visual impact from Viewpoint 5 would be moderate.

Viewpoint 7: Mill A (Figure 3.9-7)

From Viewpoint 7, approximately 35 turbines in strings A and B would be visible in the foreground, middle ground, and background of this view. The nearest turbines would be located approximately 1.62 miles away. Figure 3.9-7 shows the simulated view. The turbines would be seen against the sky. The presence of the long line of turbines may create a slight increase in the vividness of this view. The unity of the view would be decreased further by the long turbine line and the intactness of the view would be moderately compromised compared to the existing view.

The potential visual impact from Viewpoint 7 is considered to be low to moderate.

Viewpoint 11: I-84 Westbound (Figure 3.9-8)

From Viewpoint 11, approximately 19 turbines would be visible in the distance background to roadway travelers looking west into the project area from I-84. The nearest turbines would be

8.39 miles away. Figure 3.9-8 shows the simulated view. Although the turbines would be visible to travelers on the far horizon, their presence is not expected to decrease the existing quality of this view, because of their relatively small size at this viewing distance. The visible turbines would have a minimal effect on this view's vividness, unity, and intactness.

The potential visual impact from Viewpoint 11 was rated as moderate to low.

Viewpoint 12: Koberg Park (Figure 3.9-9)

From Viewpoint 12, approximately 17 turbines would be visible in the distant background to recreational users of the park and river. The nearest turbines would be approximately 6.60 miles away. The view looks west into the project area. Figure 3.9-9 shows the simulated view. Although the turbines would be visible to the viewers on the far horizon it is not expected to decrease the existing quality of this view to a great degree, because of their relatively small size at this viewing distance. The visible turbines would have a minimal effect on this view's vividness, unity, and intactness.

The potential visual impact from Viewpoint 12 was considered to be moderate.

Viewpoint 13: I-84 Eastbound (Figure 3.9-10)

From Viewpoint 13, approximately eight turbines would be visible in the background to travelers on the roadway looking west into the project area from I-84. The nearest turbines would be approximately 3.43 miles away. Figure 3.9-10 shows the simulated view. This view for travelers would be of short duration. Although the turbines would be visible to travelers on the horizon it is not expected to decrease the existing quality of this view because of the number of turbines visible and the partial screening from the middle ground ridgeline. The visible turbines would have a minimal effect on this view's vividness, unity, and intactness for these reasons.

3-192

The potential visual impact from Viewpoint 13 was rated as moderate to low.

Viewpoint 14: Viento State Park (Figure 3.9-11)

From Viewpoint 14, approximately 20 turbines in the background would be visible to the recreational users of the area. The nearest turbines would be just under four miles away. Figure 3.9-11 shows the simulated view. Although the water-related recreational activities would have the line of sight more related to the water and river banks, the recreational users moving through this area would be affected by this contrast in the view. The vividness of the scenic quality may be positively or negatively affected, depending on the user perception of turbines in the background. The unity and intactness of the existing view would be moderately compromised and the visible turbines would have a moderate effect on the view's scenic quality compared to existing conditions, due to the distance from the park and activities in the foreground and middle ground.

The potential visual impact for Viewpoint 14 was considered to be moderate.

Viewpoint 15: Frankton Road (Figure 3.9-12)

From Viewpoint 15, approximately 10 turbines can be seen, with the nearest turbines approximately 4.51 miles away. Figure 3.9-12 shows the simulated view. At this distance, the

contrast would have a minor effect on the overall visual impact. Consequently, because the prominence of the turbines in the view would be low, the turbines would have a minor effect on the vividness, unity, and intactness from this viewpoint.

The potential visual impact from this viewpoint would be moderate.

Viewpoint 17: Province Hospital Hood River (Figure 3.9-13)

From Viewpoint 17, only two turbines can be seen, and they are diminished by the distance (just over five miles). Figure 3.9-13 shows the simulated view. At this distance, viewers would have to scan the horizon to find the turbines. Consequently, minor effect or negligible effects to the scenic quality is expected.

The potential visual impact from this viewpoint would be low.

Viewpoint 19: Columbia River Highway (Figure 3.9-14)

From Viewpoint 19, approximately nine turbines are visible in the distant background. The nearest turbines would be approximately 6.46 miles away. Figure 3.9-14 shows the simulated view. Although the turbines would be visible in the background the viewer would have to have a focused orientation to see them in the landscape. The amount of turbines and the limited prominence based on the distance is expected to have a minimal effect on the scenic quality from this viewpoint.

The potential visual impact from this viewpoint would be low.

Viewpoint 23: Ausplund Road End (Figure 3.9-15)

From Viewpoint 23, approximately eight turbines can be seen. The nearest turbine would be approximately 0.64 mile away. Figure 3.9-15 shows the simulated view. This area would be

3-193

within one mile of the project and the turbines would be highly visible at the end of this road. However, very minimal use of these roads beyond workers associated with forest management reduces the viewer types. Regardless, the impacts of the turbines on the landscape would affect the scenic quality of the view.

The potential visual impact from this viewpoint would be moderate.

Viewpoint 24: Dog Mountain

Because the project area cannot be seen from the Dog Mountain trail (either during the day or at night), no simulated view was prepared. There would be no impact.

Night Lighting

The project would be required to comply with the Federal Aviation Administration aircraft safety lighting requirements for structures greater than 200 feet tall, which includes turbines and meteorological towers. The exact number of turbines that would require lighting would be specified by the Federal Aviation Administration after final project plan review; however, current guidance requires that warning lights be mounted on the first and last turbines of each string, and from those end turbines, lights should then be positioned such that the next lit turbine is no more than 1/2 mile, or 2640 feet, from the last lit turbine. The lights would be synchronized to flash together to illuminate the full extent of the wind project area (Patterson 2005). These lights would be visible as small blinking points of red light; they would not light up the sky or the surrounding landscape. Aside from any required aircraft warning lights, the turbines would not be illuminated at night. There will be one meteorological tower located within the project site area. Its location will be selected during the micro-siting process. Depending on its proximity to turbine towers, it may or may not require aircraft safety lighting.

The Draft EIS for the Nine Canyon Wind Project contains a generic illustration of night lights and can be found online at <http://www.efsec.wa.gov/wildhorse/deis/figures/40%20Fig%203.109%20and%2010.pdf>.

Columbia River Gorge National Scenic Area

During scoping, some commenters expressed concern that project operation would impact the Scenic Area adversely since turbines would be visible from some Key Viewing Areas inside the Scenic Area. Analysis of KVAs and viewpoints within the Scenic Area were sought and analyzed. The presence of the project would cause low to moderate visual impact to viewpoints within the Scenic Area,

Congress has determined that the National Scenic Act is not to be used to regulate activities outside of the Scenic Area boundary. The Act states that “no protective perimeters or buffer zones shall be established around the scenic area or each special management area. Activities or uses inconsistent with the management directives for the scenic area or special management areas can be seen or heard from these areas shall not, of itself, preclude such activities or uses up to the boundaries of the scenic area or special management areas” (16 USC § 544O(a)(10)). This federal policy and Congressional mandate discourage projecting National Scenic Act policies, regulations and directives beyond the boundary of the Scenic Area.

Comment: “Discourages” does not mean that people and agencies can’t speak up when they don’t want turbines littering the rural landscape. The NSA is a national treasure. It is also an economic boon to this area. Tourism contributes millions of dollars to the coffers of the counties located in the NSA. SDS Lumber’s wind farm will employ 5 people when all is said and done, and maybe contribute a miniscule amount of money to Skamania County’s \$50,000,000 yearly budget. The visual scenery that thousands of people come to enjoy, and those of us who live here enjoy it all the time, would be destroyed by horizon-topping wind turbines. This is too high a price to pay. Wind farms don’t belong in forests and they don’t belong on the boundaries of the NSA.

Mitigation

Project Decommissioning

In compliance with WAC 463-72, Site Restoration and Preservation, the Applicant will provide EFSEC with an initial site restoration plan at least ninety days prior to the beginning of site preparation. The plan will address site restoration that would occur at the conclusion of the project's operating life (estimated to be 30 years), and restoration in the event the project is suspended or terminated during construction or before it has completed its useful operating life. The plan will include or parallel a decommissioning plan for the project. Visual and aesthetic impact from decommissioning would be similar to those expected during the construction phase.

The initial site restoration plan will be prepared in sufficient detail to identify, evaluate, and resolve all major visual resource issues presently anticipated. If impacts to visual resources are anticipated to occur as a result of site restoration and project decommissioning, mitigation measures will be proposed as part of the plan.

3.9.3.2 No Action Alternative

Under the No Action Alternative, turbines would not be built. Existing visual conditions would continue unchanged, and would be influenced primarily by ongoing timber harvest until and unless a different applicant proposed to develop the wind energy potential of the area. In the event the failure to construct this project results in continuation and expansion of fossil fuel energy generation sources, it is foreseeable that air quality, including haze conditions, would continue to be a negative impact to the air quality and scenic resources of the of the Columbia River Gorge National Scenic Area.

3.9.4 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential visual resource impacts during construction and operation of the propose project to the extent feasible.

Comment: These are not "potential" visual impacts! These are real impacts and they would be very annoying and intrusive in our rural environment.

- Ensure that a non-reflective flat neutral gray or light color is the choice of color for the turbines so that visual impacts would be minimized. The primary mitigation measure available for visual impacts is the choice of color for the turbines. Although a brown turbine color would reduce visual contrast in views where the turbines are seen against the landscape, it would also accentuate the visibility of the turbines where they would be seen against the sky. In addition, the brown color would have a greater contrast when snow is on the ground. Because the turbines are most frequently seen against the sky, particularly in close-range views where visual concerns are the greatest, a non-reflective

flat neutral gray or light color would be ideal.

- Comply with Federal Aviation Administration requirements for safety lighting. Lights typically used to meet Federal Aviation Administration requirements would to some extent be shielded from ground level view due to a constrained (3–5 degree) vertical beam. The Federal Aviation Administration will independently review the lighting of individual turbines during the micrositing process and consult on mitigation. However, the project must comply with the safety lighting requirement.

3-195

3.9.5 UNAVOIDABLE ADVERSE IMPACTS

The project would cause some visual impact to surrounding areas where turbines were visible, including some areas inside the Columbia River Gorge National Scenic Area. However, the visual impact analysis showed that the anticipated level of visual impact would not be higher than low to moderate at any of the viewpoints examined.

3.10 HISTORICAL AND CULTURAL RESOURCES

This section describes existing historical and cultural resources in the project vicinity and identifies potential impacts to these resources from construction and operation of the proposed project. Cultural resources include buildings, sites, structures, and objects, each of which may have historical, architectural, archaeological, cultural, or scientific importance. Artifacts, records, and material remains associated with these properties, and traditional cultural properties, which can include archaeological, traditional procurement, and religious sites and landscapes, are types of cultural resources.

The primary source of information for this section is the Cultural Resources Inventory Report

prepared in support of the Application for Site Certification by URS (2009), as supplemented by fieldwork done by URS in December 2009 (URS 2010). The Cultural Resources Inventory Report was designed to identify, evaluate, and record pre-contact and historic cultural resources in accordance with Chapter 36 CFR §800 of the National Historic Preservation Act (NHPA). The survey objectives include identifying archaeological resources and historic properties that might be considered eligible for the National Register of Historic Places (NRHP) located within the direct area of potential effects (APE) for the proposed project.

3-196

3.10.1 REGULATORY SETTING

3.10.1.1 Laws and Regulations

Several federal and state laws protect cultural resources, including NEPA and SEPA, which require that impacts of federal and state actions on cultural resources be identified and assessed in environmental documents, as well as the NHPA, which establishes a national policy of historical preservation and requires that the effects of Federal actions (such as BPA's interconnection with the project) on significant cultural resources be determined. Collectively, these regulations and guidelines establish a comprehensive program for the identification, evaluation, and treatment of cultural resources.

To be eligible for the NRHP, properties must be 50 years old (unless they have special significance) and have national, state, or local significance in American history, architecture, archaeology, engineering, or culture. They also must possess integrity of location, design, setting, materials, workmanship, feeling, and association, and meet at least one of four criteria:

- Criterion A: be associated with important historical events or trends
- Criterion B: be associated with important people
- Criterion C: have important characteristics of style, type, or have artistic value
- Criterion D: have yielded or have potential to yield important information

If a resource is determined eligible for the NRHP, then Section 106 of the NHPA (80 Stat. 915; 16 USC 470) and its implementing regulations (36 CFR 800) require that effects of the proposed project to that resource be assessed. If a property eligible for the NRHP would be adversely affected by the proposed action, the action agency must evaluate alternatives or modifications to the proposed action that would avoid, minimize or mitigate adverse effects.

3.10.1.2 Area of Potential Effect

The NHPA requires that the APE for the project area be determined. The APE for direct effects to cultural resources is considered to be the footprint for potential ground-disturbing activities that are anticipated to occur during construction and long-term maintenance of the project. For the Project, ground disturbance could take place in the turbine string corridors, road corridors inside the project site, the West Pit Road outside the project area, overhead and underground transmission corridors inside the project site, the Operation and Maintenance facility (two alternative sites), and the substation and lay-down areas. These activities have a total footprint

of approximately 384 acres (Figure 3.10-1) and constitute the APE for direct effects to cultural resources. The indirect APE is the area outside of the project boundary where the project may have, for instance, a visual impact on significant cultural resources. On February 1, 2010, the Washington Department of Archeological and Historic Preservation (DAHP) sent a letter to EFSEC concurring with the definition of the APE. See Appendix E.

Job No. 33758687 Area of Potential Effects

3.10.2 AFFECTED ENVIRONMENT

3.10.2.1 Cultural Context

Pre-Contact Background

The archaeological record of the Columbia Plateau documents the prehistory of a region that is distinguished by local adaptations to a unique set of resources and its inland maritime environment (Chatters and Pokotylo 1998). Archaeological research near the site has focused principally within the Columbia River corridor, and models for the Portland Basin of the Northwest Coast culture area (Pettigrew 1981), the Columbia Plateau culture area (e.g., Galm et al. 1981), and the White Salmon and Klickitat rivers specifically (Masten and Galm 1989) can be applied. An overview of archaeological research within the Columbia River Gorge has been summarized by Beckham et al. (1988). Recently, Griffin and Churchill (2001) synthesized the multiple cultural chronologies that have been posited for the region; the following discussion is based on their synthesis.

The Early period dates from 11,000 to 4,500 years BP, though recent studies at Paisley Caves in Oregon suggest an even earlier date of regional occupation at least by about 14,300 BP (Jenkins 2009). A mobile lifestyle focused on intensive riverine resources with periodic use of uplands is inferred. Subsistence shifted from reliance on large game to an increase in the importance of fish, root, and vegetable resources by the end of the period. Permanent structures are not found in association with the earliest sites, but semi-subterranean house settlements appeared along major rivers at the latter stage, reflecting an increase in sedentism. Sites dating to this period have mostly been found around The Dalles at the eastern end of the Columbia River Gorge (Griffin and Churchill 2001).

The Middle period occurred from approximately 4,500 BP to 250 years BP and is characterized by increased occurrences of semi-subterranean houses and the appearance of food storage facilities, indicative of further sedentism and decreased mobility. Concurrently, there was intensification of use of fish, roots, and vegetable resources during the first half of the period, with hunting of secondary importance. The pattern of winter sedentism was apparently established during this period. There are more archaeological sites, including villages, fishing camps, and hunting camps that date to this period and that are found in the area between the Cascade Mountain Range and the town of Lyle, as well as The Dalles area (Griffin and Churchill

2001).

The Late period, dating from 250 to 100 years BP, is defined by the appearance of the horse on the Columbia River Plateau (circa 1730s), which increased the mobility and resource acquisition patterns of local groups. The period is also marked by the introduction of trade goods and the devastating effects of introduced diseases on the local populations, as well as the arrival of Euro-Americans. There is an increase in the quantity and distribution of sites dating to this period, with most being located along the confluences of major rivers and the Columbia River, though several sites are found on sandy terraces as well as within the islands. A large number of historic villages were noted by Lewis and Clark between Beacon Rock and The Dalles during their 1805–1806 travels (Griffin and Churchill 2001).

3-199

Along the lower White Salmon River, Middle and Late period projectile point styles are common. Recorded site types in this area include housepit villages, temporary camps, petroglyph sites, and cemetery sites (Griffin and Churchill 2001).

Ethnographic and Ethnohistoric Background

The proposed project site is located near the boundary between two ethnographic culture areas of the Pacific Northwest, the Northwest Coast, and the Columbia Plateau. Local groups living in the Columbia River Gorge at the time of historic contact are known from the languages they spoke as the Upper Chinookans and the Echeesh-Keens (Sahaptins)²⁰ (Beckham et al. 1988; Griffin and Churchill 2001). In the general area of the project, the Columbia River Gorge was used by the Eastern Chinookan-speaking Wishram, White Salmon, and Cascades people, as well as the Echeesh-Keen-speaking Yakama and Klickitat (Griffin and Churchill 2001).

The Upper Chinookans occupied the Gorge from the vicinity of the mouths of the Sandy and Washougal rivers east to the Deschutes River. Various Echeesh-Keen speaking groups lived to the east, including the Tenino, Klickitat, Yakama, and Umatilla. The Yakama primarily occupied territory north of the Tenino, while the Klickitat occupied inland regions to the northwest, extending to the Columbia River in the vicinity of the Klickitat River, along with Wishram peoples (Beckham et al. 1988, French and French 1998). Of these groups, the project area falls within territory that would have probably been used most intensively by the White Salmon, who comprised several small bands residing primarily in an area extending from about ten miles below The Dalles to the White Salmon River area, especially at the mouth of this river, although they lived away from the river as well (Ruby and Brown 1992).

During the nineteenth century, White Salmon usage most notably overlapped with the Klickitat, the Echeesh-Keen-speaking group primarily occupying the upper drainages of the Klickitat and White Salmon rivers. Several villages were found at the mouth of the White Salmon River, including at least one that was shared with the Klickitat (French and French 1998, Ruby and Brown 1992, Spier and Sapir 1930). White Salmon winter villages were found upriver along the White Salmon near the contemporary communities of Husum and BZ Corner, and along Rattlesnake Creek to the north (Griffin and Churchill 2001). Use of Namnit (45SA22), an

important ethnohistoric period fishing village at the mouth of the White Salmon River, continues into the present.

Less information appears to be available in the historic record regarding traditional use of the Little White Salmon River west of the White Salmon River. Another important village site was situated at the mouth of the Little White Salmon River: Skatxlmmax, or 'eating place,' and sqtdalpt, or 'it keeps tearing out', both refer to the village located at modern-day Cook along the Columbia River (French and French 1998). Salmon came to spawn here, and in winter whitefish could be taken from the spawning pools (Nielsen 1959). A trail from Drano Lake traversed the east side of the river into the upper valley. Two main huckleberry fields, including Big

20 Griffin and Churchill (2001) note that the Yakama Nation prefers the use of "Echeesh-Keen" over the term "Sahaptin."

3-200

Huckleberry Mountain on the south side of the lava beds and Little Huckleberry Mountain towards the headwaters of the Little White Salmon River, were frequented. Bark was peeled from many cedar trees along this trail for use in basket making. The racetrack near Red Mountain was the location of a big annual social event held in conjunction with the berry picking and drying (Nielsen 1959).

The Upper Chinookan and Echeesh-Keen peoples followed a similar seasonal pattern of subsistence activities, except that the former relied more heavily on fish than the latter (Griffin and Churchill 2001). In winter, limited hunting and fishing took place but subsistence was based on stored foods. With the arrival of the spring Chinook salmon, people would gather roots in the nearby hillsides. After the snow packs melted away, movement into the uplands occurred since fishing sites were usually inundated. Dried roots would then be hauled to the winter villages for storage in semi-subterranean cellars. Important spring gathering areas included Camas and Panakanic prairies, Deadhorse Meadow, and the Snowden area. Following the spring root gathering, people returned to the fishing areas along the major rivers to fish for blueback and Chinook salmon, and women would gather golden currant, gooseberry, dogwood, service berry, and choke cherry from the river and nearby uplands. A type of tobacco was planted and harvested by Chinookans (French and French 1998). In late summer and early fall, huckleberries were picked in the uplands near Mt. Adams, and hunting for deer and elk occurred. Toward late fall, the winter villages would be reoccupied. The White Salmon River was a focal area for tule salmon harvested in the fall that attracted many families to the region (Griffin and Churchill 2001, Norton et al. 1983, Schuster 1998, Winthrop and Meninick 1996). The fishing village at the mouth of the White Salmon River also functioned as a minor trading center (Griffin 2001).

In sum, the ethnographic and ethnohistoric context indicates that the project area is situated along a high-elevation ridgeline about two to three miles from two ethnographic riverine village sites, and within approximately one mile of the Little Salmon River valley, which would have formed a natural travel corridor providing access from the Columbia River to upland regions to the north, such as the popular berry picking grounds in the Mount Adams country. No specific

reference to the promontories that are in or near the project area, now known as Chemawa Hill or Underwood Mountain, were encountered in the reviewed literature, but proximity to known village sites suggests these high places and the adjacent ridgelines composing the project area could have been visited occasionally for non-residential, transient uses such as for spiritual activities, burials, or resource acquisition activities related to hunting, cedar peeling, plant gathering, and berry picking.

Historic Background

The first white pioneers to settle the section of the Columbia River between the Cascades and the confluence of the Snake River were reportedly the Joslyn family, who arrived at the White Salmon flats in 1852 and attempted to purchase their lands from the local Klickitats, in addition to filing a Donation Land Claim (McCoy 1987). Increased settlement by whites led to the creation of reservations throughout the region during the 1850s. Fourteen tribes and bands were signatories to the Yakama Treaty of June 9, 1855, when the Yakama ceded around 11 million acres to the US Government, while retaining rights for hunting, fishing, and gathering at traditional locations, and agreed to the establishment of the 1.3 million-acre Yakima Reservation.

3-201

The White Salmon Reservation was temporarily established at the mouth of the White Salmon River at the Joslyn claim in 1856 for around 800 Native peoples who were not active in the Yakima War of 1855–1856, during which time a coalition of interior tribes led by Kamiakin fought against the US Army and local settlers. At the end of the war two years later, the White Salmon Reservation was closed and residents were removed to the Yakama Reservation. Some avoided relocation and claimed lands their families had traditionally used, including around Northwestern Lake and along the area's minor drainages such as Buck Creek. Although a few took up farming, most continued to practice traditional subsistence activities at traditional places such as the Underwood In Lieu Site (Griffin and Churchill 2001).

The Underwood town site, located about six miles southeast of the project area and along the Columbia River, was among the earliest of the pioneer settlements in this portion of the Columbia River Gorge. Amos Underwood was a contemporary of the Joslyns who arrived in the region in 1852 and married Chief Chenowith's daughter, Ellen. In 1861, Amos and Ellen Underwood built a log house at the site of the present town bearing their name, as well as a dock and pier to accommodate sternwheelers. Amos' brother Edward Underwood also settled here and his house reportedly served as an Indian gathering place, especially in the fall during the salmon runs on the White Salmon River (Thun 1959). The Underwood brothers platted a town site in 1904, in anticipation of growth related to the construction of the Spokane, Portland, & Seattle Railway beginning the following year (McCoy 2003).

The upper drainage of the Little White Salmon River Valley, including the location of the proposed alternate site for the Operations and Maintenance facility along Willard Road, was not homesteaded until the 1880s and 1890s, when the more desirable lower-elevation lands had already been taken (Thun 1959). There were a reported 35 homesteads from Cooks to the present day Oklahoma park at the head of the river (Nielsen 1959). A review of late-nineteenth

century General Land Office maps (BLM 2009a) dated 1876 does not depict any settlement or other features of historic interest in or near the project area.

The history of the White Salmon and Little White Salmon region has a long association with the logging industry. Initially, the Menominee Lumber Company cut the easily-accessible timber into logs that could be floated down the White Salmon River. Oxen and horses were used to drag the timber, which traveled across several constructed rollaway dams before reaching the Columbia River, where they were rafted for towing to the Hood River mill (McCoy 1987). Wind River Lumber Company succeeded Menominee, using their dams along the White Salmon as they removed virgin timber from the Buck Creek, Mill Creek and Underwood Mountain areas (McCoy 1987). It was at this time that the upland forests of the project area were probably first harvested.

As of 1896, there were seven sawmills operating in Skamania County, the most notable of these being the Oregon Lumber Company's along the Little White Salmon River (Price 1896). After the logging of Underwood Mountain was complete, the Oregon Lumber Company established the Mill A sawmill and headquarters along the west side of the Little White Salmon River, and another sawmill at Chenoweth Flat on the east side of the Little White Salmon River at what was known as Mill B (less than one mile to the south of the proposed Maintenance Yard Alternative Location at Willard Road) (Attwell 1975, McCoy 1987). There were flumes on both sides of the

3-202

river that carried the lumber to the Columbia (Atwell 1975). When the supply of timber became more difficult to access, the company closed the mill in 1907, and moved it to Oregon (McCoy 1987, Nielsen 1959, Thun 1959).

Broughton Lumber Company was established around 1916 by Harold Broughton and D.M. Stevenson, who operated a mill at Willard along the Little White Salmon River. Using water diverted from the Little White Salmon River, Broughton Lumber Company transported the timber via a flume connecting the mill at Willard to the Columbia River, and then rafted the logs across the river to Oregon for railroad transport. The flume originally consisted of a 4.5-mile long segment from Willard to Drano Lake, and was constructed by the Drano Flume Company around 1913. In 1923, Broughton purchased the Drano Flume Company and expanded their operation by building an additional 4.5 miles of flume from Drano Lake eastward along the Columbia River to a new resaw and planing mill located along the railroad near Underwood (McCoy 1987, Thomas 2007). Following its completion, boards could travel the nine -mile long flume to the planning mill in less than an hour.

From 1923 to about 1940, Broughton Lumber Company constructed and operated a railroad for transport of logs to the primary mill. Two steam engines were used and a maximum of nine miles of track that were laid to haul timber from the woods to the mill at Willard, but the tracks had no permanent location, as they were moved and re-laid as necessary. The Broughton Lumber Company operation closed in 1986, and portions of the flume from Willard to the Columbia River were dismantled by the company shortly thereafter (Thomas 2007).

The logging activity that cleared extensive areas on Underwood Mountain in the early-twentieth century opened up these lands for orchard use at the same time. Settlement occurred quickly as a result of the “Apple Boom,” the period between 1905 and 1920 when vast orchards were planted along the White Salmon Valley, on Underwood Mountain, and elsewhere throughout the region. In 1908, the completion of the railway across the north shore of the Columbia River contributed to this influx of residents. White Salmon emerged as a main trading center by 1910, and fruit packing plants were established along the railway (McCoy 1987 and 2003).

Land patents were filed relatively late, from 1905 to 1910, for the high elevation ridgelines that characterize most of the project area (BLM 2009b). The correlation of the land patent dates with the regional orchard boom and railroad completion date in the project area is suggestive of prospective claims either for orchards or as investments for lumber resources. It has not been determined how many of the early-twentieth century claimants actually resided on their parcels. A 1929 USGS Hood River topographic quadrangle depicts the presence of one residential structure, an access road, and a trail within the project area.

Orchard growers at Underwood initially attempted to irrigate their crops with water pumped from the White Salmon River, but when the pump house was washed away by a flood, they attempted to take water out of Little Buck Creek using a gravity flume until the flume burned. Irrigation was not restored, and some orchard growers and farmers lost their land by foreclosure due to inability to pay taxes. A hard freeze in 1919 killed many apple trees, and several growers switched to winter pear crops (Thun 1959). Commercial orchards generally failed in the White Salmon Valley due to dry land and lack of organized irrigation, severe winters, and a short

3-203

growing season at higher elevations. Many orchards were simply abandoned and reclaimed by second-growth timber (McCoy 1987 and 2003).

Improvements in transportation along the north shore of the Columbia River occurred after the 1919 opening of the North Bank Highway, especially when the five tunnels west of Underwood were completed in 1937. The Hood River to White Salmon Bridge was opened in 1924 (McCoy 2003), further connecting the economies of the two towns.

3.10.2.2 Cultural Resources Overview

Tribal Consultation and Traditional Cultural Resources

Based on the archival review, no specific traditional cultural properties or sacred sites are documented within the project area. Given that this information is culturally sensitive, however, the reviewed records are not likely to contain specific references to traditional or sacred sites that could occur within the project area and tribal consultation is required to address their potential presence (Parker 1993). BPA will conduct the government-to-government tribal consultation for this project as per Section 106 of the NHPA.

To incorporate tribal involvement at an early stage in the process, the Applicant has initiated

contact with the Confederated Tribes and Bands of the Yakama Nation. The Applicant invited the participation of both the Yakama Nation Cultural Resources Department and two local resident tribal members to assist with the identification of potential sensitive, traditional, and/or sacred resources.

Through the Yakama Nation's Cultural Resources Department, the Applicant has requested participation of tribal members for the archaeological field inventory, has sponsored a field trip to the project area, and has attempted to solicit concerns with regard to potential cultural resources of importance to the tribe. The Applicant contacted the Yakama Nation Cultural Resources Department to review their confidential data sources and to report any potential areas of sensitivity, as appropriate, so that these areas can be avoided and protected early in the planning process. A field investigation by Yakama Nation cultural resources specialists occurred in December 2009. The Yakama Nation's findings, currently in preparation, will supplement the information contained in this EIS.

Separate from Yakama Nation Cultural Resources Department, the Applicant has invited the participation of two local residents, also members of the Yakama Nation, who have long-standing ties to the area. Chief Wilbur Slockish of the Klickitat Tribe and Chief Johnny Jackson of the Cascades Tribe met with URS archaeologists prior to the November 2009 field inventory and jointly toured the project site. Both individuals stated that based on their knowledge of this area, the project area was not specifically used by their ancestors or contemporary Indians. Neither individual identified any traditional cultural properties or other sensitive or sacred sites within the project site.

3-204

Previously-Recorded Cultural Resources in the Project Vicinity

The DAHP maintains a state-wide database of previously-recorded cultural resource sites, historic register properties, and completed inventories. The locations of the cultural resource sites (e.g., archaeological sites) are managed as restricted access information. The locations of historic register properties (e.g., buildings and structures listed on the state or national register) are non-restricted information.

The DAHP database does not have any record of previous inventories within the project area. Prior inventory coverage in the general vicinity depicts a few small, scattered inventories in upland areas near Underwood Mountain, mostly related to development review projects in the Columbia River Gorge National Scenic Area. A limited linear inventory for a proposed timber sale occurred adjacent to and north of the APE and did not identify any resources (Stilson 2005). In general, few inventories have been completed in the vicinity; those that have been completed are limited in scope and do not allow for comparisons or predictions to be made about the types of resources that could be found in the project area. Intensive inventory coverage has only occurred along the White Salmon River drainage several miles to the east of the project area, where numerous pre-contact and historic period sites have been identified.

One cultural resource was previously-recorded within the project area, consisting of the

Broughton Lumber Company flume (45GP596). The flume formerly paralleled Willard Road at the western boundary of the alternative location for the Maintenance and Operations facility. The flume was dismantled and removed from this area following the 1986 closure of the mill along the Columbia River. Although sections of the historic flume are still present elsewhere, none remain in the project area. This site therefore reflects a former alignment rather than extant physical remains.

Within a one-mile radius of the project area are two additional sites: a mortar and peeled cedar found about 0.5 mile west of the Maintenance Yard at Willard, and an early-twentieth century debris scatter associated with an old homesite, found about one mile north of the APE within a similar forested, upland setting. No historic register properties (e.g., buildings and structures) are found within the project area or within 1.5 miles of the project area based on the DAHP database.

In general, the density of cultural resources is greatest along the White Salmon River to the east, with scattered resources also found along the north shore of the Columbia River. Most archaeological research in the area has focused on riverine sites found along the Columbia River, and, more recently, along the lower White Salmon River. Fewer non-riverine archaeological sites have been documented in the general area, with several archaeological sites, mostly historic period, found in the Underwood Heights vicinity, several miles from the project area. It is unclear whether the higher site density documented along the White Salmon River is reflective of more intensive survey coverage, more intensive use of this area, or both, as compared to the Little White Salmon River. However, it appears unlikely that the higher elevation project area would have the same density of sites as the riverine areas along the Columbia and White Salmon rivers.

3-205

3.10.2.3 Project Site Inventory

A preliminary cultural resources inventory of the project site was conducted in 2003, based on the project design at that time (Ballentyne 2003). Because the proposed project area was subsequently revised and expanded, a new survey was completed in 2009 (URS 2010). A wider survey corridor of 650 feet for the turbine strings necessarily overlapped the 2003 inventory's 300-foot wide survey corridor. Much of the project area was therefore inventoried on two separate occasions, six years apart. The two survey areas are shown on Figure 3.10-2.

The 2009 URS inventory of the project area consisted of a pedestrian survey of the 384-acre APE where direct impacts to cultural resources could occur. Prior to the field inventory, oral interviews were conducted with the landowner and local tribal informants, and historic maps and historic and modern aerial photos were reviewed to identify potential resources within the project area.

Field Methods

An intensive pedestrian survey of the APE was conducted for this project in November 2009 for

the cumulative 384-acre APE. Transects were spaced no greater than 100 feet (30 meters); most were at 65-foot (20-meter) intervals or less. Survey methods depended on the project component being surveyed and the steepness of the slopes, as well as the presence of any hazards such as burning slash piles. Slopes greater than 30 percent were usually not inventoried. In several areas, survey coverage extended beyond the APE, depending on the topography. Ground visibility at the time of the inventory was variable; areas that had been most recently harvested provided excellent visibility, while forested areas were found to have dense accumulations of duff, slash, and dense vegetation that obscured the ground surface. Soil exposures provided by animal burrows, cut banks, roadways, and root casts were inspected closely.

Promontories associated with the proposed turbine strings were examined for potential rock cairns, rings, walls, or other alignments that could indicate sensitivity. Large old-growth stumps were examined for evidence of scarification, and large boulders were examined for evidence of petroglyphs, pictographs, or processing activities. The inventory was especially vigilant in looking for historic features such as residences, camps, roads, railroad alignments, flumes, or other evidence of historic logging and homesteading activities.

3-206

33758687_171.cdr

Figure 3.10-2

Job No. 33758687 Cultural Resources Survey Locations

Limited subsurface probing was conducted for this project at the location of an historic period archaeological resource, referred to as the Haran Farmstead, recorded at the time of the 2009 field inventory. This resource is located within one of the turbine strings, and is characterized by several rock features and a small artifact scatter related to an abandoned early-twentieth century residence and fruit orchard. The subsurface probing investigation employed close-interval systematic, as well as intuitive, sampling methods. Shovel probes were placed at close intervals around each of the recorded rock features to determine whether any associated archaeological deposits could be identified. Wider-spaced, systematic (20 to 30-meter interval) probes were placed within the lower-probability former orchard fields and within expansive areas found between several the rock features, where no surface artifacts were observed, to determine the presence or absence of buried resources.

A total of 52 shovel probes were excavated. The probes measured 30-cm in diameter and were generally excavated at 5 to 30-meter intervals to an average depth of 50 cm. Sediment was passed through alternating screen mesh sizes, both 1/4-inch and 1/8-inch mesh sizes were utilized. All artifacts were replaced within the excavated probe after documentation; none were collected.

Prior to subsurface probing, a metal detector was used to aid in the identification of metal artifacts obscured by the layer of duff that is present across much of the site due to its forested setting. The metal detector was used intensively around each of the recorded rock features. Systematic transects of 10 to 30 meters were walked in lower probability areas such as the

former orchard field. Shovel scrapes, or simple removal of snow and duff to expose the ground surface soil, were utilized as an additional method to improve surface visibility. Shovel scrapes were placed at 30-meter intervals within the former orchard lands, where probability is considered low, in order to provide additional validity to the surface reconnaissance.

Beyond the Haran Farmstead, no additional exploratory probing was conducted elsewhere in the project area. The majority of the potentially higher sensitivity landforms such as the ridgelines and promontories either had excellent ground surface visibility due to recent timber harvesting activities, and/or had exposed basalt rock with little potential for subsurface soils. Much of the project area is characterized by steep topography where exploratory subsurface testing is neither warranted nor practicable. Although Little Buck Creek crosses the project area within a proposed Overhead Transmission Line corridor, this area was found to be a small stream crossing surrounded by steep terrain with no areas likely to contain potential cultural resources.

Inventory Results

The 2003 draft survey report, which was never finalized or submitted for agency review, preliminarily noted two separate resources, including an historic rock wall feature and a small, disturbed historic artifact scatter of glass, ceramics, and tin cans within a roadway (Ballentyne 2003). As part of the 2009 inventory, one historic period archaeological site, the Haran Farmstead, was identified within one of the turbine string corridors, and incorporates the rock wall feature identified in 2003. The historic artifact scatter previously documented in 2003 was not relocated during the 2009 inventory, and appeared to have been buried or obliterated by later road improvements in this same area (URS 2010).

3-208

The Haran Farmstead, documented in 2009, consists of several rock features and a sparse historic artifact scatter associated with a former rural homesite related to James A. Haran, who had a small plum orchard here around the 1920s. A total of nine archaeological features were recorded, including two rock walls²¹ (probable property or field clearing boundaries), two structural rock foundations (probable residence and milking parlor), and several rock features of indeterminate function but possibly remnants of appurtenances such as privy, pump house or food storage structures. One small concentration of fewer than 20 historic artifacts, including aqua and colorless glass fragments, galvanized metal water pipes, crockery and porcelain fragments, and tin cans, also was observed. Approximately 100 to 150 artifacts, mostly metal fragments and tin cans, were found scattered across the site during a pedestrian survey supplemented by use of a metal detector.

In December 2009, URS archaeologists conducted exploratory subsurface sampling across the site to define the site boundaries and to determine the presence or absence of associated buried deposits. About 20 artifacts were encountered during the subsurface probing investigation, limited to wire nails, a water pipe, several small colorless glass fragments, and metal can or non-diagnostic metal fragments.

The NRHP eligibility of the Haran Farmstead is addressed in the Cultural Resources Inventory

Report. Each of the four criteria of eligibility is applied, and aspects of integrity are addressed. The Haran Farmstead is recommended as ineligible for the NRHP, due primarily to insufficient association and altered key aspects of integrity, which limit its potential to be considered under Criterion A (association with important events), Criterion B (association with important people), and Criterion C (having important characteristics of style). For Criterion D (information potential), the results of the inventory and exploratory subsurface probing indicate there is inadequate data potential to warrant eligibility. URS's recommendation for ineligibility is pending agency review and concurrence.

Summary

One historic period cultural resource was recorded within the APE: the Haran Farmstead archaeological site, which consists of rock features and a sparse artifact scatter related to a circa 1920s orchard and residence. Systematic subsurface probes were placed within this site and did not identify significant, buried deposits. The site is recommended as ineligible for the NRHP.

Additional historic farmsteads or other sites within the project area are not indicated by the results of archival research, which included review of historic maps and aerial photos. Field inventory confirmed that no aboveground resources, such as buildings, railroads, or flumes, are found in the project area.

A preliminary review of the ethnographic and ethnohistoric literature did not document this area as having any specific association for traditional resources, though uplands such as these could

21 The Haran Farmstead as recorded in 2009 incorporates the rock wall observed during the 2003 inventory. The other resource identified during the 2003 inventory, a small concentration of historic artifacts found within an existing access road, was not located in 2009.

3-209

have been used at least transiently, for example, for plant resource gathering or spiritual purposes. The Applicant has initiated participation of the Confederated Tribes and Bands of the Yakama Nation in order to identify any potentially sensitive resources or traditional cultural properties in the project area. Two local tribal members with long-standing ties to the area toured the project area and did not identify any cultural resources or concerns. A review by Cultural Resources Department of the Yakama Nation is pending. The 2003 and 2009 inventories did not observe any pre-contact Native American site types, such as lithic scatters, petroglyphs, or peeled cedars during the inventory.

Only one water source was observed during the field inventory: the outlet of Little Buck Creek, downstream of the earthen dam that was constructed in 1947 to create the "Cedar Swamp" fire pond (located outside the APE). This small watercourse is surrounded by steep terrain and is not likely to have significant, associated archaeological resources.

Promontories associated with the proposed turbine string, especially Chemawa Hill and others with panoramic views of the surrounding area, were inspected closely for potential rock cairns,

rings, walls, or other alignments that could indicate sensitivity. No such features were observed. It appears that even if such resources had been present, the historic and modern logging practices would have obscured this type of resource.

Although the project area was logged at least 100 years ago, no features such as camps, historic roads, railroad features, or other evidence clearly related to the historic use of the area was observed. Large old-growth stumps are occasionally encountered, but most are in an advanced state of decay and springboard notches were not observed. No evidence for historic road alignments was observed during the inventory; existing roadways are mechanically-graded, usually rocked and graveled, modern-use alignments that lack historic distinction. As no old-growth forest remains in this area, potential sensitivity for scarified, peeled trees is not indicated.

Much of the current APE examined in the Cultural Resources Inventory Report conducted in 2009 was surveyed in 2003. This overlapping of inventory coverage, nearly six years apart, at different times of the year, and with the surrounding forest in different stages of harvest, provides additional support for a general absence of cultural resources to be found in the APE.

3.10.3 IMPACTS

3.10.3.1 Proposed Action Construction

The proposed project has the potential to affect one historic period archaeological site, the Haran Farmstead, through ground disturbance during construction of the new project road and turbine and transformer pads. The degree of impact would depend on the final location of the road and turbines. The Cultural Resources Inventory Report recommended this site as ineligible for the NRHP subject to agency review and concurrence. If the Haran Farmstead is determined through agency concurrence to be ineligible for the NRHP, then no further management would be required and the project would not be considered to have an impact on significant cultural resources. If the Haran Farmstead is determined to be eligible for the NRHP, then the Applicant

3-210

would consider avoidance and/or mitigation alternatives so that a finding of no effect or no adverse effect would be achieved.

Construction also would have the potential to impact other, currently undiscovered cultural or historic resources. Based on the extensive inventories conducted, the likelihood of encountering additional sites is low.

Effects on traditional cultural properties or other sensitive or sacred resources that might be of concern cannot be determined until consultation with the tribes is concluded. This consultation is not expected to be completed until after the Draft EIS is issued.

Operation

The ongoing maintenance of the access road or emergency procedures such as fire suppression

activities have the potential to cause additional impact to the Haran Farmstead or other, currently undiscovered resources.

Project Decommissioning

Project decommissioning could have impacts similar to those during initial construction, including ground disturbance from turbine, transformer and pad removal. As with construction, the degree of impact would depend on the final location of the road and turbines, and on the determination of NRHP eligibility for the Haran Farmstead.

3.10.3.2 No Action Alternative

Under the No Action Alternative the project would not be built, and no impacts to historic or cultural resources would take place.

3.10.4 MITIGATION MEASURES

The following mitigation measures are identified to avoid, minimize, and compensate for potential cultural resource impacts during construction and operation of the propose project to the extent feasible.

- Implement avoidance and data recovery if the Haran Farmstead (a historic period cultural resource recorded within the APE) is determined to be eligible for nomination to the NRHP. The Haran Farmstead archaeological site, which consists of rock features and a sparse artifact scatter related to a circa 1920s orchard and residence. If the Haran Farmstead is determined to be eligible for nomination to the NRHP, then avoidance and mitigation measures such as data recovery would be considered to achieve a finding of no adverse effect for the project. Though none have been identified to date within the project area, properties considered as significant for reasons other than research potential, such as traditional cultural properties, may require mitigation measures other than data recovery that would be determined in consultation with the Tribe and agencies.

3-211

- Utilize BMPs to minimize impacts to any additional cultural or historic resources that may be encountered during construction of the proposed project. These BMPs include preparation and use of an Inadvertent Discovery Plan, which would establish procedures to deal with unanticipated discovery of cultural resources before and during construction. The plan, among other provisions, will require immediate work stoppage and appropriate notification in the event of discovery of previously unknown cultural materials. The plan also will specify protocols for the treatment of human remains that fulfill the requirements of the Native American Graves Protection and Repatriation Act in the event that human remains and/or funerary items are encountered during construction or operation of the project.
- Design the locations of road, turbine, and transformer to avoid and minimize impacts during construction regular maintenance operations.

3.10.5 UNAVOIDABLE ADVERSE IMPACTS

With the use of appropriate mitigation measures, the proposed project is not expected to produce any unavoidable impacts to historic or cultural resources.

3.11 TRANSPORTATION

This section discusses the existing network of roadways and rail, river, and air transportation in the project vicinity, as well as the potential impact of the proposed project on transportation.

3.11.1 AFFECTED ENVIRONMENT

3.11.1.1 Roadway Transportation

Existing Roadways

In the Columbia River Gorge, the two major roadways extending generally from east to west along the Columbia River are State Route (SR) 14 on the Washington side of the Columbia River and Interstate 84 on the Oregon side of the Columbia River. Other major roadways, such as State Routes 141 and 142 in Washington and State Routes 35 and 197 in Oregon, intersect these two highways generally in the vicinity of cities and communities located in the Gorge.

3-214

SR 14 between Interstate 5 in the Vancouver, Washington area and the project site is generally very narrow with 12-foot lanes and 2- to 4-foot paved shoulders. It also has many hills, and curves with tight corners in several places. East of the project site on SR 14, there is one low and very narrow tunnel east of the town of Lyle, Washington, and also a very narrow bridge east of The Dalles at approximately milepost (MP) 86. Between Cook-Underwood Road and SR 97 (Goldendale), SR 14 is generally narrow with 12-foot lanes and 2- to 4-foot paved shoulders. It also has some tight low-recommended-speed corners and a number of hills. Between SR 97 and the junction with SR 395/I-82, SR 14 is generally narrow with 12-foot lanes and 2- to 4-foot paved shoulders.

Existing access to the project site is provided by various county roads that extend northward from SR 14, along with existing private logging roads (see Figures 3.11-1 and 3.11-2). Key roads in the immediate project vicinity include:

- Cook-Underwood Road. Cook-Underwood Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. In general, the side slope begins at the fog line. This road is under the jurisdiction of Skamania County and generally is in good condition. There are currently no over-size or over-weight load restrictions in force. The Skamania County Comprehensive Plan lists Cook-Underwood Road as Federal Functional Classification “Major Rural Collector.”
- Willard Road. Willard Road has two 12-foot lanes and paved shoulders that are 1 foot or less in width. This road is under the jurisdiction of Skamania County and generally is in good condition. There are currently no over-size or over-weight load restrictions in force. The Skamania County Comprehensive Plan lists Willard Road as Federal Functional Classification “Rural Local Access.”
- West Pit Road. West Pit Road is a private logging road that connects to a network of existing private logging roads located on S.D.S. Co., LLC and Broughton Lumber Company property. West Pit Road varies in width from 20 to 26 feet. It is a dirt road covered in light pit run. This road has portions that generally are in poor condition; however, during summer 2009, various roadway improvements were made and segments of the road were widened for logging purposes.

Existing Traffic Volumes

Average annual daily traffic (AADT) values for SR 14 are shown in Table 3.11-1. Peak hour directional volumes were developed based on typical rural highway traffic patterns and proximity of business centers. Typical rural highway traffic patterns conservatively assume AM peak hour volumes to be approximately 7 percent of the total daily volumes, and PM peak hour volumes to be approximately 10 percent of the total daily volumes, with a directional split of 70/30. PM peak hour volumes are traditionally considered to be the highest during a given day. Since no current traffic data is available for Cook-Underwood Road at either the west or east junctions with SR 14, existing traffic volumes are based on typical patterns for small rural towns. Estimated 2009, 2011, and 2012 peak hour traffic volumes at the west and the east junctions of Cook-Underwood Road with SR 14 are presented in Table 3.11-2. Traffic volumes for 2011 and

Project Roadway Access from the West 2012 were based on an expected average weighted growth rate of approximately one percent per year.

Table 3.11-1
Annual Daily Traffic at West and East Junctions of SR 14 and Cook-Underwood Road

Location
Average Annual Daily Traffic (all vehicles)
2008 2009 (est)^a
SR 14 – west junction w Cook-Underwood Road 3,000 3,100
SR 14 east junction w Cook-Underwood Road 3,300 3,400

Source: WSDOT (2008)

a. A growth rate was developed for the project vicinity using historic data from annual traffic reports between 1996 and 2008. During several years between 1996 and 2008, there was no recorded historical growth in this area. Using this data, an average weighted growth rate of approximately 1 percent per year was determined.

AM Peak Hour is 7:00 AM to 8:00 AM

PM Peak Hour if 4:00 PM to 5:00 PM

Existing Level of Service

Level of service (LOS) is an estimate of operational performance based on delay to motor vehicles. The Highway Capacity Manual (TRB 2000), which is generally used when determining LOS, defines LOS using a letter scale from A to F. LOS A is defined as minimal or no delay to vehicles and LOS F is defined as extreme delays to vehicles. LOS C or better is

3-218

typically considered acceptable for rural intersections and is the LOS threshold of acceptable traffic flow for Skamania County. Table 3.11-3 presents the LOS delay criteria for two-way stop-control intersections.
