6773	8	wwpinneys@gmail.com	N/A	Lines 16873 through 16886 is blatantly incorrect and designed to mislead to indicate that increasing hatchery factory fish supplementation for both harvest and wild fish genome replacement (more naturalized surrogates) is acceptable. Only a PR exercise that result in extinction of the wild and extirpation of the natural, and eventually the majority of the hatchery once the agencies and Congress decides they are too expensive. The origin or characterization of the proposed 85% hatchery SR Spring/summer-run chinook salmon are not mainstem produced related to their genotype or wild stock ancestry, other than possibly a twist in wordage given their release or hatchery facility place, but predominantly come from state and tribal managed hatcheries spread throughout the Salmon and other river subbasins.	Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Diversity is an important factor in an ESU's ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. There is an extensive body of literature developed from studying these factors and managing the conservation of salmon and steelhead, including hatcheries as one tool. Hatchery programs have long been a part of the approach for salmon recovery. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as proposed under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. Figure 3-111, which combines hatchery and wild fish, in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. The three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The co-lead agencies do not have authority over tribal, commercial or recreational fishing; however, through increased abundance anticipated under the Preferred Alternative, more fish may be available for catch. Overtime, the Preferred Alternative is anticipated to benefit both wild and hatchery fish and the co-lead agencies continue to support information developed by the Hatchery Scientific Review Group and the Northwest Power and Conservation Council's Three-Step Review process.
6773	9	wwpinneys@gmail.com	N/A	Salmon survival/mortality data insufficient. - Most specifically for SR fall chinook salmon, the purely qualitative evaluations of response to alternatives shows the co-leads lack of care and knowledge for managing for such stocks. Qualitative only treatment professes too much over-speculation weighted on the authors wants and desires. Both sides of the argument are not addressed. More data and science has been collected for SR fall chinook than for any of the other ESA-listed stocks, but since they spawn and rear in the impounded mainstem and tributary confluence regions of the SR, NOAA has followed suit with BPA and the Corps to mitigate this critically important stocks productivity with factory hatchery stock transgression, thus diluting their fitness and genomes into the newly created naturals instead of producing more larger bodied and more fecund robust wilds. Yes, the alternative evaluation tables in the main text of the CRSO EIS recognize the Appendix statements that MO3 would restore 15x (as in multiplied times more, and not %) spawning habitat acreage restored (but mis-interprets the 140 miles of restored bankfull width of rearing habitats because they failed to consult the 2002 FR/EIS Appendix H, by design, since the River Dynamics team was the only entity that used existing evaluations such as Appendix H Fluvial Geomorphology). The additional habitat restoration and designations were not used in either the LCM/COMPASS or CSS production modeling exercises, as clearly requested during Scoping and within the Corps own staff. But since SARs for fall chinook are not even addressed in the CRSO EIS, then if the restored habitat place, space, and function (fecundity) under MO3 (given 2-5 (2002) or 7 years (CRSO DEIS)) would be incorporated in the models production functions, then SARs would likely peak beyond 8-10%. The restored habitats and macroinvertebrate productivity, diversity, and distribution of biomass in a breached and restored channel of the SR would be near equivalent to 2-4 Hanford Reach spawning area footprints, thus producing as much as and up to 4 times more wild-determined spawner falls that Hanford Reach and/or that expanded habitat currently not used to carrying capacity in the Snake and Clearwater rivers confluence, lower reach of the Clearwater River, and the Grande Ronde subbasin tributary mouths. Yes, there are ample datasets for production modeling for SR fall chinook population demographics (Fall Chinook Recovery Plan and many other sources either compiled or un-compiled), but NOAA continues to decide against them for model development citing too complex, as well as in their incompetence-by-design aimed at burying the issue through slow replacement into extirpation, and ultimately extinction via unsuccessful hatcheries. Fall chinook are key to ecologically adequate feeding of chinook eating ecotype of orca, only unrecognized due to no poop sampling capability to date within the too-rough-for-human-work near-ocean orca distribution in late-fall and early winter timeframes. NOAA, and the co-leads in this CRSO EIS need to recognize such publications such as Wietkamp 2010 coded-wire tag catch evaluation in Transactions that clearly and robustly illustrate the fall chinook overlap in place and time with orca.	The commenter is correct that extensive research and monitoring of Snake River fall Chinook and unlisted upper Columbia fall Chinook has taken place in the recent decades by USGS, USFWS, University of Idaho and others. In drafting the CRSO EIS, the CRS Fish Technical Team evaluated the use of a USGS Snake River fall Chinook model, and a second model developed at U.S. Dept. of Energy (Perkins et al. 2011). Unfortunately, neither of these high-quality models was adequately capable of representing fish response to the proposed changes in CRS operations under the MOs. Therefore qualitative analysis was appropriate. The co-lead agencies disagree that the qualitative analysis was "over-speculation weighted on the authors wants and desires", but rather objective and accurate. It is correct that neither the NMFS Life Cycle model or CSS Life Cycle model included expanded spawner capacity in their modeling. There is considerable uncertainty around expectations for expanded spawning areas under MO3. In the pre-impoundment era before the construction of Ice Harbor dam, most Snake River fall Chinook spawning occurred in the tributaries and middle/upper Snake upstream of Lower Granite (Groves and Chandler 1999). Scour from ice in the winter and relatively high water temperatures during fall (compared to the upper Columbia) were believed to be limiting factors. It is not known if ice formation would be a contemporary issue below Hells Canyon, and there is some doubt whether adequate gravels would be available in the lower Snake. However, temperatures would be expected to cool earlier in fall. Perkins, T. A., & Jager, H. I. (2011). Falling behind: delayed growth explains life-history variation in Snake River fall Chinook salmon. Transactions of the American Fisheries Society, 140(4), 959-972. Groves, P. A., & Chandler, J. A. (1999). Spawning habitat used by fall Chinook salmon in the Snake River. North American Journal of Fisheries Management, 19(4), 912-922. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
6773	10	wwpinneys@gmail.com	N/A	Purely qualitative analyses do not satisfy the intent of NEPA, ESA, and the other environmental Acts, laws and statutes, especially those used in the CRSO EIS due to being based on self-interest opinions and the overly-complexed and mis-representative and mis-used CEMs (Conceptual Ecological Models) of Bureau of Reclamation (BoR) contribution to the dead-end processing. It is impossible to address all those boxes and their linkages in a meaningful and biological or scientifically logical means, totally unsupported. The other agencies have long abandoned such practices of persuasion decades ago. Plus, no evaluation of non-ESA-listed stocks that are robust because of free-flow natural river habitat and hydraulics, such as the Hanford Reach fall-summer stock that is vital to the regional harvestable monitoring. Such comparative evaluations have been routine in past NEPA and ESA consultations to help identify critical causative factors that robust and healthy populations possess, but the ESA-listed populations/ESUs/DPSs lack and need restored.	Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. The evaluations are clear, transparent, and repeatable based on high quality information. The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as Cooperating Agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the CRS system. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
6773	11	wwpinneys@gmail.com	N/A	Does not assess the contribution of latent and reservoir mortalities to reach survival trends and SAR values, and recovery standards for each multiple objective even though the Biological Assessment confirms that the PA adversely affects all stocks. Applied only a guessing what if exercise in COMPASS/LCM, thus leaving the critical question to more research with more requested funding if it actually comes during times when co-leads are in a no funding or significantly cut funding era. In reality, all passage routes in the NAA and MO1, MO2, and MO4 have some level of latent mortality stress and pressures leading to insufficient ocean survivals, so not even a 30+ year research program will rectify and split any uncertainties caused within one or more of the smolt transport, spill program, or bypass survival parameter vectors. Any combination of synergistic latent mortalities from multiple passage route proportions passed concurrently is dramatically confounding, and the process to tease or parse these route determined cause-and-effects just leads to a repeat of the much wasted (in funding and smolts and adult straying) NMFS welfare research smolt transportation program. The smolt transportation program is a well-defined near-40 year long RM&E that has proven beyond a doubt to either provide even slightly inconsequential or negligible beneficial nor detrimental bumps to SARs, so it just gets repeated annually, but it and bypass have proven to high latent mortality effectiveness in most flow years. It just depends how the co-leads and NMFS wishes to redefine latent mortality. MO3 breaching save substantial monies and time (for which has run out for salmon) successfully eliminates this boondoggle RM&E instead of perpetuating its no-ending trajectory into oblivion.	Multiple mechanisms have been proposed to understand the impact of delayed mortality or 'carryover effects' between experiences in one lifestage influencing survival or physiology in subsequent lifestages (Gosselin et al. 2018). These include transportation related delayed mortality, injuries caused by passing multiple dams via any route, delays caused by reservoir and dam passage, and exposure to toxins. (Gosselin, J. L., Zabel, R. W., Anderson, J. J., Faulkner, J. R., Baptista, A. M., & Sandford, B. P. (2018). Conservation planning for freshwater-marine carryover effects on Chinook salmon survival. Ecology and evolution, 8(1), 319-332. The benefits of transportation for Snake River ESUs have been estimated as a ratio of the post Lower Granite Dam SAR of the transported group vs. all smolts that travel in-river (TIR) or the T:B ratio of transported smolts vs. those detected at the dam bypass. It has been more challenging to estimate the fraction of fish passing undetected over dam spillways using mark recapture methods, however the new detector at the surface passage weir at Lower Granite Dam should make this easier. Both the TIR and T:B time series from the lower Snake show that both hatchery and natural origin steelhead, yearling Chinook and sockeye benefit from transport during most years, especially late in the season and in warm conditions. Some groups such as hatchery steelhead benefit substantially, with an average of twice more transported adults returning, per capita. If the transportation program was ended, there would be fewer adults returning, available for spawning, harvest, and supporting marine mammals in the food chain.
6773	12	wwpinneys@gmail.com	N/A	One of the most significant fatal flaws is the non-reporting and non-addressing anywhere in the primary text of the main report what the COMPASS model Snake River (SR versus Columbia River (CR) reach survival results are for the NAA and the MOs. The Lower Granite to McNary (through Ice Harbor), sometimes called the SR reach survival (4 dams) and the lower Columbia River (4 dams McNary through Bonneville) reach survivals that have been parsed out of or constitute the entire Columbia River hydrosystem (8 dams) passage is the comparison required to attribute effects between alternatives.	The CRS anadromous technical team did not request separate lower Snake and lower Columbia reach survival rates for Snake River ESUs because the CSS model is not designed for estimating survival for each reservoir. In the appendix, travel times are reported for the Lower Granite to McNary dam reach and McNary to Bonneville dam reach, with NMFS COMPASS. Survival rates for both Rock Island (RIS) to Bonneville Dam and McNary to Bonneville Dam (the reach with only Federal dams) are reported for the Upper Columbia spring Chinook ESU by COMPASS, and McNary to Bonneville also with CSS. If one assumes some comparability between the upper Columbia and lower Snake ESUs, one could use these data to compare changes between the alternatives for the lower Columbia and lower Snake reaches.
6773	13	wwpinneys@gmail.com	N/A	Predominantly the salmon analyses are based upon hatchery fish passage and productivity since so few wild spawners are truly protected (realistically on the short-edge of extinction). The 80-85% hatchery component of all stocks is highly subjective due to the allowance of naturals being produced. Spawner and rearing sizes and fitness has declined as time goes on as more hatchery broodstock are used in place of lost and mined wild spawners for broodstock, even as NOAA keeps including and subtracting certain hatcheries they have deemed wild supplementation, to no benefit of the true wild remnant component. NOAA needs some real true and honest biological demographic evaluation and recovery management for this critical issue because it is most probable that the end is here for wild fish, as both wild, natural, and hatchery fish replace one another and all dwindle exponentially. NOAA and the co-leads do not even use the wild terminology anymore, as it was mandated for the listing, due to some harvest lawsuits around 2005 and their own mismanagement interpretation of ESA, out of convenience and pandering to industries like BPA. The true percent hatchery component is most likely 95-99%.	This Draft EIS analyzes the effects of the operations, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Current high quality information was utilized to evaluate the metrics for that purpose (juvenile survival, travel time, transportation ratio, powerhouse passage, smolt-to-adult returns, and adult abundance). This evaluation includes both hatchery and natural-origin fish. As described in the Methodology Section (Section 3.5.3.1 on page 3-358) both CSS and NMFS life cycle models include both hatchery and natural-origin fish in both the input data and the output results. Also, hatchery programs are discussed briefly in the Affected Environment description to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. Based on our analysis of fish resources in Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Hatchery origin fish are very important to Tribal and sport harvest within the CRB, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.

6773	14	wwpinneys@gmail.com	N/A	Buried and hidden deeply with Appendix E are the Tables 4-3 through 4-12. These rather long and complicated tables contain the Raw Data outputs of the biologically important metrics that populated and resulted as output metrics from the COMPASS model for each MO and NA Alternative, most importantly the individual subbasin reach survival and travel time, et al, estimates for each year of the 80+ year inflow record (1929 through 2008), BUT not for the proposed Preferred Alternative (PA) as composited by BPA. In COMPASS the PA run will be a negative response in reach survivals compared to all MO3s except the Power MO2. These Tables included the 2-4 different versions of COMPASS calibrations for MO3 derived to analyze the effects on the reach survival estimates. Since these alternate calibrations are poorly written up anywhere in the CRSO EIS body and Appendices, one had to use the Raw Data outputs in order to evaluate if these alternate calibrations were really different enough to calculate different outcome statistics for reach survival. Basically some verification was warranted that the breaching routines and files that Pinney of Corps and Beers of UW develop was being used and was the best science, instead of proposals by BPA that unimpounded reaches of the parr lifestage individuals (non-migratory and non-smolted) would be used for reach survival estimation. The corrected breached reach surrogate reaches appear to be used and tested within the 4 COMPASS MO3 calibrations, in that the result column for Snake River (SR) reach survival of spring-run only chinook is consistently 88-99% (with only 1 or 2 down in the 70%s) for all iterations of MO3 calibrations (NOTE: THESE ARE NOT the un-composited dam/concrete only survival tests for individual dams as BPA and the Corps perpetuate in the media, BUT THE LGR-IHR/MCN reach post breach survival through the 4 post-breached dams and reservoirs), whereas the NAA and other MOs 1, 2, and 4 reach survival estimates for the SR for spring-run only chinook is consistent for a much more variable range between 71 to ~80% (with a few years up around 84%) indicating the capture of a very status quo derived strategy. When each annual (year) SR reach survival for MO3 (88-99%) is combined with the totally consistent Columbia River (CR between McNary and Bonneville) reach survival estimates for the rest of the MO3 (40-mid60%s), generated at the same time step and river conditions as the SR estimates, you get the overly averaged and washed out entire Lower Granite to Bonneville reach survivals of 40-mid60%s (since SR MO3 natural condition survivals are consistently in a tight range across all years near 100%, even though the CR has quite a lot of variation in its annual reach survival range for NAA, MO1, MO2, and MO4 (although MO4 does have a slight bump in reach survivals a few % higher than the other MOs, just as MO2 range has a slightly lower % range, which the main text write-up for COMPASS results discredits in its treatment for spill)). Results for steelhead show the same trends although the survival calculations are a few % lower than those comparable for spring-run Chinook. Bottom line: The NOAA-constructed information for the best selection of a Preferred Alternative is there in only the Appendices and NOT in the CRSO DEIS body, and these tables fully supports 4 LSR dam breaching in alternative MO3, but the information is well hidden in the complexity of reporting in the Appendices, and by design of the co-leads to dissuade the reader to their pre-determined and pre-selected status quo is acting woefully and gravely to salmon and steelhead that these vital and critical reach survival statistics were not brought forth in any adequate means or manner by the co-lead synthesizing authors. The resultant COMPASS modeled reach survivals in the Appended Tables of Raw Data of Appendix E are very consistent with both NOAA NWFSC annual reporting of the PIT-tag detection modeling (50-70%s SR and 40-60% CR reach survivals) and the PATH modeling statistical exercises for breach Alt 4 in the 2002 FR/EIS for Snake River juvenile salmon migration (85-96% SR reach survivals, CR variability stays near the same). Plus, the COMPASS model has not even been run for the PA, or any fall chinook stocks, and any variability or range metrics around any of the average survival estimates have not been reported and addressed (as is typical if you wish any scientific vigor in review or presentation because technically this is a publication that gages how competent the analyzers are, be they statisticians or just simply computerized modelers). If, or when, COMPASS is run for the PA it will demonstrate a more negative response than even the incorrect NAA that has been used.	The co-lead agencies direct the commenter to Chapter 7 of the Draft EIS and FEIS for all life cycle model based estimates of effects to salmon and steelhead associated with the Preferred Alternative. These results are based on both NOAA LCM and COMPASS models as well as from the CSS life cycle models. Appendices have also been updated in the FEIS with additional technical data generated by the models. However, as described in Chapter 3.5, there are no quantitative model results for Snake River fall Chinook salmon. That species has a life history that is unable to be modeled effectively by either NOAA or the CSS. For the 2000 Biological Opinion, NOAA proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap, and from the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from these difference between these two trap-to-dam estimates (Ferguson et al (2004). For the 2020 Draft EIS, NMFS used a similar method of estimating free-flowing survivals and travel times with their COMPASS model. PIT-based monitoring efforts have occurred at 20-plus additional hatchery and wild trap locations in the Snake and upper Columbia since the 2000 BiOp. In the appendix, NOAA carries out a sensitivity analysis for the choice of upstream trap location by comparing free-flowing survival rates estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent dam breach conditions under alternative MO3. There is a wide variance in per-kilometer travel times and survival rates to Lower Granite Dam among all of the possible hatchery release sites and screw trap locations upstream of Lower Granite Dam. The river conditions and migration behavior of fish in tributaries to the Snake River is much less representative of river conditions we expect in the Lower Snake river following dam breaching than are the river conditions in the free-flowing Snake River between the confluence of the Clearwater River and the confluence of the Salmon River. NOAA selected the three locations because each trap location was low in the tributary and are very close to the mainstem Snake River; we expect that reach of the free-flowing Snake to be very similar to what the breached lower Snake would look like in MO3. Traps further up in the tributaries are likely to tag more parr while these three traps tend to intercept mostly smolt-aged fish which arrive at Lower Granite time without further rearing behavior. Yet it does appear that some fish in the GRN and IMN data exhibit parr-like behavior, especially in early April. This is a major contributor to why the GRN-IMN model predicts slower migration and lower survival in MO3 than the other calibrations, and the reason for why it was placed into the appendix. The Salmon trap-to-Lower Granite reservoir free-flowing survival rate is used as a representative yearling Chinook population for the main text of the MO3 analysis. In response to the comment "outside the range of the data so the model is useless," this criticism can only apply to the SNK calibration. Yes, MO3 is outside the range of the calibration data for the SNK calibration, as is noted in the Draft EIS text. The calibration between the Snake River Trap and LGD was just a calibration used to get at the GRN-IMN and SAL calibrations, and was not used in any prospective model runs for the Draft EIS. However, the SAL and GRN-IMN calibrations are NOT outside the range of the calibration data when used for MO3. Flow, water velocity and temperature are all comparable between the free-flowing reaches of the Snake River used for calibration and the breached Lower Snake in MO3. Ferguson J. (2004) Memorandum to FCRPS biological Opinion Remand Administrative Record RE: Updated estimates of free-flowing river survival. NW Fisheries Science Center.
6773	15	wwpinneys@gmail.com	N/A	The NAA is not the required baseline to be used for salmon and steelhead, the No Jeopardy and/or recovery (NOT the improvement standard as wished-for in the objectives, this merry-go-round has been fought and lost in the Courts for several times) of the MPGs that constitute the ESU and DPS vitality away from extinction and simple just surviving is the basecase. The CRSO must use the analyses in the 2008 BiOp, the 2002 FR/EIS for Snake River juvenile salmon migration, and those stock-specific recovery plans that are currently available. The link to the Fish Passage Center documents that were illegally held under NEPA and ESA et al regarding the FPCs analysis of the CRSO DEIS alternatives finds that: (1) the Preferred Alternative in the DEIS is usually the third or fourth best alternative in terms of different fish survival analyses; (2) the beneficial results of the Preferred Alternative likely are overstated; (3) other best alternatives for maximizing salmon and steelheaddam breaching combined with spill and seasonal drawdowns for water temperature regulation at the lower Columbia Damswas not included in the DEIS after it was proposedthe breach alternative in the DEIS, MO3, has high spill at the mid-Columbia dams; (4) the new turbines likely kill more fish than the old turbines, because they draw water in at greater speeds, drawing more fish to the turbines, and the new turbines have about the same mortality rates for juvenile salmon and steelhead. Balloon tag (rotating steel striking and pressure differential damages alone) and sensor fish releases and mostly bead strikes are not justifiable and robust enough means of extrapolating for the estimated turbine induced survivals for various well-established and regionally articulated problems. http://www.fpc.org/documents/CSS.html SAR calculations should be include jack numbers because they cannot be verified biologically successful spawners. Through a non-disclosure agreement, the federal agencies required the Fish Passage Center to withhold these documents from the general public until the CRSO DEIS was made public on 2/28/20.	The co-lead agencies developed the No Action Alternative consistent with regulations implementing NEPA, which allow that for ongoing actions, the No Action Alternative represents no change from current management direction and intensity at the time of the Notice of Intent to the Prepare the EIS. NEPA and ESA have different requirements and thus, it is appropriate to use different baselines to comply with the requirements of the respective laws. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the draft EIS. Any additional modeling that was not presented in the draft EIS is not part of the CRSO EIS and was not developed by the co-lead and cooperating agencies. Improving juvenile and adult anadromous salmonids were two of the eight objectives of the CRSO EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), and also meets most of all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions. It minimizing adverse impacts to communities and the economy. The Preferred Alternative is likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies disagree the Improved Fish Passage turbines would adversely affect SARS. See Section 3.5 and Section 7.7.4 for additional information. The new John Day and Ice Harbor turbines will be designed to operate within the existing turbine operating range. McNary turbines will be designed with an increased range. Once installed, the new turbines will be tested and validated for fish survival. Although only the McNary turbines will be designed for an increased operating range, the overall level of spill at any given project is determined not by the individual turbine unit capacity but by overall project operations management decisions. These decisions will occur through the Regional Forum and guided by the Adaptive Management Plan. Adaptive management strategies will be used to assure no detrimental impact.
6773	16	wwpinneys@gmail.com	N/A	Snake Chinook deemed insignificant prey source for Southern Resident Killer Whales (SRKW). - Ignores past and more recent NOAA and independent (plus NOAA contracted-UnivWash and many others) data on SRKW diet, for example the February 2020 Risk Assessment on chinook harvest effects to SRKW's (even given its critical weaknesses that include analysis only with an unjustified 2 lower Columbia River spring chinook populations because they are in the FRAModel, while also failing to incorporate any analyses on the more important fall chinook stocks (including Snake River and mid-Columbia River (Hanford Reach)) that comprise the greatest substance of their FRAModels, and correlative salmon tag recovery and catch statistical mapping that would be highly correlative to orca hunting and feeding distribution datasets for both fall and spring and summer lifestages of important salmon stocks to orca viability. Weitkamp (2010) in Transactions (Fig 5 pp 159-160 as just one example) and many others (Lichatowich book Salmon without Rivers as just one example), if NOAA would actually look, clearly demonstrates historical passage of Snake/Columbia river origin fall, summer, and spring spawners through Johnstone Strait and the Salish Sea environments that would be taken by feeding orcas in past years.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6773	17	wwpinneys@gmail.com	N/A	NAA is incorrect baseline for alternative comparisons. It is the jeopardizing status quo, where the required most informative baseline is similar to the more appropriate salmon and steelhead production baseline that can be readily developed in consulting the orca scientists datasets and documentation, such as what was used in the recent renditions of the SRKW Recovery analyses and plans.	As stated in the Purpose and Need in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As stated in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 Code of Federal Regulations [CFR] 1502.14) and is provides benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change.
6773	18	wwpinneys@gmail.com	N/A	Irrigation mitigation of MO3 based on devaluing irrigated land, 47,840 acres at cost of $313.7 million. - Mitigation method justifies loss of 4,800 jobs, $232 million in labor income and 460.5 million in sales. - Pipe extension and pump installation mitigation overlooked, estimated at $20 million from Sampson, Rob 2018 A brief review of the impacts to irrigated farmland from breaching the four dams on Lower Snake River.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks. This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
6773	19	wwpinneys@gmail.com	N/A	25 to 50% increase in rail shipment costs cannot be justified without cost estimate modeling and supporting data. - Use of recently upgraded rail line along the snake that can move all grain to market is not mentioned.	How rail rates would change without lower Snake River shallow draft barging can not bet known with certainty. Therefore, in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased, freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable.
6773	20	wwpinneys@gmail.com	N/A	Flood conveyance dredging at Lewiston absent in multiple objective costs and should not exist in MO3. - Should increase cost by approx. $12 million/year for NA, MO1, MO2, MO4 & PA.	Dredging costs were developed based upon historic dredging quantities and costs. Although these costs may generally be referred to as simply dredging costs or navigation dredging costs, dredging outside of the federal navigation channel could still occur in the future if needed and are captured within the historic quantities. Dredging costs were included for all alternatives, and it is recognized that dredging would no longer be needed on the lower Snake near Lewiston, ID under MO3. These dredging costs are reflected under the operations and maintenance costs reported in Section 3.19 of the EIS, and described in more detail in Appendix Q.
6773	21	wwpinneys@gmail.com	N/A	LSRD breach cost from 2002 EIS without mitigation uncorrected and escalated to $994 million. - Error of approx. $600 million, from Waddell et al. 2016 Reevaluation of The Lower Snake River Juvenile Salmon Migration Feasibility Report and Supplemental Environmental Impact Statement Appendix D Natural River Drawdown Engineering. - Stated as $994 million in chapter 3, inconsistent with appendix Q that says it is $955 million. - Failure to recognize and document that breaching MO3 still is the least cost alternative (Table 3-4, pp 3-11) even given the major critical flaws based on un-truths perpetuated in the cost and economic evaluations.	Engineers and cost estimators at the USACE reached out to dam breaching experts at Reclamation and considered techniques used at other facilities. Approaches and constraints associated with those techniques were compared to those used in the 2002 EIS and determined the approach used in the 2002 EIS was still appropriate. The USACE engineering and cost estimators then double checked engineering requirements, quantities, and reestablished cost estimates based on current prices. Breaching costs are estimated to be $994 million in project first costs (no discounting), $955 million discounted and presented in 2019 dollars, or $36 million in annual-equivalent costs over the 50-year period (using a discount rate of 2.875%). In terms of the implementation and system cost analysis (Section 3.19), MO3 would result in the largest decreases in costs (increases in cost savings) compared to the No Action Alternative. However, this does not account for losses in other benefits under MO3, such as hydropower, navigation, and irrigation. The Preferred Alternative was chosen to meet the purpose and need to operate the system for the congressionally authorized multiple purposes, including fish, hydropower, and water supply, while minimizing adverse effect to biological and socioeconomic resources.
6773	22	wwpinneys@gmail.com	N/A	Congressional authorization assumption for MO3 incorrect and has been overly bastardized for over two decades to dissuade and delay the necessary breaching alternative, be it Alt 4 in the 2002 FR/DEIS for the Snake River and the 2002 FR/FEIS for the Snake River and this CRSO DEIS. The Corps HQ down to the Division needs to apply some true leadership to rectify this false whose got the power and authority excuse derivation. The Corps has the power and authority to manage, thus decommission and deconstruct, its water projects, as demonstrated by the failed bill put before Congress by the southeast and central Washington representatives to the House.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
6773	23	wwpinneys@gmail.com	N/A	Breach alternative MO3 conflated with construction and mitigation costs on other dams. See comment that the original hatchery-for-harvestable fish mitigation for the Snake River dam construction will not vanish since the detrimental effects of the dams themselves, even under no operation/decommissioning, would still be present until the mitigation targets are completed or the salmon and steelhead are recovered to the pre-dam condition within the Snake River.	The method proposed for breaching the lower Snake River Dams is based on extensive analysis completed for the 2002 Feasibility Study, which also considered dam breaching. The methodology developed is intended to minimize impacts to ESA fish runs, other aquatic organisms, the built environment, and provide maximum protection to human health and safety. The EIS uses the same assumptions. For the purposes of this EIS, the 2002 cost estimates were inflated to 2019 price levels. The co-lead agencies will continue to adhere to Federal standards for dam and levee safety and human life safety considerations. In the event that breaching of the lower Snake River dams is implemented, additional analysis will be conducted to refine methods and costs. Funding decisions for the Bonneville F&W Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W Program costs are included to inform the broader cost analysis for each alternative in the EIS. In the case of the Preferred Alternative, Bonneville included a range of potential F&W Program costs to acknowledge the possibility that the Preferred Alternative could provide biological benefits to anadromous fish species (see Chapter 7 of the EIS, Preferred Alternative) and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville F&W Program. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. In 2016, Bonneville's F&W Program budget was $267,000,000, and the LSRCP budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP facilities, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17 percent, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative. This information can be found in several places in the body of the Draft EIS, but the best citation is probably Appendix Q, Chapter 7 Summary of All Costs. Finally, Chapter 5 describes mitigation proposed for MO3, including increased short-term hatchery production and trap-and-haul in the short-term to offset effects of sediment and low DO associated with breaching.
6773	24	wwpinneys@gmail.com	N/A	Power Replacement Costs & Loss of Load Probability overstated for 1,000 MW. - Least-cost power resource acquisition strategy not modeled, most up-to-date costs of wind and solar not used for cost replacement, if needed. - CRSO DEIS admits that the more extreme spill MO4 and other spilling alternatives, such as the loosely described and formulated proposed PA, would require just as much and quite a bit more power replacement with its inflated costs.	The EIS presents a range of replacement resource costs that would be needed to maintain regional reliability at the No Action Alternative level based on two resource portfolios: one that is based on renewable resources and another that is based on natural gas resources, which are generally the least cost means to maintain reliability (see Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS). The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources, with the exception of batteries which used newer sources, namely, 2018 and 2019 Integrated Resource Plans from Northwestern Energy and Puget Sound Energy. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, at Section 2.2. The final EIS addresses updated costs to resources based on publicly available draft information being prepared for the Councils 8th Power Plan. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for MO3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Section 3.7.3.1 and Appendix H, Section 2.2 in the Final EIS.) To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the final EIS. The Final EIS also includes the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan. The statement that MO4 would require more replacement power than MO3 is consistent with the findings of the EIS; however, the Preferred Alternative does not require replacement power to maintain power system reliability, contrary to the statement in the comment (see Section 7.7.9).
6773	25	wwpinneys@gmail.com	N/A	Greenhouse gas emissions from LSRDs ignored in MO3. - From US Department of Energy 2013 Evaluating greenhouse gas emissions from hydropower complexes on large rivers in Eastern Washington. The increasing incidence of lubricate spills and leakage and higher water and climatic temperatures have increased the incidence and distribution of algal blooms that produce methane released upon their dying. Substrate sediment methane is not a concern upon a breach implementation due to low incidence and dissipation rates as the water is more turbulent under higher velocities and that sediment drops out. The CRSO EIS mischaracterizes this scare tactic issue. The reservoir producing releases of methane throughout the upper water column depths and the decaying algal mats will continue to be a more detrimental effect to the water quality and ecology of the reservoirs. Vast peer reviewed and technical literature informs a logical and data-driven based scientist to conclude, not speculate, that the greatest time period of methane generation and release within the Snake and Columbia rivers would have been the extremely massive daily concrete manufacture and placements required for each dams construction, in that the lime dependent concrete forming of similar scaled large construction pours have been routinely monitored to produced greatly health exceedance concentrations of methane release. - The water quality sections and appendix C treatment of dissolved oxygen (d02) is chemically and physically illogical with intent to scare away from MO3. 02 is not oil or decaying vegetative biomass found pouring into the deeply located soils or sediments. 02 depletion or anoxia is known in deep reservoir and pool environments that are stagnant with slow seepage under extreme low velocities, hence even run-of-river reservoirs on the Snake and Columbia rivers where pool velocities are consistently much below 1 fps. The Snake River has always had exceedingly higher 02 throughout the majority of its water column, and the turbulence and higher water velocities derived during a breach would act to not only release those compounds at a negligible rate but dissipate those compounds, of which higher 02 concentrations would be readily transported from upriver and transformed in the replaced water entering the mainstem reach. If the CRSO DEIS would accept and use the much more robust and logically-thought-threw and scientifically debated evaluation for sedimentation, turbidity, water temperature, and timing and methods of breaching the earthern fill sections at each dam documented in the 2002 FR/FEIS for Snake River juvenile salmon migration, much as the CRSO DEIS did for the 3-d GIS and 2-d MASS2 modeling files by the River Mechanics team, the CRSO DEIS would clearly conclude that no to near zero (or inconsequential or negligible) migratory salmon and steelhead lifestages would be present or passing through the impact zones during the water evacuation of MO3 and consequentially any stored methane or releasing oxygen would have no adverse effect, but only	We chose to use a process-based model to predict impacts to dissolved oxygen rather than empirical models that may have little relevance to the system. Our analysis was based on the data that has been collected in the lower Snake River over the past 20 years. Specifically for dissolved oxygen (DO), two different methodologies were used to estimate impacts to DO under MO3, using CE-QUAL W2. The EIS results were compared to reservoirs with similar sediment composition and agreed based on this comparative analysis. The first method was developed using correlations of measured data from Fall Creek Lake, Oregon (USGS Gage 14151000, Fall Creek Blw Winberry Creek, Near Fall Creek, OR). The second method was based on the mobilization of anoxic pore water and the biochemical oxidation of organic matter associated with deposited and re-mobilized/re-suspended sediments during reservoir drawdown and dam breach. This method assumed sediment oxygen demand (SOD) rates of 0.1, 0.5, 1.0, and 2.0 grams per square meter per day (g/m2/day). The two highest rates are based on measurements obtained from several Snake River sediment cores that were collected in 1997 (Normandeau 1999) and ranged from 0.8 to 2.2 g/m2/day. The estimated number of days when the oxygen concentrations would be less than 5 mg/L, 2.5 mg/L, and 0.5 mg/L (anoxia) under Method 1 (data correlation) and Method 2 (with an SOD of 0.5 g/m2/d) in the headwater are similar and range from 21-23 days, 15-19 days, and 11-17 days, respectively. The estimated number of days when the oxygen concentrations would be less than 5 mg/L, 2.5 mg/L, and 0.5 mg/L (anoxia) under Method 1 (data correlation) and Method 2 (with an SOD of 0.5 g/m2/d) in the forebay range from 17-20 days, 4-7 days, and 0 days, respectively. Method 2 with a SOD of 0.1 g/m2/d results in nominal dissolved oxygen concentration effects with respect to the three dissolved oxygen criteria and locations selected, while estimated dissolved oxygen concentration effects with SOD rates of 1.0 and 2.0 g/m2/d suggest the longest periods of low dissolved oxygen within the Lower Monumental reservoir. Regarding methane emissions, Appendix G, Chapter 5 of the Draft EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. and Appendix G include references to and discussion of Arntzen et al. (2013), research supported by the U.S. Department of Energy that is referenced in this comment. In the case of the four lower Snake River dams, recent research concluded that data were insufficient to estimate the reservoir methane emissions specifically for the CRS, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams. Section 3.8 discusses the greenhouse gas effects from breaching the four lower Snake River dams.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				an uncertain low probability for near zero (or inconsequential or negligible) on the possible few juvenile salmon or steelhead remnants. Vast positive experience from other national and international dam breaching and removal projects across a relatively high range of dam heights and river channel and pool configurations clearly show that free-flowing waters will repair 02 sinks, as well as produce much lower methane emission in short timeframes.	
6775	1	robertggriswold@gmail.com	N/A	The preferred alternative continues the long-standing tradition of making incremental improvements when meaningful changes are clearly required. This approach invites litigation, additional court remands and continued declines in Snake River salmon and steelhead populations, particularly the wild component. The need to increase survival of endangered Snake River sockeye is particularly urgent. Sockeye recovery requires increasing smolt-to-adult survival by an order of magnitude, under the proposed alternative smolt-to-adult survival would likely remain well below 1%. The Northwest Power and Conservation Council established a goal of 2- 6% smolt-to-adult survival. The only alternative identified in the CRSO-DEIS that can meet this goal is MO 3. This alternative would provide the most benefits, based on your analysis, including shortened smolt travel times, decreased gas exposure, reduced predation, and increased survival rates and population productivity. I request that you reconsider this plans preferred alternative. Based on your analysis the preferred alternative will not provide the survival benefits needed to stabilize and recover Snake River salmon and steelhead populations. MO3 is the only alternative identified that can achieve sufficient population productivity to achieve this goal.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
6779	1	N/A	N/A	Appendix P provides documentation provided by the Native Nations on Environmental Justice concerns regarding the Snake River Dams. Construction and continued operation of these dams has been documented to be detrimental to the Religious beliefs and practices, Environmental welfare, personal health, the availability and abundance of Subsistence Resources. The costs and injustices that are addressed in these concerns are not adequately analyzed nor sufficiently valued in the discussion of each of the options in this Draft EIS.	Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7).
6780	1	sedgemon@ci.richland.wa.us	N/A	We submit the following comments for consideration as the Agencies finalize the EIS. Maximizing hydropower produced from the Columbia River System and Lower Snake River Dams enables the City to provide affordable, low-cost electric rates. Any increase in spill means a decrease in hydroelectric generation, which results in increased wholesale power costs and higher retail rates negatively affecting City customers. Replacing the carbon-free power and dispatchable peaking capacity and flexibility from the Lower Snake River Dams with a similar portfolio could result in a 50% increase in BPAs wholesale rates. Since the Citys wholesale power costs are over 60% of its electric utility total costs, customers could experience a 25% increase in retail power costs. Higher electric rates cause businesses to reduce employment and increase prices negatively impacting employees, customers, and the economy. Power that is more expensive affects all customers, but it provides the largest financial burden on low- and fixed-income customers.	The comment that power costs in the region would increase under Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams, is consistent with EIS findings. See Section 3.7.3.5, at pages 3-918-924, and Table 3-166 in the Draft EIS. The Preferred Alternative does not include breaching the four lower Snake River dams, which was a measure within MO3 and included in the evaluation of that alternative. The statement that increased power costs decrease economic activity is also consistent with the findings of the EIS. The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The Environmental Justice analysis in Section 3.18.3 and Chapter 7, provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
6780	2	sedgemon@ci.richland.wa.us	N/A	The Lower Snake River Dams provide the City grid stability, critical capacity, and flexible carbon-free power. Breaching the Lower Snake River Dams will impact the reliability of the Columbia River Systems energy system, doubling the risk of blackouts in the Northwest. The Lower Snake River Dams – especially Ice Harbor Dam – provide critical peaking capacity for our area during periods of high loads like cold weather events. Without the dams the City and Tri-Cities will likely experience brownouts and blackouts. Power production at Ice Harbor Dam has averted Tri-Cities blackouts in the past with the most recent critical event occurring March 2019.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative (PA) identified in the Draft EIS. The effects of the PA on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. See Section 3.7.3.5, pages 3-904-910 in the Draft EIS. Without replacement resources, however, the statements in the comment about the effects of breaching the four lower Snake River dams on regional power system reliability unless and until replacement resources are acquired are consistent with the findings of the EIS. The importance of the four lower Snake River dams, particularly Ice Harbor, for stability in the Tri-Cities area is also consistent with the findings of the EIS. See Draft EIS Section 3.7.3.5, Bonneville Transmission System Reliability and Operations. The loss of generation at Ice Harbor would require that a transmission reinforcement project be in place prior to breaching of the dams. If the dams were breached prior to completion of the reinforcements, the Tri-Cities area would be vulnerable to a potential loss of load event.
6780	3	sedgemon@ci.richland.wa.us	N/A	As noted in the EIS, the loss of hydropower generation at Ice Harbor Dam would require BPA to build a $94 million transmission reinforcement project prior to breaching. Costs of this magnitude would increase power costs substantially.	The statement that under Multiple Objective (MO) Alternative 3 (which includes breaching the four lower Snake River dams) transmission reinforcement would be required and cost $94 million is consistent with the findings of the draft EIS in Section 3.7.3.5, Bonneville Transmission System Reliability and Operations. The wholesale transmission rate pressures and the retail rate effects associated with the costs under MO3 are discussed in the draft EIS in Section 3.7.3.5, Bonneville Wholesale Transmission Rate Pressure and Retail Rate Effects.
6780	4	sedgemon@ci.richland.wa.us	N/A	The City needs the hydroelectricity the Lower Snake River Dams produce in order to meet Washington States Clean Energy Transformation Act carbon-neutral requirement by 2030 and carbon-free target by 2045. Replacing the hydroelectricity lost from breaching the dams with a flexible, dispatchable resource to meet loads would mean using higher cost and higher greenhouse- gas-emissions natural gas generation to augment periods when renewables cannot generate.	The comment that costs and greenhouse gas emissions increase from replacing the hydropower from the four lower Snake River dams, even using renewables is consistent with the findings of the EIS (see draft EIS, Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation). The statement that replacing the lost capability of four lower Snake River dams with additional resources, whether carbon-emitting or zero-carbon, could lead to higher overall costs is consistent with the findings in the EIS. See draft EIS, Section 3.7.3.5 at pages 3-918-924 and Table 3-166.
6780	5	sedgemon@ci.richland.wa.us	N/A	Breaching the dams and the locks will eliminate a low-cost, efficient way to barge bulk farm commodities and other goods up and down the Columbia and Snake Rivers. The barges would be replaced with semi-trucks and railcars. In 2018, it would have taken 38,966 rail cars or 149,870 semi-trucks to move the cargo that was barged on the Snake River. The additional semi-trucks and railcars would increase greenhouse gas emissions. The City would no-doubt be impacted due to additional demands on existing road and rail infrastructure, increased traffic, and more air pollution. The highways and roads would need to be expanded and new infrastructure built. This would require increased infrastructure maintenance and cost to taxpayers.	The impacts described by the commenter are consistent with the effects described in the EIS in Section 3.10.3.5. Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear-and-tear costs may occur.
6780	6	sedgemon@ci.richland.wa.us	N/A	Breaching the Lower Snake River Dams would decrease the Citys tourism and recreational opportunities. Approximately 18,000 passengers vacation annually on the Columbia and Snake Rivers using commercial cruise lines. The City estimates it could lose over $2.2 million dollars in total tourist spending if the commercial cruise lines operating on the lower Columbia and Snake Rivers were eliminated due to dam breaching. This does not include potential reduction in jobs and income of associated businesses and employees in Richland. Even if the number of cruises was reduced to voyages only on the Columbia River, the City would be adversely affected.	Cruise ship visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). As described under MO3, a substantial portion of these trips and associated regional economic benefits would be lost under MO3.
6780	7	sedgemon@ci.richland.wa.us	N/A	The Citys potable and irrigation water supplies would likely be disrupted by breaching the Lower Snake River Dams. The City has two intake structures on the Columbia River for its potable water supply and an intake for irrigation. If breaching the Lower Snake River Dams affects the water level of the McNary Pool, the Citys potable water supply could be adversely effected. A 1.5 ft. decrease in water level below its current intake design level would necessitate dredging and building containment basins large enough to handle the 30 million gallons per day demand. It is unknown if this work could be achieved due to the cost and environmental impact.	McNary pool elevations are not anticipated to drop below current operating minimums under any alternative. The breaching of the lower Snake dams in MO3 may cause a temporary increase in sediment, which may require increased maintenance.
6780	8	sedgemon@ci.richland.wa.us	N/A	Studies have shown that removing the dams would increase salmon returns by only 17%. The most updated science from the National Oceanic and Atmospheric Administration Fisheries finds that conditions in ocean waters need to improve in order for fish numbers to increase. Focusing primarily on the Columbia-Snake River System where BPA has made over $17 billion in improvements have been made in world-class fish passage infrastructure is not the solution to increasing fish returns. Ninety-three to 97% of fish make it through the Lower Snake River Dams due to the investments in safe fish passage. Forty to 50% of juvenile fish make it through Columbia and Snake River dams which is comparable to survival in free-flowing rivers such as the Frasier River. Predation is a huge source of mortality for endangered and threatened juvenile and adult salmon. Birds consume 4% to 21% of migrating juvenile salmon each year. Eleven years of research from 2008 to 2019 indicate that a greater number of upper Columbia steelhead smolt, including those from the Snake River, were consumed by avian predators than died from all causes combined. Regarding adult salmon predation, in 2017, sea lions consumed over 40% of adult salmon migrating through the Columbia River estuary.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids
6780	9	sedgemon@ci.richland.wa.us	N/A	We are concerned additional spill is included in the preferred alternative since it results in less power generation. The 125% of TDG spill operation is untested. It is not known that additional spill will benefit fish and in fact, may harm them.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6780	10	sedgemon@ci.richland.wa.us	N/A	Fish mitigation costs are a tremendous expense for BPA customers. Over $17 billion for fish and wildlife habitat restoration has been funded by BPA customers and ultimately, every business and residential customer NW electric utilities serve. It is time to have others benefiting from fish mitigation efforts share these costs as well. Incremental costs resulting from system operations that reduce hydropower production, including increased spill at the dams, should be equitably allocated so that preference customers do not solely bear incremental costs that provide broader social and environmental benefits.	Bonneville is statutorily obligated to pay for its share of project costs, including fish mitigation. Bonneville's share of project costs are established by existing cost allocations at each FCRPS dam. The cost allocations used in this EIS were developed based on methodologies adopted by Corps and Reclamation and reflected in their policies. Although each methodology has a different approach, the fundamental goal of any cost allocation is to allocate a share of the projects costs (capital and O&M) to each of its authorized purposes (e.g., flood control, navigation, power, irrigation). Fish mitigation costs are assigned to each authorized purpose based on each purposes overall share of project costs, as determined by the cost allocation. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Although Congress authorized Bonneville to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)), in some situations, including the Columbia River Fish Mitigation program, Bonneville does not directly pay for the capital costs of fish mitigation structures; instead it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual Congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife, the Bonneville Fish and Wildlife Program funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. This program is funded by Bonneville's electricity ratepayers as part of the rates Bonneville sets to recover its costs. Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
6790	1	N/A	N/A	Climate Change A fault of the DEIS is its dismissal of wind and solar power as reliable substitutes for the loss in hydropower generation if the dams are breached. As noted in the Washington State Department of Natural Resources Plan for Climate Resilience, published in February 2020, among its priorities is to "accelerate salmon and orca recovery efforts." The agency also is "leasing state trust lands for wind and solar power production and is exploring the power potential of geothermal energy," according to the DNR plan. In a no-dam scenario, the CRS DEIS implies the loss of hydropower can only be replaced by greenhouse-gas emitted electricity generation from coal or natural gas sources. As noted in the 2019 study, "ECONorthwest Lower Snake River Dams: Economic Tradeoffs of Removal," hydropower generated by the four dams now is a fraction of what is used statewide.	Contrary to the statement in the comment, the EIS did not dismiss renewable power sources and does not imply that the loss of hydropower can only be replaced by fossil fuel generation. The EIS considered a zero-carbon replacement portfolio to replace lost generation from the four lower Snake River dams in Multiple Objective Alternative 3. See draft EIS, Section 3.7.3.5 at pages 3-904-910. The zero-carbon replacement portfolio included solar, demand response, and storage technologies; wind was less cost-effective for this alternative. See draft EIS, Section 3.7.3.5 at pages 3-907-910. Under the zero-carbon portfolio, the EIS finds that fossil fuel-based generation from existing power plants would increase to replace lost balancing resources and maintain reliability (i.e., to meet the demand for power and avoid outages). See draft EIS, Section 3.8.3.5 pages 3-1009-1010. Regarding the statement about the amount of generation, while the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System from which Bonneville markets power. Using average water conditions and 80-year water data, the four lower Snake River dams produce between 460 aMW to upwards of 1400 aMW of power during the winter months of December through February, which are typically the most energy intensive months for Bonneville. See draft EIS, Section 3.7.3.5, Changes in Power Generation and Table 3-159.
6790	2	N/A	N/A	Fish Federal efforts to restore salmon habitat in the region have cost taxpayers $17 billion dollars, yet Chinook salmon and 12 other species remain listed as endangered, and the last five plans have been found inadequate and illegal. Throughout these failed mitigation efforts, the one constant has been the existence of the dams, which, among the added stresses of passage, in part obstruct the fish from hundreds of miles of pre-dam habitat critical to juvenile salmon development. A key component of the Southern Resident Orca Task Force final report is to increase the supply of Chinook through increased production of hatchery-spawned fish. But the abundance of hatcheries has not yielded an increase in Chinook. According to the Washington Department of Fish and Wildlife (WDFW), 90 percent of all salmon caught in the Columbia River are hatchery raised; 40 percent never migrate to the ocean and do not benefit the orcas. Removing obstacles to upstream habitat for the wild fish population is the best option for increased survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS.
6790	3	N/A	N/A	Without the benefit of reservoirs if the dams are removed, motorboat users are estimated to lose $7.41 per-person per trip (McKean et al, 2012, 2005). However, that loss is far outweighed by what a free-flowing river would offer: multiple-day float trips, wildlife viewing, and drift-boat fishing are estimated to generate a per-user-day recreational value of $228. Additionally, a random utility method analysis found there will be a 68 percent increase in trips to the area if the dams are removed. When considered in the context of discount rates of 2.75% and 7%, the increase in recreational value ranges from $341 million to $1.2 billion, according to ECONorthwest. The ECONorthwest study also cites a variety of studies indicating there is a willingness to pay to reduce the extinction risk of the region's iconic salmon and orcas, as high as $356 in one case (Stratus Consulting, 2015).	Section 3.11.3.5 describes river recreation in the long-term post breach when river conditions are established. Visitation would be predicated on the development of recreation access and roads to access the river resource. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with river recreation post dam breach were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users. In addition, the timeline of the EIS precluded an extensive survey of post dam breach recreation. The EIS has a different charge than the ECONorthwest study. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon. The study used a very limited sample of 20 trips to the region. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
6796	1	kairos42@earthlink.net	N/A	Irrigation impacts under MO3 vastly overstated old and flawed assumptions brought forward into the DEIS. No loss in farm income with breaching. Corrected cost to modify irrigation systems is $20 million, instead of a farm value loss of $314 million. This is a fatal flaw of the DEIS and renders immediate breaching highly beneficial to the region. The DEIS, Chapter 3 page 1267 used the 2002 EIS as a basis for concluding that modifying the existing pump system was cost prohibitive. The 2002 EIS irrigation modification concept was based on a single large pumping station, sedimentation pond and approximatively 10 miles of pressurized pipeline for distribution sized for the maximum August demands of over 850 CFS. This was roughly estimated to cost $291 million which was more than the farmland was valued at. Hence a farmland valuation analysis was used in 2002 and carried forth as a planning assumption in the 2020 DEIS. However, at the time this $291 concept and cost estimate was challenged as being incorrect, but was not changed given the time constraints and the belief by Walla Walla planners that even if it was of no cost, it would not change the overall economic analysis and benefit cost ratio in favor of keeping the dams. Devaluing farm land led local irrigators to undertake a long term pro breaching agenda for fear of loosing their farms to a government buyout. In 2016 EarthEconomics validated the amount of acreage in the 2002 EIS and in 2018 Rob Sampson, a water supply civil engineer, recalculated the initial pump and pipe line extension plan noted in the 2002 EIS. His work showed it was entirely feasible	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. The MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. In Region C (lower Snake River) and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, the MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				using widely excepted screening and pumping technologies to add additional pipes and pumps to the natural river elevations after breaching. This revised cost estimate is $20 million in 2019 dollars. Additional electricity costs of approximately $1 million per year could be fully or wholly paid for by BPAs Irrigation Assistance Program. Conclusion, Irrigation famers on Ice Harbor pool can be kept whole at a tiny fraction of the the $314 million cost due to lost value of non-irrigated farm land. Job losses of 4,800 are incorrect, there would be no job losses with breaching. Indeed, approximately 5,000 acres of former farmland, orchards and vineyards could be reclaimed with breaching adding approximately 1,000 agricultural jobs in the lower Snake Valley. Sampsons report, A brief review of the impacts to irrigated farmland from breaching the four dams on Lower Snake River is attached. Link to prospective piece on agriculture in lower Snake Valley after breaching: https://indd.adobe.com/view/5f823ffb-2346-4bb5-91e2-58ab339ebe21	
6804	1	N/A	N/A	Fish management at the dams is continuously being redesigned and upgraded, and I am fully confident that it is the best action for all concerned parties and issues. Those who want to remove or redesign any dams to enhance fish migration should look at the appalling Dworshak Dam on the North Fork Clearwater River in Clearwater County, Idaho. It is the third tallest dam in the United States and lacks fish ladders, thus blocking fish passage, and has completely extirpated anadromous fish migration into the upper reaches of the North Fork Clearwater River and its tributaries in Idaho. Further, water pollution in and around Puget Sound is much more hazardous to fish life than the dams of the Columbia and Snake Rivers and should be thoroughly analyzed for cleanup and intelligent clean water management.	Dworshak Dam is one of the 14 Federal projects included in the CRSO EIS and analysis of the alternatives considers effects of operations, maintenance, and configuration of Dworshak. The co-lead agencies did not consider an alternative to remove Dworshak Dam. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project
6812	1	MagicFan031@gmail.com	N/A	I would like to first address the things that I believe are remiss in the CRSO DEIS. The most vital: the importance of Columbia Basin salmon to the endangered Southern Resident orca population. The DEIS is not providing an adequate, scientifically supported summation of this relationship within the document, downplaying the role of one of the largest river systems that supplies critical sustenance to these orcas year-round. In the National Marine Fisheries Services (NMFS) 2008 Recovery Plan for the Southern Resident orcas it is stated that: perhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. Reading further into this document, NMFS concludes that Columbia-Snake River Basin salmon stocks maintain the largest potential for increasing Chinook salmon abundance throughout the Southern Residents range. This declaration is a jarring contrast to the CRSO DEIS assessment that Puget Sound Chinook salmon stocks yield a higher importance to Southern Residents than Columbia-Snake River salmon. The argument provided for the attention around Puget Sound Chinook salmon stocks is that Puget Sound salmon are available to Southern Residents over a greater period of time throughout the year than Columbia-Snake River salmon are. The DEIS goes on to claim that the food available to Southern Resident killer whales from the lower Snake River population is only a small portion of their overall diet. Changes to food availability may change the whales foraging behavior patterns slightly but will not change their overall condition or population dynamics. This statement is simply not correct when compared to ongoing data analysis of Southern Residents diet and movements. Multiple papers, studies, and reports from the National Marine Fisheries Service, National Oceanic and Atmospheric Administration, Washington Department of Fish and Wildlife, et al., concerning the Southern Residents, have shown through surveys, satellite-tagging data, prey fecal samples, and acoustical monitoring that these orcas are spending over half of the year outside of the Salish Sea, off the coasts of Washington and northern Oregon. NOAA has identified this coastal region as a high-use foraging area for Southern Residents and their satellite-tag data has shown that all three pods in this population utilize this range year-round, not just in winter and early spring. The timing and use of this range has been shown to directly correspond with the timing of seasonal Chinook salmon returning to the Columbia River system to spawn. In turn, prey fecal samples show that Columbia Basin salmon make up over half of the Southern Residents coastal diet while they occupy this region. Based on the data and summations provided by these experts, I struggle to understand how the conclusion drawn by the DEIS is that body condition and population dynamics within the Southern Resident orca population would not improve if we remove the structures that have squelched out certain salmon stocks to extinction while rendering other stocks to merely a fraction of their historic numbers? The chosen alternative currently indicated in the DEIS will do nothing more than slow the continued decline of salmon stocks in the Columbia-Snake River. As salmon stocks remain remarkably low, Southern Resident mortality will increase. And with their community believed to be down to 72 individuals, with Center for Whale Research reporting a missing male in January, they are facing the very real threat of functional extinction at a rapidly increasing rate.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.
6812	2	MagicFan031@gmail.com	N/A	Of the other alternatives listed in the CRSO DEIS, MO3 Snake River dam breaching plus increased spill over the Columbia River dams represents the best, wholistic approach necessary to achieve the recovery and protection of endangered salmon, therefore also recovering Southern Resident orcas. To add support for MO3, I would like to suggest reviewing the stakeholder process and report that was mandated in 2018 by Governor Inslees Southern Resident orca task force. While the final report still did not adequately represent the Columbia-Snake River Chinook salmon stockSouthern Resident orca relationship, and does not present a perfect solution for all stakeholders, this process was vital in bringing the people most affected by any decisions regarding these dams to one table. It would be a considerable waste of taxpayer money, effort, and time if this overall process was not weighed as a factor when considering the DEIS alternative options.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Regarding stakeholder involvement: NEPA by design involves the public. In addition to public meetings and public review, many cooperating agencies were involved in development of the EIS, including State of Washington agencies.
6813	1	spuddybuddy@ubertuber.org	N/A	The analysis of the MO3 alternative is flawed by making outlandish assumptions about the cost of renewable energy infrastructure to replace the hydropower generated by the lower Snake River dams. It assumes that the entire generating capacity is replaced by solar with exorbitant estimates for the cost of operating solar. Solar energy costs are below $50/MWh and dropping rapidly, which works out to a little over $100M/year for watt-for-watt replacement. It also assumes that any battery capacity costs would be borne by the BPA alone and not shared with other utilities and state and Federal agencies building out the legally mandatory zero carbon grid across the West coast. The analysis of the MO3 project should be redone using a competitive bidding process to determine the least cost method for replacing the hydroelectric power generation. It is clear that the DEIS stacked the deck against breaching the lower Snake River dams through inflated cost estimates for power replacement. Correct cost estimates will show that the true costs are much lower and in fact lower than maintaining the dams themselves.	The four lower Snake River dams are cost effective. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of capability in certain months of the year. While the increase in solar and wind generation is consistent with the EIS discussion in 3.7.2.1 Power Generation, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under MO3. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6814	1	N/A	N/A	The preferred alternative should include elements of multiple objective alternative 3 (MO3), specifically breaching of the four lower Snake River dams.	There were a number of reasons that the dam breaching measure in MO3 was not included in the Preferred Alternative. These reasons are summarized in the Executive Summary and described in more detail in Sections 7.2, 7.3, and 7.4 of the CRSO EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6816	1	moffett007@gmail.com	N/A	I am a enrolled member of the Nez Perce Tribe. I am the president of the nonprofit organization called Nimiipuu Protecting the Environment (NPtE). We do not represent the Nez Perce Tribe. We act, advocate & teach about environmental protections within the Nez Perce Tribe's traditional territory covered by the Treaties and agreements with the United States. It is because of the federal undertaking of the CRSO DEIS that I comment. The DEIS does not adequately protect Nez Perce Treaty Rights & Responsibilities. NPtE, strongly recommends the breaching of the 4 Lower Snake River Dams (LSRD). The DEIS does not follow the Court's decision to consider breachi g as the viable alternative to restore anadromous fisheries, restore the Snake River to a more free flowing Riverine ecosystem improving habitat. Essentially, this DEIS maintains the status quo, which condemns Snake River fisheries closer to extinction. Treaty fishing has been closed because of deteriorating runs. Tribal members such as myself & family have had to curtail treaty fishing, which we depend on for our daily living & cultural survival. This condition, & 2020 may be even a worse year for the fish runs, is not sustainable & the DEIS does nothing to improve the situation for fish, the River, or in meeting Treaty obligations, except to require more Tribal sacrifices, which does not even contribute to any substantial improvements to Treaty fishing.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement of NEPA, after evaluating scoping comments from the public, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single objective alternatives, and then four Multiple objective alternatives (MOs). The MOs were also determined to be more efficient and reasonable, as the MOs were composed of combinations of measures from the single objective alternatives. The twelve single objective alternatives were not effective in meeting the Purpose and Need Statement or multiple objectives, and were therefore not complete or implementable. Dam breaching measures were developed in the MO3 which considers the benefits and adverse effects of breaching the four lower Snake River dams. The Draft EIS considered the environmental consequences of the range of alternatives and disclosed to the public those consequences through Chapters 3, 4, 5, 6, and 7. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. See Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-leads to meet the stated Purpose and Needs Statement while minimizing impacts to affected ESA species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. See Chapters 6 and 7 for information on cumulative effects to ESA-listed species. As described in Section 2.4, Range of Alternatives, MO3 includes a measure to breach the Lower Snake River dams. New congressional authority and associated funding would be required to implement the dam breaching measures evaluated in the EIS. However, the measures are carried forward in the analysis to align with the District Courts Opinion and Order, as well as in response to comments received during public scoping.
6816	2	moffett007@gmail.com	N/A	All federal agencies have a trust responsibility to Treaty Tribes & their members. Treaty Fishing Rights & Responsibilities are being mismanaged. Treaty environmental protections help to ensure Treaty resources, like water, animals & plants exist in perpetuity. Only breaching the 4 LSRDs meet U.S. Treaty obligations & will make sure we are doing our utmost to protect Mother Earth.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6818	1	brees@pacifier.com	N/A	The federal government as had 2 decades and several federal lawsuits to get it right, but the salmon crisis remains an obstacle to robust rural commerce and propagates an adversarial environment between neighbors in our rural communities. The current DEIS does much the same and most importantly, continues the trajectory of the extinction of wild salmon forever from the Columbia River Basin. This is something we simply cannot accept as a society. In the case of this DEIS, its clear that we need our NW policymakers to foster a process that brings together our regions stakeholders to have a meaningful discussion and come to a collaborative solution that works for farmers, fishermen and maintains a reliable energy grid for our communities.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using current, high quality information, the co-lead agencies developed the Preferred Alternative. This alternative best meets the purpose and need for the system operations in the region, as well as meets most of the objectives of the EIS in consideration of changing operations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Finally, the co-lead agencies disagree the Preferred Alternative is a continuation of same actions. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
6823	1	dstone@sbtribes.com	Shoshone-Bannock Tribes	Purpose and Need Statement (CRSO DEIS) During the Tribes review of the available materials our perspective is the Preferred Alternative (PA) does not meet the DEIS intent as expressed in the Purpose and Need. The DEIS does not provide for the conservation of fish and wildlife resources, including threatened, endangered, and sensitive species. primarily due to the lack of a reasonably foreseeable recovery for listed stocks and in some instances inherent risks to listed stocks from the PA. The DEIS does not protect and preserve cultural resources from the Tribes perspective; as stated elsewhere in Tribal comments, anadromous fish are considered a gift from the Creator to sustain our people and are inherently a cultural resource that the Tribes have relied upon from time immemorial. The DEIS does not comply with environmental laws and regulations and all other applicable federal statutory and regulatory requirements, including those specifically addressing the System such as requirements under the Northwest Power Act to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with other purposes for which such system and facilities are managed and operated. The DEIS does not protect Native American treaty and reserved rights and trust obligations for natural and cultural resources throughout the environment affected by System operations based on the projected lack of abundance within the Snake River basin where the Tribes primary fisheries occur. Furthermore, the DEIS and associated PA do not meet the stated CRSO Objectives. The PA does not meaningfully Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival and does not appreciably Improve ESA-listed anadromous salmonid adult fish migration through the hydrosystem. Using the CRSO Definition of Effects, the best available science (CSS and COMPASS) suggests that, at best, the DEIS PA would have a Negligible or Minor effect on juvenile and anadromous adult survival relative to the No Action Alternative (NAA). For example, the DEIS states that the PA represents a 35% increase in survival relative to the NAA. Presently, many listed Snake River Basin stocks have an average SAR survival of 0.7% (or less). A 35% increase from 0.7% would be a 0.95% SAR. Given current freshwater productivity levels, SARs less than 1% put listed stocks in a steep decline, below replacement, and at a high risk of near-term extirpation. In fact, the best-available science suggests that Snake River populations need to be at or above a 2% SAR just to be at replacement; population recovery will only occur in the SAR range of 2-6% (4% average) consistent with NPCC goals. Therefore, the DEIS PA appears to knowingly put ESA listed Snake River stocks in jeopardy. This outcome is unacceptable to the Tribes and does not appear to meet the stated purpose and need, nor objectives, outlined in this environmental review. The purpose and need for any environmental document delineates the boundaries for a specific evaluation; in the case of the DEIS, those boundaries are roughly characterized as maintaining navigation, contract water delivery, hydropower generation, mitigation measures for fish and wildlife impacted by system operations, and considering treaty rights and interests during the decision making process. As with most evaluative criteria, there are weighted lines, or stated another way, some issues will have a higher priority than others due to the scope of impacts for the agencies involved in the decision-making process. For example, the marketing of power generated from the Columbia River System is the primary purpose for the Bonneville Power Administrations existence, likewise the delivery of contract water to users is the primary purpose of the Bureau of Reclamation, and finally, the Army Corps of Engineers maintains the navigation portion of the system; while each agency has an obligation to comply with the tenets of the other boundaries, these overriding purposes are viewed as hard lines in the decision-making process. The Tribes have a different perspective of the values that make the Columbia River Basin unique. To protect these values, the Northwest Power Act requires the Action Agencies to develop programs to protect, mitigate, and enhance fish and wildlife in a	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Finally, Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and the Northwest Power Act.

				manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated. The concept of Equitable Treatment is often used as a measure of inputs compared with received outputs, it does not necessarily mean that all scales are equally balanced; but it does require a demonstration of fairness and equal consideration for different user groups. In the current evaluation, one of the primary drivers for the in-depth evaluation of the entire system is that there are significant impacts to anadromous fishes, to the point that the current system configuration contributes to species level decline and in some instances, impedes that species ability to recover. From a concept of equitable treatment, the fish and user groups who rely on them would been seen as an input, while the resulting decision made in this DEIS would determine the projected output for that group of users and the actual resource itself. The Tribes primary concern is that the PA does not adequately balance the scale of equity by promoting a condition where listed salmonids will avoid risks of extinction and move towards stability and recovery. Another stated purpose is to promote the protection of Native American treaty rights and interests for natural and cultural resources. It has been clear that federal agencies and most tribes do not view the obligations in the same manner. For example, the Tribes would consider the perpetuation and presence of anadromous fishes on our homelands reserved by a treaty right to harvest, as a trust asset that the federal agencies must protect in a conservative manner; this is not a view shared by the Action Agencies. For the right to have meaning, to promote the protection of the traditional harvest of anadromous fishes throughout the Columbia River Basin, there must be fish to harvest. Minor or negligible improvements in anadromous fish returns will not sustain tribal communities and cultural practices, will not provide meaningful fisheries, and will not alleviate the near-term risks of anadromous stocks currently at risk of extirpation. The underlying need the Action Agencies are responding to is to evaluate the management of the system in the context of new information or changed circumstances in the Columbia River Basin. From the date of petitions to list various anadromous stocks in the Snake River Basin under the Endangered Species Act conditions are little changed and, in some cases, adult returns in 2016-2019 reflect population levels that led to listings in the early 1990s. This evaluation should respond to several decades of litigation over the management of the Columbia River Basin by taking decisive action to protect, enhance, and ultimately recover listed stocks of salmonids. The recovery of anadromous fishes in the Columbia River Basin is the primary driver for most of the conflict, and it relates to the current abundance issues that we are collectively facing as managers. Having a hard line on promoting the recovery of anadromous fish in the face of the current crisis is no less significant for the Tribes than generating energy, navigating goods downriver, or delivering contracted water from reservoirs.	
6823	2	dstone@sbtribes.com	Shoshone-Bannock Tribes	In an effort to protect important resources the Tribes developed policy that offers guidance to technical staff and federal resource managers regarding habitat conditions that sustain natural and cultural resources in the Snake River system. The Tribes stress the importance of initiating efforts to restore the Snake River system and affected unoccupied lands to a natural condition; it should be noted that this policy is truly a ridgetop to ridgetop view of a holistic watershed. The Shoshone-Bannock Tribes Policy for Management of the Snake River Basin Resources states: The Shoshone Bannock Tribes (Tribes) will pursue, promote, and where necessary, initiate efforts to restore the Snake River systems and affected unoccupied lands to a natural condition. This includes the restoration of component resources to conditions which most closely represents the ecological features associated with a natural riverine ecosystem. In addition, the Tribes will work to ensure the protection, preservation, and where appropriate-the enhancement of Rights reserved by the Tribes under the Fort Bridger Treaty of 1868 (Treaty) and any inherent aboriginal rights. It is the intent of these Tribal comments to offer our unique perspective on natural resource management in the Columbia River Basin. The Tribes believe that through responsible and collaborative partnerships with managers in the region, we will ensure that future generations of Tribal members have opportunities to enjoy the natural landscape, gather resources, and continue traditional cultural practices. In the context of the DEIS, it is important to recognize the challenges faced by listed or sensitive species across the landscape and to critically evaluate whether this document recognizes the exigency of the current context and addresses those issues in an appropriate manner. We expect that the Action Agencies will consider all comments from the Tribes and make every effort to consider our perspective during the decision-making process.	Thank you for your comment and participation as a cooperating agency and a sovereign Tribal government. The co-lead agencies have engaged in a three-tiered process for engaging Tribes at technical, policy, and leadership levels to ensure all Tribal comments and perspectives are carefully considered. Tribal input has been critical and important to improving the quality of this EIS.
6823	3	dstone@sbtribes.com	Shoshone-Bannock Tribes	Consideration during the NEPA Process The National Environmental Policy Act (NEPA, 42 U.S.C. 4321-4347, January 1, 1970) requires federal agencies to provide a process that results in a more comprehensive and strategic approach to decision-making; integrating environmental considerations into proposed federal actions to achieve a productive harmony among our various social, economic, and environmental objectives. Tribal input is a necessary part of the NEPA process, helping managers effectively consider Tribal rights and issues; prior to implementing a decision. Without effective consultation, the Tribes often bear the burden of conservation activities or the adverse impacts from management decisions, such as the impacts from diminished anadromous fish returns. It must be noted that the Tribes and numerous other groups requested an extension on consultation processes and comment periods due to the current pandemic and that these requests were denied in favor of holding the timeline intact. For consultation to have meaning there must be an opportunity to participate, while conference calls are one avenue it does not replace the significance of a formal meeting at a Reservation, with the elected leadership of those most affected.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period. The co-lead agencies appreciate Shoshone-Bannock Tribes' contributions throughout the development of the CRSO EIS and looks forward to continued coordination as part of government-to-government consultations.
6823	4	dstone@sbtribes.com	Shoshone-Bannock Tribes	Cultural Resources Tribal perspectives of cultural resources are significantly more holistic than the current federal definitions offered in the DEIS. Plainly speaking, a cultural resource is any material, resource, or practice of a cultural nature. The unique relationship of a Tribal member and the environment influences a worldview where the geographic location, the equipment used to harvest, the oral history and songs, and the species sought by that member are all one cultural resource that defines our Tribal existence. The fish is as inseparable from the river as a cultural resource as it is in a biological sense; each of these relationships define our culture, they make us who we are as Shoshone and Bannock (Newe) peoples. The Tribes recommend this expanded definition of cultural resources be utilized in the immediate evaluation because of the landscape level proposal to manage a cultural resource at risk of extinction. Simply because artifacts are not present within a specific polygon, does not necessarily mean that the resource is not culturally significant to the Tribes.	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources," as this is consistent with Federal laws and regulations, which focus on specific bounded properties. Tribal interests and holistic perspectives on the integration of Native American culture with the environment were addressed throughout the EIS and by inclusion of statements from the Tribes, see Section 3.17. The co-lead agencies note that many of the Traditional Cultural Properties analyzed in the Draft EIS incorporate elements of the natural environment. Please see Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas.
6823	5	dstone@sbtribes.com	Shoshone-Bannock Tribes	As clearly stated in the Tribes Perspective, we fully support the implementation of Multiple Objective 3 (MO3) from the DEIS as it represents the clearest path to sustainable fisheries and preservation of Tribal Rights and Interests. In reviewing available materials, the Tribes recognize that the Action Agencies do not have the absolute authority to implement MO3 due to overlapping Congressional purposes for the affected infrastructure on the Lower Snake River. In an effort to promote a diplomatic approach to the various management perspectives on the Columbia River, the Tribes would like the FEIS and ROD to clearly authorize the respective heads of the Action Agencies to develop a recommendation to Congress requesting a standing committee be appointed to study the issue and develop a dam breaching authorization that meets the needs of the Pacific Northwest region. The benefit of a standing Congressional committee would be to inform a select group of bipartisan legislators from the Pacific Northwest regarding the challenges and solutions available at the conclusion of this EIS process. It is evident the current draft PA will not solve the multitude of issues that are present in the Columbia River Basin, primarily due to extremely low survival and associated low abundance of numerous listed anadromous fish stocks and marine mammals such as southern resident orcas. The Tribes support an approach that would allow for ongoing recovery projects to protect, restore, and enhance listed Snake River stocks while the legislative process is allowed to develop a more comprehensive solution to this problem. Beginning in 1991, with the listing of Snake River Sockeye Salmon, the Tribes have watched as the region developed approaches to reconcile hydrosystem management with anadromous fish. Meanwhile, while salmon stocks collapse in the Snake River, the conflict between extractive resource use and conservation has only grown. There is a need for a regional solution and it appears the only entity able to resolve this conflict is Congress. This solution needs to include all of the stakeholders, regardless of their perspective, to ensure that in the end all parties are kept whole. The Tribes urge the Action Agencies to work directly with cooperating agencies and the Northwest Congressional delegation on developing a legislative effort to find a comprehensive solution to end the salmon wars gripping our region.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6823	6	dstone@sbtribes.com	Shoshone-Bannock Tribes	Meaningful Abundance and Tribal subsistence for Anadromous Fish The Tribes remain committed to advocacy for pristine waters and to promote the subsistence consumption of fish as a component of our culture, preserved indefinitely by the Fort Bridger Treaty of 1868. Shoshone and Bannock peoples believe strongly that water is life, everything living owes its very existence to the presence of water, and our procurement of subsistence foods	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				from our home has been diminished to the point where our members are fortunate if they receive a single anadromous fish meal in a year. The Tribes represent a unique group of high fish consumers whose very subsistence lifestyle can be impacted by the loss of fisheries resources; indeed, we have seen a notable transition from anadromous fish to resident fish species during the decline in abundance in Idaho for virtually every population. Subsistence hunting can be characterized in a number of ways, but generically it is the procurement of nutrients from the natural environment to sustain life. A subsistence diet includes the pursuit of protein sources, like anadromous fish, and in the case of Shoshone and Bannock peoples they relied on the presence of anadromous protein to sustain their communities and perpetuate successive generations. While that perspective is relatively common, the magnitude of historical subsistence or the needs of our contemporary communities is often severely underrepresented in most discussions about salmon recovery. In the Tribal Perspectives section, the Tribes describe our historic consumption in detail, but would like to further translate the semblance of what subsistence harvest might look like for a Tribal member in a contemporary setting. In an effort to use existing policies from the State of Oregon, the Tribes would represent this abstract concept by using Oregons Fish Consumption guidelines for subsistence of 175 grams, per person, per day of salmon. The following equation shows the approximate values to meet the needs of SBT Tribal members living in a subsistence manner from salmon . (175 gr/day * 365 days * 6000 Tribal members)/1000 = 383,250 Kilograms annually. Assuming a generous 4 kilo/per salmon, this would equate to a harvest of approximately 95,812 salmon per year or ~16 salmon per year, per person. Currently, the Shoshone-Bannock Tribes estimate an average of 460 salmon for the last 39 years, this equates to less than .3 kilo/year, per member; it is common that some of our members do not receive a single salmon meal in any given year. The PA and DEIS demonstrate that our membership will continue to share the burden of conservation and the impacts to our culture will continue to be multi-generational. As you can see, the number for a subsistence need of salmon for one Tribe, the SBT, is orders of magnitude above projected returns, even under a recovery scenario described in the DEIS. Conceptually, this shows a need for a paradigm shift across the entire basin in how we discuss and manage anadromous fish resources in tandem with the Columbia River hydrosystem. The Columbia River was sustained by the pulse of abundant, annual returns of anadromous fishes, and as stewards of this resource we have come dangerously close to severing this ecological and cultural exchange. The Tribes now find ourselves watching a slow march toward extinction for numerous populations of Pacific salmon and steelhead. The purpose in describing this abstract vision of subsistence is not to castigate federal or state fish managers, nor is the intent to lay out a vision for anadromous fish returns that cannot ever be attained because it would come close to historical returns; the Snake River Policy of the Tribes recognizes that we will never return to pre-contact conditions. The intent of this comment is to demonstrate what our desired future condition would be; every Tribal member procuring organic and high-quality protein from anadromous fish resources in our homelands. The primary concern with current abundance in the Snake River Basin is that our membership has been significantly limited in meaningful fisheries, particularly in Idahos wild waters. One way to visualize this scenario is the current concern for populations in the Middle Fork Salmon River, specifically the population located in Bear Valley Creek. Over the past decade the Tribes have intensively monitored the population to minimize harvest related impacts from Tribal members, and to monitor the relative stability of this wild fish population. The last five years have seen a precipitous decline in abundance to levels where it may be at risk if immediate improvements to SARs are not achieved. Fisheries are constrained by the abundance of returning adults, a conservation measure the Tribes manage through the implementation of our Tribal Resource Management Plan; simply put, when abundance is high Tribal members can harvest throughout the season at a conservative rate, when returns are low, then our Commission adopts minimal harvest guidelines that range from three adult salmon to 1% of the return. At the current SAR rate, averaged over the past decade, it would take expanded decades to restore meaningful fisheries. A projected increase in SAR of 28-35% would change the current rate from less than half a percent to just under one percent; still far below replacement and orders of magnitude from populations like Bear Valley recovering in a significant way. The breadth of this issue becomes clear when you measure abundance across the 26 listed wild populations in the Snake River Basin. For the past three years, and highly probable in 2020, not a single wild population in Idaho could be considered viable; and in the same time frame only seven of those populations remained above the critical population threshold. In reviewing the available materials, it seems highly unlikely that the measures proposed by the Action Agencies in the PA, even if implemented immediately, would resolve the current stock collapse in the Snake and Columbia River basins. [Text contains tables that do not transfer to database.] *This figure demonstrates the need for urgency in every discussion about salmon recovery in the Snake River basin. The trend is increasing for stocks performing below the critical population threshold, an issue that could cause a myriad of population level and ecological problems for stocks attempting to reach recovery targets. It is important to note that we are currently undergoing a status review for specific Snake River populations under the Endangered Species Act. The current population level status of threatened is in place for almost all stocks except Snake River Sockeye Salmon who are listed as endangered. The comments in the DEIS assume none of these stocks will be re-classified in the latest status review, which would fundamentally alter the landscape for fish management in Idaho. Fisheries in central Idaho have not received an equitable share of attention or support to promote conservation of these stocks in the DEIS. Specific measures need to be included in the FEIS and Record of Decision (ROD) that demonstrate a clear path forward for programs specifically targeted to conserve wild populations in Idaho. Snake River Sockeye Salmon Tribal Sockeye staff has reviewed the available materials and remain concerned about the specific direction, and lack of discussion, for this endangered population of salmon. The Tribes have remained staunch advocates for conservation measures for Snake River Sockeye Salmon, petitioning for the listing of this stock in 1991. The DEIS does not adequately describe how proposed management of the Columbia River System will alter, improve, or affect Sockeye Salmon recovery. It is critical to highlight the need to include specific, measurable, and reasonably certain to occur mechanisms to avoid extirpation of this population. For example, an adequate discussion in the DEIS would include detailed plans to support Snake River Sockeye Salmon passage at all life stages and mechanisms to avoid adult mortality while migrating through the Lower Four Snake River dams and associated reservoirs. The Tribes recognize that there are difficult decisions in managing river operations for a myriad of listed species, particularly in the lower Snake River; however, there is an alternative that demonstrates abundance can be improved significantly by divesting aging infrastructure such as the lower Snake River dams. Based on our decades of experience working in the Upper Salmon River with this species, we find it unlikely that negligible improvements in SAR will alter the current conditions hampering recovery. Snake River Sockeye Salmon are the longest and latest returning runs in the Columbia River Basin, which amplifies the risks of poor migratory conditions during late-summer migration. The FEIS and ROD should adequately address, in a specific narrative, how the system operations will impact this stock specifically and measures that will mitigate for known or foreseeable impacts.	diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Section 3.18, Environmental Justice, describes the unique conditions of minority populations, low-income populations, and tribes that may heighten their vulnerability to effects from the alternatives.
6823	7	dstone@sbtribes.com	Shoshone-Bannock Tribes	Climate Science The Tribes would like to see climate change addressed in greater detail throughout the DEIS and how potential changes in climate could drive significant impacts to Tribal resources, such as salmon, located within assessment area. The Tribes recommend including specific adaptation strategies to ameliorate the projected effects of climate change within the assessment area in an effort to increase ecosystem resiliency. The presented analysis should establish quantifiable recovery metrics based on the available data to promote climate regulating ecosystem services, as well as maintenance and enhancement of large landscapes that are dominated by native assemblages of fish and wildlife. The current projections show that by the 2050s, if global greenhouse gas emissions continue on their current path (referred to as Representative Concentration Pathway (RCP) 8.5), at minimum average annual temperatures will increase 5 F in the fall and at maximum, 9.5 F in the winter. As a consequence of this anticipated temperature increase, the Tribes climate assessment finds that species such as Bull Trout, Chinook Salmon, Sockeye Salmon, and Snake River Steelhead are extremely vulnerable to the effects of climate change by the 2050s. Even under a best case scenario (RCP 4.5), which assumes that global greenhouse gas emissions will peak by the 2040s and then begin to decline, those previously described four fish species are expected to be extremely vulnerable to climate change. Specific measures and clearly described adaptive management triggers should be included in the FEIS and ROD to demonstrate the Action Agencies awareness of this issue and commitment to operate the system in a manner that prioritizes fish survival during low water conditions or extreme weather events.	The technical and policy elements of this Draft EIS are in full compliance with binding the Corps' policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the the Corps' Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full Corps Agency Technical Review), and were tested using the set of analytical measures created by the Corps Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with the Corps' climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in the Corps' Engineer Technical Letter 1100-2-3, "Guidance for Detection of Nonstationarities in Annual Maximum Discharges." The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. Regarding blocked areas, measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4).
6823	8	dstone@sbtribes.com	Shoshone-Bannock Tribes	Marine Derived Nutrients and Freshwater Productivity Abundant populations of anadromous fishes (e.g., salmon, steelhead, and lamprey) historically contributed large amounts of marine-derived nutrients (MDN) to aquatic and terrestrial ecosystems in the Pacific Northwest (PNW) of the United States of America (California, Oregon, Washington, and Idaho). In the Columbia River Basin an estimated 5-9 million anadromous fishes returned annually.	The CRSO EIS addresses abundance of anadromous fish among alternatives, which is the driving mechanism of marine nutrient cycling. The commenter is correct that there are broad ecological effects from marine nutrient cycling. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in this Draft EIS were for the purposes of comparing the effects of operation, maintenance and configuration of the CRS projects to one another and to the No Action Alternative. For the purposes of comparing alternatives, a more detailed analyses of marine nutrient transfer throughout the spawning habitats was not completed. Section 3.5 identifies that fish migration through the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Nutrients and carbon (C) sequestered in the marine environment, where approximately 95% of the body mass of Pacific salmon accumulates, are subsequently delivered to inland watersheds via upstream migrations. These migrations represent a major energy vector from the marine environment to freshwater and terrestrial ecosystems. Following periods of intense commercial harvest, hydrosystem development, hatchery production, and habitat loss, significant declines in Pacific salmon abundance have occurred throughout the region. Returning anadromous adults in the Columbia River Basin, once estimated at 5-9 million fish annually, now return at an average of 2-3 million fish per year. Healthy populations of Pacific salmon, steelhead trout, and Pacific lamprey that once provided annual subsidies to otherwise nutrient-impoverished environments largely remain depressed or have been extirpated. Currently, Pacific salmon occupy approximately 40% of their historic range and contribute just 6-7% of the MDN historically delivered to PNW rivers and streams. Consequently, many forested streams and rivers of the region are now characterized as ultra-oligotrophic, a condition of low nutrient concentrations suggested to result from a combination of parent geology and low numbers of returning anadromous fishes. In the Upper Salmon River Basin of central Idaho, primary production is often nutrient-limited, and reductions in the amount of marine-derived nutrients delivered by spawning salmon and steelhead could be exacerbating the degree of oligotrophication. The paucity of returning adult anadromous fishes and watershed scale nutrient deficits may constrain freshwater productivity and effectively limit efforts to recover salmon and steelhead populations. This is truly a landscape-scale issue. For example, Scheuerell et al. (2005) examined P-transport dynamics by spring/summer Chinook salmon (Oncoryhnchus tshawytscha) in the Snake River Basin and estimated that over the past 40 years <2% of historical marine-derived phosphorus is currently delivered to natal spawning and rearing streams. Across large spatial scales, Alldredge et al. (ISAB 2015) and Achord et al. (2003) found evidence of density-dependence at population sizes well below historical levels, suggesting nutrient deficits as a limiting factor capable of reducing stream rearing carrying capacities. In the state of Idaho, Thomas et al. (2003) estimated that 25-50% of streams and rivers are nutrient-limited. Moreover, observations of variable density-dependent factors at low spawning densities could lead to a net nutrient export from freshwater ecosystems, as more nutrients leave as smolts than are returned as adults. In a recent analysis of Idaho Chinook salmon populations, Kohler et al. (2013) demonstrated that in the majority of stream-years evaluated, adults imported more nutrients than juvenile progeny exported; however, in 3% of the years, juveniles exported more nutrients than their parents imported. On average, juvenile emigrants exported 22% 3% of the N and 30% 4% of the P their parents imported. Similarly, Evans et al. (2019) reported nutrient export by juveniles exceeded nutrient import by adults in Sockeye salmon nursery lakes in the Upper Salmon River. Given contemporary anadromous production, hydrosystem conditions, low smolt to adult returns (SAR), and ocean productivity trends, conservation efforts could be stymied by a lack of available organic material and nutrient subsidies in the form of anadromous fishes returning to freshwater rearing habitat in the Snake and Salmon River basins. To place this in context of salmon recovery, the Tribes have spent a significant amount of time working in the Yankee Fork Salmon River (Yankee Fork). In the Yankee Fork primary production is often nutrient-limited, and reductions in the amount of marine-derived nutrients (MDN) delivered by spawning salmon and steelhead could be exacerbating the degree of oligotrophication. In the Yankee Fork watershed, results from nutrient diffusing substrata experiments (NDS bioassays) indicated that biofilms were primarily nitrogen-limited; biofilm chlorophyll a and ash free dry mass (AFDM) increased on nitrogen-amended NDS bioassays. Biofilm biomass represents the foundation of the aquatic food web from which bottom-up trophic transfer of MDN can occur. In upper Salmon River streams, biofilm standing crops on natural substrates was positively correlated with total nitrogen (N) and phosphorus (P) concentrations, suggesting that low levels of total and dissolved nutrients constrain primary production. In the YFSR, water samples collected and analyzed for total and dissolved N and P concentrations supports the classification of this watershed as oligotrophic. Furthermore, N:P ratios are extremely low (i.e., <10) and suggest strong N-limitation. Taken together, a large body of empirical evidence from the YFSR highlight nutrient limitation as a factor limiting primary production and potentially constraining stream rearing carrying capacities and ultimately recovery efforts. The purpose of clarifying this issue, is that salmon recovery is linked to virtually every ecological process in anadromous influenced areas. While setting goals to promote restoration of fisheries to recovery targets is laudable, the Tribes view significant increases in abundance as having positive ecological benefits across the entire region. The DEIS discusses improvements in habitat as primarily a physical characteristic, dealing with structure and hydrology, without spending a great deal of time to discuss the functional impacts that a lack of marine derived nutrients can have on habitats that support listed species like Snake River Sockeye Salmon, Chinook Salmon, and steelhead trout. The Tribes would like the FEIS to discuss the correlation between depressed levels of marine nutrient import into tributary habitats and the projected abundance of anadromous fish returning to those habitats for spawning or freshwater rearing.	lower Snake River corridor would improve under MO3. Section 3.5.2.3 recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. This indicates that, in some areas, MO3 would likely improve freshwater and terrestrial ecosystems where these populations of anadromous fish return to spawn as compared to the No Action Alternative. However, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6823	9	dstone@sbtribes.com	Shoshone-Bannock Tribes	nake River Blocked Area The Tribes remain concerned about the significant amount of historically accessible habitat that is currently unavailable to Chinook Salmon and steelhead trout above the Hells Canyon Complex and other federal facilities on tributaries to the Snake River. The current aspirations for implementing ceremonial fisheries and research is currently limited by the lack of abundance in available stocks. While this is not necessarily a result of CRS operations, the Tribes vision for bringing fish back into historic watersheds is currently lacking a clear path for these actions. In the FEIS and ROD, the Action Agencies should describe the actual effects for Snake River stocks at a population level and ultimately support actions to bring fish back across their historic range. The Tribes acknowledge the difficulty of this request and would offer support to Agency staff if this recommendation is considered for the FEIS and ROD.	We understand and appreciate the Tribe's concern. While the co-lead agencies don't have legal authority to affect passage conditions at the Hells Canyon Complex, effects of the lack of fish passage in the Hells Canyon Complex are nevertheless reflected in the No Action Alternative.
6823	10	dstone@sbtribes.com	Shoshone-Bannock Tribes	Discussion about CSS, COMPASS (Life-Cycle Modelling) According to the CSS model, MO3 (Lower Snake River dam breach with 120% spill) resulted in the highest modeled SARs and in-river survivals followed by MO4 (spill to 125%). Among the federal DEIS alternatives, only MO3 and MO4 appear likely to meet the NPCC regional SAR goal of a range of 2-6% with a 4% average SAR. Meeting this SAR goal is supported by the best-available science that suggests that listed Snake River salmon and steelhead trout populations are at imminent risk of precipitous decline when at or below a 1% SAR and are merely at replacement when SAR is ~2%. To avoid risks of extirpation and achieve recovery, SARs in the 2-6% range with an average of 4% are necessary. This appears to be true for listed Snake River Chinook Salmon and steelhead trout populations; however, SAR levels would likely need to be even higher (>6%) to avoid extinction and achieve recovery for Snake River Sockeye Salmon. That said, only MO3 and MO4 appear to decrease travel time, decrease powerhouse encounters, and increase in-river survival, and thus SARs, in any biologically meaningful way. For example, the DEIS states that the PA represents a 35% increase in survival relative to the NAA. Presently, many listed Snake River Basin stocks have an average SAR survival of 0.7% (or less). A 35% increase from 0.7% would be a 0.95% SAR. Given current freshwater productivity, SARs less than 1% put listed stocks in a steep decline, below replacement, and at a high risk of near-term extirpation (Figures 1 and 2). In fact, the best-available science suggests that Snake River populations need to be at or above a 2% SAR just to be at replacement; population recovery will only occur in the SAR range of 2-6% (4% average) consistent with NPCC goals. Therefore, the DEIS PA appears to knowingly put ESA listed Snake River stocks in serious jeopardy. As stated previously, this is unacceptable to the Tribes.	The co-lead agencies used current high quality information and best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region). The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. SAR values reflect the methods used for estimation, and this should be taken into account when comparing against the Council's regional SAR objectives for recovery. SARs reported by hatcheries using coded wire tags often incorporate a harvest correction factor for ocean, recreational and Tribal harvest. Due to the different approaches of the models, including the length of the historical survival time series, use of different hatchery and natural origin populations, and other factors, the two models estimated different SAR under the No Action Alternative for Snake River spring Chinook: 0.88% SAR for COMPASS, assuming no latent mortality, and 2.0% SAR for the CSS lifecycle model, which is at the low end of the Council's targeted range for recovery. As the commenter points out, density dependence and freshwater productivity rates among tributary populations influence the SAR rate necessary to reach the rate-of-replacement for adult spawners (CSS annual report 2017, 2018). The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6823	11	dstone@sbtribes.com	Shoshone-Bannock Tribes	Request for Formal Consultation The Tribes would like to request a government to government consultation with the Action Agencies and the Fort Hall Business Council on the DEIS and the remaining NEPA process in anticipation of the FEIS and ROD. The foundation of government relations is the consultation process and the Tribes would like to acknowledge the Action Agencies efforts to engage in consultation from the initiation of this process in 2016. The formal consultation meeting is an opportunity for leadership to engage in policy level dialogue on important issues around salmon recovery and the wildlife program; as well as discuss any issues raised in these comments or issues that require resolution by the Action Agencies.	The co-lead agencies coordinated and held a virtual government-to-government meeting between the Shoshone Bannock Tribe Fort Hall Business Council and the co-lead agency executives on May 20, 2020.
6823	12	dstone@sbtribes.com	Shoshone-Bannock Tribes	From a Tribal perspective the federal trust responsibility doctrine should require federal agencies to manage lands and resources for the benefit of Tribal rights and interests. The Tribes recognize that the Action Agencies have endeavored to maintain an open and honest exchange of information regarding cultural resources; now the Tribes request that the Action Agencies consider these comments to support an alternative that would help heal the Columbia River Basin in a meaningful way for everyone who calls it home. Meaningful restoration of anadromous fish species across the Snake River basin would demonstrate a commitment to protect cultural resources and uphold the trust responsibility to tribes across the basin. Consistency with Fish Accord Obligations In 2008 the Tribes joined with other regional managers in developing an agreement (Fish Accord) to manage our portfolio of projects in a manner consistent with the Fish and Wildlife Program (Program). The Tribes further extended that agreement with the Bonneville Power Administration, Bureau of Reclamation, and the Army Corps of Engineers through 2022 or when the Action Agencies issue a final decision on the ongoing environmental evaluation for the CRSO. The Tribes have shared these comments to the DEIS with the Action Agencies and view each of our recommendations as consistent with our commitments through the Fish Accord as a partner in managing the resources of the Columbia River Basin. Nothing contained in this letter is intended to be, nor shall it be construed to be, inconsistent with our commitments through the Fish Accord or subsequent extension agreement. It is the intent of these comments to offer the Tribes perspective on the available materials and our view on the most appropriate alternative presented in the CRSO DEIS.	Thank you for the comment and your commitment through the Fish Accords as a partner in managing resources in the basin. The co-lead agencies appreciate the contributions and input of the Shoshone Bannock Tribes in the EIS, including discussions and comments pertaining to the Preferred Alternative.
6824	1	mitch@endangered.org	N/A	As an American who is concerned about the health of our rivers and the communities who rely on them, I value the opportunity to express my concerns regarding the Draft EIS. The ability for all citizens to make their voices heard in regards to decisions that impact the natural systems and species	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				which are held for them in public trust by the U.S. Government is critical. Thus I must express my alarm at the way this comment period was conducted. The Draft EIS is a highly controversial and complicated document. The complexity of this issue, as well as the global emergency caused by the spread of the Corona Virus in the Pacific Northwest and across the country, calls for an extension of the comment period to provide adequate opportunity for feedback.	determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6824	2	mitch@endangered.org	N/A	n addition to a lack of adequate response time, the mechanism used to collect comments through phone calls faced significant challenges, limiting participation in the public comment process, I do not feel that the public has been given adequate opportunity to make concerns fully heard.	The public had several ways to submit comments such as the online comment form and through the mail. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined the 45-day public comment period was consistent with NEPA regulations.
6824	3	mitch@endangered.org	N/A	In conclusion, a new approach is urgently needed to develop a comprehensive plan. The people of the Northwest and nation require and deserve one that (1) recovers salmon abundance (not merely avoids extinction), (2) invests in vibrant fishing and farming communities to provide them a healthier future, (3) supports a reliable, affordable and increasingly decarbonized regional energy system and (4) addresses the historical damage that the construction of these dams have done to the tribal communities in the region.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA species is the purview of NMFS and the U.S. Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The EIS analysis of the Preferred Alternative found the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. Socioeconomic effects were analyzed in the Draft EIS. Investing in fishing and farming communities, however, is outside the scope of this project and outside the authorities of the co-lead agencies. The U.S. Government supports the development of alternative forms of energy through many different programs and policies. For example, the Bonneville Power Administration also has a robust conservation program, from which about 90 aMW in conservation are saved a year. Further, when acquiring long-term resources, the Bonneville Power Administration statutory directives give priority to conservation and renewable resources. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, including protecting Native American treaty and reserved rights and trust obligations for natural and cultural resources throughout the environment affected by the CRS operations. Addressing the historical damage that the construction of the dams has done to Tribal communities is not part of the EIS or required by NEPA. However, mitigation programs that are currently in place to address construction of the dams would continue. This includes such program as the John Day Mitigation program which was originally authorized to offset mainstem fall Chinook salmon production losses that resulted from construction of The Dalles and John Day Dams and is implemented by the Corps. Mitigation for these losses is particularly important to regional Tribes that historically depended on these salmon for ceremonial, subsistence and economic support. Lower Snake River Fish and Wildlife Compensation Program would continue and this program was initiated to provide fish and wildlife compensation for construction of the four lower Snake River projects (Ice Harbor, Lower Monumental, Little Goose, and Lower Granite). Other mitigation efforts such as Operational Loss Assessments would also continue.
6824	4	mitch@endangered.org	N/A	I strongly urge this body to extend the comment period to provide adequate opportunity for thorough feedback from the public and to restructure their Preferred Alternative proposal to reflect independent science around the urgency of dam impacts on salmon, tribal communities and Southern Resident Orca.	See response to Comment 6824-1.
6829	1	N/A	N/A	Introduction This EIS was drafted in response to the need to review and update operations, maintenance, and configuration of the 14 multiple purpose dams and facilities, the Lower Granite Dam significantly impacts my operation. The topography of the Snake River region differs greatly from some of the areas of the Columbia River System (CRS). The geographic scope and climate vary greatly throughout this entire system and it should be noted that there cannot be a one-size fits all analysis.	Analysis in Chapters 3, 4, 6, and 7 analyzed effects of the alternatives at each project by different geographic region (A through D). For example, Region A includes three projects geographically located in the upper basin - Hungry Horse and Libby in Montana and Albeni Falls in Idaho. Effects of operation, maintenance and configuration to each one of those projects are analyzed separately. Similarly, the analysis for the remaining 11 projects is broken out by region and focuses on each respective geographic scope.
6829	2	N/A	N/A	Fish Modeling The EIS correctly used two different approaches to estimate how changes to the CRS operations would change the rates of adult salmon and steelhead returns to the Columbia and Snake Rivers. It is commendable that both of these approaches were used as it shows transparency as well as a well-rounded analysis. Reintroduction The concept of reintroduction, is again, one that is complex in nature as well as one that requires in-depth analysis and sound, peer reviewed science to help make determinations. The EIS correctly identifies that a coordinated approach is needed and that there are gaps in information. Steps to develop a framework and fill the informational gaps are taking place.	The co-lead agencies agree that using both the NMFS COMPASS/Life Cycle model and the CSS Life Cycle model was appropriate. The NMFS COMPASS/LCM models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival, and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of CRS operation with respect to flow and spill. The Fish Technical Teams for the EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods.
6829	3	N/A	N/A	Water Quality This is a very concerning section as it states that there are elevated water temperatures in the Columbia River Basin due to regular climatic events and climate variability, along with regional controversy regarding the role that the federal agencies may play in higher water temperatures. This management section must undergo serious scrutiny. Any conclusion regarding causation for water temperatures must be based upon scientifically proven, evidence based science, not blanket statements of fault.	Consistent with the requirements of NEPA, the co-lead agencies are using up-to-date, high quality, and relevant information and models in the alternative analysis. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Additionally, the EIS has undergone a third party, neutral Independent Expert Peer Review on the tools used, as well as the assumptions and conclusions in the EIS.
6829	4	N/A	N/A	Multiple Objectives 1 through 4 The WCA concurs with the EIS that the multiple objectives 1 through 4 are not ideal to meeting EIS objectives as set forth.	Thank you for your comment. The co-lead agencies presented a range of alternatives, including extensive measures, for the continued operation and maintenance of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. The co-lead agencies agree that the EIS followed the required NEPA process and fulfills the intent of NEPA in terms of sufficiency. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6830	1	communications@portwhitman.com	N/A	As the draft EIS states, breaching the dams would eliminate this valuable shipping method, increasing transportation and associated production costs, crowding our roads and increasing carbon emissions. The draft EIS captures some of this economic and societal impact, but we believe it is understated still. An independent engineering study commissioned by the Pacific Northwest Waterways Association (PNWA) concluded that to adequately move 2.4 million metric tons of grain from farms to overseas ports by truck and rail instead of barge would cost more than 10 times the capital cost assumption used in the draft EISmore than $800 million. While grain accounts for 62 percent of shipments on the Snake River, other commodities make up 38 percent. As the draft EIS only accounts for grain, the transportation impacts of breaching the lower Snake River dams are underestimated by at least 38 percent. These transportation impacts, coupled with a $458 million loss in irrigation, places many family farms at great risk. If farm subsidies are not increased, more than 1,100 farms could be at risk of bankruptcy, according to the study for PNWA. The average regional net farm pre-tax income was only $40,211 in 2017. With wheat prices already down near the break-even point, the study calculates that the federal government would need to increase annual direct payments to farmers by up to $38.8 million to maintain current income levels. Among the farmers who escape bankruptcy, how many would rather retire than face steep losses? How many future generations would forfeit a rich farming tradition as their family operations go under? According to the 2017 Census of Agriculture, the average age of a farmer in the United States is 57.5, and 96 percent of farms and ranches are family owned. In Washington state, the greatest number of centennial farms reside in Whitman County. About 20 percent of the states centennial farmsfarms that have been in the same family 100 years or moreare located in the county, according to a 2014 report by the state Department of Agriculture. Family farms, the foundation of our county and our nation, would crumble under an extreme decision to breach the lower Snake River dams. The agribusiness industry that supports our farmers would face similarly adverse outcomes. Dam breaching would eliminate all or most of the jobs at ports that rely on river navigation. All jobs at the Port of Almota and about 75 percent of the jobs at Port of Central Ferry would be eliminated under MO3. In 2016, these ports together employed 67 people, generated about $6.4 million in gross regional product and supported $3.3 million in labor income payroll. While the draft EIS correctly states that ports would be adversely affected, it does not estimate the number of jobs that would be lost under MO3. Other social justice considerations should be elaborated in the report as well. Nearly one in five people living in the 10-county area most impacted by a dam breaching alternativeincluding Whitman Countyare at or below the federal poverty level. Cutting the affordable transportation and hydropower supplied by the dams would exacerbate the challenges faced by our rural communities.	The EIS discusses in Section 3.10 that barge traffic ceases on the lower Snake River under MO3, regional businesses that support port and barge activities as well as associated employment opportunities would be affected, including towing companies. The EIS states that the commercial navigation industry supports employment for a wide range of transportation and material moving occupations, and points out that while some of these positions, such as material moving workers, including freight, stock, and material movers, may be readily transferable to support for road or rail transportation activities, others, such as boat captains, pilots and operators, and ship engineers, would not be transferable, and could result in relocation of some workers to areas downstream or to other professions not dependent on river navigation. The EIS also report points out that the tow boat companies state that approximately 50 percent of their business is conducted on the lower Snake River, and that they expect that removal of the ability to utilize the river could threaten their ability to maintain profitability. The EIS evaluates the increases in transportation rates that would likely result from removal of lower Snake River navigation capability from dam breach in Section 3.10. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled, depending on their specific location and other conditions. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects Section in Section 3.10.3.5.
6830	2	communications@portwhitman.com	N/A	As the draft EIS states, breaching the lower Snake River dams could cost up to an additional $1 billion annually to replace the energy alone and raise customer rates by 25 percent or more. However, these figures underestimate the total economic burden, as they do not include the loss of jobs and	The information cited in the comment is consistent with the findings of the EIS. The EIS evaluates the costs of replacement resource portfolios that would be required to avoid increasing the risk of an outage. See Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS. The approach in the analysis is to first evaluate the increased risk of power outages related to an alternative, but then to identify the resources that are needed to avoid that increased

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				income associated with an energy shortage. During the last energy shortage in 2000-2001, the Northwest lost 5,000 jobs as customer rates spiked and companies shuttered.	outage risk. Thus, instead of identifying the potential socioeconomic costs of power shortage, it identifies the costs of replacement resource portfolios that would be required to avoid increasing the risk of an outage. Given this, the analysis identifies that the expected outcome of MO3, which includes breaching of the four lower Snake River dams, would be an increase in the cost of power and resulting regional economic effects. See Sections 3.7.3.5, Potential Replacement Resources and Associated Costs, page 3-904 in the Draft EIS and Social and Economic Effects of Changes in Power and Transmission, page 3-928 in the Draft EIS.
6830	3	communications@portwhitman.com	N/A	Finally, we are pleased that your preferred alternative sustains reservoir-based recreation. Boyer Park and Marina in Colfax is one of only a few places to recreate on water in Whitman County. If the Lower Granite Lock and Dam were breached, the park would lose its marina, and with it, much of its recreational valueas we saw with Red Wolf Marina during the 1992 drawdown experiment. This significantly limits access to recreational opportunities in our community, especially for those without the physical ability, training or means to navigate a powerful river current. Our neighboring ports, the Port of Clarkston and Port of Lewiston, would also face missed recreational opportunities if the dams are removed. Each summer, thousands of passengers enjoy the Columbia and Snake rivers on cruise vessels, which travel the 325 river miles between Vancouver and Clarkston, relying on the locks to get up and down the rivers. More than 18,000 cruise passengers visited riverside communities in 2017, contributing over $15 million to the local and regional economies. Without the dams, this growing river cruise industry would cease to bring tourism dollars to the surrounding communities.	Cruise line visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). Section 3.10.3.5 describes the adverse effects to cruise line operations under MO3. Similarly, effects to recreation are described in Section 3.11.
6830	4	communications@portwhitman.com	N/A	As you prepare the final EIS, we urge to consider the port districts along the lower Snake River and the broader communities we represent. Please expand your analysis of the cumulative impacts of dam breaching to include the above figures.	Absent more specific parameters for requested further study, please see Chapter 3, Section 3.10.3.5 for three social welfare scenarios and regional economic effects analyses of M03 (dam breach).
6834	2	N/A	N/A	The solutions lie in recognition that this is a Northwest-wide problem requiring significant change across the salmon life-cycle. People concerned about salmon are likely expecting far too much from an EIS limited to examination of operational changes for the federal hydrosystem when a comprehensive effort addressing Harvest, Hatcheries, Habitat and Hydro is required.	The co-lead agencies agree that there are many ongoing, important efforts related to salmon and steelhead management in the Northwest. There are many factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion.
6838	1	eisenba2@wwu.edu	N/A	The EIS looks at how the alternatives will produce emissions but does not discuss current emissions, aside from claiming its clean power generation. In addition, consequences of climate change need to be considered for future mitigation techniques.	The EIS evaluated current emissions as part of the No Action Alternative and changes to emissions resulting from changes to operations, maintenance and configuration of the CRS projects under the Multiple Objective Alternatives, including the Preferred Alternative. See Section 3.8 and 7.7.10. Regarding climate change, through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for the No Action Alternative and the Multiple Objective Alternatives, including the Preferred Alternative. With the uncertainty associated with climate change, it is important that the co-lead agencies establish methods for adapting and increasing flexibility on the system. There are measures in the Preferred Alternative that are adaptive to emerging changes in climate and ensure there is flexibility to respond to future changes. One example of this is the habitat restoration program that counters increased stream temperature with deeper pools and more shaded areas. See Chapters 5 and 7 for additional information on the mitigation proposed for each alternative.
6838	2	eisenba2@wwu.edu	N/A	The EIS use of the indigenous peoples plight as a tool is highly inappropriate. It does not look at them as a current people with an ongoing problem that was in part, exacerbated by the created of the LSRDs. The EIS cites, flood control as a reason the dams should remain in place. Stating that it would destroy important native sites but ignores the fact that important native sites were destroyed when the dams were created in the first place. These tribes which include Umatilla, Yakima, Nez Perce, Coleville, Wanapum, Burns Paiute Tribe, Couer dAlene Tribe, Kalispel, Kootenai Tribe of Idaho, Northwestern band of the Shoshoni Nation, Shoshone-Bannock Tribes, Shoshone-Paiute Tribes, Confederated Tribes of the Warm Springs Reservation of Oregon, and the Spokane Tribe4 are not just experiencing a physical problem but cultural and spiritual problems. I understand I cannot speak for the tribes but they have been vocal enough about the situation and deserve to be heard. They are losing their identity as a people. Gary Dorr, former chairman of the Nez Peirce tribal council has states that [o]ur culture is the salmon, the dams destroy our way of life. The fight against the dams is a fight for our fishing rights and sovereignty. Keeping the Nez Peirce tribe from fishing violates their treaty rights 5. Explaining that the LSRDs need to be kept in place to protect he tribes, while the tribes rights were exploited is insulting.	The EIS and the co-lead agencies recognized and considered the past and present effects that resulted from the construction of the CRS. The environmental justice analysis takes into account the cumulative effects analysis in the EIS, which adequately considers the ongoing effects of the existence of the system to anadromous fish and other resources affected by the CRS. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6838	3	eisenba2@wwu.edu	N/A	Five of the six purposed alternatives do not address the mandate to restore the salmon populations and by proxy the Southern Resident Orca (SRO) populations, whose plight has been grossly omitted from the EIA. The actions for the Columbia River EIA include flood control, navigation, hydropower, irrigation, fish and wildlife conservation, recreation, water supply, and water quality. The EIA addresses a variety of issues, but the main issue is the health and population of the Chinook Salmon and the Southern Resident Orcas (SRO).	The co-lead agencies are not mandated to restore ESA-listed species. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Regarding Southern Resident killer whales (SRKW), the population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the CRS directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the SRKW depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. SRKW also are known to eat some steelhead, coho, and chum salmon, halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea. SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to SRKW would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases will come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
6838	4	eisenba2@wwu.edu	N/A	The preferred alternative is not suitable enough to address the while ecosystem. That alternative looks at the river as a closed system when river and terrestrial ecosystems are just as connected as river and ocean ecosystems. Modifying the John Day Reservoir to disrupt predation ignores animals that are not aquatic that rely on salmon. Salmon are a food source for orca, birds, other fish, and humans. Denying the ecosystem predation is not the answer to increase salmon numbers. Denying non-human animals, the right to predate on salmon not only harm river and estuarine ecosystems they harm terrestrial ecosystem as well along with its biodiversity. According to EPA Laws and Regulations, practices can only be ensured that do not cause harm to endangered species or their habitat by destruction or modification6. Both the salmon of the Columbia river7 and the Southern Residents are listed as Federally Endangered. The prolonged presence of the LSRD contradict this law. Even though the dams use spillways, turbines, and juvenile bypass system if the fish is too big than its ability to get through the dams is diminished8. The Orca Taskforce has highlighted three main problems that affect our SRO ability to thrive including prey deficiency, vessel noise, toxic contaminants 9. first problem that should be addressed by the EIS is prey	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Section 7(a)(2) does not require the co-lead agencies to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				deficiency and the solution doesnt seem to be hatchery fish. The survival of these types of fish are two-thirds lower than wild fish10. Again, the SRO should have been taken into consideration when drafting the EIS.	Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
6839	1	Kristin Meira	Pacific Northwest Waterways Association	The DEIS understates the harm to transportation that would be caused by the dam breaching measures included in MO3. Although the DEIS recognizes the transportation-related harm that would occur in the dam breaching scenario, it understates those impacts. First, the DEISs traffic impact analysis does not fully account for the economic impacts of the dam breaching alternative because it only considers downriver grain shipments. This is problematic because grain accounts for only 62 percent of the shipments on the Snake River; other commodities make up the remaining 38 percent. Because the DEIS fails to account for the non-grain commodities, it understates the dam breaching impact by at least 38 percent. It also fails to account for the fact that the total commodity shipments on the Snake River increased by 11 percent between 2017 and 2018, which amplifies the extent to which the economic harm of dam breaching is understated. Second, the DEIS underestimates the increase in truck and train transportation that will flow from MO3, and the corresponding increases in air pollution. The DEIS projects that dam breaching would cause an additional 182 unit trains per year and 79,250 added truck trips. But those assumptions consider only one-way trips, and as noted above, they exclude non-grain commodity movements. As a result, they underestimate air quality impacts by a factor of 2.38breaching the dams would actually result in the addition of 1,251,000 tons of CO2 per year. Third, the DEIS incorrectly assumes that transportation costs attributed to MO3 will be limited to: increased shipping cost increases (of up to 50 percent or $0.38 per bushel of wheat); increased highway maintenance costs (of up to $10 million per year); and increased rail/grain storage/other capital infrastructure costs (of up to $86 million total). In fact, extensive capital April 13, 2020 Page 9 PNWA Comment on CRSO Draft EIS Pacific Northwest Waterways Association 4224 NE Halsey Street, Suite 325 Portland, OR 97213 Telephone: 503-234-8550 Fax: 503-234-8555 investments in roads, grain storage facilities, and rail networks will be required to implement MO3. The DEIS estimates improvements would cost up to $86 million but does not identify where funding for these projects will come from. An independent engineering study on this issue concluded that to adequately move 2.4 million metric (MM) tons of grain from farms to overseas ports by truck/rail instead of barge would cost more than 10 times greater than the capital cost assumption used in the DEISwhich equates to more than $800 million. Fourth, the DEIS fails to consider the impact that increased transportation costs will have on the regions dryland farmers. Over 1,100 of these farmers are operating in affected areas, with average pretax income of only $40,211 per establishment. (USDA 2017 Census). Many farmers could be at risk of bankruptcy or foreclosure if MO3 were implemented due to the 25 percent to 50 percent (or higher) increase in transportation shipping costs. Wheat is a dryland crop in these areas, and the land and climate is perfectly suited to this particular crop, but not many others. Irrigation is impractical on most of these lands. It is likely that wheat farms that are made less competitive by the loss of this federal transportation system will have production and net income risk, with severe loss of land values as well. Unless federal farm subsidies were raised significantly or outright buyouts initiated, farm bankruptcies are the likely result. The DEIS does not evaluate the cost of these increases in farm subsidies or bankruptcies. In addition, anything that inhibits movement of grain to export facilities can negatively influence the regions reputation as a reliable supplier to world markets. The barging system on the inland Snake and Columbia Rivers is extremely reliable from an on-time arrival perspective at export facilities on the deep draft Lower Columbia River. In contrast, rail on-time arrivals at export facilities can be quite variable, which adds costs and uncertainty in meeting shipping schedules. This is another reason that shifting from barging to rail adds more cost and uncertainty to the reliability of service. Fifth, the DEIS does not account for many national costs that are typically evaluated with transportation capital facilities, such as transportation and infrastructure capital and lifecycle costs, safety issues, fuel costs, and property value impacts. Using the United States Department of Transportations (USDOT) Benefit-Cost Analysis Guidance for Discretionary Grant Programs, January 2020 guidelines, the national cost impacts associated with MO3 may exceed $4 billion over 30 years. This equates to a net present value of $1.9 billion (30-year analysis at standard 7.0 percent annual discount rate). In assuming that the transportation-related costs associated with MO3 are below $100 million, the DEIS likely understates the national cost of MO3 by approximately $1.8 billion in net present value dollars, based on the USDOT guidelines. And the DEIS does not evaluate increased highway deaths from increased truck traffic. Sixth, the DEIS underestimates the costs of necessary improvements to the short line rail system. The DEIS concludes rail improvement costs for short line systems would be only $30 million to $36 million. But those estimates are based on the findings presented in the 2002 draft environmental impact statement, which is nearly 20 years out of date. Based on feedback received from shippers and farmers within the study region, many of the elevator and rail network assumptions contained in the DEIS depend on facilities that have been abandoned or April 13, 2020 Page 10 PNWA Comment on CRSO Draft EIS Pacific Northwest Waterways Association 4224 NE Halsey Street, Suite 325 Portland, OR 97213 Telephone: 503-234-8550 Fax: 503-234-8555 are no longer in working order. As a result, short line rail network costs contained in the DEIS significantly understate the actual capital and rolling stock investment that is required. Actual rail capital costs required to handle the shift in commodities that would occur with dam breaching would be $300 to $353 million, which is about 10 times higher than what is assumed by the DEIS. The final DEIS should be revised to account for these discrepancies so that it accurately portrays the negative impacts that dam breaching would have on both the economy and the environment.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The co-lead agencies' working level of traffic for the model was 2.4 million, which reflects the average over the past 10 years. In 2018, 72 percent of overall freight volume on the Lower Snake system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the Lower Snake River was petroleum products that terminated below Ice Harbor Dam. Since these shipments do not utilize the Snake River locks, they would not be directly affected by dam removal under MO3. Other commodities that utilized the Snake River system included pulp and paper products (4 percent) as well as chemicals and iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under MO3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5. How rail rates would change without lower Snake River shallow draft barging cannot be known with certainty. Therefore in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. The FEIS includes an additional discussion of sensitivity to some parameters in Appendix L. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear-and-tear costs may occur. The EIS acknowledges that under some scenarios the profitability of farms could be severely affected. The EIS does not employ a cost-benefit framework for decision-making. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. Estimates were developed for infrastructure costs based on input from local stakeholders during this study period, as well as using published reports as information sources, including the 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report. To the extent possible, the CRSO EIS navigation and transportation model structure reflects the best available current information based upon input from both shortline and mainline rail representatives. As described in Section 3.10.3.5, increases in infrastructure demands could vary widely following dam breach, depending on factors such as the changes in rail rates, which influence the mix of alternative transportation modes that are utilized. In EIS scenarios, the largest demands on rail would occur under Scenario 1, when rail rates are assumed not to increase and rail transit would be relatively more attractive. In contrast, increased highway use would be highest under Scenario 3, when rail rates are assumed to increase by 50 percent. The EIS also notes that the high rail demand scenario and the high highway demand scenario would not both occur. In addition, infrastructure investments are transitional costs, and would primarily be borne by private entities, including rail lines and grain shippers. Over time, prices should adjust to cover these costs. Some highway costs would be transferred to the trucking industry through fees, though most costs would likely be borne by public entities. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. Ultimately, rail infrastructure investments would be at the discretion of the railroads.
6839	2	Kristin Meira	Pacific Northwest Waterways Association	The salmonid survival benefits associated with MO3 are speculative, uncertain, and subject to scientific dispute. The salmonid survival benefits predicted in the DEIS with respect to MO3 are uncertain, speculative, and subject to scientific dispute. The projected benefits of MO3 are based largely on predictions of salmonid smolt mortality from downstream passage at Lower Snake and Columbia River dams, estimates of adult returns, and the premise that dam breaching could potentially increase smolt to adult returns (SARs). In assessing predictions for seaward migrating spring Chinook salmon and steelhead smolts relative to the corresponding adult return run size, the DEIS relies on two different models: the Life Cycle Model (LCM) and Comparative Survival Study (CSS) model. These models use different assumptions and different combinations of environmental variables to predict survival including how delayed smolt mortality factors into the respective analysis. As a result of these differences, predictions of Snake River Chinook salmon and steelhead SARs vary significantly depending on the model used. The CSS model predicts that MO3 will increase SARs by 170 percent compared to the No Action Alternative. By contrast, the LCM predicts SARs to increase by only 14 percent. The DEIS fails to adequately explain the uncertainty and scientific dispute associated with the CSS model prediction. First, the DEIS should be revised to include additional technical scrutiny of the CSS model and its projections. As noted, the two models on which the DEISs survival predictions are based project wildly different SARs increases. That variance, in itself, calls into the question the reliability of the predictions. As the DEIS acknowledges, the fact the two models predict a wide range of improved SARs for MO3 indicates higher uncertainty pertaining to the level of benefits compared to the other alternatives. Yet, the DEIS reports and apparently relies on the same projections in articulating the survival benefits associated with each of the alternatives. Before issuing the final EIS, the co-lead agencies should conduct a more robust analysis of the models and the validity of their predictions, particularly the extreme magnitude of the benefits protected under the CSS model in connection with MO3. April 13, 2020 Page 11 PNWA Comment on CRSO Draft EIS Pacific Northwest Waterways Association 4224 NE Halsey Street, Suite 325 Portland, OR 97213 Telephone: 503-234-8550 Fax: 503-234-8555 Second, the DEIS fails to explain how the inflated SARs increase projected by the CSS Model for MO3 comports with existing data assessing overall dam passage survival rates. Data collected between 2010 to 2014 report the mean survival of juvenile salmon over the dams was between 94 and 99 percent, with a higher survival rate at the Snake River dams. This fact calls into question the CSS models prediction that removal of the Snake River dams would result in such an extraordinary increase in salmonid survival, when the more limiting downstream dams remain in place. The final version of the EIS should be revised to address this discrepancy. Third, the DEIS fails to explain how the extreme SARS increase projected by the CSS model comports with a region-wide trend of declining smolt-to-adult survival rates. Smolt-to-adult survival rates for Snake River Chinook salmon consistently have fallen short of objectives provided by the Northwest Power and Conservation Council, and they have hit a record low in recent years. The same is true with respect to the smolt-to-adult survival rates for the John Day River basin, which have experienced a dramatic decline observed since 2013 and are also at a record low. Given this declining trend throughout much of the Columbia Basin, the CSS SARs prediction solely based on the removal of the Snake River dams is questionable. The DEIS does not explain how dam removal could reverse a declining trend in smolt-to-adult survival that has been occurring since the mid-1990s, and which has continued even as improvements to spill operations have been implemented. There is strong evidence to suggest the downward trend is actually attributable to factors unrelated to the dams, including those occurring in the ocean during the bulk of the fish lifecycle. Such factors may include changes in the Pacific Decadal Oscillation, which effects ocean productivity, or the blob of warm water within the Northeast Pacific Ocean that was in place from 2014 through 2016. These or other offshore factors could have a greater influence on survival rates than reducing challenges during freshwater migration under MO3 by removing only half the dams Snake River fish would encounter. Another non-dam factor likely contributing to declining survival rates of salmonid populations is avian and marine mammal predation. One study conducted on upper Columbia steelhead smolts over the course of 11-years found that birds were responsible for between 31 and 53 percent of juvenile mortality in the river. A similar one-year study on the Snake River produced similar results. These studies suggest that avian predation plays a significant role in juvenile salmonid survival. Likewise, marine mammal predation is a growing problem on the lower Columbia River, as the population of California sea lions at the	To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. Models used in this EIS have all undergone independent external peer review and will continue to be reviewed as the Preferred Alternative is implemented. All models will be updated with new data annually. The co-lead agencies have used caution when comparing SARs between different populations, ESUs, and river basins as it is extremely challenging to find two populations that are suitable references for each other. The ISAB has noted those challenges in using that line of reference specifically related to comparisons of John Day populations to Snake River populations (ISAB 2020-1). It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. We look forward to participating in that discussion. The commenter is correct, modeling of alternatives for the CRSO EIS did not consider additional hatchery production or habitat restoration projects as mitigation. Mitigation program measures are described in the EIS in Chapter 5. With regards to the number of hatchery fish that would be produced in the absence of the Snake River dams, the co-lead agencies acknowledged in the EIS that funding levels would likely shift, but that changes in production levels are unknown as other funding sources outside of the Lower Snake River Compensation Plan could be increased.

				Bonneville dam has dramatically increased in recent years. Although the DEIS touches on some of these issues, it does not fully address them. The DEIS correctly acknowledges some survival challenges unrelated to the dams. For example, the DEIS notes potential increases in juvenile salmon and steelhead survival, decreases in travel time, and reductions in powerhouse encounters projected to occur under MO3 could be offset by the effects of climate change, which is likely to cause warming and increased predation. However, the DEIS does not adequately explain how the survival increases predicted by the CSS April 13, 2020 Page 12 PNWA Comment on CRSO Draft EIS Pacific Northwest Waterways Association 4224 NE Halsey Street, Suite 325 Portland, OR 97213 Telephone: 503-234-8550 Fax: 503-234-8555 model under MO3 account for ocean conditions, predation, and other factors unrelated to the dams. The final EIS should address these issues. With regard to predation, the final EIS should also consider alternatives such as the successful active management model established by the Columbia River Inter-Tribal Fish Commission (CRITFC). Fourth, the DEIS fails to adequately address the scientific dispute regarding the assumptions underlying the CSS Model. The CSS Model relies on the concept of delayed mortality, which hypothesizes that smolt salmonids experience stress events when passing through dam turbines, juvenile bypass systems, and spillways, and those stress events cumulatively reduce survival. But that hypothesis is subject to vigorous scientific dispute. For example, Welch et al. (2008) measured the survival of salmon smolts and found survival during downstream migration of some Columbia and Snake River Chinook and steelhead stocks appears to be as high, or higher, than that of the same species migrating out of the Fraser River, a large river system in southern British Columbia, which has no dams. Also of note, smolt survival during migration through the hydrosystem, when scaled by either time or distance migrated, was higher when compared with survival in the lower Columbia River and estuary where dams are absent. These results raise important questions regarding the factors that are preventing the recovery of salmon stocks in the Columbia and Fraser basins. Rechisky et al. (2014) tested whether there was support for hydrosystem induced delayed mortality of migrating yearlings from the Snake River versus migrating yearlings from the mid-Columbia River. They found no support for hydrosystem delayed mortality, as survival of in river migrating Snake and mid-Columbia River yearlings was indistinguishable. Similarly, Haeseker et al (2012) calculated seasonal, life-stage specific survival rate estimates for Snake River Chinook and steelhead, conducting multiple regression analyses to identify the freshwater and marine environmental factors associated with survival of each life stage. They found the most important variable for characterizing the smolt-to-adult survival rates for both species was the Pacific Decadal Oscillation Index, not freshwater variables. The DEIS should be revised to account for the substantial body of literature calling into question the delayed mortality assumptions on which the extreme CSS model predictions are based, and to address the mounting evidence that ocean conditions have a significant influence on smolt-to-adult survival. Fifth, we have noted inconsistencies in the assumptions with regard to hatchery fish in the fish survival models versus other assumptions elsewhere in the document. The DEIS correctly notes that "currently, hatchery fish account for 80-90 percent of all juvenile Snake River fish passing CRS projects. COMPASS and CRS models do not account for this potential major reduction in juvenile fish production." (3-548, lines 16557-16558), and that "closure of the hatcheries funded by BPA will result in a loss of 19 million salmon, steelhead and resident rainbow trout." (2-36, lines 1151-1164; 3-897, line 24727). Further, the "COMPASS and CSS modeling results indicate that survival rates would increase by as much as 25% and travel times would decrease April 13, 2020 Page 13 PNWA Comment on CRSO Draft EIS Pacific Northwest Waterways Association 4224 NE Halsey Street, Suite 325 Portland, OR 97213 Telephone: 503-234-8550 Fax: 503-234-8555 by as much as 30% relative to the No Action Alternative. However, as reductions in hatchery fish could reduce the numbers of juvenile Snake River chinook by as much as 85%, this reduction in the number of hatchery fish would likely result in a reduction of these predicted survival rates of wild Chinook because of increased predation rates" (3-559, lines 16895-16902). The 2002 EIS rightly recognized that increased fishing in the area could not be assured post-breaching: "recreational fishing visitation was not included in the 2002 study due to the uncertainty around it being an allowable activity, given the current measures to regulate, protect and support ESA-listed fish populations and habitat in the region."(3-1219, lines 1821-1824). Yet in the current DEIS, improved recreational fishing after dam breaching is touted, with no explanation for this reversal in logic. Notwithstanding these important unanswered questions regarding the extreme survival rates predicted for MO3 under the CSS model, the DEIS appropriately rejected MO3 in favor of the preferred alternative, which provides evidence-based survival benefits while protecting the regions other environmental, economic, social, and cultural values.	
6840	1	N/A	N/A	The Chamber of Commerce relies heavily on the tourism that the Dworshak Reservoir brings in for our community. We do not support the CRSO DEIS because both direct and indirect impacts it will have on our tourism. Clearwater County is home to Dworshak Reservoir, the Dworshak National Fish Hatchery and Clearwater Hatchery provide direct local economic value through a number of avenues: federal jobs (USACE, USFWS), state jobs (ID Fish & Game, ID Parks & Rec), commercial vendors (licensed outfitter-guides, campground operations); and indirectly from the hospitality industry (hotels, eating establishments and retail). The Dworshak Reservoir was built to help prevent flooding and also for recreational use. Taking even more water out will only reduce the recreational aspect that it was created for. According to ID Fish & Game angler surveys, steelhead fishing contributes $ 31,677,943 (inflation adjusted) are spent annually in the Clearwater River; and, throughout the region $ 80,815,718. An additional $4,614,444 in angler spending is directly contributed from fishing on Dworshak Reservoir.	Section 3.11.3.2 describes the economic contribution of visitation, including fishing visitation at Dworshak reservoir and the other reservoirs in Region C. Under the Preferred Alternative (Section 7.7.5.3 and Section 7.7.13.1), reservoir elevations could be lower in January through March during wet years in Dworshak Reservoir as a result of the Slightly Deeper Draft for Hydropower (Dworshak) measure. During typical water-level years, there would be no differences in water surface elevations compared to the No Action Alternative. There would be small adverse impacts to resident fish from entrainment from this measure, as described in Section 7.7.4; access for water-based visitation, including fishing, would be affected during wet years between January and March, decreasing by approximately one percent. Regional economic effects from this small change in visitation would be negligible.
6841	1	mike.edmondson@osc.idaho.gov	State of Idaho	The EIS has identified some controversial issues. In addition to flex spill operations and the intended benefits to ESA-listed anadromous fish, MO3 examined breaching the four lower Snake River dams. Both NMFS Science Center and Fish Passage Center modeled the anticipated outcomes and come up with notably differing predictions. This has created a dueling science scenario between the NMFS Science Center and the Fish Passage Center models. The issue of dam breach requires more than a biological perspective. It has a replacement power component that includes not only the sources of replacement power but also the transmission line usage and location. If possible, this EIS, biological opinion and final Record(s) of Decision should try to document latent mortality of juvenile fish in the hydro system to clarify this factor which impedes closer compatibility between the models	The commenter is correct: the two primary modeling approaches used in the CRSO anadromous fish analysis yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty related to latent mortality and the effects of increased spill, the Preferred Alternative will be implemented using a robust monitoring and adaptive management plan. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6841	2	mike.edmondson@osc.idaho.gov	State of Idaho	Idaho commends the action agencies for replying to our comments and recently sending the response matrix to us. Idaho asks to work through the outstanding comments from the ADEIS process and hereby requests a continued dialogue with the action agencies to resolve these issues. Idaho looks forward to working through these comments cooperatively in the time between the Draft EIS and Final EIS.	Thank you for your comment, and the co-lead agencies look forward to continued coordination with Idaho.
6841	3	mike.edmondson@osc.idaho.gov	State of Idaho	Lack of economic analysis on sportfishing in Idaho in the DEIS Fishing is tremendously important to the Idaho economy. Multiple studies of Idaho sportfishing economics conducted in the past two decades estimate annual angler-related expenditures range from about $450 million to $750 million. Anadromous fisheries typically comprise 20-25% of the total, meaning salmon and steelhead fisheries generate well over $100 million in spending each year. The 2001 chinook fishery, which was an exceptional return year, generated an estimated $90 million in a period of weeks. The City of Riggins received an estimated $10 million in spending, which comprised about 25% of the total spending in Riggins for the year.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare effects under MO3 on commercial fisheries (Section 3.15.3.5) are described as major and beneficial in the long-term in this reach, with increases in regional economic effects if commercial fish catch rates increase. Again, there is uncertainty around recreational visitation and commercial fishing in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
6841	4	mike.edmondson@osc.idaho.gov	State of Idaho	Lack of inclusion of hatchery Salmon and Steelhead abundances in the DEIS All the Alternatives (except MO3) include the continuation of the Lower Snake River Compensation (LSRCP) hatchery programs, yet the DEIS anadromous fish models do not explicitly analyze the changes in hatchery-origin adult returns. Because the LSRCP is a mitigation action for the operation of the dams on the Lower Snake River the EIS should evaluate how the alternatives would affect LSRCP hatchery returns. In Idaho Chinook salmon and steelhead fisheries are directed almost entirely on hatchery salmon and steelhead, and therefore hatchery adult abundance is directly related to non-treaty fish harvest and fishing opportunity. As a result, the abundance of hatchery-origin returns has substantial economic and social impacts within Idaho. The lack of analysis of the effect of actions on hatchery-origin adult returns is a major oversight in the DEIS	This Draft EIS analyzed the effects of the operation, maintenance, and configuration of the CRS projects and compared the alternative approaches to one another and to the No Action Alternative. Current high quality information was utilized to evaluate the metrics for that purpose (juvenile survival, travel time, transportation ratio, powerhouse passage, smolt-to-adult returns, and adult abundance) includes both hatchery and natural-origin fish. As described in the Methodology Section (Section 3.5.3.1 on page 3-358) both CSS and NMFS life cycle models include both hatchery and natural-origin fish in both the input data and the output results. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. The Draft EIS (page 3-550) objectively presents these factors and discusses the tradeoffs, including: 1) the predators that remain after dam breach would by mostly native fish adapted to riverine systems and there would be lower predation by non-native reservoir fish; 2) decreased travel time through the corridor would reduce avian and piscine predation; 3) the reduced predation risk may be offset by a reduction in hatchery fish and lower predator swamping effect. A summary of this qualitative discussion is provided for the reader for each Snake River species. Note, abundance estimates were only available for select populations with enough return data upon which to build the models, so the changes in abundance are considered an index upon which to compare alternatives, which meets the purpose of the NEPA process. They are not an absolute estimate of all fish returning to the basin of origin. See Section 3.5.3.1 for a summary of populations used, and Appendix E for specific results for each population.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6841	5	mike.edmondson@osc.idaho.gov	State of Idaho	Anadromous Fish Models and outputs used in the analysis The models employed in the CRSO DEIS are poorly described in the DEIS. Understanding the models and what drives them requires extensive study of other documentation, which may not be referenced in the DEIS. Further elaboration of the model details, particularly CSS, should be included in the CRSO EIS. Neither Chapter 3 Affected Environment nor Chapter 7 Preferred Alternative of the DEIS differentiate between the CSS LCM and CSS Cohort analysis when discussing the results despite the differences in design and data inputs between these two models. The two are presented as separate in Appendix E but the PA is not included in appendix E. Therefore, the results for the PA are difficult to interpret relative to the other MOs, particularly for Snake River Chinook Salmon. Several models were used to quantitatively evaluate the results of the various Alternatives relative to the No Action Alternative. The NWFSC-LCM uses the COMPASS model to predict abundances of smolts heading to the ocean (# smolts below Bonneville, see Appendix E; Figure 1-1, pdf page 28) to estimate the adult abundances presented in Appendix E. It is not clear whether this input was the deterministic output from COMPASS or the Monte Carlo output of COMPASS. We can only assume they used the deterministic COMPASS output which does not include any estimate of uncertainty (or variation) surrounding the smolt LGR-BON survival estimates and may be highly sensitive to small changes in the input parameter datasets such as river velocity, temperature, and spill proportion. Therefore, the inputs to the NWFSC- LCM were static and we are left to assume all uncertainty in the SAR produced with NWFSC LCM arose in ocean survival only. However, uncertainty around the SARs is not clearly presented in Appendix E and Chapter 7 of the DEIS, so it is not possible to evaluate how variable the outcomes of the alternatives would be and if that variability would arise in freshwater or the ocean. Reservoir temperature seems to play an important role in juvenile survival with the LCM model and may lead to the lack of sensitivity of the juvenile survival metrics across alternatives. Mean temperature experience for smolts from in the Snake River varied little between the NAA, MO1, MO2, and MO4 from 11.24 to 11.49 (Appendix Table 3-12, E-3-16, pdf page 187, units not provided but assumed Celsius). Meanwhile, it varied more within the four groups modelled in MO3 (Mean temp experience 11.73 for Grand Rhonde-Imnaha to 11.09 for Snake Wild/Hatchery) and the difference in predicted smolt survival within the four MO3 groups (0.55 0.63) varied more than all other alternatives (0.5010-0.5096). This is evidence that temperature is a major driver of the results of the COMPASS model, potentially dampening positive survival effects of any measure that does not directly contribute to a change in temperature within reservoirs. For example, mean temperature experience in MO4 is the highest of the non-MO3 alternatives and juvenile survival (Table 3-12) and SARs (Table 3-22, p E-3-21, pdf page 192) are also the lowest of the non-MO3 alternatives. The LCM may be further reducing smolt survival of MO4 by the TDG model predicted mortality, but it is not clear in available documentation how the TDG model is embedded within the survival calculation in COMPASS (See confusing, seemingly unused results on L4899 Table 3-17). Appendix 8 of the COMPASS 2.0 documentation presents a sensitivity analysis of the model that demonstrates the COMPASS model for estimating juvenile survival is not sensitive to changes in proportion of spill, therefore the characteristics of the model regarding its application to some of the Multiple Objective Alternative (MO4 and the PA) were known. We suggest the Action Agencies review and discuss the sensitivity analysis of the COMPASS model contained in Appendix 8 of the COMPASS 2.0 documentation, where the authors point out that juvenile survival estimates are very dependent on temperature and respond to spill proportion only at the lowest levels of spill (COMPASS 2.0 documentation). This is also the conclusion for the lack of sensitivity to spill described in Faulkner et al. (in press). In addition, ISAB (2017) provided an extensive list of recommendations, and it is unclear how many were accounted for in COMPASS version 2.0 (released as a draft in 2019) and subsequently applied in the CRSO DEIS analysis.	Extended discussion of methods for the NMFS COMPASS/LCM models are available in cited documentation (Zabel, Jordan et al. 2019). The LCM does include Monte Carlo sampling for estimating quantile results for adult abundance, which is presented in Appendix E. COMPASS is a mechanistic model estimating dam and reservoir passage through the hydrosystem. A mean and variance is estimated as a functional relationships between river environment and dam operations and output metrics such as survival, travel time, and powerhouse passage and so forth. Confidence intervals are presented for survival in the appendix. For this analysis, variance is driven by both within year and interannual variance from the 80-year water record. The COMPASS model estimates SAR as a function primarily of arrival timing in the estuary (and a random function matching observed variance of ocean survival rates). The commenter makes a valid point in asking how TDG impacts potentially influence adult abundance in the Life Cycle model. The TDG model was created as a secondary survival function with results always presented separate from both the COMPASS and LCM model results. Thus the effects of potential gas bubble trauma resulting from high TDG in MO4 do not influence adult abundances in the results. It is most straightforward to compare potential additional TDG related mortality to the in-river survival metric from COMPASS. We agree with the commenter's observation that temperature does not vary substantially between MO1, 2, and 4, in which spill volumes are the variable that changes to a large magnitude under the alternative operations. Thus temperature is not driving the observed changes in survival and travel time. Incidentally, when interpreting model results, it is important not to overlook the effect of % transported, which increases under MO2, and declines a large amount under MO3 and MO4. The CSS cohort model takes a statistical approach to estimate the effect of change % transported on SAR. In the COMPASS model, transported smolts have higher in-river survival; Smolt-to-Adult returns (SAR) are estimated separately based on historical PIT data for in-river and transported fish, and uses time of arrival in the estuary as a predictive variable.
6841	6	mike.edmondson@osc.idaho.gov	State of Idaho	Statement on Hatchery Mitigation Congress authorized the Lower Snake River Compensation Plan (LSRCP) as part of the Water Resources Development Act of 1976 (90 Stat. 2917) to offset fish and wildlife losses caused by construction and operation of the four lower Snake River dams. The EIS needs to insure sufficient operation and maintenance funds are provided so the steelhead and fall chinook mitigation programs continue to meet the congressionally authorized mitigation goals. While the LSRCP has been a successful mitigation program for steelhead and fall chinook, the LSRCP Snake River spring/summer Chinook program has never achieved the mitigation goal of 58,700 adults since the inception of the program in the 1980s. The DEIS needs to commit the necessary resources to meet the mitigation goals for spring/summer Chinook salmon. This will not only entail sufficient operation and maintenance funds to maintain current levels of production, it will require commitment of sufficient capital funds for facility expansion and improvement. The 58,700 adult return goal to Lower Granite is the congressionally authorized return level. On average, the returns are over 30,000 adults short of the goal (see Figure 1 below). In order to fully achieve the total adult goal of 58,700, the LSRCP will require an additional production of about three million smolts. This could be achieve by expanding capacity at existing facilities most logically Sawtooth Fish Hatchery (SFH) and Clearwater Fish Hatchery (CFH). CFH has rearing space for approximately 1.6 million smolts with the existing infrastructure on the hatchery. A new water supply pipeline would allow utilization of all existing raceways, ultimately returning, on average, an additional 6 thousand adults. Total capital cost of the project has been approximated at $45 million. Alternatively, SFH smolt production could be increased by about 3 million smolts through construction of additional raceways and development of water supply. This would result in a projected annual return of an additional 10,000 adults. Total cost of the infrastructure development would be approximately $10 million. [Text contains trables that do not transfer to database.] Figure 1. Returns of Lower Snake River Compensation Plan adult Spring/Summer Chinook Salmon relative to the mitigation goal of 58,700 adults above the project area. Graph from US v. OR Production Advisory Committee unpublished report.	Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Diversity is an important factor in an ESU's ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. There is an extensive body of literature developed from studying these factors and managing the conservation of salmon and steelhead, including hatcheries as one tool. Hatchery programs have long been a part of the approach for salmon recovery. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as proposed under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. Figure 3-111, which combines hatchery and wild fish, in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. The three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. Hatchery production goals for harvest are outside the scope of the EIS. The co-lead agencies do not have authority over tribal, commercial or recreational fishing; however, through increased abundance anticipated under the Preferred Alternative, more fish may be available for catch. Overtime, the Preferred Alternative is anticipated to benefit both wild and hatchery fish and the co-lead agencies continue to support information developed by the Hatchery Scientific Review Group and the Northwest Power and Conservation Council's Three-Step Review process.
6841	7	mike.edmondson@osc.idaho.gov	State of Idaho	Evaluation and inclusion of avian and pinniped predation impacts and management on Salmon and Steelhead The management of predators is an important mitigation program in the Columbia River Basin. The DEIS does not evaluate whether the control of predation is sufficient to achieve the contributions toward improving adult abundance and juvenile survival numbers. Avian Predation – Recent and ongoing research shows avian predation can be a leading cause of mortality. Smolt predation by Caspian terns, Double-crested cormorants and Ring-billed gulls is now considered the dominant mortality factor limiting survival of some ESA-listed steelhead populations. While ongoing federally approved plans over the last decade specific to Army Corps-owned lands have helped, a more aggressive set of actions is required. The federal agencies need to lead and implement a basin wide strategy in cooperation with state, tribal and other non-federal partners to reduce the numbers of avian predators that colonize in large numbers in the Columbia River estuary and areas in the interior Columbia basin. Such actions might include: Better alignment of conflicting federal missions, particularly the U.S. Fish and Wildlife Services implementation of the Migratory Bird Treaty Act, the National Wildlife Refuge Act, and other similar laws with NOAA Fisheries and the U.S. Fish and Wildlife Services implementation of the Endangered Species Act to ensure priority protection of ESA-listed salmon, steelhead and other listed fish to aid recovery of these species. Streamlining of federal permit processes to allow for states and tribes to expedite non-lethal and lethal control of avian predators. Maintaining necessary bird array devices and wires, boat crews and depredation programs at federal hydropower dams and ensuring operation and maintenance budgetary resources and authority for them. In addition to actions in the preferred alternative to control bird nesting on the Blalock Islands near John Day Dam, increased management of colonies and nesting in additional areas of the Columbia River, including Miller Rocks, the Umatilla National Wildlife Refuge and the McNary Wildlife Refuge near the Dalles, John Day, and McNary Dams. Better coordination with states and tribes to enhance control of avian predators on state-owned or managed lands near the Columbia River estuary. Comments on pinniped predation Each year thousands of adult salmon that migrate from the Pacific Ocean up the Columbia River are eaten by sea lions. A recent study by NOAA Fisheries found that, in 2017 alone, over 24,000 adult salmon were consumed by sea lions. The Independent Scientific Advisory Board also recently noted that pinnipeds likely have the greatest impact on smolt-to-adult returns (SARs) because they consume fish close to the end of their life cycle. Public Law 115-329 was enacted with bipartisan support to address pinniped predation on ESA-listed salmon and steelhead. This important law authorizes streamlined implementation to control sea lion predationFull implementation of the law has not yet been realized. Control efforts are labor intensive and resource demanding. To date, states have been challenged with implementing actions given the limited funding. In recent years, Stellar Sea Lions have increased in abundance below Bonneville Dam, presenting additional challenges. The presence of Stellar Sea Lions through summer and early fall extends the period of necessary sea lion management by a period of months. Additionally, the much larger size of Stellar Sea lions require much larger and heavier duty equipment. In addition to the limited resources for control efforts, we understand ongoing research to estimate predation rates on adult Chinook salmon is in jeopardy of losing funding. This research has been extremely valuable to fisheries managers in evaluating run sizes and return timing prior to fish being detected at Bonneville Dam. Furthermore, the results from this study will be important in informing the congressional report required by Public Law 119-329. The PA should include actions to more effectively manage pinniped predation, such as but not limited to: A more expeditious approval process of state and tribal permits to control these sea lions. Support for pinniped removal activities from April through September, to minimize impacts of both CSL and SSL. Support for research to continue monitoring mortality rates of adult Salmon and Steelhead survival.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from the CRS operations, through funding, direct implementation, and other means. Sea lions are protected under the Marine Mammal Protection Act. With the exception of continuation of the pikeminnow program, the co-agencies are not proposing additional predator management actions in the Preferred Alternative. The avian management plan encourages birds to nest in alternate locations outside of the Columbia River Basin. As analyzed in Section 7.7.7, the Predator Disruption Operations measure in the John Day reservoir could delay nesting water birds, forego nesting, or relocate to other areas, reducing avian predation on migrating juvenile salmonids. As discussed in Section 3.6.3.2, Caspian terns are highly mobile during the breeding season and move between breeding colonies in a given year and between years, demonstrating a willingness to nest away from the Columbia River while still foraging on juvenile salmonids (Corps 2014, 2018, 2019). Under the Preferred Alternative, actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with ESA as described in Section 7.6.4.1, Ongoing Programs, including ongoing measures to haze and monitor pinniped predators. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators. The co-lead agencies will continue to work closely with and assist NOAA, States and tribes efforts to benefit ESA-listed salmonids, including pinniped removal efforts near Bonneville Dam.
6841	8	mike.edmondson@osc.idaho.gov	State of Idaho	Appendix R: Monitoring and Adaptive Management Part 1, Framework Appendix R lays out a process by which the region will try to balance power supply, infrastructure integrity, and fish passage while learning to better manage the system. Overall, it describes a process that has largely occurred since the 2008 Biological Opinion. The Flexible Spill Working Group was the result of a settlement agreement reached by some parties in the Columbia	The co-lead agencies are currently in discussions with the states and Tribes on the structure of this forum. While the intent is to keep the spirit of the FSWG, there will be some modifications to the Draft EIS in this area based on our current discussions.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				River Basin and its continuation after the FEIS is released and the ROD is signed appears to be redundant to other regional fora both in membership and responsibility. If this group is formally established its responsibilities relative to other regional forums needs to be clarified and dispute resolution guidance needs to be standardized.	
6841	9	mike.edmondson@osc.idaho.gov	State of Idaho	General comment on preferred alternative, MO4, and northern Idaho concerns It appears there will be negligible changes or impacts to Lake Pend Oreille under the preferred alternative. Idaho continues to have concerns related to MO4, which proposed to lower Lake Pend Oreille up to three feet during the summer months, eliminating the stable summer pool that is required under the Congressional authorization for Albeni Falls Dam. Without the opportunity to engage the action agencies on this specific topic following the official release of the draft preferred alternative, we remain unsure how the preferred alternative could potentially impact lake levels in northern Idaho, but it does seem clear that the potential operational change that we were concerned about under MO4 has been removed from the preferred alternative. We are supportive of this decision to exclude the operational measures in MO4 affecting lake levels in northern Idaho and agree with the action agencies analysis that it would have a severe impact on recreation and the socioeconomics factors surrounding Lake Pend Oreille. The annual uncertainty of summer lake levels, alone, would have created economic hardship, regardless of whether the operation would have been implemented.	The Preferred Alternative is not expected to have adverse effects to Lake Pend Oreille when compared to the No Action Alternative. Information on how the Preferred Alternative may effect reservoir elevations is included in Section 7.7.1, Hydrology and Hydraulics. The figures that show the summary hydrographs of the reservoirs are particularly useful to see effects on reservoir elevations under different water year conditions.
6841	10	mike.edmondson@osc.idaho.gov	State of Idaho	Introduction Ch 1 Line 727-734: Federal agencies operate a series of 31 multipurpose dams known as the Federal Columbia 727 River Power System on the Columbia River and its tributaries, 14 of which are operated as a 728 coordinated system, referred to as the Columbia River System. The 14 CRS projects are 729 described below. The other FCRPS projects, such as those in the Willamette subbasin, the Yakima subbasin, or the Boise River Basin, operate more independently. The output at the projects with hydropower facilities is used in meeting the regions electricity demand. However, the multi-purpose operation of these other FCRPS projects is generally not factored into the coordinated planning scenarios of the CRS. The DEIS should specify that operations of the upper Snake River (USR) projects (i.e., federal projects upstream from Brownlee Reservoir) are covered under a separate Biological Opinion. Reference the USR in the in Section 1.8: Relevant NEPA and ESA Reports and Documents.	The comment is correct that the 14 projects comprising the CRS are operated together as a system separate from other components of the broader Federal Columbia River Power System. The co-lead agencies have carefully defined the action subject to this NEPA analysis to included only the integrated operation of the 14 CRS projects. As described, in Chapter 1 "The Dalles, and Bonneville. Projects in the upper Snake, Willamette, and Rogue River Basins are excluded from the CRS because these are coordinated and operated separately."
6841	11	mike.edmondson@osc.idaho.gov	State of Idaho	Ch 1 L 1299: Water temperatures in the lower Snake River are primarily determined by a combination of the temperature of the water originating from the middle Snake River and the Clearwater River. Lower and middle Snake River maximum summer temperatures exceeded the current 68 F (20 C) Washington standard before the dams were constructed (Corps 2002, Peery et al. 2003). Although this may be an accurate statement, the EIS should recognize that the Run-of-river projects can exacerbate the already present temperature issues during the summer. The lower Snake River downstream of Lower Granite Dam has severe temperature issues despite the influence of cool water from Dworshak Reservoir.	The co-lead agencies agree with the commenter's concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally, high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Temperature in the Snake River upstream of the confluence with the Clearwater River often exceeds state water quality standards. Drier and warmer years such as 2015, as summarized in NOAAs 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. The EPA is the lead agency on developing the temperature TMDL, and in doing so will evaluate the impact of all anthropogenic and natural sources of heat in the Columbia and Snake rivers. For information regarding the recently issued TMDL for temperature in the Columbia and lower Snake rivers, please see https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers. In contrast, the EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. Thus, the EIS did realistically and clearly analyze, to the extent practicable, whether the hydrosystem is causing or contributing to compliance with the water quality standards as compared to historic river temperatures. In addition to investigating the operational impacts on water temperature, the co-lead agencies have taken other actions to address water temperature effects on fish passage. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the EIS. In addition, the co-lead agencies are actively working on implementing the recommendations identified in NMFS' 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision making and reduce, to the extent practicable, the negative effects of high summer temperatures on migrating salmon, including adult sockeye salmon.
6841	12	mike.edmondson@osc.idaho.gov	State of Idaho	Ch 3 L124: For purposes of comparing MOs and developing preliminary costs, the EIS assumes that (1) operations under the MOs, including the measures in MO3 that include lower Snake River projects embankment breach, would be initiated at the signing of the RODs and (2) the construction period for these structural measures would occur over 2 consecutive years. It is not valid to assume that measures in MO3 (breaching) would be initiated at the ROD and would occur within two consecutive years. Breaching would require approval from Congress because the action diverges from the congressionally authorized purposes of the projects as noted in the document in Chapter 3 line 138 and Section 2.4 of the Executive Summary, Section 7 paragraph 4 of the Executive Summary, and elsewhere in the DEIS. Recognizing an assumption regarding timelines needed to be made, the two year assumption in this context is not supported in the document or by case studies of dam removal elsewhere in the U.S.	The co-leads agree that initiating the construction of a dam breach could not start with signing of the ROD. However, by choosing a single start year applicable across MOs, the EIS provides a level playing field from which to compare the impacts and costs of each MO (See Section 3.19 and Appendix Q for additional discussion). Establishing an actual year of implementation for each of the MOs would have injected a subjective timing element into the measurement of the relative impacts of differing CRS operations on each of the alternatives. For example, MO3 with dam breaching requires Congressional action. Had a timing element been included in the comparison of the MOs, the EIS could have assumed that Congress would not act by 2022, but by 2035, or some other subjective date. The impacts of the MO on the various objectives identified in the EIS would then have had to be scaled to these subjective future dates, skewing the results. MOs that could be implemented more quickly (such as those involving only operational changes) would generally show smaller costs and more overall benefits compared to those requiring long lead times (such as dam breach). This subjectivity would have been added to the analysis with little additional analytical benefit and potentially a detriment to the EIS because of the speculative nature of the timing assumptions the co-lead agencies would have had to make. The more analytically sound approach is the one adopted by the EIS. The use of a single study year for implementation of the alternative allows for a comparison of before-and-after effects for each alternative, utilizing the most recently available and vetted models and data up and through 2022. The single start year ensured that the effects of the MOs could be compared fairly with each other and the NAA without the co-lead agencies speculating on when Congress might act, when resources would be removed, or when resources would be constructed and online. Finally, if MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
6841	13	mike.edmondson@osc.idaho.gov	State of Idaho	L 7225 page 3-300 and Figure 3-111: Although the number of adult salmon and steelhead has declined since 2014, even with consistent operations of the CRS, and NMFSs 2020 status review will encompass years with lower returns and declining ocean conditions, these returns show that salmon and steelhead can pass upstream and downstream through the system in its current configuration when conditions are suitable. The figure and associated text t present an inaccurate picture of the returns to the Columbia River. For a more accurate picture of the status of Columbia River Salmon and Steelhead returns we suggest plotting returns of Salmon and Steelhead to the Columbia River mouth rather than Bonneville Dam Counts. These values are available from the Joint Staff Report Status Report of Columbia River Fish Runs and Fisheries from 1938 to 2000. This report is available at https://www.dfw.state.or.us/fish/OSCRP/CRM/reports.asp . Updates are available through 2018. Also including the total salmon and steelhead returns for the time series for Lower Granite Dam and Priest Rapids Dam provides a more complete picture of the status of returns to significant portions of the Columbia River Basin. The recent increases are, in part, due to reductions in harvest below Bonneville dam which is a management decision in response to declining runs and court cases which recognized the treaty rights of tribes fishing upstream of Bonneville Dam (see US v Oregon). For example, total salmon landings exceeded 20 million pounds and peaked at 32 million pounds in 1941 (Johnson et al. 1948. The effects on salmon populations of the partial elimination of fixed fishing gear on the Columbia River in 1935. Oregon Fish Commission. Contribution No. 11, Portland, OR) L 7244 and Figure 3-112: This references a figure that shows concrete to concrete survival (aka dam passage only) while discussing reach survival in the next paragraph. The concrete to concrete survival figure is misleading because the vast majority of freshwater mortality occurs in the reservoirs. We suggest including a figure showing NOAAs overall juvenile reach survival estimates for the system.	For the purpose of supporting the following Draft EIS statement which references Figure 3-111: these returns show that salmon and steelhead can pass upstream and downstream through the system in its current configuration when conditions are suitable, we feel this figure is appropriate. Regarding Figure 3.112, we agree that NOAA's overall juvenile reach survival estimates for the system should also be presented and will add it to the FEIS. However the intent of Figure 3-112 was to show progress towards meeting individual dam survival goals. The Draft EIS reference to this figure clearly states that the dam survival estimates do not include systemwide or latent effects and that discussion of these can be found in Section 3.5.3.1. All of the MOs include modeled results of in-river system survival estimates relative to the No Action Alternative. The inclusion of a figure showing NOAA's overall juvenile reach survival estimates for the system will add value, but not affect the analysis. In general, the NMFS COMPASS model results track well with the annual empirical estimates of in-river system survival.
6841	14	mike.edmondson@osc.idaho.gov	State of Idaho	L 9971 p 3-364: Because the quantitative results below are not presented with any estimates of uncertainty or statistical precision (e.g. standard error, or confidence bounds) these estimates are best suited for relative comparisons of the differences between alternatives, rather than comparisons between models. Uncertainty, or variation in simulation outputs, is an important consideration when interpreting the results for juvenile survival estimates and SARs. The ability to evaluate uncertainty weighs heavily on the readers ability to interpret whether the decisions based on the modeling results are justifiable whether in the context of comparing Alternatives within models or across models. We cannot find a justification for why uncertainty for these model results are not presented in this DEIS. Documentation for variation in the CSS cohort-specific model from the Fish Passage Center (McCann et al. 2019, Chapter 2) presents interquartile ranges for the SARs estimates generated in that model. It should be noted that for every alternative, the interquartile range is skewed downward suggesting that there are higher probability of low SARs (i.e., << 1) occurring than high SARs (i.e., < 5). This is important for evaluating the conditions under which we can expect very low adult salmon and steelhead returns. The variation included in the CSS results documentation should be included in the FEIS. Additionally, there is no public documentation of the variation around the model results from the NWFSC-LCM. Variation (or uncertainty) is a necessary model output for assessing the validity of a model and uncertainty for all model results involving SAR and juvenile survival (included in EIS) needs to be presented.	Relative comparisons of trends is appropriate when comparing outputs from different models or comparing trends in different metrics. Values of absolute change are also reported for all metrics, however the co-lead agencies echo the advise of the CRSO modeling teams that trend analysis is an appropriate framework to analyze complex model results with their inherent uncertainty. As noted by the ISAB in their review of the CSS model results generated for this EIS (ISAB 2020-1), changing climate conditions should be carefully assessed when considering potential impacts to salmon and steelhead, but the co-lead agencies note the concerns raised by the ISAB regarding the CSS's interquartile range analysis and the likelihood or probabilities of SARs falling below 1 percent or above 2 percent. The co-lead agencies will evaluate that analysis as it evolves but are not relying on the probability analysis at this time. Confidence intervals for in-river survival is included in Appendix E, although the commenter is correct that confidence intervals were not published along with mean estimates in the main tables of the EIS. NMFS' Life Cycle model presents adult abundance with quantiles of 2.5, 25, 50, 75 and 97.5. In contrast with reporting measurements from a study, with a mean and standard error, in a model it can be challenging to define the source of variance that is creating the confidence interval in a life cycle model. Variance is created by the changing river conditions within each season, and additional variance is created by using the 80-year water record. Metrics spanning multiple life stages, such as SAR and adult abundance, reflect variance in the different stages, both from the 80-year water record and data uncertainty from historical fish survival estimates.
6841	15	mike.edmondson@osc.idaho.gov	State of Idaho	Chapter 7 Preferred Alternative Anadromous Fish section Ch 7 L 1404 1409: Relative to the development of a trap and haul plan and Line 1409 relative to refurbishing the adult trap at Ice harbor. IDFG developed the Trap and Haul Emergency Procedures and Feasibility Plan at Lower Granite Dam for sockeye salmon and shared it with the region in 2017. It is available on the TMT website here: https://pweb.crohms.org/tmt/022217_Emergency_Trap_and_Haul_Plan_FINAL.PDF Given the existence of this document we do not see the need for consideration of the matter in the DEIS. We appreciate the attention paid to adult sockeye migration concerns as it relates to structural and temperature issues. However, we do not believe refurbishing the adult trap at Ice Harbor Dam for the purpose of trapping and hauling sockeye salmon is necessary, and believe it would be a misuse of limited resources. Since 2017 weve seen no evidence to suggest that trapping at Ice Harbor Dam or Snake River dams other than Lower Granite Dam has become feasible or warranted. If anything we have stronger data indicating the number of Upper Columbia River sockeye stray into the Snake River as far as Lower Granite Dam. Adult sockeye trapping at Lower Granite Dam is feasible because of the large contingent of fisheries personnel from multiple agencies (NOAA, USACE, IDFG and NPT) who routinely operate the adult trap and handle ESA listed adults and routinely transport adults for brood collection programs this experience as well as the infrastructure contribute the successful	The 2015 Adult Sockeye Salmon Passage Report (NOAA 2016), included a recommendation to consider trapping downstream of Lower Granite as potentially more fish could be collected for brood stock. The Trap and Haul Emergency Procedures and Feasibility Plan (IDFG 2017) supports a pilot study to better assess the logistic and operations difficulties. The Ice Harbor Ladder trap provides and existing opportunity to trap in the ladder for studies, or brood stock. However, IDFG and members of other regional forums, in particularly FPOM would collaborate on any such use of the trap. Removal of turbine intake screens as temperature management measure would likely have significant adverse effects on fall Chinook. This would eliminate juvenile salmon transportation, which after 1 July typically results in greater returns than those left in-river, presumably because the transported fish are out of the hot water and in the estuary in three days. However, instead of being collected, they would all pass through the turbines, not the bypass. The survival rate of subyearling Chinook through turbines in warm water is consistently very low due the very active predator populations in the tailrace. The higher turbine efficiency would not lead to fewer powerhouse encounters, because the spill cap would not change. Removing the screen would increase power production 1-2%, so would have very little effect on hydrology even is not operating to a spill level. As part of the No Action Alternative and Preferred Alternative, engineering efforts are ongoing to design structural improvements that would protect the stilling basin and allow removal of the 150 kcfs constraint at Bonneville Dam. While there are not any physical constraints limiting spill at The Dalles, spill is generally managed to be contained within the spillwalls to optimize egress conditions and survival of spillway passed fish. Maintenance efforts are underway to ensure all spillgates and in proper working order. Decisions to spill for fish beyond current levels at both dams would continue to be evaluated in the future and balance juvenile survival benefits, adult passage impacts, and TDG management.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				implementation of trap and haul when emergency conditions warrant. Water temperatures at Snake River dams downstream of Lower Granite Dam is another key consideration. If emergency trap and haul is given serious consideration then a thermal emergency already likely exists and the temperatures in the tailrace, fish ladder, and adult trap are consistently warmer than at the adult trapping facility at Lower Granite Dam. Increased temperatures increases the risk of handling mortalities. L 889: The removal of fish screens needs to be carefully considered as increased turbine efficiency could translate into additional powerhouse encounters from migrating salmon and steelhead smolts. Evaluations should be coordinated with state and tribal fish managers as well as federal fishery agencies. L 1016: We appreciate the consideration of adaptive management for the juvenile spill operations program. The adaptive management should consider defined performance metrics such as powerhouse encounters, juvenile reach survival and juvenile fish travel times. L 1037: The EIS should consider structural improvements to allow spill to increase beyond the 150kcfs constraint at Bonneville Dam and beyond performance spill at the Dalles. L 1164 7.6.3.16: Predator Disruption Operations at John Day --This action is an attempt to mitigate the establishment of nesting colonies of Caspian terns. Continuation of this operation needs to be evaluated on an annual basis in the context of the risk of colony establishment and ongoing success. L 1207: The DEIS should recognize the established mitigation goals. The DEIS should also recognize the age of the facilities and their ability to continue to meet mitigation goals in the future is contingent on sufficient allocation of capital funds for maintenance and repair. Additional resources are needed to meet mitigation goals where they are not being met (Snake River Spring/Summer Chinook Salmon). Meeting the LSRCP Snake River Spring/summer Chinook salmon mitigation goals will require increases to production and increases in survival. L 2696 Table 7-24: This table includes Number of Powerhouse Passages predicted by COMPASS and CSS. However, there is no analog to the COMPASS value presented in this table relative to Appendix E Table 3-12. Appendix E Table 3-12 reports proportion of fish experiencing a powerhouse, and the mean number of bypass passages, turbine passages, and spillway passages. Metrics in the PA should match metrics presented for the other alternatives in Appendix E. The PA presents a limited number of salmon and steelhead metrics relative to the MO1, MO2, MO3, and MO4 in Chapter 3 and Appendix E. The results of the Preferred Alternative should include the same tables for outputs related to Salmon as presented for the other MOs in Appendix E. L 4522: The DEIS states, Avian predators displaced from nesting habitat in Lake Umatilla under the Preferred Alternative would be expected to relocate to other islands and continue to forage within the Columbia River Basin. This is concerning and indicates that predation on salmon and steelhead may not be reduced only displaced resulting in no net change in survival of juvenile salmon and steelhead. L 5838: The DEIS states, increased stream temperatures could impact fish in all regions and any positive changes from the DEIS could be offset by climate impacts. The DEIS has no actions outside of Dworshak Dam operations designed to mitigate the effects of potentially increasing water temperatures. The DEIS should evaluate additional thermal management operations to mitigation potential increasing trends in water temperatures.	The co-lead agencies recognize that there are hatchery maintenance and infrastructure needs in the region. This is a regional issue that is being worked through a variety of public and regional forums that are broader than the scope of the CRSO EIS. The direct funding agreement between Bonneville and USFWS provides operational and maintenance funds for LSRCP to administer their mitigation program. Capital funding is currently not a component of the direct funding agreement between Bonneville and USFWS. In response to the statement regarding status of meeting mitigation goals, details around how USFWS manages and administers the LSRCP is appropriately outside the scope considered in the CRSO EIS. Predator dissuasion could redistribute nesting within the basin and an adaptive management plan is being developed for this measure. The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used high quality information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature, but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally, high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Drier and warmer years such as 2015, as summarized in NOAAs 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the Draft EIS. In addition, the co-lead agencies are actively working on implementing the recommendations identified in NOAA's 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision making and reduce, to the extent practicable, the adverse impacts of high summer temperatures on migrating salmon, including adult sockeye salmon. The water temperature analysis specific to MO3 (the dam breaching scenario) utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-demesional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. No Action Dworshak operations were used in the MO3 analysis. Results were provided to the fish team for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change at the appropriate resolution (river-scale vs. global- or regional-scale), and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3 and Section 7.8.4). The EPA is the lead agency on developing a water temperature TMDL for the Columbia and Snake Rivers, and in doing so will evaluate the impact of all anthropogenic and natural sources of heat in the Columbia and Snake rivers. In contrast the Draft EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. Thus, the draft EIS did realistically and clearly analyze, to the extent practicable, whether the CRS is causing or contributing to compliance with the water quality standards as compared to historic river temperatures. In addition to investigating the operational impacts on water temperature, the co-lead agencies have taken other actions to address water temperature impacts on fish passage. See Chapters 3, 4, 7 and 8 for additional information.
6841	16	mike.edmondson@osc.idaho.gov	State of Idaho	Appendix R: Monitoring and Adaptive Management Part 1, Framework Appendix R Chapter 5 Decision making, action agency author, and the regional forum L 291-304: This language is confusing because it appears to use verbiage directly from the 2019-2021 Flexible Spill Agreement, except for the last sentence Given that this framework will be applied after the expiration of the Agreement, the FSWG would be open to any interest CRS sovereign that requests to be included. We believe that the addition of a working group that lies between TMT and RIOG is unnecessary beyond the current Flexible Spill Agreement. The FSWG served as an explicit acknowledgement that some CRS sovereigns had signed a CRS operation related legal agreement while others were not signatories. We assume this will not be the case after that agreement has ended. Operations involving spill have to date, and should continue to be, coordinated and discussed at TMT. It is unwieldy to have yet another forum with the authority to elevate to RIOG on only issues related to spill. That said, we assume that the issues envisioned to move from TMT to the FSWG would only involve spill patterns, but that is not made clear in the dEIS.	The co-lead agencies are currently in discussions with the states and Tribes on the structure of this forum. While the intent is to keep the spirit of the FSWG, there will be some modifications to the Draft EIS in this area based on our current discussions.
6841	17	mike.edmondson@osc.idaho.gov	State of Idaho	Appendix E- Ch 1 Methods and Models Results from the analysis of the Preferred Alternative should be included in the appendix alongside the other MOs rather than as a standalone in Chapter 7. Comparisons of the PA against the MOs is challenging given the current format. . It also appears that there are anadromous fish metrics estimated for the MOs in appendix E that are not reported for the PA. Currently, only the overall adult abundances are presented in the PA, whereas population specific adult abundance is presented in Appendix E. L 473 478 & Table 1-4 & Table 1-5: The reduction in turbine associated mortality reported in this methods section is direct mortality occurring through a blade strike or barotrauma only. However, fish passing through an IFP turbine experience forces that are still difficult to comprehend (80-90 G acceleration; See 2020 AFEP Annual Meeting presentations) and, when they survive it, is equally difficult to understand the validity of discounting indirect mortality after turbine passage on the grounds of lack of data. While the COMPASS model uses a conservative 50% reduction in turbine-related mortality, it seems more reasonable to assume that fish that pass through turbines return as adults at very low rates. Additionally, the referenced modelling is not available to the public at present and should be made available and appropriately cited in the FEIS. L 564: The COMPASS model was substantially reconfigured to evaluate Chinook Salmon population response to breaching of the lower Snake River dams in MO3. Compass modeled four groups of juvenile salmon based on the location of tagging (Salmon River Trap at Whitebird; SAL, Snake River Trap at the head of Lower Granite Pool; SNK, and the Grand Rhonde & Imnaha River Traps; GRNIMN). The DEIS states that the alterations in the calibration of migration rate does not fit the scenario of higher water velocities through the Lower Snake relative to any velocity contained in the calibration dataset (L593). While acknowledging it caused no numerical issues, extrapolation beyond the range of a dataset is problematic (e.g., See L587 where the calibration data is from Lower Granite to McNary). Throughout the results, this caveat should be noted. While modifications to the COMPASS analysis may have been mathematically correct it is likely that this was not an appropriate model for MO3 because the parameters used in the Reservoir Survival Module (Temperature, Flow, and Spill Proportion) are too far outside the bounds of the calibration dataset and results from that analysis should be used with caution. Rather than split the three separate groups of fish, it may be easier to understand the results if only the analysis on the Snake River Trap is presented as it represents fish from the majority of the ESU. Fish tagged at the Salmon River Trap and recaptured at the Snake River Trap may be the best calibration dataset for migration rates in the MO3 analysis because of the free flowing nature of the river. L 629-638: Caveats regarding the calibration noted above should also be included as a footnote in the results tables (pdf page 187) so that it is clear in both places that calibration of the COMPASS model is not adequate for evaluating MO3. This explains why MO3-GRNIMN is drastically lower than the Salmon Trap or Snake River Trap estimates. L 641-644: The DEIS states, It appears that both assumptions for the MO3-GRNIMN calibration are being violated to some extent. Given this statement of violating the assumptions of the model, we disagree that including it in the DEIS provides a valuable measure of uncertainty. Rather it is a misuse of the model. We suggest removing the analysis of this trap group. L 677-681: This paragraph describes the four populations groups analyzed with the NWFSC-LCM, one from the upper Columbia and three Salmon River populations. The LCM uses COMPASS hydropassage inputs to produce adult return metrics. It is not clear anywhere in this section which COMPASS survival and smolt numbers where used for the Salmon River populations for MO3 given the separate analyses for different trap groups (SNK, SAL, GRNIMN). Presumably, this was analyzed using the MO3 SAL COMPASS results as inputs to the adult portion of the model. This needs to be specified. The EIS should clarify the term population groups. The recovery plan and data collected for the Snake River Spring Chinook Salmon ESU is organized by populations and Major Population Groups (MPG). The South Fork Salmon and Upper Salmon River are names of populations and also names of MPGs however the East Fork Salmon is not an MPG. Later in the DEIS on line 696 the description of the data inputs indicates that three Salmon River Major Populations Groups L 709-713: Survival and travel time output from the COMPASS model representing alternative scenarios of hydrosystem management was integrated into the model of wild adult abundance (Faulkner et al. in press). Data from both hatchery and wild origin juveniles was used to calibrate function relationships with dam operations and river conditions in COMPASS The sentences here imply that hatchery and wild fish interactions with the hydrosystem were used to estimate the parameters used in the LCM for wild fish only. Given the differences between hatchery and wild fish, this analysis should be completed with COMPASS outputs from wild fish only. Alternatively, the EIS should provide a defensible justification for combining hatchery and natural origin fish for calibrating COMPASS for use within the LCM. Combining hatchery and wild fish in the calibration data is problematic as noted by Burke et al. (in press) who explicitly state that they limited their analyses to wild fish only because of clear differences in the responses and survival rates between wild and hatchery fish. L 731-738: This sensitivity analysis consists of scaling adult abundance and SARs by incremental percentages. Given the latent mortality issue was important enough to include in the sensitivity analysis, the DEIS should clarify how the reduction in latent mortality was estimated and on which outputs the values were applied. As written it is not clear. It appears the 10% reduction in latent mortality was estimated as follows: SARoutput * 1.10 but applied only to the in-river migrating group. Alternatively, it may have only been applied to the ocean survival component (i.e., OceanSurvival * 1.10)? This is not necessarily a sensitivity analysis, but rather a scaling exercise, which underscores a major concern of the model outputs that it does not account for freshwater experience in its estimate of ocean survival. The modeled output describes population declines or population increases depending on which level of latent mortality the reader chooses to focus on making this effort considerably less useful for management decisions. We suggest acknowledging this model was not designed to account for latent mortality and this represents a minimum return from MOs that could reduce latent mortality substantially (MO3 & MO4). L 761-769: We suggest citing the Fish Passage	Because the Preferred Alternative was developed after the other multiple objective alternatives, incorporating measures from those other alternatives, analysis of the Preferred Alternative is described in Chapter 7 and not in Chapter 3.5 or Appendix E. It is correct that neither the NOAA Life Cycle model or CSS Life Cycle model included expanded spawner capacity in their modeling. There is considerable uncertainty around expectations for expanded spawning areas under MO3. In the pre-impoundment era before the construction of Ice Harbor dam, most Snake River fall Chinook spawning occurred in the tributaries and middle/upper Snake upstream of Lower Granite (Groves and Chandler 1999). Scour from ice in the winter and relatively high water temperatures during fall (compared to the upper Columbia) were believed to be limiting factors. It is not known if ice formation would be a contemporary issue below Hells Canyon, and there is some doubt whether adequate gravels would be available in the lower Snake. However, temperatures would be expected to cool earlier in fall. Groves, P. A., & Chandler, J. A. (1999). Spawning habitat used by fall Chinook salmon in the Snake River. North American Journal of Fisheries Management, 19(4), 912-922. For the 2000 Biological Opinion, NOAA proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap, and from the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from these difference between these two trap-to-dam estimates (Ferguson et al (2004). For the 2020 Draft EIS, NOAA used a similar method of estimating free-flowing survivals and travel times with their COMPASS model. PIT-based monitoring efforts have occurred at 20-plus additional hatchery and wild trap locations in the Snake and upper Columbia since the 2000 BiOp In the appendix, NOAA carries out a sensitivity analysis for the choice of upstream trap location by comparing free-flowing survival rates estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent dam breach conditions under alternative MO3. There is a wide variance in per-kilometer travel times and survival rates to Lower Granite Dam among all of the possible hatchery release sites and screw trap locations upstream of Lower Granite Dam. The river conditions and migration behavior of fish in tributaries to the Snake River is much less representative of river conditions we expect in the Lower Snake river following dam breaching than are the river conditions in the free-flowing Snake River between the confluence of the Clearwater River and the confluence of the Salmon River. NOAA selected the three locations because each trap location was low in the tributary and are very close to the mainstem Snake River; we expect that reach of the free-flowing Snake to be very similar to what the breached lower Snake would look like in MO3. Traps further up in the tributaries are likely to tag more parr while these three traps tend to intercept mostly smolt aged fish which arrive at Lower Granite time without further rearing behavior. Yet it does appear that some fish in the GRN and IMN data exhibit parr-like behavior, especially in early April. This is a major contributor to why the GRN-IMN model predicts slower migration and lower survival in MO3 than the other calibrations, and the reason for why it was placed into the appendix. The Salmon trap-to-Lower Granite reservoir free-flowing survival rate is used as a representative yearling Chinook population for the main text of the MO3 analysis. In response to the comment "outside the range of the data so the model is useless": this criticism can only apply to the SNK calibration. Yes, MO3 is outside the range of the calibration data for the SNK calibration, as is noted in the EIS text. The calibration between the Snake River Trap and LGD was just a calibration used to get at the GRN-IMN and SAL calibrations, and was not used in any prospective model runs for the Draft EIS. However, the SAL and GRN-IMN calibrations are NOT outside the range of the calibration data when used for MO3. Flow, water velocity and temperature are all comparable between the free-flowing reaches of the Snake River used for calibration and the breached Lower Snake in MO3. Ferguson J. (2004) Memorandum to FCRPS Biological Opinion Remand Administrative Record RE: Updated estimates of free-flowing river survival. NW Fisheries Science Center. Related to estimating passage through IFP turbines, sensor fish successfully identified and played in a significant role in solving spillway passage injuries at both The Dalles and Ice Harbor and are also commonly used to assess fish passage conditions through turbines.. Although certainly not an analogy for a fish, their motions are controlled by the hydraulics of the water and structure the impact and do provide a measure of the physical environment fish are passing through. Less violent sheer and turbulence is obviously a benefit for fish. Balloon tags, do best represent the potential for trauma to passing fish and not total mortality. Certainly, fewer traumatic injuries would lead to a lower mortality rate. The magnitude of the survival rate increase for naturally passing fish is unknown. The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Relying on the best available science, the co-lead agencies assumed mortality would be halved. All of the empirical ecological models implemented for the CRSO EIS have entered into a peer review process using the IEPR process, although evaluations were not yet available at the time the draft CRSO EIS was distributed. These include the University of Washington (UW) TDG model. As there is no empirical data for the 125% TDG spill targets under all flow conditions, we felt the need to model this to assess possible exposure rates. The UWs TDG model was already built, so we used that. This model does incorporate empirical data on fish behavior and survival, but the TDG-survival relationships are (necessarily) based on laboratory relationships. Because of the limitations of current models related to TDG and survival, those outputs from the TDG model were not used for decision making purposes. Experiments with confined fish will not accurately represent free swimming fish, which we know from telemetry studies of both adults and juveniles change depth regularly and can spend significant time at compensating depths, which reduce gas loading. Results from the IEPR process on the UW TDG model will be included along with review of CSS and NOAA in the FEIS.

				Center memorandum which detail the methods for the CSS Life Cycle model for clarity and transparency. Update this section by referencing Chapter 2 of the 2019 CSS Annual report where this specific CSS analysis is contained. Section 1.5 TDG model The TDG model is part of the NWFSC-LCM. The TDG section needs to be included with the NWFSC-LCM earlier in the appendix rather than after the CSS model. The current organization is not logical and this comment was made by Idaho on previous iterations of the Administrative Draft of the CRSO EIS. While Appendix E states that the TDG model is a standalone module within COMPASS, there is no description of how the Reach Average Exposure is integrated with the LGR-BON survival estimate from COMPASS or, to what degree, TDG may be altering that survival rate. Understanding how much influence the TDG model exerts over juvenile reach survival requires a more detailed description of how the TDG model fits within the LCM. This is especially true when evaluating the effects of the PA and MO4 which contain higher TDG exposure given the operations proposed in the alternatives. L 891: A major limitation in the outputs of the TDG model is that the dose dependent mortality rates were estimated from laboratory studies of fish held in constant levels of supersaturation– not the variable levels of TDG fish are actually exposed to in the environment. The DEIS should provide the outputs of the reach level survival predictions in context with observed reach level survivals to determine if the assumptions used in the models produce mortality in the range of observed values. L 1070-: The TDG model recognized the need to account for vertical distribution of fish in the water column due to its effects on TDG exposure. However the isosceles triangle which was chosen for simplicity fails to account for behavioral actions of fish to avoid TDG levels that may cause stress and mortality. Stevens et al. (1980) showed a behavioral response in a laboratory experiment that indicated juvenile rainbow trout and coho, sockeye, and Chinook salmon can detect air-supersaturated water and will move laterally to avoid it. Stevens,D.G., A.V. Nebeker and R.J. Baker. 1980. Avoidance Response of Salmon and Trout to Air-Supersaturated Water. Transactions of the American Fisheries Society 9:751-754. L 4904 & L4904 (Tables 3-18 & 3-40): These tables are identical and its unclear why Table 3-40 is in this section because it refers to the Cohort model while the other results refer to the CSS Life Cycle Model. L 4906 Table 3-21: This table refers to CSS results, but the column headings are the same as the NWFSC-LCM results presented in Table 3-20. It would be simpler to have different column headings because, while it is true that the reduction in latent mortality columns are Not Applicable (N/A) to the CSS models, it implies that CSS did not account for latent mortality. It did, but not in the same way. Additionally, the MO3 column refers to MO3-SAL, but the CSS life cycle model did not model abundance using data from the Salmon River.	
6841	18	mike.edmondson@osc.idaho.gov	State of Idaho	Appendix R - Ch 6 L 313-321: The DEIS states, The Flexible Spill Work Group (FSWG) role in implementation of the flexible spill operation component of the selected alternative is outlined for each step of the process below. Opportunities for input are confined by the sideboards of the selected alternative, as outlined in Record of Decision (ROD), and consistent with the Endangered Species Act consultations associated with the CRSO EIS. Further, the Action Agencies retain the authority to make final decisions related to actual project operations planned and completed consistent with the FEIS/ROD. However, if at any time a FSWG member has a specific question or concern related to any aspect of flex spill implementation, the appropriate Action Agency will respond to that input to the extent practicable and will provide feedback on how the members concerns were addressed. This paragraph appears to ignore the role of TMT and other subordinate working groups (i.e., Fish POM, SCT, etc) in the process of adaptive management of the CRS operations. Furthermore, it appears in the language retain the authority to make final decisions pushes the boundaries of what we see as the collaborative process that involves State and Tribal fish and water managers. L 348-374: Each of these steps listed as a FSWG Opportunity is already coordinated in regional collaborations under the current RIOG structure. It is clear that the Flexible Spill Working Group proposed in this DEIS adds a forum and if it is retained there needs to be a clear plan for how the responsibilities of the new group fits into the existing regional fora. It is not clear how the FSWG will add to these processes or steps, except for adding an analog to the Technical Management Team. Some of the current forum that deal with regional aspects of CRS management are: 1. Columbia River Treaty (CRT) Sovereigns make suggestions for preparing recommendations by the U.S. Entity, BPA, and COE. Recommendation move from Entity to Department of State 2. Treaty and NON-Treaty Operations and Treaty Operating Plans- Discusses, formulates, water storage and releases from Canada, funding for management with consideration for flood control management and the Fish Operations Plan (FOP) 3. Regional Implementation Oversight Group (RIOG) Formerly named the Policy Working Group. Formed to be a policy group to make operational decisions elevated from the Technical Management Team and Systems Configuation Team. This is a sovereign group. There are several working groups that deal with hydropower, hatcheries, habitat, and harvest- but can also include predation and Research, Monitoring, and Evaluation. The group provides NOAA a sovereign perspective on issues. Originally a non-agreement in RIOG was elevated to the Executive Committee, and four Governors, Federal administrators of BPA, COE, NOAA, BOR and the Tribal Chairs. Recently the Federal Administrators are just making the call, but this undermines State and Tribal sovereign input. 4. Technical Management Team (TMT) - created by NOAA as part of a process to gather fish/water managers for discussions on reservoir and river operations for fish and suggest changes to FOP if necessary. TMT meets every week (Wednesday) beginning in late March or Early April until about the 30th of August. TMT deals with operations, the Systems Configuration Team (SCT) deals with science and structure. 5. System Configuration Team (SCT). The SCT reviews the physical make-up of the hydroelectric system in the Basindams, fish screens and ladders, spill deflectors, and other structures to determine what the optimal system would look like that incorporates all the needs of the system. 6. Fish Operation Plan (FOP) describes the COE operations for fish passage at Columbia River dams, the Lower Snake River dams, and Dworshak Reservoir. State and Tribal fish managers help construct the plan with the Action Agencies and coordinate on drafts/final documents. Changes to the FOP are generally made in the Technical Management Team (TMT). 7. Army COE Implementation Report the Corps of Engineers prepares report of exceptions to the FOP or operations set forth in TMT. Covers from April 3rd until June 20th, the spring salmon operational period. 8. Dworshak Board Operational Plan a process contained in the Nez Perce Settlement Agreement and formulated in an MOA. Consists of COE, Nez Perce Tribe, Idaho, BPA, and NOAA/NMFS; An Operational Plan is prepared that details the release of 200,000 acre feet of water from Dworshak reservoir after salmon season, August 30th. This release of water is in September until the elevation reaches 1520 feet. Water is primarily for breaking a thermal block in the main stem Snake River from Lower Granite to the confluence of the Columbia. 9. Fish Passage, Operations, and Maintenance (FPOM) FPOM is comprised of the regional sovereigns, COE, and BPA and meets monthly or more frequently as necessary. FPOM deals with the day to day management and maintenance of fish passage structures and coordinates turbine outages and spillway issues. It also directs the fish transport program. Issues in FPOM coordination can be elevated to TMT. 10. Fish Passage Advisory Committee (FPAC) FPAC is comprised of state, tribal, and federal fish managers. They construct and present operation measures aimed at improving fish passage conditions to TMT. They also oversee Sort-by-Code PIT tag requests to ensure conflict does not occur between studies.	Based on comments to the Draft EIS, the future of the FSWG, after the expiration of the 2019-2021 Spill Agreement, is currently being evaluated. Options include the formal incorporation of the FSWG into the Regional Forum process or the integration of the FSWG function into the RIOG. Were the FSWG to continue, participation would be open to any Columbia River System sovereign that expresses a desire to participate. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6841	19	mike.edmondson@osc.idaho.gov	State of Idaho	Analysis in Chapters 3 and 7 of the Draft EIS utilize a 2017 coal retirement dataset and 2017 coal capacity assumptions for the base case scenario analysis. The dataset and assumptions are outdated; they no longer present current coal capacity in the Northwest; and they inaccurately portray the future impacts of alternatives. It is inaccurate to assume that 4,246 MW of coal generating capacity would continue to serve regional loads over the study period. The limited coal capacity scenario and no coal capacity scenarios are more accurate assumptions for coal capacity in the Northwest. The coal capacity generation assumption throughout the CRSO EIS should be improved by utilizing more recent coal capacity assumptions for all critical analysis throughout the document. The Northwest Power and Conservation Council released the Pacific Northwest Power Supply Adequacy Assessment annual update in November 2019. The report claims that 1,619 MW of coal-fired generating capacity has been announced to retire by 2021, and that an additional 127 MW of coal-fired generating capacity has been announced to retire by 2024. The social and economic effects of changes in the power and transmission section of 7.9 fails to analyze the limited coal and no coal scenarios. Analysis in Chapters 3 and 7 of the Draft EIS fails to include the cost of reconfiguring transmission resources. This analysis is critical for capturing the complete direct and indirect effects of MO3 and the Preferred Alternative. With so much baseload coal capacity being retired WECC-wide, and the requirement to replace that capacity with renewables and other low-carbon resources, the region will require adequate transmission infrastructure to accommodate a reconfigured grid whilst maintaining reliability.	The statement in the comment that potential additional coal power retirements would decrease power reliability in the region is consistent with the findings in the EIS. As noted in the comment, since development of the No Action Alternative, additional coal retirements have been announced. To address this concern, the EIS considered two potential coal retirement scenarios. See draft EIS, Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842 and Section 3.7.3.2, Table 3-123. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017. See draft EIS, Section 3.7.3.1, Base Case Methodology and Cost Sensitivity Analysis, at page 3-816; see also Id. at page 3-823. To address these changes, the EIS analysis uses additional analysis to inform the rates results of the updated coal retirements. This was done by developing an other regional cost pressure analysis. The Other Regional Cost Pressure analysis shows the incremental resource costs to the region of the limited coal retirement scenario and the no coal scenario for each Multiple Objective (MO) Alternative. In other words, the Other Regional Cost Pressure analysis combines the effects of the MO with a limited coal or no coal scenario and identifies the incremental resources needed (above those identified in the base case analysis for the MO) to return regional reliability to the level of the No Action Alternative. See draft EIS, Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis at pages 3-829-830. This cost is represented as an additional unassigned cost (i.e., it is not reflected in the rates analysis) because the EIS does not take a position on what entity would be responsible for the incremental costs created by additional coal retirements (e.g., the region, Bonneville). The Preferred Alternative also discusses the potential effects of coal capacity; see Section 7.7.9, Table 7-30 in the draft EIS. Given the uncertainty of the amount of capacity needed, the technology that would be available at the time, and the type and timing of resources to replace future coal retirements, the replacement costs, and thus, the potential economic effects were not estimated for any alternative. A full-scale assessment of transmission system reliability was not performed for a coal replacement scenario. Rather, the coal replacement analysis was intended to consider a set of replacement resources and the power reliability challenges the region faces with the combination of the removal of coal plants and potential changes in hydropower generation from the EIS alternatives. The scope of coal replacement was not known at the outset of the CRSO EIS analysis and did not inform the base assumptions. During the development of the EIS, it became apparent that additional coal retirements would occur independent of the CRSO EIS. The EIS added the sensitivity analysis to augment the detailed assessment considered under the CRSO EIS alternatives to ensure the EIS properly evaluated all effects.
6841	20	mike.edmondson@osc.idaho.gov	State of Idaho	Additional inadequacy of the existing transmission system would occur under MO3 with the retirement of baseload hydropower resources. Analysis in Section 3.7 of the Draft EIS fails to acknowledge the difficulty of acquiring new resources. Acquiring and permitting new resources is time consuming, and there are major costs of delay, including jeopardizing reliability and other socioeconomic impacts on energy sector jobs and the price of electricity. These costs should be analyzed and included in Chapter 3 and Chapter 7.	Contrary to the comment, the EIS acknowledges permitting requirements and developing replacement resources; see draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources, at pages 3-820-21. In response to this suggestion from Idaho and other public comments, Appendix H, Section 2.2.4 in the Final EIS describes the process and timeline associated with acquiring new resources. The EIS also acknowledges that potential delays in developing resources would have adverse effects on power reliability and assesses these potential delays qualitatively for each alternative (see Sections 3.7 and 7.7.9, Other Social Effects section for each alternative).
6841	21	mike.edmondson@osc.idaho.gov	State of Idaho	Chapters 3 and 7 of the Draft EIS fail to analyze the effects of alternatives to regional service providers, specifically the municipal and cooperative utility providers that utilize Bonneville Power Administrations (BPA) generation and transmission. These service providers face more constraints than vertically integrated utilities and will be disproportionately affected by changes to CRSO. These effects should be robustly analyzed in the environmental justice sections of Chapter 3 and 7, as many municipal and cooperative utility providers serve low-income and minority communities identified in Appendix O. Chapter 7, section 7.7.20: Claims that increases to power and transmission rates from the Preferred Alternative would occur across the region at levels	The EIS does acknowledge that regional utilities that purchase most or all of their power from Bonneville would likely be more directly affected by retail power rate pressure. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 and Section 7.7.20 of the EIS) provides further detail on this as well as the potential disproportionate effects to tribal, low-income and minority populations. As pointed out in the comment, the EIS also discusses that Bonneville customers, such as the municipal and cooperative utility providers mentioned in the comment, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. See draft EIS, Sections 3.7.3.3, 3.7.3.4, 3.7.3.5, 3.7.3.6 and 7.7.9, Social and Economic Effects of Changes and Power and Transmission. Although the power generation effects analysis does not focus on individual public power utilities, Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				that would not be considered disproportionately high and adverse to environmental justice populations compared to the No Action Alternative. However, Page 7-173, lines 5133-5135, claims, "Regional utilities that purchase most or all of their power from Bonneville would experience larger effects than independently operated utilities (IOUs) or other public utilities that do not purchase Bonneville power directly." Given that Appendix O identifies populations that meet the low-income criteria to be considered environmental justice populations and are BPA customers, additional socioeconomic analysis is required to illustrate the effect of the Preferred Alternative to these populations. These populations are subject to socioeconomic vulnerabilities that must be included within analysis of the Preferred Alternative. Throughout environmental justice sections in the Draft EIS, discussions on power generation and transmission only include analysis on the energy cost burden of residents within and surrounding the CRS, and how energy cost burdens for residents may change with alternatives. Alternatives will also have a large impact on commercial and industrial energy cost burdens that will impact the costs of goods and services to low income populations, minority populations, and Indian Tribes, and should therefore be included in the environmental justice analysis. Changes in hydropower generation and pricing amongst alternatives will impact power providers trading in the wholesale energy market and the Western Energy Imbalance Market, which will subsequently impact reliability and electricity prices throughout the region affecting low income populations, minority populations, and Indian Tribes. There is also no discussion on the impact of alternatives to transmission services and the subsequent impact on reliability and electricity prices throughout the region affecting low income populations, minority populations, and Indian Tribes.	The EIS also analyzed the wholesale market prices mentioned in the comment and the effect of changes to market prices were included in the rate analysis. Regarding the potential effect of the Preferred Alternative, these estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore, already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
6841	22	mike.edmondson@osc.idaho.gov	State of Idaho	Page 3-1064, Line 31831: Idahos Port of Lewiston has shipped numerous pieces of oversized equipment to Canada. Dam breaching would eliminate utilization of the Columbia/Snake River and U.S. Highways 12 and 95 as shipping routes to Canada and the interior of the U.S. Page 3-1087, Line 32284, Survey responses could be bias due to a 4-month extended lock closure during 2016. This bias may would be reflected in the modeling assumptions. Page 3-1093, Line 32490: If 2016 is the base year for the analysis, would the 4-month extended lock closure impact the analysis? Page 3-1095, Line 32518: Question the assumption that grain shipped down the river system will remain constant over time. For example, when the cost per barrel of oil increases to 2012 levels, Class A rail companies will dedicate equipment to oil shipments causing rail car shortages for other commodities. Furthermore, rail companies will institute rail car surcharge rates costing thousands of additional dollars to secure a rail car. The agriculture industry is unable to compete with the oil industry when high rail surcharge rates are instituted. This has been observed in the past and this scenario will undoubtedly occur again in the future. The river system will be needed to ship grain due to rail car shortage and pricing, however if dams are breached, river transportation will not be available.	The survey data was not collected during the four-month extended lock outages. Although there was a planned shutdown of the Snake River at the end of 2016 for a few weeks, the freight tonnage on river was not significantly affected. Freight tonnage in 2016 was 4 percent lower than the 10-year average. This would not substantially affect the SCENT model results, and would not affect the modeling conducted for MO3 (dam breach). For additional information, please refer to L.2.2 in Appendix L. The assumption that grain volume remains constant through time has been described relative to how Northwest wheat competes in the world wheat market and is not comparable to oil production. Most Pacific Northwest wheat merchants and cooperatives benefit when Class I rail capacity is tight and rail cars on the secondary freight market increase.
6841	23	mike.edmondson@osc.idaho.gov	State of Idaho	Page 3-1099, Line 32567: Question 124,000 cy of dredge material per year. The confluence of the Clearwater and Snake River was dredged in 2006. The next dredging project was undertaken in 2015 a period of 9-years between dredging projects. In the 2015-2016 dredging project 372,603 cy of sediment was removed. If we divide 372,603 by 9 years = 41,400 cy average per year sedimentation rate. The 124,000 cy of dredge material per year is a high estimate. Additional information on page 3-1081, Line 32108.	It is true that in recent years the average annual dredged volume of material has been much lower than the 124,000 CY/year cited. This is because the number cited is an average from 1975 to 2015. Typically longer averaging periods are more representative. However, there has been a change in dredging patterns that should be acknowledged. The PSMP has a provision for dredging outside of the navigation channel for the sole purpose of increasing flow conveyance to maintain flood risk at Lewiston. This provision is in harmony with the Lower Granite Water Control Manual, which states that maintaining levee freeboard at Lewiston is a project function. The current requirements for conveyance dredging, which are outlined in the PSMP, are more stringent (i.e. several criteria need to be met before performing conveyance dredging) than conveyance requirements during the early years of the project. As such, conveyance dredging has not been performed in recent years. Since conveyance dredging has not been performed since the new requirements were put into place, data to determine annual conveyance dredging volumes, does not exist. While 124,000 CY/yr might be a high estimate, in the absence of data it was judged to be the most representative number, given that 41,000 CY/year is a low estimate that does not include any conveyance dredging. A clarification of navigation dredging volumes has been added to EIS, Section 3.10.3.2.
6841	24	mike.edmondson@osc.idaho.gov	State of Idaho	Page 3-1118, Line 33058: The EIS states that others agree that a 50% increase is likely to be a reasonable upper limit. The term others must be defined and or a citation by provided. Idaho Cooperating Agencies and meetings with agricultural representatives have stated that a 100% increase is reasonable to expect in a monopolistic transportation market. The EIS does not demonstrate that a 50% increase in rail rates would entice shipping volume back to barge movements at the Tri-Cities. Stating that a 50% increase is a reasonable upper limit is without foundation. The EIS does not provide empirical data to support this constraint. The cost of trucking is the only constraint to rail pricing. Current trucking rates are $3.81per mile. Realistically, rail companies would find the sweet spot for pricing at a rate that would be optimal for rail revenues, but not enough to support a truck/barge move to the Tri-Cities. Additional analysis is required to arrive at a valid upper end increase in rail rates. Page 3-119, Line 33086: Question with some limited expansion. Please see explanation for line 33092 below. Constructing facilities to handle an additional 39 M bushels of capacity cannot be reasonably defined as limited expansion. Page 3-1119, Line 33089: The EIS states that shippers have reported that shuttle rail facilities can accommodate up to 25 million bushels per year with some storage adjustments The shuttle storage facilities themselves MAY be able to handle the volume of grain, however the rail infrastructure serving the shuttle rail facilities is not adequate to handle the increased rail volume. Significant rail improvements would be necessary at Four Lakes and McCoy unit train facilities. Additionally, the unit train facility at Endicott (Lacrosse) is not capable of handling 25 million bushels per year. Rail construction costs are approximately $1 million per mile. The cost to improve rail in order to reach a volume of 25 million bushels at the shuttle facilities is significant. The EIS must further define these costs. Page 3-1119, Line 33092: This sentence seems to imply that the 3 M ton (99 M bushel) capacity of the four-unit train facilities is adequate to transport 138 M bushels of grain (71 M bushels (rail) + 67 M bushels (barge). It appears that the capacity of the four-unit train facilities are 39 M bushels short. The first assumption under Scenario 1 would not be true without constructing 39 M bushels or 39.4% of additional handling capacity to make up the difference. Page 3-1119, Line 33110: Typo Should be Ritzville. Page 3-1119, Line 33108: There appears to be a disconnect between line 33108 and line 33121. In the first sentence, the EIS states that the four shuttle rail facilities can absorb the increased grain shipments. In Line 33121, the EIS states that Due to this required increased in capacity, it would seem that this increase would be unlikely to occur without an associated increase in rail rates. Line 33108 is inaccurate. Page 3-1120, Line 33157: As previously noted, should the number of unit trains increase by 94%, the rail infrastructure is unable to handle the increase. As stated in Page 3-1102, Line 32669: the cost to upgrade the entire PCC rail network to the 286,000-pound standard, WDOT would have to invest $150 million. Page 3-1123, Line 33193: The EIS notes that Pasco, WA would experience a large volume increase, mostly from shipments arriving via truck traveling longer distances to access river ports. What substantiates this statement? An explanation or citation is needed to support this assertion. Current trucking rates are approx. $3.81 per mile ($3.29 per mile + fuel costs of $0.52/mi.). Pasco is 130 miles from Lewiston. The McCoy unit train facility is 72 miles from Lewiston. Hauling to Pasco adds approximately $0.44 per bushel in transportation costs. It is questionable whether Idaho grain would be transported to Pasco even if rail rates increased by 25%. Costs associated with Scenario 2 should be further researched. The NAA cents/ bushel appears low. Page 3-1125 Line 33226 33233: Question the accuracy of 50% representing a reasonable high estimate. The EIS states that rail rates increased by 40% during periods of lock closure. Lock closures are temporary and grain transport is planned for months in advance. Grain is prepositioned at Lower Columbia River elevators ahead of lock closure. Overseas buyers are aware of lock closures and plan for scheduling grain purchases. Breaching dams is permanent. If rail companies increase rates by 40% under a temporary lock closure, then increasing rates by only 50% under a monopolistic transportation scenario is not reasonable. Rail companies will price their services just under trucking rates. Page 3-1126, Line 33242: Noted that Idaho farmers will experience rate increases double or triple a 24 cent per bushel increase in transportation costs. Page 3-1126, Line 33253: See comments for Page 3-1123, Line 33193. Page 3-1127, Table 3-246: The total change from NNA of 24 cents per bushel is low when considering the cost of trucking is $3.81 per mile. Additionally, it should be noted that 24 cents per bushel does not reflect how farmers will be impacted by the increased cost to improve rail lines (short line and class 1), unit train facilities, storage facilities, highways and additional handling costs. Page 3-1132, Line 33414: For the cost comparison of a Colfax farmer versus a Grangeville farmer, the trucking cost component should reflect $3.81 per mile throughout the comparison. Page 3-1137, Line 33587: Typo Scenario 3. Not Scenario 1. Page 3-1137, Line 33593: Clarification Construction cost should be $25 million. Not $25 million per year. Page 3-1140, Line 33605: Quoting the 2002 EIS, states if carrier face effective competition in rail-served markets. The point being that there would not be serious competition to rail service other than trucking. Page 3-1140, Line 33613: Reference Page 3-1102, Line 32667. WSDOT estimated the cost just to upgrade the PCC network to handle 286,000-pound cars at $150 million. Page 3-1140, Line 33620 33626: Referencing the 2002 EIS concerning mainline rail capacity is not appropriate. The 2020 EIS should not rely on statements by a BNSF representative from 18 years ago. Additional research should be undertaken concerning mainline rail capacity issues. Page 3-1142, Line 33697 33702: A study by FCS Group found that the average regional net farm cash income was only $42,825. Given the devastating increase in agricultural transportation costs, over 1,100 farms may be at risk on bankruptcy. Page 3-1142, Line 33707 33715: This paragraph illustrates several questions which the EIS should analyze: Will the U.S Government subsidize the increase in transportation costs to the agricultural industry, farmers, timber interests and other businesses negatively impacted by dam breaching? Adequate rail capacity could take decades to construct, if ever. Rail companies will have monopolistic pricing opportunities. What is the economic impact to rural Idaho communities due to the impact of higher transportation costs? For example, how many rural Idaho farmers are expected to go out of business? When the first barge departed from Lewiston in 1975, rail rates fell throughout Idaho and eastern Washington as railroads now had to compete with barge transportation. If dams are breached, rail rates will increase due to monopolistic pricing opportunities throughout Idaho and eastern Washington. The EIS should provide analysis on not just local increases in rail rates, but increases throughout the region. Page 1145, Line 33795: Question the increased transportation cost range of $0.07 to $0.24 per bushel. This analysis should be revised to reflect actual truck rates of $3.81 per mile.	The response to these comments can be found in comment IDs 31766-8 through 31766-27.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Additionally, it should be noted in this section that the full impact of increased transportation costs is not captured within the $0.07 to $0,24 per bushel range. Costs associated with improvements to unit train loading facilities, storage capacity, rail lines (short line and class 1), highways and additional handling costs are not captured within the stated cost increase. These additional costs will be substantial and ultimately paid by the farmer. Page 3-1145, Line33808: See comments for Page 3-1140, Line 33613.	
6841	25	mike.edmondson@osc.idaho.gov	State of Idaho	Appendix L Navigation and Transportation Content of Appendix L and Chapter 3 of the EIS shows that the content concerning navigation and transportation in the two document is very similar. Concerns express above for Chapter 3 of the EIS are similarly expressed for Appendix L.	Thank you for your comment. The responses for the concerns for Chapter 3 content reflect responses to similar concerns for Appendix L.
6853	1	jeff@ioga.org	N/A	Despite five judicial invalidations and the overwhelming longitudinal-evidence demonstrating the impact of the hydro system (viz. the Lower Four Snake River Dams) on anadromous fish decline, this Federal plan's recommended alternative prioritizes a flex spill approach spilling more water over the dams during juvenile salmon out-migrating to the ocean and continuing the transport of fish around dams using trucks and barges. Both approaches are already in use, and while each has utility in particular cases and in degrees, neither have yielded results approximating Federal obligations to conserve endangered fish populations even just above extinction-trend levels. The rearview strategy and limited scope of the DEIS bars it from providing recommendations that actually stand to realize our most pressing priorities: fishing and farming communities, forward-looking energy planning, and salmon & steelhead restoration. Whereas the Action Agencies plan details the impacts (positive and negative, across the different alternatives) on other industries, including agriculture, subsidized barging, and power generation, Idahos outfitters, guides and rural fishing communities are literally and completely ignored from the impact analysis. For all management alternatives and their Preferred Alternative, the economies of recreation and fishing (guiding, outfitting, hotels, restaurants, gas stations, boat shops, license fees, etc.) were not even accounted for despite existing, publicly available data.Previous EISs included such information, but this newest iteration does not. Moreover, the Preferred Alternative implements strategies already in use and makes small tweaks to reservoir releases in the higher tributaries. The economic and cultural impacts of salmon and steelhead in Idaho must be given full consideration by the federal agencies that control this system. To date, Bonneville Power Administration has spent $17 billion in fish recovery efforts to mitigate for downriver impacts with little to show for it. Yet despite evidence supporting a need for change, the draft plan seeks to continue with the same strategies and failed, irresponsible spending.	The co-lead agencies recognize the importance of fishing and recreation to the economy. The EIS recognizes the social and economic values associated with salmon although these values are not all expressed in monetary terms. Section 3.15 provides a discussion of the value of fisheries (commercial and subsistence) associated with salmon, as well as passive use values that people hold for these fish. Section 3.11 describes recreational values associated with the fish. Given uncertainty associated with the specific effects of the alternatives on overall fish abundance, these values are described qualitatively. Additionally, Section 3.17 provides information on the cultural significance of the salmon to regional Tribes. The comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
6854	1	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	On behalf of the Confederated Tribes of the Umatilla Indian Reservation (CTUIR), Department of Natural Resources, I attach comments on the Columbia River System Operations Draft Environmental Impact Statement. The CTUIR is a federally recognized tribe, 84 Fed. Reg. 1200, 1201, with rights reserved by the Treaty of 1855, 12 Stat. 945, entered into with the United States on June 9, 1855. The CTUIR is a cooperating agency pursuant to an MOU entered into between the Tribe and the Lead Agencies effective February 2, 2018. The attached comments are technical in nature and self-explanatory. However, the ability of the CTUIR to meaningfully participate in the CRSO process was materially hampered by the arbitrary shortening of the review period by the administration and Lead Agencies.	This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate and consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
6854	2	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The CTUIR DNR looks forward to written responses to our concerns and resolution in the final document.	Appendix T of the Final EIS provides responses to comments that were submitted on the Draft EIS.
6854	3	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Confederated Tribes of the Umatilla Indian Reservation (CTUIR) has worked for decades with the Action Agencies and other co-managers to protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by Columbia River System Operations (CRSO). The collaborative nature of this work with the Action Agencies increased markedly following the signing of the 2008 Columbia Basin Fish Accords and the 2018 Extension of those Accords. One of the goals of the CTUIRs efforts is to secure equitable treatment for such fish and wildlife with the other purposes for which the CRSO system and facilities are managed and operated. This work led to the planning and implementation of important measures to improve the operations and configuration of the dams, to habitat protection and restoration projects, and to the supplementation of naturally spawning populations of fish through state of the art fish production facilities. This work alone has not been enough, however, as much work remains to be done to restore, protect and enhance the salmon, steelhead, lamprey sturgeon and freshwater mussel resources of the Columbia Basin. These resources are all First Foods of the CTUIR on which it members depend. The CRSO Environmental Impact Statement (EIS) effort presented an opportunity to study and present a meaningful restoration path forward, in conjunction with the other purposes of CRSO. Unfortunately, based on the DEIS released February 28, 2020, substantial revisions are needed to achieve a meaningful path forward for these important resources. Under its Treaty of 1855, 12 Stat. 945, the CTUIR reserved for itself and its members the right to take fish at all usual and accustomed areas. Tribal members have fished on the Columbia River for subsistence, ceremonial and commercial purposes since time immemorial. The Supreme Court of the United States has repeatedly recognized the significance of the treaty reserved right to fish at off-reservation usual and accustomed places, holding that the right is not much less necessary to the existence of the Indians than the atmosphere they breathed. Washington v. Washington State Comml Pass. Fishing Vessel, 443 U.S. 658, 680, 99 S. Ct. 3055, 3071-3072 (1978), quoting United States v. Winans, 198 U.S. 371, 380 (1905). This treaty right to fish is a property right, protected by the Fifth Amendment to the Constitution of the United States. See Muckleshoot Indian Tribe v. United Sates Corps of Engineers, 698 F.Supp. 1504, 1510 (W.D. Wash. 1988), citing Menominee Tribe of Indians v. United States, 391 U.S 404, 411-412, 88 S.Ct. 1705, 1710-1711 (1968). The Treaty also creates a federal trust responsibility under which the federal government maintains an affirmative obligation to safeguard the subject matter of federal treaties. Thus, federal agencies must use their authorities in a manner that will protect and enhance– not degrade – the fish species that underlie treaty fishing rights. Further, [i]n carrying out its fiduciary duty, it is the government's, and subsequently the Corps', responsibility to ensure that Indian treaty rights are given full effect. NW Seafarms v. US Army Corps, 931 F.Supp. 1515, 1520 (W.D.Wash. 1996), citing, Seminole Nation v. United States, 316 U.S. 286, 296-97, 62 S. Ct. 1049, 1054-55, 86 L. Ed. 1480, 86 L. Ed. 1777 (1942) (finding that the United States owes the highest fiduciary duty to protect Indian contract rights as embodied by treaties). This duty does not cease once a fish run becomes viable. Tribal members must be allowed to achieve their CTUIR Public Comments April 13, 2020 Page 2 of 46 "moderate living," even if this living standard may only be achieved by allowing the tribes to enjoy the "same level of exclusive use and exploitation" they had at the time the treaty was signed. United States v. Adair, 723 F.2d 1394 (9th Cir. 1984) cert. denied, 467 U.S. 1252 (1984). In short, the Tribe has an absolute right to a fair share of the fish destined to pass tribal fishing places. U.S. v. Oregon (Sohappy v. Smith), 302 F. Supp. 899 911 (D.Or. 1969). These fish include those artificially propagated for rebuilding, mitigation and enhancement purposes. United States v. Washington, 759 F.2d 1353 (9th Cir. 1985)(en banc) (holding that hatcheryreared fish are fish within meaning of treaty fishing clause and subject to allocation thereunder). The harvest rights and federal fiduciary obligations properly cabin any consideration of the Treaty right to harvest to the environmental baseline. Including Treaty harvest in the baseline is consistent with the purpose of the CRSO EIS, which is to examine different hydrosystem operation configurations. All alternatives studied in the CRSO EIS should have been analyzed for their effect on Columbia River fisheries and their ability to contribute to the recovery of stocks to harvestable levels that support tribal fisheries and communities.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study.Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
6854	4	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The CTUIR worked with and utilized staff of the Columbia River Inter-Tribal Fish Commission in the CTUIRs participation as a Cooperating Agency in the CRSO EIS study. As a Cooperating Agency the CTUIR submitted comments to the Action Agencies on draft products as they were produced, including but not limited to draft EIS chapters, the December 2019 Administrative Draft EIS, and the January 2020 draft Preferred Alternative. All of the CTUIR comments submitted on those products, and throughout the CRSO EIS study process, are incorporated as if restated in these comments on the DEIS.	Thank you for your comment.
6854	5	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian	Further, while the CTUIR is submitting these comments to comply with the unreasonable April 13, 2020 comment deadline which precluded a transparent and full review of the DEIS due in part to the COVID-19 pandemic, the CTUIR reserves the right to submit further comments on this DEIS through its government-to-government or Fish Accord relationships with the Action Agencies.	Thank you for your comment. The co-lead agencies appreciate CTUIR's contributions throughout the development of the CRSO EIS and looks forward to continued coordination as part of government-to-government consultations and Fish Accords discussions.

			Reservation Department of Natural Resources		
6854	6	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Executive Summary of Comments The DEIS is a product of a failed process. It suffers from structural flaws. These structural flaws include, but are not limited to, overly narrow purpose and goal statement, overly narrow Affected Environment, inconsistent and improper modeling analyses, and the absence of fishery impacts analyses.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies disagree that the Purpose and Need Statement is too narrow given the wide breadth of resource and legal and institutional purposes it encompasses. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) as well as the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies relied on high quality information in the evaluation of effects to resources, including in the modeling analyses, affected by CRS operations, maintenance and configuration. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. The EIS does analyze, however, impacts to fisheries are analyzed in Section 3.15 and 7.7.17. See response to Comment 31775-2.
6854	7	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS is also inadequate due to incomplete and improper cultural resources analyses, poor analyses of mitigation and questionable assumptions.	The co-lead agencies respectfully disagree that the cultural resources analysis presented in the Draft EIS is incomplete or improper. The cultural resource analysis presented in Section 3.16 and Section 7.7.18 in the Draft EIS provides a complete review and impact analysis of known and/or identified cultural resource property types within the EIS study area. The impact analyses demonstrate a comparison of impacts to cultural resources from the alternatives across the Columbia River System.
6854	8	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS also does not appropriately incorporate tribal sovereign perspectives.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the development of the Draft EIS analyses and in the formulation of the Preferred Alternative. Please see the Tribal discussion in the Executive Summary, the Tribal Perspectives Section of 3.17 and submittals from Tribes in full in Appendix P. Effects to resources are discussed in Section 3.17.2, Tribal Perspectives Summaries.
6854	9	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS also fails to adequately address Indian Trust Assets.	Indian Trust Assets are analyzed in Section 3.17.1. Given the importance to the Tribes of these resources that do not meet the Department of Interior's definition of an Indian Trust Asset, effects to those resources are discussed in Section 3.17.2, Tribal Perspectives Summaries.
6854	10	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS further suffers from a bias in favor of power generation and flood control throughout.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. As required by the National Environmental Policy Act (NEPA), the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and presented for comparison in Tables 7-1 and 7-55 in the Draft EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4. In the Draft EIS, Table 3-61 compares expected survival by alternatives, and Table 3-62 provides a comparison of the alternatives specific to anadromous fish. The EIS considered the impact of all of the actions and measures in the alternatives for a multitude of ecological resources, such as water quality and fish, as time progresses from implementation into the future. There are many ecosystem and individual resource effects that occur outside the operation and maintenance of the CRS. Salmon and steelhead and other resources have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS. The co-lead agencies also looked at the cumulative effects of past, present, and reasonably foreseeable future actions and trends in Chapter 6 (Cumulative Effects) and Chapter 7 (Preferred Alternative), of the EIS. Further, Chapter 4 (Climate) provides an overview of the project changes in future regional climate and discusses how these changes would affect each of the resources under each alternative.
6854	11	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	In sum, the DEIS fails to disclose and analyze significant considerations that are part of the fabric of laws and policies that address the protection, mitigation and enhancement of fish affected by the development and continued operation of the CRSO.	The agencies are aware of their responsibilities under all applicable laws, including their responsibilities under the Northwest Power Act and will demonstrate compliance in Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders in the Final EIS and in their decision document.
6855	1	N/A	N/A	Introduction This EIS was drafted in response to the need to review and update operations, maintenance, and configuration of the 14 multiple purpose dams and facilities, the Lower Granite Dam significantly impacts my operation. The topography of the Snake River region differs greatly from some of the areas of the Columbia River System (CRS). The geographic scope and climate vary greatly throughout this entire system and it should be noted that there cannot be a one-size fits all analysis.	Analysis in Chapters 3, 4, 6, and 7 analyzed effects of the alternatives at each project by different geographic region (A through D). For example, Region A includes three projects geographically located in the upper basin - Hungry Horse and Libby in Montana and Albeni Falls in Idaho. Effects of operation, maintenance and configuration to each one of those projects are analyzed separately. Similarly, the analysis for the remaining 11 projects is broken out by region and focuses on each respective geographic scope.
6855	2	N/A	N/A	Water Quality This is a very concerning section as it states that there are elevated water temperatures in the Columbia River Basin due to regular climatic events and climate variability, along with regional controversy regarding the role that the federal agencies may play in higher water temperatures. This management section must undergo serious scrutiny. Any conclusion regarding causation for water temperatures must be based upon scientifically proven, evidence based science, not blanket statements of fault.	Consistent with the requirements of NEPA, the co-lead agencies are using up-to-date, high quality, and relevant information and models in the alternative analysis. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Additionally, the EIS has undergone a third party, neutral Independent Expert Peer Review on the tools used, as well as the assumptions and conclusions in the EIS.
6868	1	info@narn.org	N/A	Fish scientists have monitored Snake River wild salmon population declines since the 1950s. They have intensively studied the plight of the wild salmon in the last several decades using advanced tagging methods and modeling. The role that dams and reservoirs, habitat, hatcheries, harvest, predators and the ocean play in salmon survival is well understood. In order to restore Snake River salmon populations to sustainable numbers, scientists have determined that they must consistently return adults to the uppermost Snake River dam, Lower Granite, at a minimum rate of 2% to 6%. Since 1975 when the eight dams (four on the lower Columbia River and four on the lower Snake River) were completed, return rates have only rarely exceeded the 2 percent survival minimum. From 1994 to 2004, they ranged from 0.35 to 2.5 percent, exceeding 2 percent in just a single year. An extensive modeling	The agencies used current, high-quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over 20 years old and does not reflect current CRS operations. The Smolt-to-Adult return (SAR) rate necessary to meet the rate-of-replacement for each population has been found to vary as a function of the level of density dependence in the spawning and early juvenile rearing stages, and also by the life history strategy of the salmon species. For example, species that spend relatively shorter periods in freshwater such as chum or fall Chinook often are able to increase in adult abundance despite SARs below 1%. It should be noted that the 2-6% SAR target referenced in this comment refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				effort completed in 2000 analyzed of the causes of mortality for Snake River salmon. The model demonstrated that the four lower Snake River dams were the most significant factor preventing recovery. The cumulative effect of eight dams on the lower Columbia and lower Snake Rivers is too much for salmon survival and if the four dams on the lower Snake were removed (cutting the total number of dams Snake River stocks face in half), these salmon can rebound to healthy levels. More recent studies also show that populations of other Columbia Basin salmon that migrate through four or less dams and reservoirs, such as those from the Yakima and John Day rivers are performing significantly better than those from the Snake river. Those populations, like the Snake, also encounter mortality as a result of habitat destruction, harvest, hatcheries, predators and ocean conditions, but they are not imperiled. The difference lies in the number of mainstem dams they encounter. A key benefit for Snake River populations is the amount of high quality habitat they have that is not found in the other Columbia basins. As a result of this extensive research, hundreds of federal, state, tribal and independent scientists have concluded that removing the four lower Snake River dams is the best and perhaps only means to protect these fish from extinction and recover healthy populations.	by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average SAR rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Councils recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In relation to the comment that fish passing few dams have higher SARs and survival, the co-lead agencies follow the guidance from the Independent Science Advisory Board, and do not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons (ISAB 2020-1).
6868	2	info@nam.org	N/A	The federal governments salmon plans have failed because they circumvented legal requirements and politicized science. The Endangered Species Act lays out certain basic principles and requirements to ensure that we do not inadvertently allow species to go extinct. Instead of following this species protection law, the federal government has ignored its requirements, reinterpreted them in inconsistent and dangerous ways, and attempted to rewrite them. In the latest plan, for example, the federal government treated dams as unchangeable parts of the environment, much like a mountain.	The CRSO EIS analyzes the impacts of operations, maintenance and configuration of the CRS projects. Consistent with NEPA's treatment of ongoing actions, such as the CRS, the co-lead agencies evaluated changes to operations, maintenance and configuration as well as breaching the four lower Snake River dams. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6868	3	info@nam.org	N/A	Additionally, the federal government has ignored sound science. Tribal, state and federal fisheries biologists have all supported the removal of the four lower Snake River dams as a keystone action necessary for any valid salmon plan. To date, the federal government has ignored this scientific consensus due not to scientific principles, but rather due to political issues.	Consistent with the requirements of NEPA (40 C.F.R. 1500.1(b)), the co-lead agencies used current, high quality information to evaluate the effects of MO3, which includes breaching the four lower Snake River dams. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. The evaluations are clear, transparent, and repeatable based on the best available information. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6874	1	N/A	N/A	The impetus for the preparation of this DEIS is derived from an order by Judge Simon that emerged from yet another successful challenge to an unlawful and scientifically deficient Biological Opinion. In his order, it was clear that the Judge wanted a review of the effects of the four Snake River dams. The DEIS is far more expansive than the Judge intended and addresses many extraneous issues. The intent was to examine the needs of the endangered fish species however; the Agencies have proposed yet again, a biased analysis that does not place the endangered fish at the top of the list of issues of concern.	The commenter correctly notes that in his Order of Remand, Judge Simon urged the Corps and Reclamation to evaluate breaching the four lower Snake River dams. The Opinion and Order, however, also invalidated for staleness the underlying system operations NEPA document relied upon by the Corps and Reclamation. Thus, the scope of the CRSO EIS appropriately responds to the Opinion and Order by incorporating current information and conditions into a CRS-wide EIS as well as evaluating breaching the four lower Snake River dams. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. In this EIS, the Preferred Alternative meets the eight objectives of the EIS, including two objectives to improve passage and survival for ESA listed fish. Additionally, it meets the EIS purpose and need and minimizes adverse impacts to the human and natural environment. The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6874	2	N/A	N/A	This DEIS does not adequately implement the provisions of NEPA and has wasted valuable time and money through failure to analyze appropriate measures to achieve delisting. The DEIS appears to fall short of the requirements of many federal laws, particularly the Clean Water Act and the Endangered Species Act. At a bare minimum, one should expect full compliance with relevant federal laws.	Chapter 8 describes how the co-lead agencies complied with all applicable laws, regulations, and executive orders including the Endangered Species Act (ESA) and Clean Water Act. As stated in Chapter 8, a biological assessment (Appendix V) was submitted to both NMFS and USFWS dated December 20, 2019, to support development of biological opinions. The biological opinions from NMFS and USFWS were received in July 2020 and can also be found in Appendix V. NMFS and USFWS determined that the proposed action would not likely jeopardize the continued existence of ESA-listed species, and would not likely destroy or adversely modify designated critical habitat for the same species. Compliance with Clean Water Act is described in Chapter 8. The Clean Water Act Section 404 b(1) evaluation of the CRSO project can be found in Appendix W. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA-listed species for delisting. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6874	3	N/A	N/A	This long and voluminous document is without vision or planning for a future that continues to generate hydropower while also recovering the endangered population of native anadromous fish. In short, it dramatically fails the region by continuing to follow the same old path to decline of the endangered anadromous fish. Upon review of the DEIS, it is clear that only alternative MO-3 will result in the recovery of endangered fish in the Snake River. After many years of intensive efforts and billions of dollars expended, we are now faced with the reality that while improvements have been made, the removal of the Snake River dams is the only proposed alternative that could lead to full recovery of the fish. The DEIS fails to adequately or appropriately analyze MO-3, and how our region can move to economic prosperity and modernization. Instead, it regurgitates the false choices of the past, (energy vs salmon, transportation vs salmon, irrigation vs salmon) which have kept salmon runs depressed, starved Southern Resident Killer Whales and destroyed jobs in sport, commercial and tribal salmon dependent communities. The preferred alternative is worse than the status quo. It is preposterous that this alternative has been chosen. Allowing additional water withdrawals for irrigation and municipal uses will reduce the ability to manage flows for smolt travel and will increase water temperatures during the summer migration. Winter use of water for hydropower now used for these purposes only benefits revenues from the hydro system at the expense of endangered anadromous fish. It is very hard to rationalize the reasoning for this decision. Finally, the economic analysis that supports the DEIS is flawed. The analysis of the effects of MO-3 gives short shrift to the economic benefits of dam removal. The DEIS does not include an equitable economic analysis of recreational, commercial and tribal fisheries. Improvements in the sport fishing and outdoor recreation activities are under estimated while the costs of removal received full attention within the analysis. Again, it is a reflection of Federal Action Agency bias that has been prevalent for years	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. TThe Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and the Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall run (Upriver Brights), Lower Columbia River spring run, Middle Columbia River fall run, and Snake River spring/summer run. SRKW also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). NMFS CSS and Lifecycle models predict that lower Snake River Chinook salmon Smolt-to-Adult return rates (SARs) would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long-term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short-term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the CRS directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NMFS BiOp 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short-term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. Moreover, the potential economic effects from breaching of the lower Snake River dams are presented in the EIS, organized by resource area and type of economic impact, with additional details provided in resource specific appendices. Economic effects are described for changes to Power and Transmission (Section 3.7), Navigation and Transportation (Section 3.10), Water Supply (Section 3.12), and Recreation (Section 3.11). Potential economic impacts are evaluated for social welfare effects (national economic effect), regional economic effects, and other social effects. Additionally, the environmental effects associated with increased emissions from shipping goods by rail or truck are evaluated and described in the Air Quality Section (Section 3.8), and increase health and safety concerns are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5). Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms. Assumptions regarding the cost of reconfiguring water supply systems are discussed in the Water Supply Environmental Consequences Section for MO3 (Section 3.12.3.4, Region C). Effects to livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that follow. Please see Section 3.12 and Appendix N for additional information. Finally, the EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River). As described in Section 3.15.3.5, under MO3 commercial and ceremonial and subsistence fisheries targeting anadromous fish species across all regions may see major beneficial effects in the long term. Ceremonial and subsistence fisheries targeting residential species in Region C may see long term benefits, while those in Regions A may experience some moderate adverse effects.
6879	1	N/A	N/A	As an initial matter, we request an extension of the 45-day comment period to review the DEIS and provide the Action Agencies further information on the connection between Columbia River Basin salmon and survival and recovery of the SRKWs. The 2019 Novel Coronavirus (COVID-19) pandemic has continued to escalate dramatically from day-to-day in our region and at this time most public facilities are closed, nearly all work places have severely limited access, and many of us are subject to shelter-in-place orders. The COVID-19 social distancing and safety precautions have closed or limited the hours and access to several of the regions science labs and university facilities, which directly impacts the ability to work for some of the undersigned. In addition, at least two of the undersigned are in a high-risk category, live near a cluster of cases of COVID-19 in the Pacific Northwest, and have been subject to restrictions that are longer and more severe than most. The COVID-19 restrictions have materially impacted our ability to provide the Action Agencies will a full scientific review and analysis of the DEIS. Accordingly, we request that the public comment deadline be extended until the public health crisis is over. In case our request for an extension is not granted, we respectfully submit these comments to the Action Agencies on the Columbia River System Operations DEIS, which includes fourteen federal dams and reservoir projects in the Columbia River Basin.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6879	2	N/A	N/A	I. Increasing Columbia River Basin adult salmon returns is critical to the survival and recovery of SRKWs NOAA listed the SRKWs as endangered under the Endangered Species Act in 2005 when the population numbered 88 whales.1 Despite almost fifteen years of federal protection, the population has continued to decline from a high census count in 1995 of 98 whales to a low point of only 73 whales today.2 The National Marine Fisheries Service (NOAA Fisheries) has recognized the SRKWs as one of eight marine species most at risk of extinction and considers them a recovery priority number one: a species whose extinction is almost certain in the immediate future because of a rapid population decline . . . .3 By NOAA Fisheries own assessment, the population must increase by an average 2.3 percent per year for 28 years in order to be removed from the Endangered Species list,4 yet under current conditions NOAA projects a continued downward trend over the next 50 years.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.
6879	3	N/A	N/A	A lack of their preferred prey, Chinook salmon, is widely recognized as the primary limiting factor to their immediate survival and future recovery, with increased mortality and decreased fecundity shown to be correlated with coastwide indices of Chinook salmon abundance.12	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. 6879	4	N/A	N/A	One recent population viability analysis considered how SRKW population growth would respond to reductions in current threat levels for each of the three threats, singly or in combination.13 They found that only by addressing prey abundance could the NOAA Fisheries recovery goal of 2.3 percent growth for the SRKW population be achieved.14 The authors concluded that reaching the recovery target without increasing Chinook salmon numbers is likely impossible.15 NOAA Fisheries itself has recognized that the principle impediment to orca recovery is a severe shortage of preyparticularly Chinook salmon.16	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. 6879	5	N/A	N/A	For their immediate survival and future recovery, the SRKWs need abundant, diverse, and accessible Chinook salmon prey throughout their range and across seasons.17 Salmon are the mainstay of the SRKWs diet. This diet must support daily life activities (e.g., foraging, traveling, socializing, resting), in addition to gestation, lactation, and growth.18 To maintain this high energy balance, SRKWs preferentially consume Chinook salmon, particularly older (>3 years), larger Chinook age classes.19 Larger salmon offer the additional benefit that fewer are needed to provide a given amount of nutritional value, so larger individuals require fewer prey capture events, and less foraging effort. Chinooks large size, relatively high fat and energy content, and year-round occurrence from multiple sources within the SRKWs range contributes to the SRKWs preferenceand the preference persists despite the much lower abundance of Chinook in some areas and during certain time periods compared to other salmonids.20 Underscoring the importance of Chinook to the SRKWs, scientists have found a strong correlation between Chinook abundance and SRKW impaired 13 Robert C. April 13, 2020 5 body condition (peanut head), reduced growth rate, reduced overall length,21 reduced social cohesion,22 reduced fecundity,23 and reduced survival.24 Reproductive-age females seem to be particularly vulnerable to nutritional stress. One recent study found that up to 69 percent of all detectable SRKW pregnancies were unsuccessful; of these, up to 33 percent failed relatively late in gestation or immediately post-partum, when the energetic cost and risk is especially high (to the mother whale). The authors concluded that [l]ow availability of Chinook salmon appears to be a . . . significant cause of late pregnancy failure, and that point[s] to the importance of promoting Chinook salmon recovery to enhance population growth of Southern Resident killer whales.25 In particular, the authors concluded that the results of the study strongly suggest that recovering Columbia River Chinook (CRC) runs should be among the highest priorities for managers aiming to recover this endangered population of killer whales.26 A. The Columbia River Basin is not a small part of SRKW diet The SRKWs are some of the most well-studied killer whales on the planet.27 Despite the wealth of scientific literature available on SRKWs, and the numerous studies that were submitted to the Action Agencies by these authors and others during scoping of the DEIS, the DEIS only includes three referenced sources of information on the SRKWs.28 The DEIS does not 21 Durban, J. et al. See Columbia River System Operations DEIS at 11-9, 11-48, and 11-50. April 13, 2020 6 address or consider any peer-reviewed studies from independent scientists about the SRKWs or the most recent NOAA Fisheries conclusions, including scientific analysis and review of the SRKWs presence in coastal habitat and the importance of Columbia River Basin salmon in particular to SRKW survival. 1. The mouth of the Columbia River is a recognized hot spot for SRKW foraging and one of the most important sources of salmon for nutritionally stressed SRKWs. The SRKWs spend more than half the year inhabiting the coastal waters of Washington, Oregon, and northern California. In particular, NOAA Fisheries data compiled from tagged whales, dedicated surveys, and passive acoustic monitoring indicates the SRKWs spend significant time in the winter and spring (November through May) off the mouth of the Columbia River and have been present there thirty-five times more often than would be expected by chance.29 Although the vast majority of research on SRKWs is conducted in the Salish Sea, the majority of the population spends the majority of their time in the Pacific, and the majority of their time there is likely within the range of Columbia Basin Chinook. NOAA Fisheries itself has noted this area to be a high use foraging area, and approximately 50 percent of the time spent by the SRKWs in coastal waters is between Grays Harbor and the Columbia River.30 NOAA Fisheries recently proposed designation of the mouth of the Columbia River, along with other coastal habitat, as critical habitat for the SRKWs.31 In its Draft Biological Report in support of the proposed revision of critical habitat designation for SRKWs, NOAA Fisheries highlighted the critical importance of the prey found in the SRKWs coastal habitat, especially the Columbia River, to SRKW survival and recovery.32 In our expert opinion, Columbia River Basin salmon are critically important to SRKW survival and continued declineor only negligible increaseof Columbia Basin salmon would jeopardize the survival of the SRKWs. Analysis of fish scale and Southern Resident fecal samples collected on the outer coast indicate that Chinook are the primary species consumed on the outer coast and that over half the Chinook consumed by the Southern Residents are from the 29 Hanson, M.B., E.J. PLoS ONE 12(6): e0179824, https://doi.org/10.1371/journal.pone.0179824. April 13, 2020 8 While it may be correct that Puget Sound Chinook salmon stocks are one of the most important salmon stocks for SRKWs,36 it is equally true that Columbia River Basin salmon stocks are one of the most important stocks for SRKW survival and recoveryin particular, the fat rich spring Chinook. The SRKWs need to maintain a balance of energy year-round to support daily activities, as well as gestation, lactation, and growth.37 The orcas rely on multiple stocks of Chinook, depending on availability at different times of the year and in different parts of their range.38 The DEIS fails to account for the fact that salmon from all of the rivers within the orcas range are not available to the orcas on a year-round basis but, instead, are critical to the orcas survival in specific seasons.39 The spatiotemporal distribution of Chinook runs within the orcas range means that different runs are more available, and therefore more important, to the SRKWs at different times of the year.40 Columbia Basin Chinook provide the SRKWs with a key source of food and nutrition during the winter and spring, and they likely sustain the whales until the Fraser River runs peak in the Salish Sea in late summer.41 The size of individual salmon and their caloric content vary by species, geographic area, season, and year, and therefore have different value to SRKWs as well.42 This too makes the fat-rich inland spring Chinook from the Columbia River Basin uniquely important. The DEIS concludes that the Multiple Objective Alternative 3 (MO3), i.e. lower Snake River dam breaching alternative, would result in a moderate to major increase in smolt-to adult returns and overall abundances of adult salmon and steelhead over the long term, and that would increase the prey base available to . . . killer whale[s]. 43 However, the Action Agencies 36 Columbia River Systems Operation DEIS at 3-685. 37 NMFS (Sept. 2019) Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: raft Biological Report, available at: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killerwhale 38 NMFS (2019) Endangered Species Act (ESA) Section 7(a)(2) Biological Opinion and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Response. (2014) Energy content of Pacific salmon as prey of northern and Southern Resident Killer Whales. Endangered Species Research. 25: 265 281. 43 Columbia River System Operations DEIS at 3-758. April 13, 2020 9 conclude without citation or analysis that the effect for the prey-limited SRKWs would be only minor. 44 We agree that MO3 would result in the greatest increase in overall abundance of adult salmon over the longer term. We find no support for the conclusion that the impact on the severely nutritionally stressed SRKWs of a moderate to major increase in adult salmon returns over the long term would be minor. We challenge the Action Agencies in their response to our comments to outline a credible survival and recovery plan for SRKWs that does not include lower Snake River dam breaching. While Lower Snake River dam breaching by itself may not be enough to recover SRKWs, in our expert opinion, recovery of this population of whales is not achievable without lower Snake River dam breaching. In reaching its conclusion, the DEIS relies on the priority stock list (Priority List) developed by NOAA Fisheries and the Washington Department of Fish and Wildlife. That list, however, is not at odds with the conclusion that Columbia Basin salmon are one of the most important stocks for SRKWs. The Priority List ranks each stock in the SRKWs range, and six of the Priority Lists top ten stock groups originate in the Columbia Basin, including lower Columbia (fall), upper Columbia, Snake (fall), lower Columbia (spring), middle Columbia, and Snake River (spring/summer).45 Furthermore, as described in the Priority List document itself, a number of assumptions and caveats are incorporated in the model that give unwarranted preference to Puget Sound and Fraser River salmon stocks. First, the list of stocks and prioritization reflects the observed diet of prey-limited, endangered SRKWs.46 Second, the priority stock report states that there was no spatial correction factor for sample collection (stocks originating from near the sample locations are more likely to be collected), and, no correction factor for abundance (more abundant stocks are more likely to be identified in the diet).47 Sampling effort in Puget Sound and other inland waters of Washington State is much greater than on the outer coast due to logistical constraints for researchers.48 Another major flaw in this analysis is that it does not take into account restoration potential of these stocks, and so currently depleted stocks are underrepresented. The DEIS recognizes that under MO3 prey should increase beyond [the No Action Alternative] over the long term, and that this could change SRKW foraging behavior both over the short and long term as whales react to changes in prey availability.49 This is an important recognition that the SRKWs are responsive to changing Chinook salmon availability, and that they would indeed be likely to adapt their foraging behavior to benefit from any increase in Columbia River Basin stocks. The Columbia River Basin is a critical source of salmon for this prey limited species, and an increase in overall abundance of salmon from the largest river system in the whales range 44 Columbia River System Operations DEIS at 3-758. 45 NOAA Fisheries West Coast Region and WDFW (June 2018) Southern Resident Killer Whale Priority Chinook Stocks Report. 				Operations DEIS at 3-759. April 13, 2020 10 would have a major impact on SRKWs. NOAAs own recovery plan for SRKWs states, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin.50	
6879	6	N/A	N/A	The DEIS acknowledges that the Action Agencies Preferred Alternative would result in only a minor change in prey availability in comparison to current conditions (i.e the No Action Alternative); however, the DEIS concludes that this would have only a negligible effect on SRKWs.51 This is contrary to the science and NOAA Fisheries own findings and conclusions in other studies and reports, which consistently recognize the SRKWs as among the most at risk of extinction unless immediate action to increase prey availability is taken.52 In our expert opinion, if there is only a minor change in prey availability for the SRKWs from the largest river system in their range, the SRKWs will continue to decline and ultimately go extinct.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.
6880	1	Whitney Neugebauer	Whale Scout	The DEIS Does Not Deliver the Holistic Solution Needed to Recover Wildlife and Support Rural Economies. Our organizations share the belief that the lower Snake River can be restored in a way that benefits everyone. To ensure the sustainable recovery of salmon and other endangered wildlife, the four lower Snake River dams must be breached. The services the dams provide, though, can and should be replaced. Through strategic planning and investments, state and federal governments can build the infrastructure needed to replace the services provided by these dams, including energy production7, transportation of agricultural goods, and irrigation.8 Making these investments now will decrease local communities reliance on these dams, allowing our region to more quickly and easily transition to operating without them. Breaching the lower Snake River dams is critical to recovering wild salmon and steelhead in the Snake River basin. Rebuilding Snake River salmon runs will greatly benefit endangered Southern Resident orcas, support coastal and inland fishing businesses, and sustain the many tribes who, under various treaties, have reserved their right to harvest healthy and abundant salmon runs as they have since time immemorial. The Action Agencies evaluated breaching these four dams under Multiple Objective Alternative 3 in the DEIS. However, while the Action Agencies looked at some of the transition investments needed to accompany dam breaching, their assessment was narrowly focused, overestimated transition costs, and ignored key findings in energy sector expert reports.9 The Action Agencies Preferred Alternative does not provide the holistic plan that the region needs. Essentially, the Preferred Alternative is a continuation of the flexible spill agreement already agreed to for 2020 and 2021 by the states of Washington and Oregon, the Nez Perce Tribe, and BPA. At best, the business-as-usual approach of the Preferred Alternative will result in half as many salmon returning to the mouth of the Columbia as there would be under a dam breaching scenario, and this issue will likely compound each year.10 While increasing spill is an important short-term action for salmon, the only viable long-term solution is breaching the dams and restoring the lower Snake River. The Action Agencies have chosen a timid step when our region needs a bold, long-term, sustainable plan in which federal, state, and tribal agencies work together to solve these interlocking and complex issues. Many such solutions can be found through emerging conversations among stakeholders in the Pacific Northwest, including Governor Inslees Lower Snake River Stakeholder Process. Through these collaborative dialogues, stakeholders identified the types of investments needed to support local communities after the dams are breached.11 Restoring salmon runs by breaching the four lower Snake River dams is necessary to put Southern Resident orcas on the path towards survival, but to do this, we all need to work together. The Pacific Northwest does not have to choose between orcas and clean energy or between fishing and farming communities. The DEIS ignores these important realities and reinforces existing divisions within our region.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums. In areas where we have appropriate authority, we will continue to be strong regional partners.
6880	2	Whitney Neugebauer	Whale Scout	II. The DEIS Fails to Satisfy National Environmental Policy Act requirements. A. The National Environmental Policy Act. The National Environmental Policy Act (NEPA) requires that to the fullest extent possible all federal agencies must complete a comprehensive environmental impact statement in connection with actions that significantly affect the environment.12 In enacting NEPA, Congress recognized the profound impact of human activities, including resource exploitation, on the environment and declared a national policy to create and maintain conditions under which man and nature can exist in productive harmony. NEPA has two fundamental two goals: (1) to ensure that the agency will have detailed information on significant environmental impacts when it makes decisions; and (2) to guarantee that this information will be available to a larger audience. NEPA requires the Action Agencies to take a hard look at environmental consequences of their actions. To advance its clear policy objectives, NEPA establishes action-forcing procedures that require agencies to take a hard look at environmental consequences.15 A hard look requires a meaningful comparison of the environmental consequences of all alternatives, including the proposed alternative.16 A hard look does not allow the agency to take a soft touch or brush-off of negative effects.17, 18 To have taken the required hard look, the Action Agencies must utilize public comment and the best available scientific information.19 By focusing agency attention in this way, NEPA ensures that the agency will not act on incomplete information, only to regret its decision after it is too late to correct.20 (ii) NEPA requires the Action Agencies to assess all reasonable alternatives. The heart of NEPA analysis requires the Action Agencies to [r]igorously explore and objectively evaluate all reasonable alternatives to the proposed action and provide reasons for declining to comprehensively analyze any alternative which was eliminated from the analysis.21 While NEPA imposes no requirement to choose the least environmentally detrimental alternative for action, it does mandate that for each alternative, the agency must consider relative scientific findings on the likely environmental impacts. (iii) NEPA requires the Action Agencies to consider direct, indirect, and cumulative impacts of their actions. In analyzing the Preferred Alternative, no action alternative, and all other reasonable alternatives, the Action Agencies failed to properly consider the three types of impacts: direct, indirect, and cumulative.23 Direct effects are caused by the action and occur at the same time and place, while indirect effects are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable ... [and] may include growth inducing effects.24 Cumulative impacts include impacts on the environment resulting from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, by any person or agency, and impacts resulting from individually minor but collectively significant actions taking place over a period of time. The Action Agencies must respond to contrary opposing views and expert comments. The Action Agencies must satisfy NEPAs requirements to explain opposing viewpoints and their rationale for choosing one viewpoint over the other.26 When an informed objection to an agencys alternative(s) is presented, the Action Agencies have a duty to give a viable proposed alternative due consideration.27 A NEPA analysis is inadequate if it fails to disclose responsible scientific opposition to agency actions.28 Courts have set aside NEPA analyses where the Action Agencies failed to respond to scientific analysis that calls into question the agencys assumptions or conclusions.29 As an example, the Action Agencies must respond to opposing scientific viewpoints objectively and in good faith, including those of the governments own experts like the Fish Passage Center.	The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agencies' specific NEPA regulations. The EIS includes all required elements such as purpose and need for the action, alternatives, affected environment, and environmental consequences, necessary for an EIS as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1502.10. NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement of NEPA, after evaluating scoping comments from the public, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single objective alternatives, and then four MOs. The MOs were also determined to be more efficient and reasonable, as MOs were composed of combinations of measures from the single objective alternatives. The Draft EIS considered the environmental consequences of the range of alternatives and disclosed to the public those consequences. Section 3.1 presents the NEPA definitions of the types of impacts and assumption that effects analysis of each resource is based on current, high quality information relevant to the project area, and co-lead agency expertise. The analysis of cumulative impacts are presented in Chapter 6 and Chapter 7 for the Preferred Alternative. The Draft EIS presents opposing scientific information. For example, in Section 3.5 and Chapter 7, the fish results provide a range of effects from the NMFS Lifecycle Model and Fish Passage Center's Comparative Survival Study.
6880	3	Whitney Neugebauer	Whale Scout	B. The Action Agencies Failed to Take a Hard Look at the Direct Impacts on Columbia Basin Salmonids and Failed to Adequately Assess the Alternative of Breaching the Four Lower Snake River Dams. The CRSO has substantially affected the natural ecological structure and functionality of the Columbia River watershed.31 The Columbia River system is one of the largest in North America, with a drainage area of over a quarter million square miles.32 What was once an ecologically functional river system providing ecological goods and services for fish, wildlife, and humans has been transformed into a carefully regulated environment.33 Dam operations and alterations have resulted in the loss of once important spawning grounds and rearing habitat, and has significantly degraded migration corridors for salmon and steelhead populations.34 Many of our organizations provided the Action Agencies with citations to relevant peer-reviewed studies regarding Columbia and Snake River salmon restoration, and we provide those here again. (Appendix A). After decades of protection and management, most federally protected salmonid populations in the Columbia and Snake rivers remain in poor	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				condition and at high risk of extinction.35 Despite great efforts to restore these stocks, several evolutionary significant units (ESUs) still remain at high risk of extinction.36 Approximately 65% of the extant interior Columbia Basin ESUs are considered at high risk of extinction, ~29% are at a maintained risk of extinction (the second-highest risk category), only 4% are considered viable, and just 2.5% are considered highly viable.37 Although returns of some Chinook salmon populations have recently increased depending on good ocean conditions, these are mostly dominated by hatchery fish instead of wild fish.38 Extensive scientific papers and federal reports demonstrate that the CRSO has caused substantial harm and decreased the likelihood of survival and recovery of these threatened and endangered salmon and steelhead populations throughout the Columbia Basin.39 The National Marine Fisheries Service (NMFS) recognizes that dam presence and operations in the Basin directly and indirectly contribute to most of the mortality of juvenile and adult salmonids migrating through the system.40 Within the Columbia Basin, the annual abundance, population growth rate, and returns-per-spawner (e.g., smolt-to-adult returns) for most wild salmonid populations (i.e., not hatchery origin) are less than 1.0.41 This indicates that wild salmonid population abundance is declining, populations are not growing, and returns are decreasing generation after generation, even though hatchery-origin salmon production may be increasing. In fact, in the Columbia Basin, most salmonid population abundance is below the minimum viable abundance numbers estimated by the Interior Columbia Technical Recover Team.42 The longer a population remains at low abundance, the greater the likelihood of extinction from stochastic events, inbreeding, and environmental disturbance.43 At moderate and high risk of extinction, salmon and steelhead populations throughout the interior Columbia Basin can remain at relatively low numbers for decades without reaching recovery goals.44 Dam structures and operations substantially delay the recovery of salmonid species because they lead to several factors that reduce the likelihood of survival. Impacts from dam operations in the Snake and Columbia rivers that directly limit the survival and recovery of salmon and steelhead populations include, but are not limited to: juvenile mortality at mainstem hydro projects, physical passage barriers, reduced water flows that delay passage and lead to mortality, altered channel morphology, fallbacks, straying of adults and juveniles, drastic temperature fluctuations in both reservoirs and fish ladders.45 Indirect adverse impacts from dam operations include, but are not limited to: increase of infectious diseases due to lacerations during dam passage, increased predation by birds within reservoirs, increased predation by birds and marine mammals in estuarine areas, changes in water flows and temperature, decreased oxygen levels within reservoirs, delayed or latent mortality, and amplified climate change effects.46 For example, changes in stream flow and velocity associated with reservoirs affect salmon migration patterns in the Columbia Basin.47 Dam operations affect downstream habitat quality by increasing water temperatures, increasing metabolic demand of fishes, and inducing straying.48 Disease outbreaks are also associated with higher water temperatures.49 The Action Agencies have failed to adequately evaluate all reasonable alternatives to both reduce and offset these impacts associated with continued CRSO operations to avoid jeopardy on ESA-protected salmonids and maintain or restore essential habitat features that prevent adverse modification of critical habitat. The Action Agencies have failed in the DEIS to take the necessary hard look to evaluate all reasonable alternatives to both reduce and offset the impacts associated with continued dam operations to avoid jeopardy on ESA-protected species and maintain or restore essential habitat features that prevent adverse modification of critical habitat. More effective actions such as dam removal or modification of dam operations are necessary to eliminate the adverse modification of critical habitat for salmonids and to change the status quo. Indeed, scientific evidence shows that dam removal would provide the much-needed boost to salmon and eel populations, help the long-term restoration of riverine ecosystems, increase marine nutrients input from the ocean to freshwater habitat, and improve physical conditions within tributaries and mainstem habitat.50 The Action Agencies failed to fully assess the environmental benefits of dam removal in the EIS. Dam removal is becoming increasingly common as a management strategy for environmental restoration.51 In the Pacific Northwest, over a dozen dams have been already removed.52 Currently, four large dams on the Klamath River in California are scheduled for removal in 2022, showing that large dam removal projects are feasible.53 The EIS should analyze the potential ecosystem services of dam breaching, not only on salmonid recovery but also critical habitat of protected species. Restoring natural river flows and hydrodynamics, by removing dams and passage barriers, would likely benefit the ecological functioning of the entire river basin by increasing salmon survival, potentially increasing spawning areas, increasing salmon run numbers, and ultimately increasing nutrient supply to the interior basin.54 For example, Chinook salmon in the Rogue River spawned in newly deposited gravel just a few months after dam removal. A major benefit to removing impediments to water flow would be increased survival of smolts as well as increased passage for adult salmonids to historical spawning grounds.55 Dam removal would also increase flow volumes which decreases travel time of smolts and thus increases salmonid juvenile survivorship.56 In addition, flow restoration stabilizes water temperatures preventing drastic changes in water temperatures (increasing or declining) that are known to affect fish survival.57 Dam removal would also prevent fish concentration in certain areas that are easily predated by birds and marine mammals.58 Finally, dam removal may restore ecological important nutrient flows and sediment dynamics that are essential for ecosystem health and productivity. Scientific evidence has shown that dam removal provides several ecological and socioeconomic benefits as soon as one to three years.60 Beyond the direct positive effects that dam removals have on fish, aquatic organisms, and the species that depend on them for food, the entire watershed will benefit from increased vegetation, water flow, and biodiversity, and improved water quality.61 Cleaner water is valuable for agriculture, livestock, and human consumption. In addition, removal costs could be lower than the funds needed to maintain old infrastructure and the mitigation and restoration projects associated with the impacts of dam systems.62 The DEIS vastly underestimates both the CRSO impacts on salmonids and the value that removing the four lower Snake River dams would have on the species. What is clear is that the Preferred Alternative will not bring the Columbia Rivers treasured salmonids any closer to recovery. We expect the Action Agencies to fully and accurately assess the impacts of their status quo approach to managing the Columbia River System on salmon, including the scientific information cited to in this letter and included in Appendix A, and revisit the alternative of removing the four lower Snake River dams as the best first step towards sustainable salmon recovery.	The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6880	4	Whitney Neugebauer	Whale Scout	C. The Action Agencies Failed to Fully Consider Indirect Impacts to Southern Resident Orcas, Failed to Include the Best Available Scientific Information, and Failed to Address Contrary Viewpoints. The nations leading Southern Resident orca scientists and experts have unequivocally stated that if we do not breach the four lower Snake River dams, it may be impossible to prevent the extinction of the Southern Resident orcas.63 Extensive comment letters to the Action Agencies during the February 2017 NEPA scoping period focused on the connection between Columbia Basin salmon and Southern Resident orcas.64 Many of our organizations provided the Action Agencies with a detailed bibliography of peer-reviewed studies that highlight the importance of restoring Snake River salmon to recover Southern Resident orcas, and we provide one here again in Appendix B. Despite the extensive scientific information provided to the Action Agencies, the DEIS has only two paragraphs dedicated to Southern Resident orcas.65 Without any citations, the DEIS boldly claims that, [t]he food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whales foraging behavior patterns slightly but will not change their overall condition or population dynamics.66 Under this assumption, the DEIS falsely concludes that any increase in salmon (under any alternative) would provide only a negligible or minor benefit to the Southern Residents.67 This statement is flatly inaccurate for several reasons. First, Snake River salmon, both currently and historically, are important food sources for Southern Resident orcas. Like many predators, Southern Resident orcas travel long distances in search of their prey. Data from satellite-tagged orcas show that all three pods spend time foraging for salmon off the west coast in the spring and winter.68 During this time, the Southern Residents spend a considerable amount of time at the mouth of the Columbia River foraging for salmon as they return to spawn in the Columbia Basin, including the Snake River and its tributaries.69 Using this information, NMFS and the Washington Department of Fish and Wildlife assessed the relative importance of various salmon runs to the Southern Residents. That analysis identified Snake River Chinook salmon runs as two of the top ten most important salmon stocks to the orcas in their current diet.70 Historically, the importance of these stocks was likely much higher given that there were significantly more Snake River salmon prior to dam construction.71 Before the lower Snake River dams were built, half of all salmon returning to the Columbia Basin were bound for spawning grounds in the Snake River and its tributaries.72 At that time, the Washington Department of Fisheries warned in its 1949 annual report that the dams could have lasting impacts on salmon and the local economy: Another serious threat to the Columbia river fishery is the proposed construction by the U.S. Army Engineers of Ice Harbor and three other dams on the lower Snake river between Pasco, Wash. and Lewiston, Idaho to provide slackwater navigation and a relatively minor block of power. The development would remove part of the cost of waterborne shipping from the shipper and place it on the taxpayer, jeopardizing more than one-half of the Columbia River salmon production in exchange for 148 miles of subsidized barge route. The transportation saving to the shipper would amount to $2,000,000 annually, while salmon runs having a wholesale value of about $9,000,000 would be threatened with destruction. Second, wild Snake River Chinook salmon are particularly important to orcas due to their size and fat content. While salmon spend their adult years in the Pacific Ocean, they build up enough fat and energy to propel them from the ocean to their inland spawning grounds.74 Once adult salmon enter the river and begin the journey to their native spawning grounds, they do not eat.75 Snake River salmon have one of the longest spawning migrations in the Pacific Northwest, traveling from the ocean to rivers and streams in central Idaho and northeast Oregon.76 Because of this, Snake River salmon tend to require more nutrients stored in their	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.

				fat than other salmon, making them especially important to orcas.77 Third, Southern Resident orca recovery will require state, federal, and tribal governments to protect and rebuild salmon runs throughout the Southern Resident orcas range, which includes the mouth of the Columbia River where orcas forage during late winter and early spring.78 The DEIS myopically argues that salmon recovery efforts should be focused in the Salish Sea.79 The consequences of neglecting other foraging areas would divert resources to just half of the orcas annual range. The Southern Residents typically spend summer and fall in the Salish Sea (which includes Puget Sound) foraging for salmon returning to local rivers from June through November. In the winter, the orcas typically head out into the Pacific Ocean, foraging for salmon as far south as Monterey Bay, California.80 During this time, images from aerial photogrammetry typically document a decline in the orcas body condition.81 Reproductive-age females showed some of the greatest signs of nutritional stress during this time, and as a result, over two-thirds of Southern Resident orca pregnancies are terminated prematurely (including many dangerous late-term miscarriages) because of nutritional stress.82 If salmon recovery efforts were solely focused in the Salish Sea, as the Action Agencies suggest, orcas would not have sufficient food during the time of year they need it most. Fourth, restoring the lower Snake River will provide more salmon to Southern Resident orcas than almost any other salmon recovery project being considered. In the 2008 Recovery Plan for the Southern Resident Orcas, NMFS stated that [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. In that same plan, NMFS went on to state that the Columbia-Snake River Basin, by orders of magnitude, has the largest potential for increasing Chinook salmon abundance throughout the Southern Residents range.83 Additionally, because Snake River salmon spawn in high alpine, federally protected Wilderness areas, these runs are more insulated from the impacts of climate change and development, providing orcas with both a large and more reliable source of food into the future.84 According to the Fish Passage Center, breaching all four lower Snake River dams and increasing spill on the lower Columbia dams would result in roughly 1 million adult Chinook salmon returning to the mouth of the Columbia River annually.85 By removing these dams, we can also increase salmon access to roughly 5,500 miles of free-flowing spawning habitat in Central Idaho and northeast Oregon, much of which is both climate-resilient and federally protected.86 For all of these reasons, the future of Snake River salmon is of the utmost importance to the future of the Southern Resident orcas. Many of these points and studies have already been provided to the Action Agencies, and yet the DEIS did not mention any of them. We expect the Action Agencies to fully and accurately consider the impacts of the status quo approach to managing the Columbia River System on Southern Resident orcas, including the scientific information cited in this comment letter, those listed below in Appendix B, and in the two documents submitted with this letter as attachments: Attachment A Salmon and Orca Scientist White Paper and Attachment B Chapter 2 of the Fish Passage Centers 2019 Comparative Survival Study (CSS) Report.	
6880	5	Whitney Neugebauer	Whale Scout	D. The Action Agencies Failed to Fully Assess the Cumulative Impacts of Climate Change on Salmon and Failed to Include the Best Scientific Information on Climate Change Impacts. In the DEIS, the Action Agencies failed to fully assess the impacts of climate change on reservoir temperatures and what that would mean for salmon survival. Anthropogenic climate change is one of the greatest threats to wildlife both globally and locally. On the lower Snake River, water temperatures in the large, slackwater reservoirs created by the four dams increase every year, posing increasing risks to salmon.87 These lethal temperatures kill both adult and juvenile salmon and at the same time benefit invasive, salmon-eating fish found throughout these reservoirs. First, the DEIS does not provide any information about the efficacy of current efforts to mitigate the effects of lethal water temperatures on salmon. While the DEIS mentions the currently utilized option of releasing cool water from the Dworshak Dam into the Snake River, it does not discuss how effective that strategy has been or how effective it is likely to be given ever increasing temperatures.89 Over the last several years, Columbia and Snake River temperatures have exceeded 20 degrees Celsius (68 degrees Fahrenheit).90 At this temperature, salmon have difficulty migrating upstream, and mortality from stress and disease increases.91 The Fish Passage Center has stated that, under a climate change scenario, the long-recognized and largely unaddressed problem of high water temperatures in the [Columbia and Snake Rivers] becomes an ever-increasing threat to the survival of salmon.92 It is critical for the Action Agencies to assess the efficacy of current water temperature cooling measures, particularly into the future, in order to evaluate mitigation strategies under all alternatives in the DEIS. Second, the DEIS does not rely on appropriate models to predict climate change impacts on water temperatures and salmon. The model used as part of the water quality assessment provided in Appendix D of the DEIS looked at water temperatures over a 5-year period from 2011 to 2015. This model does not predict how climate change will further impact temperatures in either an impounded or free-flowing river.93 The DEIS also used a model developed by the River Management Joint Operating Committee (RMJOC), but, as the DEIS notes, the full RMJOC assessment of climate change is not complete: A second part of the RMJOC-II study, which is not yet available, will provide an assessment of how these projected unregulated streamflows perform in a regulated Columbia River system.94 The DEIS also states that this climate model does not include predicted water temperatures.95 These two models fail to accurately assess of how climate change will increase water temperatures in reservoirs and, thus, how that will impact salmon survival. This is particularly timely given that water temperature in these reservoirs are the subject of yet another lawsuit against the federal government for mismanagement of the river and its wildlife. In December 2019, the Ninth Circuit Court of Appeals ruled that under the Clean Water Act, 33 U.S.C. 1313(d)(2), the Environmental Protection Agency has an immediate duty to set a Total Maximum Daily Limits (TMDLs) for water temperature in the Columbia and Snake Rivers because the states of Washington and Oregon have conclusively refused to do so.96 Recently, the court denied the agencys request for an en banc and panel rehearing of this issue, so the ruling stands.97 Independent research and computer modeling suggest that even with elevated air temperatures, a free-flowing Snake River will be more resilient to climate change and water temperatures will be significantly lower than they would be in a dammed river.98 Additional modeling by the Environmental Protection Agency demonstrates that the presence of multiple dams on the Columbia and Snake Rivers has warmed the rivers to unsafe levels for salmon.99 Despite this, the DEIS claims that climate change impacts will be the same on the lower Snake River regardless of if dams are breached or not.100 This may be because the models cited in the DEIS did not examine water temperatures when considering the long-term climate change impacts. We strongly urge the Action Agencies to rectify this glaring error and update its analyses by including these other models. The Action Agencies must also assess the impacts that increasing reservoir water temperatures will have on predation of juvenile salmon by invasive, non-native fish. Several studies have indicated that predation from these invasive species is a major and potentially limiting factor for salmon recovery in the Columbia Basin.101 The DEIS notes that dams have altered habitat in a way that generally favors non-native and invasive species at the expense of native species.102 Further, the DEIS states that most of the invasive species are warm water fish while native species are cold water adapted.103 It goes on to state that warmer water temperatures increase the predation rate of invasive fish on salmonids.104 However, this analysis stops too short. Later in the DEIS, the Action Agencies claim that a free-flowing Snake River may increase the presence of many invasive salmon predators, contradicting their earlier point. 105 As stated above, dam breaching is expected to significantly reduce overall in-stream water temperatures, which will make the habitat less suitable to invasive, warm-water adapted species. Many of these invasive species are also adapted to slackwater environments like lakes and ponds, which are typically warmer than free-flowing rivers. In the 2017 Recovery Plan for Snake River Spring/Summer Chinook Salmon and Steelhead, NMFS stated, when discussing dam breaching, that, It is likely that the return to a more riverine system in this portion of the Snake River could reduce salmon predation losses to native and non-native invasive fishes that have taken advantage of the reservoir habitat, such as northern pikeminnow and walleye. Migrating smolts would be less exposed due to decreased travel times through the lower Snake River.106 The EIS must integrate these findings. Breaching the four lower Snake River dams would not only decrease salmon migration time, it would also decrease lethal water temperatures and invasive predators. The Action Agencies should recognize these added benefits to salmon survival when assessing the alternative of dam breaching in the EIS.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology would affect reservoir operations in the Columbia Basin is still under development and was not available for use in the EIS. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied, available at the resolution required (river-scale and global- or regional-scale) and validated for use with climate affected regulated flow projections of large reservoir systems. This information is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitatively assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS. Climate effects were considered a Reasonable Foreseeable Future Action (RFFA19) in both Chapters 6 and 7. The analysis in Section 3.4 for MO1 analyzed changes to Dworshak releases. Due to the effects analysis in Section 3.4, the co-lead agencies did not carry forward this measure from MO1 into the Preferred Alternative. Future analysis of Dworshak releases would be speculative at this time, and was not included in this EIS.
6880	6	Whitney Neugebauer	Whale Scout	E. The DEIS Mischaracterizes the Impacts of Dam Breaching on Other Wildlife. The Action Agencies did not sufficiently analyze all alternatives because they did not present a complete or accurate characterization of the various actions and potential direct, indirect, or cumulative impacts they may have, such as impacts on other wildlife. As written, the DEIS conveys much more optimism for maintaining the status quo than any of the alternatives, particularly dam breaching. The Action Agencies must provide additional information, context, and analysis to help guide decision making. While the DEIS lists actions the Action Agencies have taken to support ESA-listed fish, it does not provide any information about the effectiveness of these projects or programs.107 While the amount of money committed to fund these projects is impressive, it is unclear how successful these actions have been, particularly given that none of the ESA-listed salmon in the Columbia Basin have been recovered.108 Given the limited time and resources available, it is important for the Action Agencies to assess their current efforts to demonstrate that these investments are making timely and meaningful strides towards recovery. In particular, the Action Agencies should provide information about the degree to which habitat restoration and predator removal efforts have contributed to salmon recovery and returns. Additionally, the Action Agencies must report their success in a way that puts it in the context of Basin-wide salmon recovery. One of the most important data points for salmon recovery is the smolt-to-adult ratio (SAR): the number of adults that return to spawn for every smolt that hatches.109 SARs are used by managers to assess the progress of salmon runs towards recovery goals.110 Current SARs for spring/summer Chinook salmon are estimated to be around 1%.111 The Northwest Power and Conservation Council has stated that 2% SARs	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. It should be noted that the average SAR targets referenced in this comment refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. The Elwha dam in Washington State, however has little relevance to the lower Snake River dams. The Elwha dam had no fish passage and provided no economic benefits. In contrast, the four lower Snake River dams provide upstream and downstream fish passage, produce power, and provide navigation and recreation opportunities. For power, the four lower Snake River dams produce upwards of 1,000 aMW of power, which is approximately 12 percent of the average power produced by the FCRPS. See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 800,000 homes in the Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effect, at 9-935. The four lower Snake River dams would still have regulated flows due to the dams located upstream. The analysis of the impacts to vegetation and wildlife from the alternatives is provided in Section 3.6 and Section 7.7.7 for the Preferred Alternative. MO3, the alternative that includes the measure to breach the lower Snake River dams, was analyzed in 3.6.3.5. In summary, riparian vegetation would die at its current location as the water elevation lowers and invasive species may colonize newly exposed shoreline. To offset these effects, mitigation proposed would be to replant approximately 13,000 acres of arid, upland native vegetation on newly exposed soils and approximately 1,500 acres of emergent and forested, scrub-shrub wetland habitat adjacent to the new surface elevations of the lower Snake River.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				are needed to maintain current populations, while 4-6% is needed for recovery.112 Rather than relying on this metric, the Action Agencies instead use misleading data points without putting them in the appropriate context. For example, when discussing juvenile passage over the dams, the DEIS reports juvenile survival rates and migration times.113 While these numbers are indeed important to consider, viewing them in isolation paints a more optimistic narrative for salmon than the reality. These numbers only provide the percentage of fish that survive going from the forebay of a dam to its tailrace. While these survival rates seem high, these percentages do not account for deaths that occur between dams in reservoirs either from latent mortality or from predation. Models from the Fish Passage Center suggest that only 54% of juvenile salmon spawning from above Lower Granite Dam survive the journey over Bonneville Dam.114 The Action Agencies frequently state that hatchery operations, which currently produce 85% of Chinook salmon smolts in the region, would be shuttered if the lower Snake River dams were breached.115 Should this happen, the Action Agencies claim that any potential gains from river restoration would be lost or greatly reduced.116 However, while the Action Agencies would no longer be required to mitigate the impact of these dams, hatchery production would not necessarily need to halt immediately.117 The Action Agencies are presenting the public with a false choice. The Action Agencies analysis of the environmental impacts of dam breaching largely assumes that the only necessary management activity to occur would be the removal of the four earthen berms, and that the environment would be left to respond on its own. For example, the DEIS focuses on increased sedimentation and invasive plant colonization that would follow dam breaching.118 Dam breaching, though, presents an opportunity for active riparian and in-river habitat restoration, such as dredging contaminated soils behind the dams, planting trees and native shrubs in newly exposed areas, removing invasive species, and excavating areas for wetlands. The Action Agencies propose actions like these to mitigate potential impacts at the confluence of the Columbia and Snake Rivers, yet they fail to propose similar steps for newly exposed habitat along the Snake River due to dam breaching.119 The DEIS also emphasizes the negative impacts of dam breaching on local wildlife populations in the short term, only briefly mentioning the long-term benefits to species.120 Dam breaching will significantly alter the landscape by restoring the Snake River to its original state. Through active restoration, riparian forests and wetlands can recover relatively quickly. Riparian corridors are also one of the most important habitat types for many wildlife species, and while many species will be disturbed in the short-term by dam breaching activities, it is most likely that native wildlife throughout the region will greatly benefit from a restored, free-flowing Snake River. For instance, following dam removal on the Elwha River in Olympic National Parks, biologists found 1,741 spawning adult Chinook on the river, 75% of which were spawning above the recently removed lower dam.121 Following extensive dam removal on the Rouge River (which began in 2008), fall Chinook populations doubled every year from 2015 2018, despite severe droughts, El Nino, and other environmental factors that usually decrease salmon returns.122 We encourage the Action Agencies to provide a more robust and appropriately balanced assessment of the long-term benefits a free-flowing river would provide to local wildlife.	The co-lead agencies note the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. In addition, the co-lead agencies did not propose any restoration efforts under MO3 as part of the Alternative development. Therefore, the area may colonize with invasive species as described in the alternative.
6880	7	Whitney Neugebauer	Whale Scout	III. The Action Agencies Must Also Consult with NMFS to Ensure that Their Actions Do Not Jeopardize Listed Species or Adversely Modify Critical Habitat. Under the Endangered Species Act, 16 U.S.C. 1531 et seq.(ESA), federal agencies may not take an action if it is likely to result in harm to listed species or affect critical habitat. The ESA aims to conserve species of fish, wildlife, and plants facing extinction as well as the ecosystems upon which endangered and threatened species depend.123 The ESA defines critical habitat as the physical and biological features that are essential to the conservation of listed species.124 For example, in the Columbia Basin, migratory corridors are considered critical habitat defined by several primary constituent elements such as water temperature, water quantity, water quality, and safe passage.125 The ESA also requires each agency to use the best scientific and commercial data available.126 The Action Agencies must consult with NMFS on any actions that may directly or indirectly affect ESA-listed species and their critical habitat, which includes actions related to the CRSO.127 Specifically, section 7 requires that the Action Agencies insure that any action authorized, funded, or carried out by such agency . . . is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designed critical habitat.128 To jeopardize the continued existence of a species means to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species.129 NEPAs implementing regulations require that, to the fullest extent possible, agencies must prepare draft environmental impact statements concurrently with and integrated with environmental impact analyses and related surveys and studies that the ESA requires.130 Along with the other alternatives analyzed in the DEIS, the Preferred Alternative certainly may affect several ESA-listed species, including salmon and orcas, as well as the critical habitat for these species, triggering the ESAs requirements. The Action Agencies operation and maintenance of the CRSO directly impacts about 13 runs of salmon ESUs and steelhead distinct population segments (DPSs) listed under the ESA within the Columbia-Snake watershed. ESA-protected salmon and steelhead species that the Preferred Alternative will affect include: 1) Snake River fall Chinook salmon; 2) Snake River spring/summer Chinook salmon; 3) Snake River steelhead (Oncorhynchus mykiss); 4) Upper Columbia River spring Chinook salmon; 5) Upper Columbia River steelhead; 6) Middle Columbia River steelhead; 7) Snake River sockeye salmon (Oncorhynchus nerka); 8) Columbia River chum salmon (Oncorhynchus keta); 9) Lower Columbia River Chinook salmon; 10) Lower Columbia River coho salmon (Oncorhynchus kisutch); 11) Lower Columbia River steelhead; 12) Upper Willamette River Chinook salmon; and 13) Upper Willamette River steelhead.131 NMFS has designated critical habitat for 12 of these 13 salmonid species.132 In addition, the CRSO indirectly impacts the endangered Southern Resident orca DPS that depend on the Basins salmon populations as a vital prey source.133 Along with the other alternatives analyzed in the DEIS, the Preferred Alternative may affect several ESA-listed species both directly and indirectly, including salmon, steelhead, and Southern Resident orcas, triggering the requirements of the ESA. Because the CRSO may affect ESA-listed species and their critical habitat, the Action Agencies must consult with NMFS on the Preferred Alternative. After consultation, investigation, and analysis, NMFS must prepare a new biological opinion to evaluate the effects of the proposed actions on the survival and recovery of listed species and designated critical habitat. Under the ESA, recovery means improvement in the status of listed species to the point at which listing is no longer appropriate.134 NMFSs biological opinion should include a summary of the science-based information upon which the opinion is based, an analysis of the effects of the agency actions on listed species and critical habitat, and whether the actions are likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat135 If NMFS determines that the Preferred Alternative may jeopardize the survival of ESA-listed species or adversely modify a species critical habitat, the action must be modified or eliminated. Therefore, NMFSs biological opinion must specify all reasonable and prudent alternatives that avoid jeopardy and make recommendations that promote the conservation of the listed species or species critical habitat.136	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat and are included as an appendix to the EIS.
6880	8	Whitney Neugebauer	Whale Scout	Generally, the DEIS is poorly written and organized. Finding information is difficult, and it is not communicated clearly. It also contains several contradictions and grammatical errors. We expect the Action Agencies to thoroughly edit this document and organize it in a more sensible and accessible way before publishing the Final EIS.	The co-lead agencies analyzed the integrated operation, maintenance, and configuration of the 14 projects that comprise the CRS. Because the CRS has a broad geographic reach, is subject to numerous legal mandates, and implicates numerous complicated and contested subjects, the analysis is necessarily lengthy. The intent of the Executive Summary is to serve as a primer and broad summary of findings. The Final EIS will expand the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices.
6880	9	Whitney Neugebauer	Whale Scout	Additionally, the DEIS contains several inaccurate statements regarding grizzly bears (Ursus arctos horribilis).137 We are providing corrections to those statements and the relevant supporting science here: 1. The current Bitterroot population is not an experimental population. A 10J rule was approved for the Bitterroot Ecosystem, but it was never implemented. Only bears that are physically moved by wildlife managers into the ecosystem would be considered part of this experimental population. To date, no bears have been physically moved by wildlife managers into the ecosystem. The bears living in the Bitterroot Ecosystem today immigrated there on their own. These bears are fully protected as a threatened species under the ESA. 2. The size of the current grizzly bear population in the North Cascades Ecosystem is largely unknown but is typically estimated to be lower than 20 bears.139 3. The DEIS left out the Selkirk population of grizzly bears in northeast Washington, directly west of the Cabinet-Yaak Ecosystem. The Selkirk Ecosystem is estimated to have around 80 grizzly bears. This ecosystem is well within the boundaries of the CRSO analysis.	The final EIS reflects the correct listing status for grizzly bear in the Bitterroot recovery area. The Selkirk Mountains Ecosystem (SE) is located in northern Idaho, northeastern Washington, and southeast British Columbia and has an estimated 80 grizzly bears. It is located between the Kootenai River on the east and the Pend Oreille River to the west. While the boundaries of the SE come very close to the Vegetation, Wetlands, Wildlife, and Floodplains study area, the two do not overlap. Therefore, it was not described in the EIS. However, effects to grizzly bear by CRS regions were described in Section 3.6.3 and 7.7.8, regardless of whether effects overlapped with a ecosystem recovery zone.
6880	10	Whitney Neugebauer	Whale Scout	Finally, section 3.16, Cultural Resources, is not written in a culturally sensitive way. For example, a single paragraph describes all Native American cultures and history in the CRSO area from 2000 B.C. to 1720 A.D.141 This vastly oversimplifies the diversity of tribes and First Nations who have lived in the region since time immemorial. When discussing Christian missionaries, the Action Agencies only acknowledge the role missionaries played in spreading diseases that decimated many Native American communities, but the agencies should also recognize that many missionaries instituted racist systems of violence and oppression (like Indian Schools) that stole children from their families and stripped them of their cultures and languages.142 Throughout this section, the Action Agencies emphasize potential risks to cultural resources and minimize the benefits.143 We recommend that the Action Agencies consult with local tribal governments and officials in order to rewrite this section to more accurately describe the history of Native Americans in the region and the impacts dam breaching would have on their cultural resources and reserved treaty rights.	In Section 3.16, the co-lead agencies have adequately identified the historic context for which to conduct the comparative impact analysis from all of the action alternatives on cultural resources. Additional details about historical events in the Northwest would not have assisted in the comparative analysis between the No Action Alternative and the action alternatives. Content was provided to the co-lead agencies by several Tribes and is incorporated in both Section 3.17 and in other specific locations throughout the document. Some of these locations include 3.17.2 (Tribal perspective summaries), 3.17.2.2 (general overview, including documenting impacts to Tribal culture), and Appendix P (Tribal Perspectives). The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS.
6880	11	Whitney Neugebauer	Whale Scout	V. Public Engagement Was Severely Curtailed and Has Not Been Meaningful. The Action Agencies failed to provide adequate or meaningful opportunities for the public to comment on the DEIS. It is extremely disingenuous that the public was given only 45 days, the regulatory bare minimum, to provide comments on a document that is almost 8,000 pages long and covers an array of complex issues throughout the region. The Action Agencies provided no justification for shortening the timeline, which was originally scheduled for 120 days.144 Members of Congress and many of our organizations have requested that the Action Agencies extend the public comment period back to its original 120-day timeline. Moreover, many	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				individuals across the region have also been responding to the global public health crisis caused by the spread of COVID-19, leaving the public with even less time to fully or fairly review the DEIS. We strongly recommend that the Action Agencies either extend the public comment period to at least 120 days or provide a supplemental public comment period after the COVID-19 crisis has subsided. A supplemental public comment period was recently provided to solicit additional comments on the North Cascades Grizzly Bear Environmental Impact Statement. Recently, the state Department of Ecology cited the COVID-19 pandemic to justify extending the public comment period for the state environmental review of a proposed dam on the Chehalis River from April 27 to May 27.146 Both of these projects have a much narrower scope and impacts a smaller geography than the CRSO DEIS. It is not unreasonable, especially in light of the current public health crisis, that the Action Agencies would provide additional opportunities for public comment and engagement.	
6881	1	Fred Heutte	NW Energy Coalition	Effects of DEIS Alternatives for ESA Listed Species The DEIS analysis clearly shows that MO3 results in the most improvement for Lower Snake salmon and steelhead compared to the No Active Alternative and the other Multiple Objective Alternatives (see Table 3-61 below). However, the Preferred Alternative did not incorporate the main elements of Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 6 MO3. Instead, the Preferred Alternative chose an approach with allegedly lower net power costs but only a small net benefit for fish. DEIS Chapter 3, Table 3-61 (emphasis supplied)	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waivers had to be changed to implement the new spill regime. The co-lead agencies used current high quality and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be in creasing salmon and steelhead returns to the Columbia Basin. This monitoring program will include substantial monitoring efforts to track the effects of dissolved gas levels on juvenile and adult fish. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6881	2	Fred Heutte	NW Energy Coalition	1.4 NWEC/ICL Scoping Comments The Joint Commenters review of the CRSO DEIS uses the scoping comments submitted on February 7, 2017 by the NW Energy Coalition and the Idaho Conservation League (NWEC/ICL Scoping Comments) as a basis to assess the Preferred Alternative and MO3 energy analysis. That submission is submitted along with these comments for reference. In the Scoping Comments, NWEC and ICL proposed that the CRSO EIS energy analysis be conducted in accordance with widely accepted practices for utility integrated resource planning (IRP), using a scenario assessment approach, a combination of advanced computer modeling tools and expert judgment to provide a fully optimized energy portfolio selected with respect to a least cost/least risk perspective. This combination of elements, based on longstanding principles and practices of IRP analysis, is needed to effectively assess programmatic alternatives for achieving the energy oriented outcomes defined for the CRSO EIS. The NWEC/ICL Scoping Comments provided the following summary of recommendations: Ongoing support by an independent technical review panel consisting of the Agencies and a broad range of stakeholders, as well as ongoing public input to assure the full range of information and experience can be provided to the assessment. 1 https://www.nww.usace.army.mil/Library/2002-LSR-Study/ Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 10 Evaluation of the current operations of the LSR dams within the context of the Columbia River System, the Northwest regional power system, and the Western Interconnection. Assessment and comparison of continued operation of the LSR dams and potential alternative resource portfolios that could better meet CRS responsibilities while minimizing or eliminating environmental impacts and meeting all federal statutory and regulatory requirements. Alternatives to be considered should include: (1) continued operation of the LSR dams (no action alternative); (2) reduced operation of the LSR dams to provide additional spill for fish passage, including a resource portfolio of replacement energy resources; (3) full replacement of the LSR dams with a range of potential resource alternatives. Consideration of the full range of electric services provided by the LSR dams and alternative portfolios energy, capacity, flexibility and reliability from the perspective of electric system requirements, not merely the potential output of an electric resource, as well as their environmental costs and benefits. Utilization of transparent, consistent and commonly accepted methods, inputs, metrics and analysis. Consideration of future system conditions through a scenario assessment framework, to assess potential changes in energy demand, resource availability and cost, economic trends, energy policy, climate change and other key factors. Consideration of ongoing changes and improvements to the Columbia River System, Northwest power system and Western Interconnection. Balancing the costs of all alternative actions against the risks inherent in any forward looking assessment, including environmental costs and benefits. NWEC/ICL Scoping Comments at 2-3 First, the NWEC/ICL Scoping Comments proposed that the energy assessment be conducted with assistance from a technical review team, similar to the Hydropower Impact Team that assisted with the 2002 LSR EIS.2 That team included 16 subject matter experts from the US Army Corps of Engineers, 2 Lower Snake River Juvenile Fish Mitigation Feasibility Study: Technical Report on Hydropower Costs and Benefits, Drawdown Regional Economic Workgroup: Hydropower Impact Team, March 1999, https://www.nww.usace.army.mil/portals/28/docs/environmental/drew/powerdoc.pdf Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 11 the Bonneville Power Administration, other federal agencies, the Northwest Power and Conservation Council, utilities, industry representative and the NW Energy Coalition. Such a technical review had proven its worth for the 2002 LSR EIS and could assist in defining the methods and reviewing the results of the DEIS energy assessment to consider alternative federal actions to comply with NEPA and ESA requirements in a complex and fast-changing CRS and regional electric power system context. And as further explained below, utility integrated resource planning (IRP) generally includes a stakeholder technical review process to provide guidance, concepts and data for the planning process. Second, a key element of comprehensive energy analysis is the consideration of a wide range of alternative resource options and future scenarios of supply, demand and system conditions. As stated in the NWEC/ICL Scoping Comments: Considering a range of alternatives to the proposed action is the heart of the environmental impact statement and the action agencies must rigorously explore and objectively evaluate all reasonable alternatives. 40 C.F.R 1502.14. This evaluation must be based on accurate scientific analysis, expert agency comments, and public scrutiny. 40 C.F.R. 1500.1(b). Moreover, Agencies shall insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements. 40 C.F.R. 1502.24. NWEC/ICL Scoping Comments at 5 As the NWEC/ICL Scoping Comments observed, substantial changes have occurred within the Columbia River System and the electric power system of the Pacific Northwest and Western Interconnection in the two decades since the bulk of the energy analysis for the 2002 EIS was conducted in 1997-99. As discussed below, the DEIS fails to fully consider the effects these changes and others with direct bearing on the CRS, and hence fails to provide the public and decision-makers with relevant and important information to make an informed choice among the alternatives presented in the DEIS. This is a significant failure.	Referred to Power team (B. Koehler, May 7, 2020)
6881	3	Fred Heutte	NW Energy Coalition	2.1 Deficiencies of the DEIS Replacement Power Analysis The DEIS energy analysis was conducted according to a multi-step process described in DEIS Appendix H, Section 1.1, Framework for the Analysis. The figure above indicates the basic analysis stages. The focus of these comments is primarily on Step 3, Need for Replacement Power Resources and Cost of Resources, referred to below as the Replacement Power Analysis. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 14 Because the outcome of Step 3 directly shapes the results achieved in the first stage of Step 5, Wholesale Power Rate Analysis and Market Effects, and Step 6, Socioeconomic Implications of Electricity Rate Changes, the inaccurate and insufficient analysis in the Replacement Power Analysis renders the conclusion of the DEIS energy analysis on wholesale power rates and consumer bill impacts equally inaccurate and insufficient. The Replacement Power Analysis is the pivotal component of the DEIS energy analysis. This stage of the framework is essential for: (1) fully and accurately estimating the energy system value of the CRS and particularly the hydrogeneration of the four Lower Snake River project; and (2) fully and accurately assessing options for need, cost and performance of replacement power under the Preferred Alternative and four Multiple Objective Alternatives. As recommended in the NWEC/ICL Scoping Comments and further explained below, an integrated resource planning (IRP) process is the established and longstanding method for this type of comprehensive assessment, as conducted by the Northwest Power and Conservation Council and the regions electric utilities. The Oregon Public Utility Commission summarized its guidelines for IRP analysis as follows: Consistent with our guidelines, a utility's IRP must include the following key components: Identification of capacity and energy needs to bridge the gap between expected loads and resources Identification and estimated costs of all supply-side and demand-side resource options Construction of a representative set of resource portfolios Evaluation of the performance of the candidate portfolios over the range of identified risks and uncertainties Selection of a portfolio that represents the best combination of cost and risk for the utility and its customers. Oregon Public Utility Commission, Order No. 17-386, October 9, 2017 Below, we review the generally accepted process and the foundational elements for IRP analysis. We compare that approach with the specific steps, data inputs, modeling constraints and other factors Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 15 employed in the DEIS Replacement Power Analysis, and describe how the DEIS fails to achieve the provide a complete, accurate and rational DEIS energy analysis.	The steps of the EIS power analysis are consistent with the description in the comment. Within the power analysis, the EIS replacement power analysis also follows many of the steps described in the comment, including identifying the capacity and energy needs to ensure regional power reliability; constructing portfolios of resources; and evaluating the performance of the portfolios. In selecting replacement resource portfolios, the EIS evaluated a variety of factors to determine the least-cost resource including how the resource affected costs related to regional imports, exports, fuel use and capital costs for the actual resource. These costs were then divided by the reliability benefit to determine the cost effectiveness. The Northwest Power and Conservation Councils GENESYS model was used to evaluate reliability effects and cost-effectiveness. It is important to note that the CRSO EIS examines a variety of resources, not solely power. The replacement resource analysis and assumptions are further described in Chapter 2 of Appendix H in the draft EIS. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. The commenter suggests or questions why a competitive resource review, also known as an integrated resource plan (IRP), was not performed as part of the EIS analysis. An IRP is a resource planning tool that utilities use to plan for future resource builds and acquisitions to fulfill the utility's specific needs over a certain planning horizon, typically 20 years. Some utilities are required to conduct an IRP by their local or state utility commissions. Bonneville is not required to perform an IRP, but does perform resource planning to inform its decisions, including for this EIS. There are many different methods and tools that are used by utilities when performing an IRP. Furthermore, the output of an IRP is often driven by state energy policies, such as carbon emission requirements. Even if an IRP optimizes resource portfolios, the real costs of that portfolio are not known until a competitive request for proposal solicitation can be completed and evaluated. As explained in the draft EIS in Section 3.7.3.1, Base Case Methodology and Cost Sensitivities Analysis, the EIS analysis evaluates the power impacts of the Multiple Objective (MO) Alternatives on regional power system reliability, as measured through loss of load probability (LOLP). The regional scope of the EIS is necessary because the impacts of the MOs on power system reliability and costs transcend individual utilities and states. Thus, for example, the EIS addresses the cost impacts of replacement resources for each MO regardless of whether Bonneville pays for the replacement resources. If Bonneville does not replace the lost capability caused by an MO, regional reliability would still be worse than the No Action Alternative and above the Northwest Power and Conservation Council's 5 percent standard, leaving other regional utilities to acquire the necessary resources. The EIS addressed the regional nature of the costs and resources needed to maintain power system reliability under the MOs. For further discussion about the resource selection process used in the EIS in lieu of an IRP, please refer to the response to the Northwest Energy Coalition's comment 6881-4.
6881	4	Fred Heutte	NW Energy Coalition	2.2 The CRSO DEIS Does Not Follow Established Methods for Integrated Resource Planning The electric power system provides essential services and is comprised of critical infrastructure and systems supporting the entire economy, including life, health and safety. Because the system is capital-intensive	The commenter questions why an integrated resource plan (IRP) was not performed as part of the EIS analysis. The commenter describes in detail the purpose of an IRP, its use in state utility resource planning, and the resulting output of the process a preferred resource portfolio. The commenter contends that by failing to conduct a similar process in the EIS power resource replacement analysis, the EIS is incomplete and inadequate.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				and must continuously and simultaneously optimize reliability, economic and environmental objectives, integrated resource planning is designed to explore a wide range of possible conditions for electric power demand, resource supply, availability and cost, and coordination of generation, transmission, distribution and demand side components over time. IRP assessments must consider long time horizons, typically 20 years or more, because of the capital intensity and long operating lifetime of energy resources. Thus, integrated resource planning helps reduce the risks of overinvestment, threats to system reliability, and excessive environmental impacts. IRP assessment must also consider various forms of system constraints and risks. As a result, IRP assessment includes a rigorous review of alternatives in order to achieve a least cost/least risk outcome. As a consequence, IRP analysis must review existing system resources and consider the need for new resources as the consequence of potential resource retirements, future changes in power demand, and the effects of technology innovation on the cost and availability of new resources. The IRP analysis must then consider a wide range of resource portfolios, including options for new resources, using scenario assessment. Finally, the IRP must assess the range of potential portfolios through the least cost/least risk lens and select the new portfolio that can best meet system needs. As the comments below demonstrate, the DEIS energy analysis fails to achieve any of these requirements. As a consequence, the results greatly overstate the costs and understate the benefits especially of MO3. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 16 Foundational IRP Element #1: Long-Term Assessment Summary: The DEIS Replacement Power Analysis focuses on a single study year 2022 rather than a 20-year planning horizon, in accordance with established best practice. The DEIS does not explain why the single reference year was chosen for the Replacement Power Analysis and does not explain the choice of 2022 as the reference year. As a result, the DEIS analysis does not test for a comprehensive range of loads, resources, interconnection and system conditions over time, in accordance with IRP assessment. Utility IRP methods generally include a long-term planning horizon; 20 years is often used as providing the best balance between the uncertainties of future system conditions and the long lead times, capital intensity and extended lifetime of new resources, which typically ranges from 5 to 50 years. In the Northwest, the Northwest Power and Conservation Council, Portland General Electric, PacifiCorp, Chelan PUD, Avista Utilities, Idaho Power, Puget Sound Energy, Seattle City Light and many others use 20 years as the time horizon for their IRPs, even when they expect specific resource retirements. In contrast, the DEIS Replacement Power Analysis uses a single planning year, 2022. By choosing a single reference year, the DEIS energy assessment provides a snapshot view that is arbitrary, incomplete and not at all indicative of the dynamic conditions expected for CRS operations over the coming years and decades. This precludes the long-term system assessment required to consider changing conditions for the CRS over many years and decades. In addition, as discussed at length below, the use of a 2022 reference year is particularly inappropriate for MO3. As a consequence, the replacement power portfolio for MO3 is not adequately assessed and is very likely to have much higher apparent cost than would be the case with a more appropriate starting date and long-term assessment in line with standard IRP practice. Foundational IRP Element #2: Scenario Assessment Summary: Unlike standard utility IRP assessment, the DEIS conducts an extremely limited review of scenarios. The DEIS does not explain why this very limited set of scenarios was chosen instead of the multi-factor and more wide-ranging scenario assessment needed for a comprehensive, accurate and sufficient Replacement Power Analysis. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 17 Using an appropriate long-term time horizon for an IRP assessment enables planner to assess existing and new resources under a wide range of future system conditions, considering changes in electricity demand, climate change, technology innovation, energy markets and other dynamic factors. To facilitate the IRP process, these varying elements are aggregated together as scenarios. The purpose of scenario assessment, broadly speaking, is to test the feasibility space of different resource portfolios in meeting future demand requirements under widely varying conditions. For example, the Northwest Power and Conservation Councils 7th Northwest Power Plan4 includes more than 20 scenarios, each assessed against 800 futures generated from combinations of regional load and resource projections under conditions. The scenario assessment considers historical temperature, rainfall and Columbia basin hydrosystem conditions, and includes forward projections for fuel (especially natural gas), power market prices, current and future resource costs, and many other factors. In stark contrast to established best practices, the DEIS energy analysis provides a very limited assessment. The Replacement Portfolio Analysis in Step 3 of the framework, in which the replacement resource mix for each DEIS alternative is selected, effectively has only a single scenario. The subsequent wholesale and retail rate pressure analysis in Steps 5 and 6 of the process have a very limited set of sensitivities. As a result, the DEIS energy analysis, particularly for the crucial portfolio selection in Step 3, does not set forth a rational range of scenarios commensurate with standard IRP practice, and the DEIS does not explain why it failed to do so. Under NEPA, Agencies shall insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements.5 By failing to adhere to established industry practices, this DEIS is not the requisite hard look under NEPA. 4 Northwest Power and Conservation Council, Seventh Northwest Conservation and Electric Power Plan, February 2016, https://www.nwcouncil.org/reports/seventh-power-plan 5 40 CFR 1502.24. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 18 Foundational IRP Element #3: Resource Portfolio Optimization Summary: The DEIS does not conduct the iterative, progressive approach to resource portfolio optimization that is key to recommending a robust new resource plan to meet the least cost/least risk criterion. Instead, the DEIS considers a single, static metric for resource adequacy in a single year, 2022, and does not proceed to any of the other steps considered essential for rational resource optimization in standard utility IRP practice. Resource portfolio optimization in a crucial step in the IRP process, and thus a major part of any legitimate energy system plan. Without optimization, it is nearly certain that the resulting resource portfolio will have significantly greater cost, weaker performance and lower system value than it should. While the effort to optimize resource portfolios must be methodical and thorough, a wide range of methods and models can be used to accomplish this key outcome. The resource portfolio development process must be rigorous, comprehensive and as objective as possible, and must be guided by a careful mix of modeling and expert judgment. As mentioned above, the process for IRP resource portfolio optimization typically starts with development of a wide range of system scenarios and resource portfolios, which are then iterated in stages. At each stage, the range of candidate portfolios is narrowed and re-optimized, leading toward selection of a preferred resource portfolio in the final stage that best meets all relevant criteria and constraints. An optimized resource portfolio must include a review of both existing and potential new resources, including all their relevant capabilities and costs. The review must assess all current and potential new resources on a comparable basis, using multiple criteria covering capital and operating cost, environmental cost and benefit, and system resource adequacy and operational reliability. Because energy resources have varying costs, capabilities and effects, they interact differently with the overall power system. The potential contribution of each resource to total system value must be examined in concert with all others. The ultimate measure is not the performance of a given resource on its own, but rather how individual resources interact with the electric system to provide reliable, affordable energy to customers. IRP resource portfolio optimization includes many performance metrics and constraints. In overview, these include operational reliability, resource adequacy, and energy, capacity and flexibility value. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 19 The resource portfolio development process must be rigorous, comprehensive and as objective as possible, and must be guided by a careful mix of modeling and expert judgment. The outcome must be a preferred resource portfolio that meets least cost/least risk criteria. As mentioned above, the process for IRP resource portfolio optimization typically starts with development of a wide range of system scenarios and resource portfolios, which are then iterated in stages. At each stage, the range of candidate portfolios is narrowed and re-optimized, leading toward selection of a preferred resource portfolio in the final stage that best meets all relevant criteria and constraints. In contrast to these established methods, models, data and review processes, the DEIS Replacement Power Analysis, conducts only the most cursory approach to developing replacement power portfolios for the alternatives under consideration. As described more fully below, the DEIS does not explain why the analysis did not incorporate other data and factors that were readily available to the energy analysis to develop robust resource portfolios that could be selected through scenario assessment, portfolio optimization and least cost/least risk screening. The DEIS does not conduct a review of a range of potential resource portfolios, then narrow them down by testing them across a wide range of scenarios over time. The DEIS does not explain why the alternatives are assessed with respect to a single study year, 2022, rather than the long-term horizon that is standard practice. The DEIS energy analysis therefore has resulted in a materially incomplete, misleading and arbitrary assessment of replacement options for all alternatives presented, and most especially MO3. Development of DEIS Replacement Power Portfolios The DEIS describes the Replacement Power Analysis portfolio selection process as follows: To determine the optimal mix of resources under each portfolio, this analysis assesses the cost-effectiveness of specific power resources by dividing the total costs by the LOLP benefit. The most cost-effective resources were then added into the GENESYS model until the resulting LOLP reached the No Action Alternative LOLP (6.6 percent). DEIS, Appendix H at line 606 Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 20 A check against resource adequacy is a key part of any IRP process. But assessing the adequacy of an alternative is fundamentally different than developing that alternative in the first place. The use of a resource adequacy model to develop resource portfolios is not a rational way to match the demanding test of meeting all system requirements over multiple years and decades in a least cost/least risk fashion. We start by reviewing the loss of load probability (LOLP) metric. The LOLP is a measure of system resource adequacy in a future year. It is a metric that is widely used in the electric utility industry to assess whether sufficient system resources will exist in each operating hour across a year to meet anticipate system demand. The Northwest Power and Conservation Council developed the	NEPA and IRP Legal Requirements There are a number of differences between the scope and the framework of the EIS that make conducting an IRP or IRP-like analysis incompatible with the CRSO EIS analysis. IRPs are a utility resource acquisition planning tool, usually developed in response to state regulatory requirements, and are not a requirement for a NEPA analysis. Many utilities perform IRPs to fulfill regulatory requirements created by state law or state utility commissions. In this regard, the scope of an IRP in almost all cases is from a particular utility's perspective solving for that utility's energy need over a planning horizon (typically 20 years) using the utility's criteria or objectives. The scope of the CRSO EIS is much broader in that Columbia River System operations affect communities throughout the Northwest. The EIS analyzes the impacts of the various alternatives, including the No Action Alternative and five MOs, on not just Bonneville, or Bonneville's customers, but on the region as a whole. For this reason, the power resource replacement analysis in the EIS does not identify the cost of resources for a particular utility, but presents the costs as costs of either Bonneville (through its wholesale power rates) or costs of other utilities in the region (through the regional retail rates analysis). In this context, the power resource replacement analysis for the EIS produces two representative resource portfolios which reflect available resource replacement options that could achieve the reliability metric of the EIS. In analyzing these alternatives, the EIS analysis does not purport to decide which resource portfolio should be chosen to address the impacts of a particular MO. Instead, the power resource analysis provides resource options that would be available to address any energy shortfalls caused by changes to CRS operations and associated power generation under the MOs. The EIS makes no finding on which utilities would be responsible for procuring resources, or what type of resources those utilities would acquire. For this reason, the replacement analysis remains neutral on these questions, producing results that enable the co-lead agencies to compare between the differing CRS operations in the alternatives in an objective manner. In this way, the EIS resource analysis appropriately focuses its effects analysis on evaluating options and estimating regional (non-utility specific) impacts caused by alternative CRS operations. The commenter describes a number of benefits that an IRP provides to selecting least-cost/low-risk resource portfolios and raises concerns that, by not doing an IRP, the EIS resource replacement analysis does not reflect a reasonable estimate of the potential resource replacement costs for the MOs. That concern ensuring that the EIS includes reasonable estimates of the replacement resource costs is a concern that the co-lead agencies share with the commenter. To that end, the power replacement analysis performed for the EIS includes many of the features identified by the commenter as being important to a reasonable least-cost/least-risk replacement resource analysis. Based on public comments, the final EIS contains more description of the processes and steps used in the power resource replacement analysis for determining the resource replacement portfolios in Appendix H, Section 2.2.2. The specific difference between the objectives and scope of an IRP and the CRSO EIS are described in detail below. Following this discussion is a broader explanation of the steps taken in the power resource replacement analysis, which in general show that the analyses performed in the EIS included many of the rigorous methodological approaches which would be employed in an IRP. Finally, the co-lead agencies acknowledge that if there were to be a substantial need for resource development, many of the actions requested by commenter would occur in the proper regional forum at the appropriate time. Differences between EIS Analysis and IRP Scope. Although the commenter refers to an industry standard IRP, there are, in fact, multiple ways and methods to perform an IRP. Common to most, though, are a few elements. One common element in almost all IRPs is the objective to reach a preferred resource portfolio for a particular utility. That is, the IRP optimizes the utility's existing resources to meet its loads, and then looks to solve for any deficiencies (as defined by the utility) with new resources (often optimized through multiple iterations) for a particular planning horizon (typically 20 years). As the commenter notes, guiding the resource optimization decisions by the utility are a host of criteria and objectives. These objectives are typically driven by particular policies or mandates that apply to the utility's acquisitions, such as carbon elimination, reliability margins, location, fuel type, etc. The resulting resource analysis supporting the utility's IRP focuses on resources that meet the utility's power needs, following that utility's identified criteria or objectives. The CRSO EIS power replacement analysis has a much broader scope. This follows from the broader scope of NEPA, which looks to analyze the impacts of CRS operations on power generation and transmission. The EIS analysis then explains how those impacts would affect regional consumers rather than specific utilities. A broader regional scope requires a broader power replacement analysis. The analysis in the EIS provides this broader scope by comparing the expected hydropower generation of the Federal Columbia River Power System under the status quo (the No Action Alternative [NAA]) and each MO alternative, and then uses the Northwest Power and Conservation Councils GENESYS model to quantify the associated level of reliability using the Loss of Load Probability (LOLP) metric. To the extent additional resources are needed to maintain system reliability at the NAA level, the analysis proceeds to choose potential replacements using resource optimization, with these replacements sized to the amount necessary to return each MO to the same level of reliability as the NAA. (The Preferred Alternative had roughly the same LOLP as the NAA, and thus, did not require replacement resources). Both the cost and generation profile of these resource replacement portfolios, along with the expected power generation under each alternative, are then folded into the rate pressure analysis to support the socioeconomic impacts analysis, which evaluates retail rate impacts at the regional level over a planning horizon of 50 years. Importantly, the output of this analysis does not characterize the cost impacts of a single preferred resource portfolio nor assign power replacement costs to a particular utility (or group of utilities). Rather, the power rates analysis shows the cost impacts for a range of portfolios, with those impacts generically applied to Bonneville and to regional utilities. This is a key assumption and one that is fundamentally different from an IRP. In an IRP, the utility is assumed to be the acquirer of resources, so only its interest (and those of its immediate customers) are at issue. Moreover, the utility retains substantial control over the outcome of its analysis, making judgment calls on which combination of resources best align to that utility's particular needs and criteria. In this NEPA analysis, however, the EISs broader scope means the co-lead agencies must look at resource replacement from a regional perspective, rather than an individual utility (or individual state) perspective. That broader view results in replacement options that reflect groupings of resources to best meet the objectives of the EIS (maintaining regional reliability), but also leaves open further optimization by individual utilities following whatever objectives and criteria the utility chooses. Output / Solving for LOLP The commenter also raises concerns about the limited criteria the EIS uses to solve for its power resource replacement analysis. The EIS uses the LOLP metric as the measure of regional reliability. The Northwest Power and Conservation Councils (Council) LOLP standard was used because it provides an objective third-party metric from which the EIS could measure the effects of the MOs, including the Preferred Alternative on regional reliability. LOLP does this by indicating when replacement resources are needed to maintain reliability, irrespective of which individual utility has lost a resource, which better aligns with the broader scope of the CRSO EIS. When LOLP changes under an MO, the power resource replacement analysis acquires resources, if necessary, to return regional reliability to the LOLP of the NAA. The commenter contends that solving only for LOLP is not a rational way to meet load over multiple decades on a least cost/least risk basis commonly employed through resource optimization performed in an IRP. Once again, the scope of the EIS and its objectives are not comparable with an IRP. As the commenter describes, the output of an IRP is a preferred portfolio that meets the criteria and objectives identified by the utility in its process. Those objectives and criteria are generally the product of the utility's policy or state mandates, and vary from utility to utility. For example, PacifiCorps IRP targets a reserve margin of 15 percent; Idaho Powers IRP targets 13 percent. Both utilities have different carbon objectives, and thus, select different resources in their respective preferred portfolio. These criteria obviously influence which resources are chosen for the preferred portfolio from a least-cost/least-risk perspective. Unlike an IRP, the CRSO EIS is not solving for a particular utility's resource need. Rather, the CRSO EIS analysis compares alternative operations and their effects relative to a base case (in this case, the NAA) consistent with the requirements of NEPA (see 40 C.F.R. 1502.14). To measure these effects, the power replacement analysis must apply a base-line requirement that can be applied across the MOs. The decision to use LOLP as that metric ensured that the reliability impacts of the MOs could be evaluated transparently and regionally across alternatives. The LOLP metric does this by providing a regional look at the impacts of resource losses and acquisitions on the power system as a whole. This broader scope better aligns with the requirements of NEPA, mainly present[ing] the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice among options by the decision-maker and the public.(see 40 C.F.R. 1502.14). The limitations of existing regional resources and the resulting reliability, cost, and carbon emissions implications are an important impact to consider. By looking at the regional impact of the MOs, the analysis is able to show, holistically, the effects of different operations on resource adequacy and the need for additional resources, if any, to reliably meet demand for power. This enables the co-lead agency decision-makers to make informed decisions. Seeing the broader impacts of the MOs provides the co-lead agencies a fuller picture of the reliability challenges that could arise with the different MO operations, both with the current regional resource mix and with a sensitivity analysis incorporating forecasted coal-plant retirements. These broader impacts would be muted (or erroneously excluded) in a utility-specific IRP analysis. Stated another way, had the EIS solved for a particular load (or group of loads) as in an IRP, the analysis would not have addressed the MOs effects on other regional loads, muting the effects of the MO on reliability. Already, the region is above the Councils target for LOLP of 5 percent, with the NAA carrying a 6.6 percent probability of resource insufficiency. This indicates that, under certain system conditions, regional resources are already short and may not be sufficient to meet demand. Developing the power replacement analysis so that it relied on the regions already limited resources to support reliability, without incorporating associated costs necessary to meet instantaneous demand, would not have provided an accurate picture of the resources needed to maintain reliability under certain CRS operations. Ignoring the existing resource limitations would be inconsistent with the twin aims of NEPA, which are to ensure agencies consider significant impacts of an action and inform the public of these impacts to demonstrate it has considered these impacts in its decision-making. The CRSO EIS appropriately analyzed the resource limitations to the public and will use this impacts analysis and public comments in its decision-making. The commenter also appears to contend that in using LOLP as the metric for the EIS, the EIS omits other important factors that would go into the selection of replacement resources for the four lower Snake River dams. For instance, the commenter suggests that the EIS power replacement analysis selects resources that reduce LOLP, but does so in a way that is oblivious to regional objectives and policies that would influence rational resource decisions. To the contrary, the portfolios selected by the EIS reflect a reasonable range of resource options that align with regional objectives and policies. Specifically, the EIS develops two general portfolios for each MO: a conventional least-cost portfolio (comprised of natural gas-fired resources) and a zero-carbon portfolio (predominantly solar). Along with reliability, these portfolios address the two key decision variables regional utilities and policy makers would consider in making future resource replacement decisions: (1) cost and (2) emissions profile. The EIS uses these two portfolios to specifically acknowledge that different utilities would emphasize different factors in seeking to return regional reliability to the NAA levels. Some utilities would emphasize cost (conventional least-cost portfolio) while others would emphasize carbon content (zero-carbon portfolio). Between these two portfolios are many different potential variations. Selecting the right combination of resources from carbon and non-carbon, dispatchable and non-dispatchable, new technology or old technology, etc. into a preferred resource portfolio for a specific utility is not within the scope of the EIS. Having established a reasonable range of resource portfolios that would likely be in play to replace lost capability caused by the various MOs, the EIS thoroughly evaluates the costs of these bookend portfolios in the power resource replacement analysis. Duration The commenter questions the use of 2022 as the study year for the EIS and contrasts that single-year analysis with a 20-year horizon typically used in an IRP. The reason for this difference lies in the differing objectives of a power resource replacement analysis conducted pursuant to NEPA and an IRP resource process for regulated utilities fulfilling state mandates. As discussed above, the focus of the CRSO EIS is to measure the impacts of the proposed system operations on various affected resources, one of which is power reliability. To do that, though, there needs to be an established point-in-time from which to measure the effects of the MOs as compared to the No Action Alternative. The EIS accomplishes this comparison by assuming each MO (and its effects) were fully in place by 2022. Both practical and analytical reasons support this approach. Practical reasons support using 2022 as the beginning year because at the time the analysis was prepared, this year coincided with the latest available data from the Councils Power Plan to run the GENESYS model to calculate LOLP. In other words, 2022 is the latest date that data were available from which to calculate the effects of the MO on LOLP. Had the EIS used 2023 or any later date, the co-lead agencies would have had to develop their own data set to estimate the effects of the MOs on LOLP. Using 2022 allowed the EIS to use, in a non-biased fashion, the Councils existing data set to run the GENESYS model with no additional adjustments. Analytical reasons also support using 2022 as the study date. Although there would be virtually no chance that all pre-requisites for resource construction (or elimination as in MO3) would be completed by 2022, the use of 2022 as a start year does not degrade the analysis in the EIS, but in fact, enhances it because it removes the subjective variable of resource replacement timing that could have impacted the relative weighting of the MOs. By choosing a single start year applicable across MOs, the EIS provides a level playing field from which to compare the impacts and costs of each MO (See Section 3.19 and Appendix Q for additional discussion). Had the EIS adopted a later start date for the MOs or key measures within an MO for evaluating future resource decisions, as in an IRP, for the replacement resource and rate pressure analysis, the co-lead agencies would have had to speculate about when the various elements of the MOs would have been in effect. Establishing an actual year of implementation for each of the MOs would have injected a subjective timing element into the measurement of the relative impacts of differing

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				GENESYS model two decades ago to assess the resource adequacy of the Northwest regional power system using the LOLP metric as a primary measure. GENESYS is regarded as being the most capable model for that purpose in the Northwest, in particular because of its highly sophisticated emulation of CRS hydrogeneration under a full range of hydrological flow, hydrogeneration and power system conditions. The Council resource adequacy assessment is updated annually and looks forward five years. The assessment has proven to be highly robust and provides valuable guidance for regional decision makers and the public. However, that assessment only includes existing resources and committed new resources, including the Councils regional energy efficiency target. The annual resource adequacy assessment does not generate and test candidate power portfolios to fill any resource adequacy gap that effort is considered in the Councils Northwest Regional Power Plan every five years. The agencies here have ready access to the appropriate tools to develop optimized resource portfolios. To develop the preferred resource mix for the Northwest Regional Power Plan, the Council uses its capital expansion model, the Regional Portfolio Model (RPM). Capital expansion models are the core of IRP assessment, because they simulate power system conditions over the planning time horizon for the scenarios, data, constraints and resource portfolios of a full IRP assessment. Their outputs can be used to iterate, optimize and select the least cost/least risk preferred portfolio. Some capital expansion models are vendor-supplied, while others, like the Councils RPM, are internally developed. Regardless of source, the established industry practice is to use capacity expansion tools to develop Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 21 alternative portfolios, and then use resource adequacy tools to assess these alternatives. The DEIS skipped this step to develop a robust set of alternatives and thus fails to comply with NEPA. The DEIS Replacement Power Analysis consisted of three steps. First, GENESYS was used to derive loss of load probability (LOLP) values for the existing Northwest power system as modeled in 2022 under the median water scenario. This resulted in a 6.6% annual LOLP metric. This is a static annual value for the single year of 2022 and does not incorporate future changes of loads, resources, climate change and future hydro variability, changes in western power markets and many other factors that must be considered in IRP analysis. Second, changes to resource operation in the existing system were loaded into GENESYS and run for each of the Multiple Objective Alternatives. These changes included modified generation patterns at the CRS generation facilities in accordance with the hydroregulation study for each alternative. Overall, this resulted in the changes to average annual LOLP in 2022 (illustrated in column two of Table ES-10 below), before considering power replacement portfolios. DEIS Appendix J, Table ES-10 Third, resources by type (natural gas, wind, solar, battery storage, demand response) were added in economic merit order and run in the GENESYS model until the annual LOLP in 2022 again reached the 6.6% level. Note that this third step was only conducted for MO1, MO3 and MO4, because MO2 resulted in a lower LOLP than the baseline. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 22 This third step constitutes the full and entire process of developing the power replacement portfolios in the DEIS. No additional iteration or optimization whatsoever was conducted. This process is not the robust development and analysis of alternatives required by NEPA. The agencies do not explain how the cost-effectiveness for each resource type was determined and how the resources were assembled in economic order sequence to create each replacement power portfolio. Such details would normally be explained at length during a standard IRP process. The process described fails to select the best replacement portfolios considering their interaction with the entire system, as would an adequate IRP assessment As a result, it is nearly certain that the net costs of the replacement power portfolios resulting from the DEIS Replacement Power Analysis significantly exceed what a fully optimized review would accomplish. The DEIS fails to explain either why its limited approach is rational and reliable, nor why it did not take the steps of a standard IRP analysis to weigh and optimize the many factors over the long duration time horizon needed to select the lowest cost and least risk replacement portfolio, especially for MO3. Foundational IRP Element #4: Least Cost/Least Risk Assessment Summary: The DEIS does not explain why the Replacement Power Analysis does not define least cost/least risk criteria nor construct the power replacement portfolios to include all factors necessary to achieve those criteria. In particular, the DEIS energy assessment does not explicitly address system risk as well as system cost. Therefore, the DEIS does not conduct a rational or robust least cost/least risk assessment across a full planning horizon of 20 years or more. Utility IRP analysis in the Pacific Northwest generally engages in some form of least cost/least risk assessment. That is, rather than merely solving for a single objective function over time, such as minimizing cumulative system cost, IRP modeling must also account for multiple elements of risk. Among these are operational reliability, longer term resource adequacy, and financial risk. The Oregon Public Utility Commission order on the Portland General Electric 2016 Integrated Resource Plan describes the industry standard for least cost-least risk planning: The IRP is a road map for providing reliable and least cost and least risk electric service to the utility's customers, consistent with state and federal energy policies, while Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 23 addressing, and planning for, uncertainties. The primary outcome of the process is the selection of a portfolio of resources with the best combination of expected costs and associated risks and uncertainties for the utility and its customers. Oregon PUC Order 17-386 at 3 Above we describe the industry best practice for developing alternative resource portfolios. In sum: Tradeoff analysis and expert judgment must be combined with computer modeling to achieve a fully optimized system portfolio that appropriately balances cost and risk. To accomplish this result, a co-optimization approach is employed to find the best balance between minimizing production cost over time (least cost) while also minimizing variation in both direct and externality risks, usually through a proxy cost factor (least risk). There are many recognized methods for achieving a least cost/least risk planning result and defining a new resource portfolio, but the DEIS employed none of them. For example, the Northwest Power and Conservation Council uses its Regional Portfolio Model (RPM) to construct the preferred least cost/least risk resource mix for its 20-year resource portfolio and associated 5-year action plan, all of which are updated approximately every five years in the Northwest Regional Power Plan. The RPM operates in quarterly steps over a 20-year time horizon. For each of more than 20 scenarios in the 7th Northwest Power Plan, the RPM model generated about 800 futures representing ranges of load, resource and market price conditions across the 80 time steps, incorporating additional elements for risk assessment such as stochastic shocks to market prices. The RPM model selects the optimal mix of existing and new resources across all time steps for each scenario and aggregates the results to a cost metric and a risk metric. The complete set of scenario cost and risk metrics across the 800 futures is then plotted to show an efficient frontier where cost and risk are minimized. Finally, the Council reviews those scenarios falling closest to the efficient frontier and applies further analysis, extensive stakeholder input and expert judgment to select the future resource portfolio included in the 20-year regional plan and the associated 5-year action plan. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 24 In contrast, to select the new resources for the Preferred Alternatives and the four Multiple Objective Alternatives, the DEIS Replacement Power Analysis only assesses baseline conditions for the single study year of 2022, rather than a multi-decade study period with a comprehensive scenario assessment. The replacement power portfolios for each alternative consist of only two the least cost conventional portfolio and the zero-carbon portfolio. Those portfolios were selected to return MO1, MO3 and MO4 to the 6.6% LOLP baseline of the No Action Alternative but not to meet any other important performance criteria and constraints. The set of two portfolio options for each DEIS alternative is far more limited than the wide range of portfolios typically considered in IRP analysis. Rather than assessing the full range of energy, flexibility and other criteria to steer toward a least cost/least risk portfolio, the criterion for selection of the DEIS replacement portfolios is a single factor resource adequacy as denoted by the LOLP metric. This is not a rational, accurate or sufficient step to create an optimized, least cost/least risk power replacement portfolio. In conclusion, as a result of the omissions and deficiencies in the DEIS Replacement Power Analysis for MO3, the results are incomplete and inadequate. Consequently, the rate pressure analysis in Step 5 and the socioeconomic impact analysis in Step 6 of the framework analysis, which are based entirely on the Power Replacement Analysis, are likewise incomplete and inaccurate.	CRS operations on each of the alternatives. For example, MO3 with dam breaching requires Congressional action. Had a timing element been included in the comparison of the MOs, the EIS could have assumed that Congress would not act by 2022, but by 2035, or some other subjective date. The impacts of the MO on the various objectives identified in the EIS would then have had to be scaled to these subjective future dates, skewing the results. MOs that could be implemented more quickly (such as those involving only operational changes) would generally show smaller costs and more overall benefits compared to those requiring long lead times (such as dam breach). Similarly, subjective assumptions on timing could have been employed for the construction of replacement resources, especially for large-scale solar installations requiring environmental compliance, permitting, etc., and conventional gas-fired units, which are carbon emitting and potentially constrained by regulatory policy. All of this subjectivity would have been added to the power resource replacement analysis with little additional analytical benefit and potentially a detriment to the EIS because of the speculative nature of the timing assumptions the co-lead agencies would have had to make. The more analytically sound approach is the one adopted by the EIS. The use of a single study year for implementation of the alternative allows for a comparison of before-and-after effects for each alternative, utilizing the most recently available and vetted models and data up and through 2022. The single start year ensured that the effects of the MOs could be compared fairly with each other and the NAA without the co-lead agencies speculating on when Congress might act, when resources would be removed, or when resources would be constructed and online. Additionally, the commenter appears to suggest that by choosing a single study year, the costs included in the power resource replacement analysis are artificially high. The EIS does not front-load replacement costs in 2022. Rather, all resources included in the resource portfolios are amortized over their accounting useful life, and a longer useful life than might be reasonably predicted if replacement resources were constructed by Independent Power Producers or Investor-Owned Utilities. See draft EIS, Section 3.7.3.1 Additional Power Rate Sensitivity Analysis Rate Sensitivity Assumptions Resource Financing Assumptions. The starting period for that amortization is 2022, so only one year of amortization of the replacement resources is included in the EIS rate pressure analysis. Additionally, the EIS includes NPV (net present value) analysis (See draft EIS, Section Bonneville Financial Analysis under each alternative in Section 3.7.3 and in Section 7.7.9.5) as well as imputed socioeconomic impacts over 50 years (See draft EIs, Section Social and Economic Effects of Changes in Power and Transmission under each alternative in Section 3.7.3 and in Section 7.7.9.6). The combination of this before-and-after approach to assess regional reliability with the imputed impacts over time allows for easy comparison of the alternatives and informs the public and the region of the relative costs and benefits of differing CRS operations. To address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Council's 8th Power Plan is included as rate sensitivities in the final EIS. The final EIS includes the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will likely be used by the Council in the 8th Power plan. The Analysis Performed by the EIS Addresses Many of Commenters Concerns The commenter states that better resource replacement data could have been developed had the EIS used an IRP for developing resource replacement portfolios. Specifically, the commenter notes that optimization, scenario analysis, and the selection of a least-cost, least-risk optimized resource portfolio would have resulted in a more cost-effective evaluation of replacement resources. While the scope and objectives of an IRP are not directly comparable to the type of analysis needed for an EIS, the commenters emphasis on the benefits of some of the features of an IRP are well taken. In fact, the EIS power analysis includes many of the features that the commenter suggests are needed to provide an objective least-cost/least-risk, optimum resource portfolio. Source Data One of the important components of an IRP is objective data. Most IRP processes use source data from third-party vendors or other third-party sources to produce an objective assessment of future resource availability, capabilities, and costs. Like an IRP, the EIS uses data from a third-party source to estimate the effects of the MOs on future power costs: the Councils 7th Power Plan and Mid-Term Update with the exception of batteries which relied on draft data from the Council's upcoming 8th Power Plan that became available in the fall 2019. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The Council is statutorily required to focus on evaluating cost-effect resources from a regional perspective, and therefore, is a recognized leader in producing data for use in estimating regional resource replacement costs. Such data are used in each of the four key inputs to the power resource replacement analysis: (1) the projected loads to be served; (2) the types of resources that are available for selection; (3) the cost of those resources; and (4) (along with the GENESYS model), the effectiveness of those resources to influence LOLP. In addition, as described in other comments, the resource cost analysis is updated in the final EIS to reflect recent studies that indicate the declining costs for resources through an added sensitivity adjustment entitled Forward Cost Curves. In these ways, the source of the data used by the EIS follows the leading industry standard and is objectively and analytically sound. This complies with NEPAs requirement to use high quality information in the analysis (see 40 C.F.R 1500.1(b)). Optimization and Scenario Analysis The commenter highlights the importance of optimization and related scenario analysis, noting that these activities are crucial to establishing a least-cost/least-risk optimized resource portfolio. In particular, the commenter notes that various vendors and models exist that optimize resources to produce the most efficient resource portfolios. The commenter notes the EIS did not use an optimization program, but instead used a single step optimization, by resource type and economic merit order. The commenter contends additional optimization and scenario analysis should have been conducted in the EIS to produce more reasonable costs estimates. The co-lead agencies acknowledge that resource optimization and scenario analysis are important parts of resource acquisition planning. When specific utility resource needs and parameters are established, optimization and scenario analysis can help decision-makers make informed decisions about which portfolio of resources best achieves the objectives of the utility. These activities are clearly needed when establishing the utility's preferred portfolio. The EIS, however, is not designed to replace or be equivalent to a utility resource selection process, nor is it establishing a preferred resource portfolio for the region. Instead, as described above, it is intended to provide a reasonable range of replacement resource options, and their incremental costs, from which to measure the impacts of the various MOs. Utility-specific optimization and scenario analysis would occur as a separate step, independent of the EIS, constrained and directed by the particular criteria and objectives of the utility. For this reason, a vendor-supplied optimization program and detailed scenario analysis were not deemed to be necessary for the EIS. This is not to suggest that the EIS did not perform any resource optimization as contended by the commenter. Instead, the EIS performs a form of optimization that focuses on ensuring that the portfolios used in the power replacement analysis (1) reflect reasonable estimates of the cost of available replacement resources; and (2) as applied to the MOs, are the least-cost resource categories available. The EIS used the screened set of primary resources and cost data from the regions regional resource planning organization, the Council, as a primary source for these replacement resources. This approach allows the co-lead agencies to eliminate obvious non-viable resource portfolios, and provides a spectrum of primary resource portfolios to assess the impacts of the MOs. It intentionally leaves open any further optimization for utilities or policy makers to make with their respective specific criteria or objectives. The first element of this analysis (reasonable costs) occurs inherently through the data used in the power analysis. As noted above, the EIS relies on resource data developed by the Council in the 7th Power Plan (with the exception of batteries which used 2018 and 2019 regional utility IRP data). The EIS uses the data underlying this portfolio as the basis for determining the type of resource options available to replace lost capability caused by the MOs. From this data set, seven resource options were evaluated. These include (1) natural gas; (2) demand response; (3) solar; (4) Montana wind; (5) Gorge wind; (6) a combined solar/wind; and (7) batteries. These resources are identified by the Councils 7th Power Plan as primary resources for meeting future energy needs, (except batteries, which were expected to become and now are a primary resource in the upcoming 8th Power Plan). These resource portfolio assumptions (along with the Councils cost estimates with applicable updates) form the basis of the resource cost estimates used in the EIS for the MOs. To further address concerns about potential reductions in resource costs, consistent with the public comments, publicly released draft information from development of the 8th Power Plan is included as rate sensitivities in the final EIS. As discussed above, the final EIS also includes the de-escalating cost curves prepared by NREL that will be used by the Council in the 8th Power plan. In this way, the source of data used in the EIS already reflects a screened set of primary resources, and their costs, that are viable today and scalable to the region. These costs estimates are further refined through the resource evaluation process used in the EIS. Commenter highlights that part of the optimization process includes the interaction between resources and the power system as a whole. In other words, optimization acknowledges the impacts of different resources on regional surpluses, deficits, fuel costs, and other related factors. This interaction is taken into account in the EISs power resource replacement analysis. As will be explained in greater detail in the final EIS, the costs of the seven resources described above are adjusted in the EIS to reflect their variable costs or savings to the region. For example, the analysis includes not only the fuel costs of both natural gas and coal but also includes the other variable costs (operation and maintenance [O&M]) as well. Furthermore, the fixed O&M costs are also included in the annual fixed costs of the resource in addition to their capital costs. Alternatively, the solar resource reduces regional expenditures for natural gas O&M and fuel, resulting in substantial regional savings. These savings are credited to the solar resources. In this way, the power resource replacement analysis provides a robust and analytically sound basis for the costs of the resource portfolios used to support the EIS. The second element of the power analysis (least cost) occurs through the ranking of the resources by their effectiveness in reducing LOLP. To do this, the power replacement analysis compares each resource portfolios effectiveness at reducing regional LOLP and divides this effectiveness by the resources costs. For example, in the case of MO3, adding 500 MW of natural gas to regional resources has the effect of reducing LOLP by 4 percentage points. Dividing the costs of 500 MW of natural gas ($22 million as estimated from the Councils fixed cost data and the EISs change in power system costs) by 4 (the LOLP benefit) results in a cost of reliability-benefit ratio for natural gas of approximately $5,500,000 per LOLP percentage point. Applying the same math to 500 MW of Gorge wind, which reduces LOLP by only 0.4 percentage points, results in the much higher cost of reliability benefit ratio of $120,000,000 per percentage point reduction in LOLP. As a result, Gorge wind was not selected as a least-cost resource option for the MOs. Through this iterative process, the EIS establishes two portfolios that meet the reliability objectives of reducing the LOLP to the NAA levels on a least-cost basis. The conventional natural gas portfolio reflects a least-cost option, reducing LOLP the most per dollar of investment. The zero-carbon portfolio, solar with demand response, and for MO3, solar and demand response reflects the least-cost renewable resources group for reducing LOLP. For MO3, batteries were added to solar and constrained to a 2:1 ratio of solar to battery in order to return some of the lost sustained peaking and ramping capability and to avoid leaning on other regional resources to make up for these generation characteristics. The amount of replacement resources (gas, solar, and batteries) were scaled until the LOLP of each MO matched the LOLP of the No Action Alternative. As noted before, these portfolios are not intended to be the sole portfolios that utilities, policy makers, or federal agencies would choose to develop. Between these two resource portfolios are many combinations which could be optimized with other resources to achieve the specific objectives the utility seeks. In response to this and other public comments, Appendix H, Section 2.2.2 of the EIS contains an expanded description of how the replacement resources were selected. Looking to the future The Preferred Alternative discussed in the EIS is not expected to result in additional resource acquisitions to maintain regional reliability at the NAA level, so other processes are unlikely to be needed to address prospective acquisition decisions as a result of implementing the Preferred Alternative. Nonetheless, if acquisitions are needed in the future, the concerns raised by commenter would likely be addressed in those separate processes (if any), outside of a federal NEPA process, in which the utility (or utilities') resource portfolio decisions are considered. The co-lead agencies would expect those processes to involve many stakeholders, where the objectives and criteria concerns expressed by commenter could be addressed. Regional utilities and policy makers have a long-history of collaboration and cooperation in resource development, siting, and participation. Bonneville, in particular, would engage in appropriate regional processes if it needed to acquire resources to ensure an adequate, efficient, economical and reliable supply of power to meet its obligations. The detailed elements of an IRP analysis highlighted by commenter, with computer optimization, scenario analysis, and the meeting of multiple objectives throughout a 20-year time horizon, would likely occur when deciding the specific utility resource acquisition plan. The commenter identifies important considerations that warrant full development in processes outside of a federal NEPA process for planning and acquiring future resources for specific utilities.
6881	5	Fred Heutte	NW Energy Coalition	3.1 The Choice of the Year 2022 is Infeasible and Inappropriate for Assessment of MO3 Even under the most rapid process conceivable, LSR dam breach and hydrogeneration retirement cannot possibly be completed in 2022. The DEIS defends the use of the 2022 date as follows: The construction costs for the structural measures were assumed to be implemented over the first two years of the project (2021 and 2022), consistent with guidance provided by the co-lead agencies. Although some of these measures, especially the dam breaching measures, may take a number of years to implement or may not start for a number of years (pending further studies), it was necessary to provide a consistent time-frame for implementation in the evaluation to compare across the alternatives. DEIS Appendix Q at Q-3-2 While we agree that using a consistent time-fram is important, the DEIS	The commenter questions the use of 2022 as the study year for the EIS and contrasts that single-year analysis with a 20-year horizon typically used in an IRP. The reason for this difference lies in the differing objectives of a power resource replacement analysis conducted pursuant to NEPA and an IRP resource process for regulated utilities fulfilling state mandates. As discussed above, the focus of the CRSO EIS is to measure the impacts of the proposed system operations on various affected resources, one of which is power reliability. To do that, though, there needs to be an established point-in-time from which to measure the effects of the MOs as compared to the No Action Alternative. The EIS accomplishes this comparison by assuming each MO (and its effects) were fully in place by 2022. Both practical and analytical reasons support this approach.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				focus on 2022 is arbitrary because, as the agencies admit, dam breach under MO3 is not be possible by 2022. Many financial, engineering, contractual, legal and other steps are needed to accomplish dam breach, hydropower retirement and related activities, as well as acquisition of the replacement power portfolio. Completion of these activities under MO3 would take several years to put in place. The choice of the starting year for the Replacement Power Analysis is consequential. Compared to a later year that is closer to the first feasible time that MO3 can be implemented, many factors in the regional power system and CRS will have changed. Of particular importance to the anticipated cost for MO3, the ongoing decline of clean energy resource costs will proceed further because of technology innovation and policy such as the Clean Energy Transformation Act in Washington,6 decreasing the actual cost of the replacement portfolio for MO3. Furthermore, the data and models available for the DEIS energy analysis can easily accommodate a shift in the reference year for MO3. The DEIS does not provide any rationale for the use of a single reference year for the Replacement Power Analysis and other purposes, includes information to contradict that this is a reasonable date, and still proceeds with the analysis of a flawed single reference year that biases the results of the analysis. In conclusion, the DEIS's explanation that use of a single reference year, 2022, is needed for consistency across Alternatives is inadequate given the nature of resource planning. 6 See Washington State Department of Commerce, Clean Energy Transformation Act (CETA), https://www.commerce.wa.gov/growing-the-economy/energy/ceta/	Practical reasons support using 2022 as the beginning year because at the time the analysis was prepared, this year coincided with the latest available data from the Council's Power Plan to run the GENESYS model to calculate LOLP. In other words, 2022 is the latest date that data were available from which to calculate the effects of the MO on LOLP. Had the EIS used 2023 or any later date, the co-lead agencies would have had to develop their own data set to estimate the effects of the MOs on LOLP. Using 2022 allowed the EIS to use, in a non-biased fashion, the Council's existing data set to run the GENESYS model with no additional adjustments. Analytical reasons also support using 2022 as the study date. Although there would be virtually no chance that all pre-requisites for resource construction (or elimination as in MO3) would be completed by 2022, the use of 2022 as a start year does not degrade the analysis in the EIS, but in fact, enhances it because it removes the subjective variable of resource replacement timing that could have impacted the relative weighting of the MOs. By choosing a single start year applicable across MOs, the EIS provides a level playing field from which to compare the impacts and costs of each MO (See Section 3.19 and Appendix Q for additional discussion). Had the EIS adopted a later start date for the MOs or key measures within an MO for evaluating future resource decisions, as in an IRP, for the replacement resource and rate pressure analysis, the co-lead agencies would have had to speculate about when the various elements of the MOs would have been in effect. Establishing an "actual" year of implementation for each of the MOs would have injected a subjective timing element into the measurement of the relative impacts of differing CRS operations on each of the alternatives. For example, MO3 – with dam breaching – requires Congressional action. Had a timing element been included in the comparison of the MOs, the EIS could have assumed that Congress would not act by 2022, but by 2035, or some other subjective date. The impacts of the MO on the various objectives identified in the EIS would then have had to be scaled to these subjective future dates, skewing the results. MOs that could be implemented more quickly (such as those involving only operational changes) would generally show smaller costs and more overall benefits compared to those requiring long lead times (such as dam breach). Similarly, subjective assumptions on timing could have been employed for the construction of replacement resources, especially for large-scale solar installations requiring environmental compliance, permitting, etc., and conventional gas-fired units, which are carbon emitting and potentially constrained by regulatory policy. All of this subjectivity would have been added to the power resource replacement analysis with little additional analytical benefit – and potentially a detriment – to the EIS because of the speculative nature of the timing assumptions the co-lead agencies would have had to make. The more analytically sound approach is the one adopted by the EIS. The use of a single study year for implementation of the alternative allows for a comparison of before-and-after effects for each alternative, utilizing the most recently available – and vetted – models and data up and through 2022. The single start year ensured that the effects of the MOs could be compared fairly with each other and the NAA without the co-lead agencies speculating on when Congress might act, when resources would be removed, or when resources would be constructed and online.
6881	6	Fred Heutte	NW Energy Coalition	4.1 The Obligation to Acquire Energy Efficiency The Replacement Power Analysis portfolios use inadequate information for energy efficiency resource availability. This is a serious omission in the DEIS energy analysis and raises important issues with respect to the Northwest Power Act. The DEIS purports to address this issue as follows: Table 2-3 provides the per unit capital costs ($/kW) of the replacement resources identified for each alternative and portfolio. The analysis used the midpoint of the costs for the resource replacement selection. The NW Councils 2022 load forecast that was used for the LOLP reliability modeling include all cost-effective conservation. According to the 7th Power Plan, by 2022 there is 1,871 aMW of conservation available to the region price at $80 per MWh or below. There is an additional 148 aMW of conservation price at over $80 dollars per MW and half of it is price at over $140 dollars per MWh. This conservation has a higher cost than the other resources that were developed for the MOs, and therefore were not included. DEIS Appendix H at line 680 Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 27 However, analysis for the 7th Power Plan was primarily conducted in 2015 based on data available up to that time. It has been five years since the 7th Plan energy efficiency analysis was conducted, and a further two years until the DEIS Replacement Power Analysis single study year of 2022. Furthermore, as extensively discussed above, resource acquisition to cover reductions in hydrogeneration under MO3 would occur in some later year, during which time additional cost-effective energy efficiency resources are likely to become available. For the last several decades, energy efficiency has benefitted from rapidly emerging technology innovation in residential, commercial and industrial energy use. These improvements in opportunities for energy efficiency are not easily captured over long time horizons. Therefore, conservation assessments from five years ago are outdated and of limited and uncertain usefulness for the DEIS Replacement Power Analysis. Furthermore, the Councils analysis provides estimates not just for a single year, but for the changing costs and availability of energy efficiency over time. However, the DEIS did not employ such data and methods, nor does the DEIS explain why such steps were not taken to incorporate the most accurate available information. This calls into question the validity of the price and availability of the energy efficiency resource used in this analysis. In addition, the amount of cost-effective conservation chosen is a function of all the other aspects of any given scenario and portfolio. According to the DEIS Replacement Power Analysis, under alternatives MO1, MO3 and MO4, CRS hydrogeneration would decline, and therefore regional power supply would fall relative to demand. As that occurs, costs will rise and the cost-effectiveness limit for replacement resources will go up. The Councils RPM model takes all of this into account, adjusting for market price effects as it assesses, iterates and optimizes the selection of resources into its resource portfolio. But instead of incorporating all the dimensions of the Councils energy efficiency analysis, the DEIS chooses a crude average cost. This likely falls short of full assessment of additional cost-effective energy efficiency that could be included in the DEIS replacement portfolios, thus decreasing their cost. The DEIS does not explain the reasons for not using the full Council analysis.	The Northwest Power and Conservation Councils (Council) 7th Power Plan is still the current power plan until the 8th Power Plan is completed. The 7th Power Plan included conservation targets over the 20 year period of the plan. See draft EIS, Section 3.7.3.1 Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The analysis in the EIS includes all energy efficiency in the Councils plan through 2022. See draft EIS, Appendix H, Power and Transmission, Section 2.2, page H-2-3. Northwest utilities are required by law to acquire all cost effective conservation regardless of the status of the four lower Snake River dams. Therefore, if the amount of cost-effective energy efficiency increases, utilities are required to achieve it regardless of the status of the Federal Columbia River Power System (FCRPS). The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils 7th Power Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings form efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in Multiple Objective (MO) Alternative 3. The Resource Adequacy assessment for the EIS includes all cost-effective conservation forecasted through 2022. The draft EIS did not assume any costs for cost effective energy efficiency as a replacement resource because it is assumed to happen in the base case regardless of the status of the FCRPS, and therefore, is not part of the cost delta between the No Action Alternative and Multiple Objective alternatives. Stated another way, the load forecast used in the EIS analysis already assumes all cost effective conservation and energy efficiency have been achieved. Thus, the load in the No Action Alternative and each MO has already been reduced by all economic energy efficiency and conservation. Adding additional conservation in addition to that already assumed in the Councils Plan is unlikely to be either economically viable or, as discussed above, achievable. The socioeconomic discussion in each alternative discusses the potential for consumers to alter their behavior in response to changes in electricity pricing. See draft EIS, Section 3.7.5.3 through 3.7.5.6, Socio and Economic Effects, for example, page 3-932, on potential changes to residential electricity use from rate changes in MO1.
6881	7	Fred Heutte	NW Energy Coalition	4.2 Overestimated New Resource Costs The DEIS Replacement Power Analysis relies on supply resource cost data from the Councils 7th Northwest Regional Power Plan and its 2018 Midterm Assessment. DEIS Chapter 3 at line 673. These resource costs are outdated and more recent cost data sources were available for the DEIS analysis, but were not used. For example, the National Renewable Energy Laboratory launched its Annual Technology Baseline (ATB),7 which provides a sophisticated, freely available, fully documented framework for assessing future resource costs that includes estimation of technical innovation, policy drivers and market acceptance. The ATB has rapidly become an authoritative source for electric generation and battery storage resource cost estimates. Along with using stale information on costs and performance, the DEIS further overstates the cost of MO3 by electing to start in 2022, a date the agencies themselves say is not a reasonable starting point. Application of such outdated resource pricing further overstates the overall cost of MO3. If a more feasible starting point is chosen, the continually declining costs of clean energy replacement resources will materially decrease the cost of MO3. Solar photovoltaic (PV) resources illustrate these concerns. While PV systems have been commercially available since the 1970s, over the last decade PV has rapidly ascended to become a leading source of renewable energy, along with wind power. This has been driven by rapid technological innovation and development of global supply changes, and as a result costs have rapidly decline. Technical innovation continues to emerge with PV systems. In the last two years, bifacial PV modules have rapidly become a significant fraction of the market, and are poised to become the dominant format within the next few years. Because bifacial modules collect both direct insolation and reflect surface energy, it is estimated they will add about 10% to output at little or no incremental cost.8 7 Annual Technology Baseline, National Renewable Energy Laboratory, atb.nrel.gov. 8 National Renewable Energy Laboratory, Bifacial Solar Advances with the Timesand the Sun, February 2020, https://www.nrel.gov/news/features/2020/bifacial-solar-advances-with-the-times-and-the-sun.html Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 29 Secondly, while PV considered by itself is a variable energy resource, considerable effort is being made to improve its performance, decrease output variability and match system demand more precisely. These most recent and important development is the rapid emergence of integrated hybrid PV-battery storage power plants. Advances on the hybrid front have been so rapid that there was almost no cost and performance data available in 2018, but now it is estimated that hybrid PV-storage projects are nearly half of the interconnection queue in California. The potential was already apparent in mid-2019, when the California Independent System Operator noted that approximately 41% of the total capacity currently seeking interconnection to their system was hybrid resources, mostly consisting of PV-battery configurations.9 At the same time, PV-battery hybrid resource costs have declined at unprecedented rates. Two recent articles considered the costs of a new PV-hybrid project being constructed under contract with the Los Angeles Department of Water and Power (LADWP). The project will consist of 400 MW of PV and 300 MW/1200 MWh of battery resources. Analysts suggest the value of the project will be under $40/MWh for energy and $127/kW-year for capacity, below the cost of a new gas peaker power plant.10 While the costs for such hybrid projects in the Northwest will be higher due to the somewhat less favorable solar resource in this region, their value will be considerable given the potential for co-optimization with the storage and flexibility capabilities of the CRS, while providing adding to overall system energy, capacity and resource adequacy, especially during the late summer when demand is high and the spring freshet has depleted and hydrogeneration potential is very limited. DEIS Replacement Portfolio Analysis failed to incorporate these widely known and established industry trends and instead relied on stale information that consistently overstates the costs of the alternatives. 9 CAISO, Hybrid Resources Initiative: Issue Paper Stakeholder Meeting, July 22, 2019, http://www.caiso.com/InitiativeDocuments/Presentation-HybridResources-IssuePaper.pdf 10 Energy Storage News, "Battery storage at US$20/MWh? Breaking down low-cost solar-plus-storage PPAs in the USA," March 20, 2020, https://www.energy-storage.news/blogs/battery-storage-at-us20-mwh-breaking-down-low-cost-solar-plus-storage-ppas; and EnergyGPS, "Grateful for Reliability, April 3, 2020, https://www.energygps.com/Newsletter/b/Newsletter-Grateful-for-Reliability-1620014 Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 30 The DEIS analysis adopts a PV capital cost of $1,350 to $1,500/kW (2019$). DEIS Appendix H, Table 2-3. Those costs are applied to the single study year of 2022. By that time, costs are likely to decline by a significant amount, reflecting deeply embedded declining cost trends over many years, yet the DEIS made no attempt to account for that. Assessments seeking to assess future technical, performance and cost trajectories for resources undergoing profound innovation such as PV have several analytical tools at their disposal. Here we discuss and apply two that are particularly relevant to future resource cost projections at least one of which should have been employed in the DEIS energy analysis. The first is a technique is known as experience curve analysis (often called learning curve analysis, though that term is more limited in applicability). This relies on the robust and well documented process through which technologies undergoing technical innovation decline in cost by a fixed factor, known as the learning rate, for a	The battery storage comments are a duplicate of Comment 6881-8, the next comment. Response is provided in that location. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options and changes to costs. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (7th Plan at page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, Section 2.2. The EIS uses the best available resource cost information from the Council to estimate the potential range in costs of these replacement resources. The purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for Multiple Objective (MO) Alternative 3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. The final EIS incorporates the forward cost curves presented by the Council on February 27, 2020, to the Generating Resources Advisory Committee for the 8th Power Plan. In response to public comments, Appendix H, Section 2.2 in the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. The comment questions the use of 2022 as the study year for the EIS. The choice of before-and-after analysis around fiscal year (FY) 2022 was primarily made due to the availability of data and the need to establish a point-in-time from which to measure the effects of the MOs to the No Action Alternative. Establishing an estimated actual year of implementation for each of the MOs would have injected an additional timing element that could have affected the relative impacts analysis of the MOs. For example, MO3, which includes breaching the four lower Snake River dams requires an Act of Congress. To ensure this MO received equal treatment when comparing it to other MOs, the EIS assumes all pre-requisites for MO3 have occurred by FY 2022. Had a timing element been included in the comparison of the MOs, the EIS analysis could have assumed that Congress would not act by 2022, but by 2030 or some other subjective date, placing MO3 at a distinct disadvantage compared to other MOs, which could be completed by a sooner subjective date. Similarly subjective assumptions on timing could have been employed for the construction of replacement resources, especially for large-scale solar installations requiring environmental compliance, permitting, potential large acquisitions, etc., and conventional gas-fired units which are carbon emitting and politically unpopular. The choice of a single date (2022) from which to measure the environmental consequences of each MO removed the timing subjectivity from the EIS analysis and provided a level playing field from which to compare the impacts and costs of each MO (See Section 3.19 and Appendix Q for additional discussion). In this way, the choice of the modeling approach in the evaluation framework largely mitigates many of these concerns. Consistent with the statements and observations in the comment, the EIS considered battery storage coupled with solar power for the additional flexibility and capacity benefits. The use of storage technologies, is considered a long-term resource of the 7th Power Plan, but has become more commercially available since the release of the 7th Power Plan, will likely be considered a primary resource in the Councils 8th Power Plan, and is examined in the EIS. As discussed above, the EIS uses the best available resource cost information from the Council to estimate the potential range in costs of these replacement resources from the 7th Power Plan and the 7th Power Plan Mid-term Update in February 2019. For the 8th Power Plan, reference plant data was prepared by the Council between October 2019 to February 2020, which was not in time for inclusion in the draft EIS. However, the final EIS incorporates the forward cost curves presented by the Council based on National Renewable Energy Laboratory forecasts on March 3rd, 2020, to the Generating Resources Advisory Committee for the 8th Power Plan. The purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for MO3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. To address uncertainty surrounding potential costs, the EIS included the range of resource costs from the Council's Mid-term Update in the sensitivity analyses for each wholesale rate pressure analysis. To further address concerns about potential reductions in resource costs, the EIS expands the potential range of resource costs included in the sensitivity analyses to include future cost decreases. In addition, as noted by the comment, solar performance and costs are not as favorable in the Northwest as other regions, thus more regionally specific data and information, such as the costs sourced from the Council are often best suited to estimating regional resource costs.

				given amount of aggregate market expansion. Research by the Santa Fe Institute demonstrated the robust performance of experience curve assessment in considering future resource cost trajectories across 62 industries.11 In 2013, NWEC submitted a paper to the Western Electricity Coordinating Council (WECC), describing the technique and use of experience curve analysis specifically with regard to PV technology and markets.12 In general, as the global installed capacity of PV doubles in size, cost comes down by about 20% for modules and 15% for balance of system costs. That observation has remained robust since a 1978 analysis by the Solar Energy Research Institute (now NREL) to the present time. To illustrate the importance of the deficiency in the DEIS energy analysis of future resource costs, we use these two methods described above to assess the future costs of PV resources in relation to the costs in the DEIS. As mentioned, the DEIS adopts the Councils 2018 estimate of $1,350 to $1,500/kW-ac (2019$) for grid-scale PV in 2022. To simplify the explanation, we assume a midpoint 11 Nagy B, Farmer JD, Bui QM, Trancik JE (2013) Statistical Basis for Predicting Technological Progress. PLoS ONE 8(2): e52669. https://doi.org/10.1371/journal.pone.0052669 12 NW Energy Coalition, Experience Curves and Solar PV, September 3, 2012, available at: https://app.nwcouncil.org/media/6867808/2012-09-03-nwec-experience-curves-and-solar-pv.pdf Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 31 value of $1,425/kW-ac. A full assessment within an IRP analysis would consider ranges of future costs as part the scenario, portfolio optimization and least cost/least risk analysis. NWECs experience curve assessment assumes that the global PV market will double in size by 2022 and double again by 2026, a possible starting point for MO3. This results in a capital cost of $1,193/kW-ac in 2022 and $1,000/kW-ac in 2026. NRELs ATB referred to above as the industry standard for projecting future resource costs projects a midpoint cost range for PV of $1,214/kW-ac in 2022 and $1,071/kW-ac in 2026. There is good agreement between the simplified experience curve method and the more detailed ATB method. The table below compares these results to the DEIS analysis. Source PV cost per kW-ac (2019$) Change DEIS 2022 $1,425 NWEC experience curve 2022 $1,193 -16% NREL ATB 2022 $1,214 -15% NWEC experience curve 2026 $1,000 -30% NREL ATB 2026 $1,071 -25% Within an IRP context, the experience curve and ATB methods can provide valuable guidance for assessing resource costs over time. As illustrated here, projecting out-of-date resource costs forward into the future risks greatly overstating costs for resource portfolios. The DEIS does not explain why the agencies used stale data and methods for assessing future resource costs in the Replacement Power Analysis. As a result of this failure to insure the professional and scientific integrity of the analysis, the DIES significantly overstates the apparent cost of the replacement portfolios. This failure undercuts the selection of the Preferred Alternative. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 32 4.3 Hybrid Solar-Battery Storage As noted in DEIS Appendix H, Table 2-2, the zero carbon replacement power portfolio for MO3 includes 2,550 MW of solar with 1,250 MW of battery storage. First, the analysis fails to provide any explanation of why 1,250 MW is the right amount of incremental storage, and notes that this was done last in the analysis as an add-on. Further, it does not consider the perspective that the LSR dam attributes lost are the same ones that the rest of the CRS system might have in excess if significant amounts of solar and wind are developed on the system. Second, the DEIS does not consider additional storage resources when determining how much solar and demand response are necessary to return the system to the LOLP baseline. This means the analysis of MO3 is likely overbuilt from a capacity perspective. To properly build the portfolio, the DEIS should have calculated the flexibility need created, added storage to provide that, then counted this storage in the LOLP analysis to determine what additional solar/wind capacity is required to return the system to the benchmark LOLP. As a result of this one error, the MO3 portfolio likely should have had either less solar, less storage, or less of both, resulting in a material reduction in portfolio cost. Third, as shown in DEIS Appendix H, Table 2-3 below, the DEIS Replacement Power Analysis includes a cost $2,568/kW for hybrid solar plus battery storage resources, based on an October 2019 staff presentation to the Northwest Power and Conservation Council. However, the DEIS applies this value in an incorrect fashion. As shown below, the Council presentation was based on a reference facility with equivalent solar nameplate capacity and storage capacitya 100 MW-ac solar plant and 100 MW/400 MWh battery facility. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 33 However, in the DEIS Replacement Power Analysis, the hybrid resource chosen, as shown in Table 2-2, Appendix H above, is 2,550 MW solar and 1,250 MW of battery storage. The DEIS analysis does not explain whether the battery capability is the same as in the Council analysis, that is, 4-hour storage (100 MW/400 MWh). That said, use of the Councils cost for solar and battery storage significantly overstates the hybrid resource cost for MO3, because 2,550 MW of solar is paired with 1,250 MW of battery capacity instead of the one-for-one cost basis of the Councils estimate. Because battery storage is still relatively expensive, this considerably overweights the combined resource cost per kW. This apparent error should be corrected in the Final EIS. Furthermore, even since the Councils analysis in 2019, hybrid solar and battery storage project costs have quickly fallen and media reports indicate similar systems may now have capital costs at least one third less, or approximately $1,700/kW. NWEC estimates a correction to the DEIS solar+battery cost could reduce the annualized value of the capital cost of the zero carbon portfolio for MO3 (Appendix H, Table 2-4) by more than one quarter, Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 34 from $389 million to $270 million per year; and rate pressure on BPA wholesale power rates and consumer electric bills would drop accordingly.	
6881	8	Fred Heutte	NW Energy Coalition	.3 Hybrid Solar-Battery Storage As noted in DEIS Appendix H, Table 2-2, the zero carbon replacement power portfolio for MO3 includes 2,550 MW of solar with 1,250 MW of battery storage. First, the analysis fails to provide any explanation of why 1,250 MW is the right amount of incremental storage, and notes that this was done last in the analysis as an add-on. Further, it does not consider the perspective that the LSR dam attributes lost are the same ones that the rest of the CRS system might have in excess if significant amounts of solar and wind are developed on the system. Second, the DEIS does not consider additional storage resources when determining how much solar and demand response are necessary to return the system to the LOLP baseline. This means the analysis of MO3 is likely overbuilt from a capacity perspective. To properly build the portfolio, the DEIS should have calculated the flexibility need created, added storage to provide that, then counted this storage in the LOLP analysis to determine what additional solar/wind capacity is required to return the system to the benchmark LOLP. As a result of this one error, the MO3 portfolio likely should have had either less solar, less storage, or less of both, resulting in a material reduction in portfolio cost. Third, as shown in DEIS Appendix H, Table 2-3 below, the DEIS Replacement Power Analysis includes a cost $2,568/kW for hybrid solar plus battery storage resources, based on an October 2019 staff presentation to the Northwest Power and Conservation Council. However, the DEIS applies this value in an incorrect fashion. As shown below, the Council presentation was based on a reference facility with equivalent solar nameplate capacity and storage capacitya 100 MW-ac solar plant and 100 MW/400 MWh battery facility. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 33 However, in the DEIS Replacement Power Analysis, the hybrid resource chosen, as shown in Table 2-2, Appendix H above, is 2,550 MW solar and 1,250 MW of battery storage. The DEIS analysis does not explain whether the battery capability is the same as in the Council analysis, that is, 4-hour storage (100 MW/400 MWh). That said, use of the Councils cost for solar and battery storage significantly overstates the hybrid resource cost for MO3, because 2,550 MW of solar is paired with 1,250 MW of battery capacity instead of the one-for-one cost basis of the Councils estimate. Because battery storage is still relatively expensive, this considerably overweights the combined resource cost per kW. This apparent error should be corrected in the Final EIS. Furthermore, even since the Councils analysis in 2019, hybrid solar and battery storage project costs have quickly fallen and media reports indicate similar systems may now have capital costs at least one third less, or approximately $1,700/kW. NWEC estimates a correction to the DEIS solar+battery cost could reduce the annualized value of the capital cost of the zero carbon portfolio for MO3 (Appendix H, Table 2-4) by more than one quarter, Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 34 from $389 million to $270 million per year; and rate pressure on BPA wholesale power rates and consumer electric bills would drop accordingly.	The comment makes numerous statements regarding the potential of battery storage and the solar plus storage portfolio in Multiple Objective (MO) Alternative 3. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Section 3.7.3.1). The EIS explains that battery storage is necessary to replace some of the capabilities of the four lower Snake River dams such as peaking and flexibility that are not afforded by conventional solar power. The EIS assumes that half of the quantity of solar would be matched with storage. See Section 3.7.3.5, at pages 3-904-905 in the draft EIS. In response to this and other public comments, in the final EIS, the power analysis revised the portfolio to address the concern stated in the comment regarding the potential to overbuild the battery storage and solar. The Loss of Load Probability analysis is performed to size the total amount of solar and battery resources needed to return the region to the No Action Alternative level of reliability, while maintaining the 2:1 solar to battery ratio. Moreover, this comment misunderstands the calculation used. It is true that the technology priced by the Northwest Power and Conservation Council (Council) is based upon a 100MW/400MWh battery (that is, a battery which discharges at a rate of 100MWs for a four hour duration). The combined solar plus battery installation of 1,275MW was priced at this value of $2,568/kW/yr, while the remaining 1,275MWs of naked solar (i.e., not backed by batteries) is priced at the Councils Mid-term Assessment price of $1,425/kW-yr (2016$). See Chapter 2 of Appendix H in the draft EIS. The final EIS incorporates updated resource costs, including declining cost curves, into the rate sensitivity portion of the analysis. In the base case, however, the full solar amount would be priced at the Mid-term Assessment price of $1425/kW/yr, while the remaining batteries would be priced at the Councils separate battery cost of $1,400/kW/yr (also in the same presentation referenced in this comment). This allows for proper treatment of differing useful lives (30 years for solar, 15 years for batteries), and avoids unintended confusion over resource costing in the final EIS.
6881	9	Fred Heutte	NW Energy Coalition	4.4 Demand Response Demand response refers to contractual and/or rate design methods to reduce electricity end use at times of system peak demand, usually very limited number of hours per year. Demand response provides high value because otherwise the most expensive reserve generation must be activated to meet system peaks and provide other flexibility for a limited amount of hours in a year. These capabilities are particularly important in comparing a replacement resource mix to the energy services provided by LSR hydrogeneration. The DEIS Replacement Power Analysis limits demand response to 600 MW. The DEIS states: The CRSO base case analysis uses the NW Councils 7th plan for costs and amounts of achievable demand response. Consistent with the 7th Power Plans estimates, the Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 35 analysis assumes 400 MW of demand response developed in the near-term by Bonneville, in partnership with Bonnevilles power customer utilities, and another 200 MW of demand response developed by regional investor owned utilities. DEIS Appendix 3 at line 25495 However, this is not consistent with the Councils estimates. The Council 7th Plan recommendations identified 600 MW of demand response as the minimum amount available, not the ceiling assumed in the DEIS:The Councils assessment identified more than 4,300 megawatts of regional demand response potential. A significant amount of this potential, nearly 1,500 megawatts, is available at relatively low cost; less than $25 per kilowatt of peak capacity per year. As the Council explained, When compared to the alternative of constructing a simple cycle gas-fired turbine, demand response can be deployed sooner, in quantities better matched to the peak capacity need, deferring the need for transmission upgrades or expansions. Council 7th Power Plan at 1-10. The Council summarized their recommendation for demand response as follows: The Councils analysis indicates that a minimum of 600 MW of demand response resources would be cost-effective to develop under all future conditions tested across all scenarios which do not rely on increased firm capacity imports.	The EIS analyzed demand response using the Northwest Power and Conservation Councils 7th Power Plan as guidance. See draft EIS, Section 3.7.3.1 at page 3-837. The 7th Power Plan states that a minimum of 600 MW of demand response resources would be cost-effective to develop under all future conditions tested across all scenarios which do not rely on increased firm capacity imports. This is about 75% of their games. The final EIS includes a more detailed discussion of how replacement resources were selected. See Appendix H, Section 2.2. For the EIS, demand response was evaluated similarly to other resources in their ability to lower the Loss of Load Probability (LOLP) of an alternative cost effectively. Demand response was less cost-effective at lowering the LOLP than other resources. Therefore, the EIS did not include more than 600 MW. The reasons for this is that demand response is an energy-limited resource. Like the 7th Power Plan, the EIS assumed that this resource is only available 50 hours per year. Therefore, because of its energy-limited nature, demand response is only deployed when other options are not able to cover an LOLP event, essentially making demand response function as the most costly resource. Demand response is likely to be more helpful in events when the demand spikes briefly and other resources are not available, but not as useful for multi-day cold snaps or summer heat waves. Demand response is more suited to capacity than to sustained capacity and energy. Note that the EIS follows the Councils practice of considering demand response as a load curtailment, meaning that not only does it reduce demand when deployed, but that the demand does not shift to a different time. However, some forms of demand response, like space and water heat, irrigation pumping, or air conditioning is more likely to shift demand without reducing the energy need. The assumption that demand response would solely be load curtailment is a best-case scenario in terms of demand response supporting reliability. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. Demand response is discussed in Section 3.7.3.1 on pages 3-866 to 3-868 in the draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Council 7th Power Plan at 3-4 (emphasis supplied). Furthermore, the Councils Plan clearly shows that substantially more demand response would be available at lower cost than other alternatives selected by the DEIS analysis within five years if the region chose to develop it. For example, as shown in Fig. 3-7 of the 7th Power Plan below, over 2,000 MW of cost-effective demand response is available in the 7th Plan at less than $77/kW-year (2012$), compared to new natural gas power plants at $125/kW-year and above. 7th Plan, Table H-10, Frame Gas Turbine Cost Summary. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 36 7th Northwest Power Plan at 3-22 Demand response is well suited to Northwest and winter peaking needs and at scale could directly substitute for LSR hydrogeneration ramping and sustained peaking capacity, while gaining additional reliability and economic benefits from reduced transmission losses and congestion, and reducing risk from interannual hydro variability, especially during low or critical water periods when the LSR hydrogeneration operating range will be reduced by 20% or greater. The DEIS does not include the full range of the demand response resource potential identified by the Councils 7th Plan, and does not provide an explanation for this omission. The failure to use accurate availability and cost for demand response resources means that,, especially for MO3, the DEIS Replacement Power Analysis increases the need for other more expensive resources, particularly battery storage, to address the capacity gap if the LSR hydrogeneration is retired.	
6881	10	Fred Heutte	NW Energy Coalition	4.5 Wind Energy The Joint Commenters are concerned that Montana wind is not included in the DEIS replacement portfolios, especially for MO3. It is well known that Montana wind is available in vast quantities, with very high capacity factors. And as the DEIS states, Montana wind has a generation profile that is closely aligned with Pacific Northwest area loads. DEIS Appendix H at line 816. Yet the DEIS Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 37 includes solar plus battery resources in MO3, but not Montana wind. Nor does the DEIS assess wind plus battery storage or pumped storage, a significant possibility in Montana due to the potential availability of the Absaroka Gordon Butte project, a proposed highly efficient 400 MW project that could be available by 2025. The fragmentary comments on wind analysis in the DEIS make it difficult to discern the reason for this result. One possibility is that when solar PV was picked for the MO3 alternative, and then battery storage resources were added to provide winter flexibility, this sequence precluded the full consideration of Montana wind. Again in this instance, the DEIS energy analysis fails to provide sufficient information about the resource portfolio assessment, and a comprehensive IRP analysis may well have resulted in the inclusion of significant quantities of Montana wind.	The EIS included Montana wind, Columbia Gorge wind, and a combination of wind and solar as potential replacement resources. For Multiple Objective (MO) Alternative 2, Montana wind was found to be the most cost-effective avoided resource build, meaning the resource-build difference between MO2 and the No Action Alternative. In contrast, for MO1, MO3, and MO4, solar alone was found to be the most cost-effective option at improving regional power reliability. Wind in the Columbia River Gorge was not selected as a zero-carbon replacement resource primarily due to the fact that additional Columbia River Gorge wind provides very little incremental benefit in reducing the Loss of Load Probability (LOLP). Even with the addition of 25,000 MW of new Columbia River Gorge wind, regional LOLP remained at 37.1 percent when considering potential coal retirements. In contrast, the addition of 25,000 MW of solar capacity would reduce LOLP to below 10 percent (a reduction of approximately 40 percent). See draft EIS, Appendix H, Power and Transmission, Section 2.3 at page 2-12. The EIS did evaluate pumped storage as a potential replacement resource among other storage technologies. See draft EIS, Section 3.7.3.5 at page 3-909. While there are several feasible sites in the region that could provide pumped storage capacity, those projects have additional costs, permitting and environmental concerns. There is also uncertainty that these resources would provide sufficient energy and capacity to provide a credible source of replacement resources. Further, the capability of these pumped storage sites would not be able to address the scope of replacement resource needs considered in the EIS. See draft EIS, Section 3.7.3.5 at page 3-909. In the draft EIS, Appendix H, Chapter 2, provides additional details on resource selection, including discussing pumped storage. In response to public comments, Appendix H, Section 2.2 of the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS.
6881	11	Fred Heutte	NW Energy Coalition	4.6 Renewable Energy and Storage Capacity and Flexibility Value The DEIS Replacement Portfolio Analysis takes a limited view of renewable energy and storage resource capabilities, and misrepresents the capabilities of hydrogeneration. The DEIS states: Solar, however, does not produce energy during the night. Wind, however, can produce energy during both the daytime and nighttime hours. Together, these resources would allow for generation day and night, mitigating the lost firm energy production of the lower Snake River projects. Utility-scale batteries would replace the lost flexibility and ramping capability of the lower Snake River projects. However, the batteries provide an imperfect replacement for the lost capability of the lower Snake River projects because, while batteries can be discharged to provide energy, they also need to be recharged and consume energy on a net basis. DEIS Chapter 3 at line 27404 While it is appropriate and necessary to measure the net contribution any particular resource makes to system value, no resource stands alone. Wind, solar and battery resources will be operated in conjunction with CRS hydrogeneration and other resources. One of the important missing pieces of the DEIS analysis is full consideration of how CRS hydrogeneration and new renewable, storage and demand response resources can be operated in coordinated and complementary fashion, increasing overall system value. For MO3, the DEIS did not assess system flexibility following LSR dam breach and hydrogeneration retirement and optimize the resource portfolio accordingly. For example, an optimized mix of advanced energy efficiency, demand response, storage, and renewable generation diversity could enhance the ability of the remaining CRS hydrogeneration to provide flexibility. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 38 Concerning resource diversity, considerable research has shown that diversifying the system portfolio by resource type, performance and geographic diversity will add significant value. For example, the comprehensive Western Wind and Solar Integration Study found that increasing the size of the geographic area over which wind and solar resources are drawn substantially reduces variability.13 The claim that energy storage such as batteries are an imperfect replacement is incomplete and misleading. Hydropower is indeed a form of renewable energy, subject to variable energy input from climate and weather patterns just as wind and solar are. Hydropower also inherently combines energy storage and energy generation capability, the same as hybrid wind or solar plus battery storage systems. It is possible that an optimized combination of clean energy resources could provide more system flexibility year-round. Again, because the DEIS did not conduct an IRP analysis, this opportunity was not explored, and particularly for MO3, the analysis is incomplete and inaccurate.	The comment expresses concerns that the EIS misrepresents the capabilities of hydropower resources and about the combination of renewable energy and storage resources. The EIS does acknowledge that multiple resources can work in a coordinated fashion, for example the integration role of hydropower in bringing new renewable power online, or the demand response resources that reduce system costs in the renewable replacement resource portfolios for each alternative. While it is accurate that the EIS resource models such as GENESYS and AURORA are not optimizers, they do run thousands of simulations of the regional power system to evaluate various potential outcomes regarding the coordination and operation of resources under various water conditions. The EIS did evaluate changes in hydropower generation following breaching of the four lower Snake River dams under Multiple Objective (MO) Alternative 3 and then evaluated a variety of potential replacement resources, including storage, solar and wind as mentioned in the comment. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-910. The analysis also considered combinations of solar and wind, with solar power being consistently the most cost-effective resource identified in the analysis. The EIS also considered multiple potential locations for replacement wind generation as mentioned in the comment; however, these were not found to be cost effective relative to solar power at improving reliability and reducing overall power system costs. Regarding improved flexibility, the EIS finds that losing the hydropower from the four lower Snake River dams would decrease flexibility, though the addition of battery storage would address some of this loss. Based on responses to public comments, Appendix H, Section 2.2 of the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Northwest Power and Conservation Councils (Council) 7th Power Plan. All cost effective conservation identified by the Councils 7th Power Plan is included in the load forecast. See draft EIS, Appendix H, Power and Transmission, Section 2.2 at page H-2-3. Under Washington and Oregon law, all cost effective conservation must be acquired regardless of the status of the Federal Columbia River Power System. Therefore, conservation was not considered a potential resource replacement. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3. The commenter suggests or questions why a competitive resource review, also known as an integrated resource plan (IRP), was not performed as part of the EIS analysis. An IRP is a resource planning tool that utilities use to plan for future resource builds and acquisitions to fulfill the utility's specific needs over a certain planning horizon, typically 20 years. Some utilities are required to conduct an IRP by their local or state utility commissions. Bonneville is not required to perform an IRP, but does perform resource planning to inform its decisions, including for this EIS. There are many different methods and tools that are used by utilities when performing an IRP. Furthermore, the output of an IRP is often driven by state energy policies, such as carbon emission requirements. Even if an IRP optimizes resource portfolios, the real costs of that portfolio are not known until a competitive request for proposal solicitation can be completed and evaluated. For further discussion about the resource selection process used in the EIS in lieu of an IRP, please refer to the response to Northwest Energy Coalitions comment 6881-4 above.
6881	12	Fred Heutte	NW Energy Coalition	4.7 Battery Storage The DEIS Replacement Portfolio Analysis considerably underestimates the potential size and capabilities of battery storage. The DEIS states: To provide a similar level of sustained ramping (Table 3-160, above) as the lower Snake River projects, 2,265 MW of batteries would be needed. Additionally, the lower Snake River projects provide 250 MW of operating reserves. This would bring the total to 2,515 MW of batteries needed to replicate the peaking and flexibility of the lower Snake River projects. Developing utility-scale batteries of this size is untested. The largest battery facility in the world is currently 100 MW. DEIS Chapter 3 at 27427 This statement is incomplete and misleading. Large grid battery storage projects with contract commitments that are expected be completed by the end of 2021. Major utilities and producers are scaling up battery storage globally.14 In California alone these include Strata Oxnard (100 MW/400 MWh, online data December 2020), AES Alamitos (100 MW/400 MWh, 2021), Tesla Moss Landing 13 See National Renewable Energy Laboratory, Western Wind and Solar Integration Study, https://www.nrel.gov/grid/wwsis.html 14 GreenTech Media, The Biggest Batteries Coming Soon to a Grid Near You, September 3, 2019, https://www.greentechmedia.com/articles/read/the-biggest-batteries-coming-soon-to-a-grid-near-you Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 39 (182.5 MW/730 MWh, December 2020) and Vistra Moss Landing (300 MW/1,200 MWh, December 2020). And notably, the FPL Manatee Energy Storage Center will combine an existing solar project and a new 409 MW/900 MWh battery storage facility in Florida by late 2021. In Oregon, new storage development15 includes: The 2019 acquisition by Portland General Electric of a part of the Wheatridge three-way hybrid project developed by NextEra Energy Resources LLC, including 300 MW of wind, 50 MW of solar and 30 MW of battery storage starting in December 2021. Obsidian Renewables LLC has broken ground for the planned 400-MW Obsidian Solar Center in Lake County with a potential 50-MW flow battery storage system. The Avangrid Bakeoven Solar Project in Wasco County, under review by the Oregon Energy Facility Siting Council, would combine 100 MW of lithium-ion or flow batteries and 303 MW of solar generation with construction starting in 2020. Ecoplexus is pursuing the proposed 63-MW Madras Solar Energy Facility in Jefferson County, with up to 240 MWh of energy storage. Much of the capacity for these projects is already in the Bonneville transmission interconnection queue since it will require federal transmission to wheel power to offtakers. The DEIS does not accurately represent the current capability of battery storage resources.	As noted by the commenter, at the time of the Draft EIS, the largest operational battery was 100 MW. The commenter has identified a number of future planned battery projects that have expected capacity ranges from 100 MW to 409 MW. Pricing information for these projects is not provided. This comment is consistent with the EIS findings that new technologies and practices are developing in the energy markets at all times. These potential future projects, however, are also below the range of batteries needed to replace the peak capability of the four lower Snake River dams. In the draft EIS, the base case identified a need for 1,275 MW of batteries for Multiple Objective Alternative 3 and the full-replacement portfolio for the four lower Snake dams required 2,215 MW. As a result of public comments, the base-case quantity is being adjusted in the final analysis to 980 MW.
6881	13	Fred Heutte	NW Energy Coalition	4.8 Inverter-Based Resources The DEIS Replacement Power Analysis completely sets aside the value of essential reliability services from inverter-based resources, for example, solar, wind and battery storage. The DEIS states: Another limitation of the wind, solar, and battery portfolio is its inability to provide voltage and inertia benefits. As described above, the lower Snake River projects provide voltage and inertia benefits to the transmission system. Currently, wind, solar, and batteries do not provide the same level of voltage support as an installed generator, though this may change with advancements in technology. Providing inertia benefits from solar and wind resources and battery technology, however, would be more challenging because these facilities do not have the same heavy rotating mass as hydro 15 S&P Global, Kicking coal, Oregon emerges as a solar and energy storage development hub," March 6, 2020, https://www.spglobal.com/marketintelligence/en/news-insights/latest-news-headlines/kicking-coal-oregon-emerges-as-a-solar-and-energy-storage-development-hub-57104313 Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 40 generators. New technologies that would allow wind, solar, and batteries to mimic the inertia characteristics of synchronous generators have yet to be developed. DEIS Chapter 3 at line 27439 The technical and field test evidence is totally contrary to this statement. According to the North American Electric Reliability Council (NERC) Essential Reliability Services Working Group (ERSWG), these services are broadly grouped together as frequency support, voltage support and ramping and balancing.16 Inverter-based resources have inherent advantages over conventional resources using spinning mass, including coal, nuclear, gas and hydro. While hydrogeneration is clearly superior to thermal generation in terms of ramp rates, minimum power levels (Pmin), emissions and other attributes, inverter-based resources rely on power electronics and can be much faster and more faithful to a control signal for fast frequency response, voltage support, ramping and other essential reliability services.17 Two recent major field studies have validated these findings. In the first study, CAISO, NREL and FirstSolar conducted a rigorous field test of a 300 MW solar facility in Arizona. The results showed that solar projects can reliably provide frequency control, voltage control and ramping capability at scale, with much better response time and fidelity than conventional resources.18 In the second study, CAISO, Avangrid Renewables, NREL and General Electric conducted tests at a 131 MW wind facility near San Diego,	The EIS does acknowledge that Currently, wind, solar, and batteries do not provide the same level of voltage support as an installed generator, though this may change with advancements in technology. (Lines 27441 to 27443 in the draft EIS). The EIS simply recognizes that this capability is not yet proven or accepted for wide scale use. At least two of the sources cited by the commenter (https://www.nerc.com/comm/Other/essntlrlbltysrvcstskfrcDL/ERSWG_Sufficiency_Guideline_Report.pdf and http://www.caiso.com/Documents/WindPowerPlantTestResults.pdf) similarly conclude that additional work would be necessary in order to conclude that renewable resources would be operationally feasible for the provision of reliability service. Those sources also conclude that contractual arrangements for the provision of reliability services such as automatic generation control (AGC) response, voltage support, and provision of reserves from any potential replacement resources, including renewable resources, would also need to be developed. It is not currently clear that renewable resources would meet availability requirements to allow them to provide such services. The tests cited by the commenter do indicate the promise of power electronic devices to provide benefits attributable, in large part, to the ability of the electronics to respond more quickly. The tests are, however, limited in scope. The example cited was for a 300 MW resource, which is substantially smaller than the potential loss of generation considered in the EIS (a resource replacement of up to 5,000 MW under the zero-carbon replacement portfolio for Multiple Objective (MO) Alternative 4). Given the uncertainty of when battery storage plus inverter based technology might truly be able to replace the benefits of the lost hydropower generation, it would be premature for the EIS to assume that the technology would be available in a timely manner and in the quantity required to be a viable replacement resource. The EIS acknowledges that in the future, renewable resources may be able to provide these reliability services. The EIS also recognizes that the technology is not mature and is not ready for application on a utility-wide basis. Rather, the EIS chose resources that can provide reliability services with certainty to perform analysis for the EIS. To assume that the renewable resources stand ready to provide such capability in a timely manner to support actions under the various MOs would introduce additional uncertainty into the assessment for the EIS. Specifically, the EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				also finding the wind plant performed as well as or better than conventional units.19 16 NERC, Essential Reliability Services Whitepaper on Sufficiency Guidelines, December 2016, https://www.nerc.com/comm/Other/essntlrlbltysrvcstskfrcDL/ERSWG_Sufficiency_Guideline_Report.pdf 17 Michael Milligan, Sources of grid reliability services, Electricity Journal, 2018, https://doi.org/10.1016/j.tej.2018.10.002 18 Utility Dive, "California solar pilot shows how renewables can provide grid services," October 16, 2017, https://www.utilitydive.com/news/california-solar-pilot-shows-how-renewables-can-provide-grid-services/506762/ Also see Clyde Loutan et al., Demonstration of Essential Reliability Services by a 300-MW Solar Photovoltaic Power Plant https://www.nrel.gov/docs/fy17osti/67799.pdf 19 Utility Dive, Wind plants can provide grid services similar to gas, hydro, easing renewables integration: CAISO, March 13, 2020, https://www.utilitydive.com/news/wind-plants-can-provide-grid-services-similar-to-gas-hydro-easing-renewab/574070/ Also see California ISO, Avangrid Renewables and NREL, "Avangrid Renewables Tule Wind Farm: Demonstration of Capability to Provide Essential Grid Services, March 2020, http://www.caiso.com/Documents/WindPowerPlantTestResults.pdf Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 41 To be sure, much work remains to provide full system integration and compensation to enable the capabilities of inverter-based resources. However, as the electric power system expands and requires additional reliability and resilience, the superior performance of inverter-based resources will surely mean an important and growing role for wind, solar and battery systems in providing essential reliability services. By focusing its analysis on 2022 as a replacement date, the DEIS arbitrarily avoids addressing any of these developments and their potential role in replacing the power from the Lower Snake River dams. The DEIS does not explain why, in the face of abundant engineering analysis and field testing, it rejected consideration of these capabilities. This failure means it is likely the Replacement Power Analysis assumes additional resources at greater cost than necessary over time especially inflating the overall costs of MO3.	
6881	14	Fred Heutte	NW Energy Coalition	4.9 Pumped Storage While the DEIS Replacement Power Analysis provides a short description of the pumped hydro resource, it does not further review directly relevant developments in the Northwest. There are at least three pumped storage projects that could be constructed in the region by the mid to late 2020s, Swan Lake (Klamath County, Oregon), Goldendale (Klickitat County, Washington), and the Absaroka Gordon Butte project (Meagher County, Montana). Each could provide significant support and increase the capacity and flexibility of the CRS. The DEIS only discusses the prospective cost of pumped storage, and does not discuss whether these important resource characteristics were considered.	The EIS did evaluate pumped storage as a potential replacement resource among other storage technologies. See draft EIS, Section 3.7.3.5 at page 3-909. While there are several feasible sites in the region that could provide pumped storage capacity, those projects have additional costs, permitting and environmental concerns. There is also uncertainty that these resources would provide sufficient energy and capacity to provide a credible source of replacement resources. Further, the capability of these pumped storage sites would not be able to address the scope of replacement resource needs considered in the EIS. See draft EIS, Section 3.7.3.5 at page 3-909. In the draft EIS, Appendix H, Chapter 2 provides additional details on resource selection, including discussing pumped storage. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Section 3.7.3.1 and Appendix H, Section 2.2.)
6881	15	Fred Heutte	NW Energy Coalition	4.10 Future Market Value Over the last decade, power markets in the Western Interconnection have started undergoing a profound change on both the supply and demand side. These changes have already substantially affected the operation and net revenues of the CRS. The DEIS Replacement Power Analysis does not consider these factors with regard to the alternatives, particularly MO3. The first key factor is the persistently low natural gas commodity prices since 2010, when shale gas became a dominant factor in the North American market. The price of gas has varied between about Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 42 $2.50 and $4.00/mmBtu over the last decade, well below the higher prices for most of the previous decade. Natural gas power plants generally set the marginal price in western power markets, though the price may vary in different markets and trading hubs. Even in the Northwest, gas sets the price for power products at the Mid-C market hub most of the year, except during the spring runoff, when hydrogeneration peaks, and most thermal generation goes offline for annual maintenance. In California, the advent of substantial solar resources has led to the widely recognized duck curve. During the middle of the day, solar energy, which has very little variable cost, displaces natural gas and other competing resources. The less efficient gas plants reduce output or go offline until the late afternoon ramp when overall demand rises toward early evening peak. In the years since 2014, this effect has become more and more pronounced. However, while mid-day California market prices are much lower than a decade ago, evening peak prices are much higher. Overall, total annual revenue in the California market, and to a great degree at Mid-C, is still correlated to natural gas prices. The Bonneville Power Administration has been at a disadvantage selling its secondary energy from the CRS into the Mid-C and California markets. As the price of commodity natural gas has declined and market prices have fallen accordingly, BPA secondary revenues have declined, causing significant rate pressure on its wholesale firm power rates and the bills paid by its preference utility consumers. As a recent presentation on the draft BPA 2020 Resource Program Update indicated, these trends are likely to continue, especially as renewable energy that is cheaper than natural gas begins to set market prices in California and throughout the west in a greater percentage of hours across the year. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 43 As the chart above20 illustrates, the Mid-C High Load Hour product (heavy blue trace) is projected to decline substantially over this decade, partly because of continued decline in gas prices and partly from the increase in less expensive renewable energy. As the secular trend in both the Northwest and California power markets goes downward, CRS secondary energy sales revenue will decline. But because of the need for system flexibility, both in the morning and late afternoon ramp periods, the value proposition of the non-firm power capabilities of the CRS will shift from bulk secondary energy to flexibility, capacity and ramping products. Because LSR dams are primarily run-of-river facilities, their hydrogeneration is less flexible than the mainstem Columbia CRS projects, and the relative value of the LSR hydrogeneration flexibility as well as energy will decline going forward. But because the DEIS Replacement Power Analysis only considers conditions in the study year of 2022, these effects are not adequately captured, leading to an arbitrary overvaluation of the LSR hydrogeneration in the DEIS.	The conclusion of this comment is inconsistent with the findings of the Draft EIS. The comment accurately describes the trends underlying the west coast energy market in recent years, and provides a reasonable vision of how those trends might continue to unfold over time. However, the claim that the four lower Snake River dams are run-of-river and not useful for capacity and flexibility purposes is inaccurate. See draft EIS, Section 3.7.3.5, Zero-Carbon Replacement (Base Case Analysis), and Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). The four lower Snake River dams are not strictly run of the river, and have substantial peaking and ramping capability due to their ability to drop to near zero, and ramp up to full capacity for a sustained period except in very high or low water conditions or with high levels of spill for juvenile fish passage. Sustained peaking capability is limited under certain water conditions and some times of year; however, the four lower Snake River projects are instrumental to the region as renewable penetration increases and ramping requirements (say to meet the duck curve) increase. Arguably, its value would only increase over time, rather than diminish as this comment inaccurately asserts. This is because, as the commenter correctly identifies, the advent of substantial variable resources, like the solar that lead to the duck curve, creates capacity requirements that hydropower resources are well-suited to provide. Counter to the commenters claim, the four lower Snake River projects do have operational flexibility that can help provide this capacity requirement as they operate within a 3- to 5-foot elevation range in the fall and winter, and within a 1 or 1.5 foot elevation range during the fish passage season. Bonneville does use this small operating range to peak, i.e., to increase generation for brief periods of high demand when conditions permit. They provide approximately 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. The use of fiscal year (FY) 2022 as a focal point for the rate pressure analysis fairly compares each alternative relative to the No Action Alternative in a consistent manner. It distills each alternative into a before and after state, and estimates expected rate pressure relative to the No Action Alternative consistently. The socioeconomic analysis then imputes that expected rate effect over time to weigh the socioeconomic costs or benefits of each alternative with the other objectives in the analysis. Speculation on future trends, especially those far out into the future, could lead stakeholders to make decisions based upon forecasts which imply a false level of precision, and understate the degree of uncertainty involved in forecasting future trends. Recent history would certainly suggest, however, that hydropower flexibility would remain at least as important to the region as it is today, and arguably more important in the future as more and more baseload carbon-based resources are removed from the grid, and in expectation, replaced by intermittent resources (such as wind and solar). This comment does well to support the value that the four lower Snake River projects provide to the region today and may continue to provide in the future. While it is true that the four lower Snake River projects are not as flexible as some of the other Federal projects, this does not mean the four lower Snake River projects are not valuable. In fact, from a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS), and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Further, the four lower Snake River dams have considerably more value than purchases made in the spot market. To make a proper comparison, the energy shape, capacity attributes, carbon content, and reliability attributes need to be considered. The four lower Snake River dams have advantages in all of these areas relative to spot market purchases. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6881	16	Fred Heutte	NW Energy Coalition	4.11 Interregional Imports The DEIS Replacement Power Analysis does not consider increasing interregional power imports from California and other areas in the Western Interconnection for the replacement portfolios, especially MO3. The Northwest power market, particularly at the Mid-C trading hub, has followed the California market more closely in recent years, with the exception of the spring runoff period in the Northwest. That is because the Pacific Intertie allows for substantial trading between the two regions. In the near future, significant amounts of California surplus power will flow from the low-priced CAISO market to the Northwest when system conditions price the Mid-C market at a higher level. Thus, both markets will converge and, on average, decline in price. 20 Bonneville Power Administration, 2020 Resource Program Update, March 17, 2020, https://www.bpa.gov/Finance/RateCases/BP-22-Rate-Case/Documents/Combined%20PPT%20for%20workshop%203.17.pdf Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 44 The chart above21 illustrates these ongoing developments. It shows net power exports from the Northwest to California in March 2020 on the AC Intertie. The red trace shows North-South transfer capacity and the yellow trace shows South-North capacity, which vary when there are outages or planned maintenance on the AC Intertie system. The blue trace shows net exports. Over the last year, net imports to the Northwest where the blue line goes below zero, have been occurring more frequently than in the past. In the month of March, when the Northwest snowpack is beginning to melt and winter demand peaks have declined, Mid-C prices are generally lower than California market prices. As a result, over the last two decades, power almost never flowed from California to the Northwest in March. However, starting in 2019, that has changed, whenever California prices are low enough relative to the Mid-C market. It now seems clear that imports into the Northwest will continue to grow and costs will decline. There are a number of factors including the continued decline in natural gas prices, increasing solar energy, 21 https://transmission.bpa.gov/BUSINESS/Operations/Paths/Interties/monthly/AC/2020/AC_2020-03.xls Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 45 changes in demand and the interannual variation of hydro in each region. This provides an important opportunity to include interregional imports as a potential replacement resource, especially during the winter. Increased imports would be a particularly good choice for mid-winter replacement of LSR hydrogeneration. However, the DEIS Replacement Power Analysis does not address this possibility nor explain why it did not do so. Again, this likely inflates the costs of the MO3 alternative.	This comment mischaracterizes the evaluation framework used in the draft EIS. The Loss of Load Probability modeling in the CRSO EIS explicitly included the import assumptions from the Councils 2022 Resource Adequacy Assessment. Moreover, the rate analysis incorporated modeling from AURORA using BP-20 Final Proposal assumptions. See draft EIS, Appendix H, Power and Transmission, at page H-2-7. AURORA models the entire Western Interconnection and accounts for growth of solar generation within California and across the Western Electricity Coordinating Council, lower natural gas prices, projected levels of demand, and seasonal variation of hydropower generation for dozens of water years in the Northwest, California, and British Columbia. AURORA reflects the increasing likelihood of power flows from California and the expected impacts on regional market prices. Accordingly, changes to imports from California are incorporated into the market analysis used to value net secondary revenues and forecast rate pressure under each of the alternatives.
6881	17	Fred Heutte	NW Energy Coalition	4.12 Power Market Structure Because the Replacement Power Analysis only included the study year of 2022, it did not consider the profound changes in power market structure in the Northwest and the Western Interconnection. We provide two examples. In March 2022, the Bonneville Power Administration expects to become a participant in the Western Energy Imbalance Market (EIM), which optimizes generation dispatch and use of reserves within each hour across most of the Western Interconnection. On Sept. 26, 2019, BPA signed an implementation agreement with the California Independent System Operator and a record of decision in a move toward joining the EIM in 2022.22 In addition, after becoming an EIM Entity, Bonneville will be eligible to join the proposed Enhanced Day Ahead Market extension to the EIM, enabling it to change CRS operations to reduce operating costs and risks and increase revenues for both firm power and secondary sales. While the eventual fruition of the EDAM is not certain, the growing consensus through the Western Interconnection is that market expansion offers substantial reliability, economic and environmental benefits. Bonneville engaged in two substantial studies including a full net benefits study to assess the relative value of joining the EIM. The EIM Record of Decision indicates that net benefits could fall in the range of $29 to $34 million per year.23 The anticipated benefits of the EDAM are expected to be much larger, and if it commences operation in the coming years, the existing Mid-C market and other trading hubs in the Western Interconnection will	The comment questions the use of 2022 as the study year for the EIS. The choice of a single date (2022) from which to measure the environmental consequences of each MO removed the timing subjectivity from the EIS analysis and provided a level playing field from which to compare the impacts and costs of each MO. The choice of before-and-after analysis around FY2022 was primarily made due to limited availability of data and the need to establish a point-in-time from which to measure the effects of the MOs to the No Action Alternative. Establishing an estimated actual year of implementation for each of the MOs would have injected an additional timing element that could have affected the relative impacts analysis of the MOs. For example, MO3 dam breaching requires an Act of Congress. To ensure this MO received equal treatment when comparing it to other MOs, the EIS assumes all prerequisites for MO3 have occurred by FY 2022. Had a timing element been included in the comparison of the MOs, the EIS analysis could have assumed that Congress would not act by 2022, but by 2030 or some other subjective date, placing MO3 at a distinct disadvantage compared to other MOs, which could be completed by a sooner subjective date. Similarly subjective assumptions on timing could have been employed for the construction of replacement resources, especially for large-scale solar installations requiring environmental compliance, permitting, potential large acquisitions, etc., and conventional gas-fired units which are carbon emitting and politically unpopular. The choice of a single date (2022) from which to measure the environmental consequences of each MO removed the timing subjectivity from the EIS analysis and provided a level playing field from which to compare the impacts and costs of each MO. See Section 3.19 and Appendix Q for additional discussion. In this way, the choice of the modeling approach in the evaluation framework largely mitigates many of the concerns raised in the comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				diminish in participation, reducing market depth, stability and efficient price discovery. 22 Bonneville Power Administration, Energy Imbalance Market, https://www.bpa.gov/Projects/Initiatives/EIM/Pages/Energy-Imbalance-Market.aspx 23 Administrator's Record of Decision, Energy Imbalance Market Policy, September 2019, at 112, https://www.bpa.gov/news/pubs/RecordsofDecision/rod-20190926-Energy-Imbalance-Market-Policy.pdf Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 46 Yet because the Replacement Power Analysis only included the study year of 2022, no analysis was conducted to examine the potential benefits and challenges of CRS participation in the changing power market structure, even though ample information to do so was available and the effects of this interconnection process are highly relevant to assessing the feasibility and costs of implementing MO3. The DEIS does not discuss the EIM and EDAM, and does not explain this omission.	The comment also suggests that modeling Bonneville's Energy Imbalance Market (EIM) participation is an important factor that should have been included in the EIS. As the comment notes, Bonneville's Administrator's Record of Decision in September 2019 signaled Bonneville's intent to join the EIM. Bonneville, however, has not made a final decision to join the EIM, nor will a final decision to join be made until after this EIS is complete. As such, revising the EIS to include a potential decision to join the EIM would not be consistent with the decision making framework Bonneville has committed to use. Even if the CRSO EIS were revised to include Bonneville's participation in the EIM, it would not likely affect the results of the EIS. The EIM benefits noted by the commenter rely on production cost modeling techniques using an assumption of perfect economic dispatch from the moment of entering the EIM. Bonneville's rates analysis, as used in the CRSO EIS, already optimizes dispatch regionally. Therefore, the CRSO EIS already presumes some optimal dispatch and benefits similar to those expected through the EIM. The comment also notes that additional benefits of the Enhanced Day Ahead Market (EDAM) should have been considered in the EIS. As of the publication of the CRSO Final EIS, the California Independent System Operation (CAISO) has not presented any formal proposals for extending the CAISOs Day Ahead Market to the EIM. There is, then, nothing for the CRSO EIS to consider in this analysis. Even if such a proposal were made, Bonneville has not stated whether it would participate in such a market. For these reasons, the EISs omission of EDAM a market that has yet to be developed and for which Federal resource participation is uncertain was appropriate.
6881	18	Fred Heutte	NW Energy Coalition	4.13 Transmission Resources and Operations Because the Replacement Power Analysis only included the study year of 2022, it did not consider potential transmission expansion, grid modernization and more efficient operations. Among other elements directly relevant to the CRS, this includes the ongoing efforts by BPA to revise its open access transmission tariff, reshape its transmission products for the emerging needs of more diverse and flexible resources, engage in a major grid modernization program supporting its participation in the EIM and other system optimization purposes, and potentially add new transmission lines and supporting resources. One major example is the possible Montana-to-Washington transmission expansion, which would add 600 MW of transfer capacity in the federal transmission system between western Montana and eastern Washington. An earlier environmental review of the projected was halted in 2013 when Bonneville determined that commercial offtaker potential had dwindled. Now, as a result of the review of the Montana Renewable Development Action Plan in 2018, co-sponsored by Bonneville and the Governor of Montana, and with further state energy policy developments and cost reductions favoring expanded transmission capacity to carry Montana wind to load in northern Idaho, Washington and Oregon, the prospects of M2W are improving. An even larger new transmission project known as Garrison-to-Ashe is also on the drawing boards, with a prospective completion date of 2030. Federal transmission expansion, grid modernization, tariff reform and more efficient transmission system operations will improve the value of renewable energy resources that could replace LSR hydrogeneration. But the DEIS fails to address these opportunities.	The EIS did examine a Montana wind portfolio of up to 660 MW based on available transmission capacity and the Washington state shares of Colstrip 1&2, which closed in 2019 per the Montana Renewable Development Action Plan. This portfolio was selected as part of the M02 avoided build. While transmission expansion may be necessary to integrate additional resources from more remote locations, the identified resource replacements for the Multiple Objective (MO) Alternatives were able to meet the Loss of Load Probability of the existing system (No Action Alternative level) without the need for additional transmission reinforcement. The efforts cited by the commenter, such as tariff revision, different transmission products, grid modernization, and EIM participation are activities that have not been decided and would be set to happen independent of actions that may occur as a result of the CRSO EIS. These efforts, however, would not change the fundamental needs the EIS considered; the EIS would still need to consider the changes in generation resources under the various MOs. Also, there is no certainty about the benefits of the efforts cited by the commenter, which is another reason why the efforts were not analyzed in the consideration of replacement resource portfolios in the EIS. See Appendix H, which describes the approach to the analysis in detail. The EIS identified replacement resource portfolios, including zero-carbon replacement resources, to identify a set of feasible resources that might be integrated into the transmission system at the lowest cost. While the completion of the Montana to Washington (M2W) and Garrison to Ashe transmission (GASH) projects could bring in resources from Montana into the Western Interconnection, those projects would also bring a substantial addition of cost. These projects are also not committed projects at this time, rather, they have been identified in studies that Bonneville was obligated to perform in response to requests for service across multiple transmission systems. The M2W and GASH projects addressed only the needs on the Bonneville network. Those projects did not consider expansion required in Montana that might also be necessary in order to integrate the output from resources in Montana. The EIS was able to identify a set of replacement resources that may be able to meet the requirements identified under the various MOs without adding uncertainty from projects that may or may not be completed. If the efforts cited by the commenter materialize, then they could be factored into future decision making on the need to replace generation from the MOs or to replace coal-fired power generation.
6881	19	Fred Heutte	NW Energy Coalition	4.14 Columbia River Treaty The DEIS has been conducted in parallel with ongoing negotiations between the US and Canada over the future of the Columbia River Treaty, with two of the co-lead agencies, the Bonneville Power Administration and US Army Corps of Engineers jointly constituting the US Entity. Certain provisions of the Treaty expire in 2024. The DEIS states: The 2016 CRT-related operations, were applied in the EIS analysis, as the best-available information. If CRT-related operations change in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary. DEIS Chapter 2 at 2326 Because the Columbia River Treaty drives CRS planning and operations in a foundational way, it should have been analyzed in the Replacement Power Analysis, but was not due to the limitation of the analysis only to the study year of 2022.	As the comment notes, the Draft EIS captures the effects to the CRS of storage in Canada that is coordinated with the United States under the Columbia River Treaty using the best available information in 2016, which included information from 2022-based studies and forecasts. Regarding the Power Supply and Replacement Resources chapter of Appendix H, the Columbia River Treaty requires the development of certain power studies in advance, and 2022 information from those studies, as well as other information described in the analysis, represented the best available information at the time of the CRSO Draft EIS. As aspects of the Columbia River Treaty regarding Canadian operations in 2024 and beyond remain the subject of an ongoing negotiation between the governments' of the United States and Canada, the co-lead agencies--including Bonneville and the Corps as members of the U.S. Entity--must continue to use the best available information that was applied in the Draft EIS to capture the effects of the Columbia River Treaty operations on the CRS in the FEIS.
6881	20	Fred Heutte	NW Energy Coalition	4.15 Inappropriate and Incomplete Coal Sensitivity In a complete diversion from the trend of not considering anything outside of the 2022 study year, the DEIS conducts a self-styled coal sensitivity considering the impact on regional energy, capacity and resource adequacy if additional coal generation serving the Pacific Northwest is retired beyond announced retirements as of the Replacement Power Analysis in 2022. With regard to MO3, the DEIS states: In the future condition with additional coal-plant retirements, this option would not be sufficient to return the LOLP to the No Action level, because without coal, more of the capability or replacement capability of the Lower Snake River (LSR) projects would be needed for power system reliability. DEIS Appendix H at line 653 This sensitivity is built upon completely erroneous assumptions and completely disregards the likelihood that the relatively inflexible and risky coal resource can be replaced with a more diverse, reliable, less polluting and less costly portfolio that affords additional flexibility to the CRS and improves Northwest power system performance. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 48 Noting the ongoing development of public policy promoting a transition from fossil fuel generation to clean energy resources, the DEIS further states: In light of this legislative and policy trend, the co-lead agencies assume that no new gas-fired generation would be built to replace the lost generation from the lower Snake River dams, only zero-carbon resources may be selected. At the utility-scale, the current best options are solar and wind resources, some batteries, and demand response programs. For MO3, the EIS analysis identified a potential zero-carbon replacement portfolio consisting of 2,550 MW of solar resources, , and 600 MW of demand response to restore LOLP. Tis portfolio relies on using the existing regional system to help make up for some of the lost capabilities of the lower Snake River projects - primarily by operating thermal plants more frequently to meet regional load. However, in light of regional policy initiatives to curtail or cease the operation of thermal plants, a zero-carbon resource replacement portfolio with insufficient dispatchable sustained capacity may not be feasible. If the replacement does not include firm generating capacity with only 600 MW of dispatchable capability, it is likely not a realistic assumption for MO3 where a substantial amount of generation capacity is lost. DEIS Chapter 7 at line 386 The Joint Commenters agree that new gas-fired generation should not be built to replace LSR hydrogeneration. But we strongly disagree that regional clean energy policy undermines the feasibility of replacing LSR hydrogeneration with a clean energy portfolio. Indeed, as explained at length in these comments, the DEIS does not provide a valid test of that assertion. Furthermore, the manifest goal of Northwest clean energy policy is to expand the capability of those resources to replace thermal generation in a reliable, clean and affordable manner. The success already accomplished under these policies is a matter of record. Here we cite two examples. The respective utilities with requirements under the 2006 Washington Energy Independence Act have met their responsibilities to acquire all cost-effective energy efficiency and to achieve the targets under the Acts Renewable Portfolio Standards, and often exceeded them.24 And in Oregon, SB 1547, the coal-to-clean legislation passed in 2016, sets a new Renewable Portfolio Standard of 50% by 2040 and requires utilities to cease using coal-fired power no later than 2025. All three of Oregons investor 24 NW Energy Coalition, I-937: The only thing we had to fear was fear itself: The first in a series celebrating the passage of Initiative 937 and its many benefits for Washington," September 27, 2016, https://nwenergy.org/uncategorized/i-937-the-only-thing-we-had-to-fear-was-fear-itself/ Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 49 owned utilities, Portland General Electric, PacifiCorp and Idaho Power, have responded by accelerating coal retirement plans and committing to major clean energy acquisitions. Those clean energy actions replicated throughout the region by coal-owning utilities will rapidly reduce the apparent resource adequacy gap resulting from coal retirement. The Joint Commenters fully anticipate this will result in reduced energy costs, major reductions in greenhouse gas emissions, and improved environmental performance. Turning to the DEIS coal sensitivity analysis itself, as noted in the DEIS, announced coal retirements as of 2022 are already included in the energy assessment. Yet the DEIS forges on to assess how further retirements of part or all of the remaining coal fleet could affect the CRS as if they occurred in 2022. The DEIS states: While the scope of the CRSO EIS analysis is not necessarily to address resource adequacy issues related to the No Action Alternative because the coal-plant retirements are not serving Federal load, resource acquisitions made by the region for the coal-plant retirements will affect how changes in CRS hydropower would impact the region. DEIS Chapter 3 at line 25385 Yet no one would argue that all regional coal could be, or even should be retired in 2022, despite the reduction in climate change that might entail. Retiring the entire coal fleet, with its far greater contribution to the Northwest power system than LSR hydrogeneration, will require a careful and measured effort to phase out those resources and replace them with a clean energy portfolio. As discussed above, state policy and utility IRP processes under way in the region are fully taking up that task. The DEIS ignores these processes and instead makes unfounded assertions. In particular, the coal retirement sensitivity appears to build linkages between MO3 and coal-plant retirements that do not exist. In reality, coal units in the West are used to meet capacity needs of their owners. No preference customer of the Bonneville Power Administration is an owner of a share of any existing coal generation. The preference customers and Bonneville itself have no legal obligation whatsoever for the future course of such coal plants, nor for resource replacement as they are retired. Rather coal plant retirement decisions that ensure reliable, affordable energy services are the responsibility of the owners and the respective state utility commissions that regulate them. At the date of submission of these comments, Portland General Electric (PGE) is pursuing a comprehensive strategy to replace the energy and capacity services of its Boardman coal plant in Oregon and its share Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 50 of the Colstrip coal plant in Montana, as well as other system changes. In 2019, PGE and the Bonneville Power Administration executed two contracts for 100 MW of power services for five years. This contract, executed before filing of the DEIS, does not appear to be included in the coal sensitivity analysis. PGE is also currently seeking consideration of acknowledgement by the Oregon Public Utility Commission (OPUC) of its 2019 Integrated Resource Plan, including up to 150 aMW of renewable energy resources and up to 690 MW of capacity resources. PacifiCorp is addressing coal retirement and replacement in its 2019 IRP, and is also seeking acknowledgement from the OPUC and approval by other regulatory commissions in its six-state service area targeting almost 2,400 aMW of new solar resources collocated with about 600 MW of battery storage as well as almost 2,000 MW of new wind resource by the end of 2023, and construction of a new high-capacity transmission line by 2024 in order to transfer additional wind resources to replace coal, to improve reliability and address other system needs. Other investor owned	The analysis for the case of additional coal-plant retirements in the EIS was conducted as a sensitivity study. This left the base case consistent with the study assumption of a 2022 year while also addressing the issue that the regional resource mix is changing rapidly during this decade, largely due to new information that was not available when the power analysis for the EIS was initiated in 2016. The characteristics of coal plants are embedded in the Loss of Load Probability (LOLP) modeling used by Bonneville and the Northwest Power and Conservation Council. This includes the ability to dispatch to meet load. See draft EIS, Section 3.7.3.1, Base Case Methodology and Cost Sensitivity Analysis at page 3-816 and Id. at page 3-823. This sensitivity study evaluated other replacement options that may be less costly. Also, the power analysis only looked at portfolios that were less polluting as all replacement resources were non-carbon emitting. The comment is correct that the zero-carbon replacement portfolio only includes non-carbon emitting resources in the replacement resources. If new gas-fired generation was selected to replace the coal generation, gas-generation would be closer to a 1 MW for 1 MW replacement with the major difference between coal generation and gas generation being slightly lower gas generation due to lower forced outage rates relative to coal generation. For the base case Multiple Objective (MO) Alternative analysis, two different replacement portfolios were identified, a least-cost gas-fired alternative and a least-cost carbon-free replacement portfolio. See draft EIS, Section 3.7.3.5 at pages 3-904-910. The comment is correct that the regional system would have to make up for some, if not most, of the capabilities of the four lower Snake River dams putting further strain on the regional power system. As shown through the coal sensitivity LOLP analysis, this is ever more challenging if both the coal plants and the four lower Snake River dams are to be replaced by non-dispatchable energy reasons. See draft EIS, Appendix H, Power and Transmission Section 2.3. at pages H-2-8 15. For this reason, the least-cost carbon free replacement portfolio included batteries to make up for some of the sustained peaking and ancillary services that the projects provide but cannot be picked up in the GENESYS model. Removing the generation from the four lower Snake River projects in the region requires that other dispatchable generation in the region are used in place of these projects. As more of this dispatchable generation is retired (i.e. the coal plants), it increases power system reliability risks to the region as is demonstrated in the LOLP analysis requiring increasingly larger amounts of non-carbon resources and batteries (that only provide short term energy storage) to maintain reliability. The EIS analysis concurs with the assessment that the regional coal fleet is a much larger contributor to the regional power system than the four lower Snake River dams and that retirement of the entire coal fleet would require a careful and measured plan. In fact, that is the exact point of the coal sensitivity analysis, that replacing the four lower Snake River dams with non-dispatchable generation makes that careful and measured coal retirement plan even more challenging. See draft EIS, Section 3.7.3.2, No Action Alternative at pages 3-845-84 and Table 3-123. The 2022 date in the EIS was selected so that a comparison and impact assessment could be made, and it does not suggest that all coal plants would retire in 2022. The increased reliability strain is the same regardless of whether the replacement plan is implemented quickly or slowly. The power system reliability studies prepared for this EIS are done using a regional study, which includes all loads and resources of the Northwest. Therefore, all loads and resources are linked in terms of reliability. It is in this context that replacement resources for the four lower Snake River dams could occur at the same time the regional Investor Owned Utilities (IOUs) would be replacing their coal plants with alternative power sources, and the EIS does not suggest that all of this would happen in the year 2022. While the EIS is not intended to be a power optimization study of the Northwest power system, the EIS concludes that removing hydropower at the same time the region is carefully working through a measured plan to replace the coal fleet would exacerbate the challenge of maintaining a low LOLP. We agree with the assessment that planned replacement resources proposed by IOUs are not included in the analysis as the analysis only includes on-line generating resources. Further, the analysis does not reach any conclusions where the specific resource replacement plan is needed. Rather, the analysis contemplates the entire spectrum of potential outcomes for coal retirement replacements by concluding that power system reliability objectives are harder to meet if the coal replacement resources are from non-dispatchable sources and are mostly unaffected if replaced with gas generation. The analysis does not suggest that nothing is being done by utility coal owners. The point of the coal sensitivity analysis is to quantitatively demonstrate that resource replacement decisions for the coal fleet can impact the cost to replace the generation from the four lower Snake River dams. This is because reliability targets are measured at the regional level and get progressively harder and harder to meet with each unit of dispatchable generation that is replaced with non-dispatchable generation. The resources examined in the power system reliability analysis are the same types of resources that are in the planning stages by both PacifiCorp and Portland General Electric. The EIS, however, did not include Wyoming wind generation that is being developed by PacifiCorp, which could provide some diversification benefits. Regardless, the conclusions in the EIS included the full spectrum of potential outcomes from no additional cost impacts if replaced with gas resources to substantial cost impacts if replaced with non-dispatchable resources. Including the diversity benefits of Wyoming wind could likely have a modest impact on the non-dispatchable resource replacement side of the coal sensitivity analysis. A full scale assessment of transmission system reliability was not performed for a coal replacement scenario. Rather, the coal replacement analysis was intended to consider a set of replacement resources and the power reliability challenges the region faces with the removal of coal plants. The scope of coal replacement was not known at the outset of the CRSO EIS analysis and did not inform the base assumptions. During the development of the EIS, it became apparent that additional coal retirements would occur independent of the CRSO EIS. The EIS added the sensitivity analysis to augment the detailed assessment considered under the MO alternatives. The transmission analysis completed for the EIS was intended as a feasibility assessment of whether the replacement resources identified to maintain the LOLP of the existing system might reasonably be able to meet that power reliability metric. A full transmission reliability assessment as suggested by the commenter is not possible without knowing more detail about the actual replacement resources. Detailed interconnection and integration studies would be completed as detailed information becomes available. Until there is certainty about the final replacement resources, it is premature to complete a full system assessment suggested by the commenter. The EIS relied on a summer 2023 base case for its assessment. The EIS made use of the summer conditions in order to consider which conditions would create a worst case for transmission system stress. The summer conditions produce greater stress with respect to the resource locations in the CRS. With higher ambient temperatures, the transmission system equipment must operate at reduced levels to respect the reduced ratings. Inter-regional transfers combined with heavy load in Central Washington and Oregon near the major CRS projects also create stress for the transmission system during the summer. Finally, the reduced (or even removed) generation considered in the MOs means that those resources would not be available to provide needed voltage support or active power to maintain reliable operation. Winter loads, while also critical to consider for reliable system operation are not as sensitive to generation provided from the CRS projects. The winter generation levels considered in the MOs would allow for increased output to provide needed voltage support and capacity for reliable system operation. The coal sensitivity study includes state policies to remove coal resources from the Northwest by removing certain coal plants from the regional power system. However, it does not include individual utility plans to acquire resources. The study is not designed to be a regional Integrated Resource Plan, rather the analysis is designed to highlight the reliability challenges the region faces with the removal of the coal plants and reductions in Federal Columbia River Power System hydropower generation.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				utilities that own coal generation resources in the Northwest that are retiring or may retire within this decade are also considering replacement portfolios. None of these replacement plans are considered in the DEIS coal sensitivity. The assumption that nothing will be done until coal generation actually retires is false. The DEIS does not assess that state utility commissions will mandate that utility coal-owners develop fully optimized and least-cost resource portfolios as part of the approval process to replace the coal resources, thus maintaining overall operational reliability and resource adequacy on their systems and assuring continuity of operation for the Northwest power system as a whole. Indeed, the DEIS does not reference the comprehensive and detailed IRP analyses being conducted to address exactly this question by every utility owning coal resources in the Northwest and the Western Interconnection. Nor does the DEIS explain why this information was not studied. Furthermore, increased coal retirements in the West will change the landscape of operational reliability and resource adequacy. The new resource portfolios being developed by PGE, PacifiCorp and others are more diverse by resource type, performance and geography than has ever been the case in the past. They rely strongly on fast-response generation, demand side and storage resources, all with inverter-based grid interconnections that can respond much faster and more precisely to a control signal that coal generation. They do not require minimum run rates that require uneconomic operation during Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 51 periods of low system demand. They do not produce the wide array of environmental pollutants and greenhouse gases of coal generation. They do not depend on volatile fuel markets. The replacement portfolios will not only be cheaper than continuing operation of most of the Northwest coal fleet, they will also provide improved reliability and resource adequacy. None of these factors, well developed in technical literature and demonstrated in the IRPs referred to here, are reflected in the DEIS energy analysis. The timing of coal generation retirements and the nature of potential replacement resources will have an effect on CRS operations, given that the Western Interconnection is a synchronous system under federal mandatory reliability standards for frequency regulation and other compliance requirements. Under the NERC transmission planning (TPL) mandatory reliability standards, studying these factors is a legal requirement for the BPA transmission system, and studies must be conducted for time frames out to 10 years. However, no such analysis was undertaken for the DEIS energy analysis. Indeed, the related transmission studies in Step 4 of the DEIS energy analysis framework have deficiencies of their own. The transmission reliability analysis (Appendix H, page H-3-14) was only performed for the base case for a 2023 study year using WECC powerflow cases. Oddly, the DEIS used a summer WECC case but performed a peak load analysis where it assumed minimum hydro output. Yet the DEIS transmission analysis appears not to have made use of the WECC Heavy Winter powerflow case. In any event, there was no explanation nor any demonstration of analytical results to justify this choice. In summary, the DEIS coal sensitivity completely ignores the policy, planning and resource acquisition steps that are being taken to retire coal and gain immense economic, climate, environmental and reliability gains. The DEIS justifies its inadequate and misleading analysis with vague references to impacts on the CRS, but provides very little analysis or evidence, especially on transmission impacts. The DEIS does not explain why it did not conduct the long-term IRP analysis that would be required to assess potential impacts of coal retirement on the CRS and the resource portfolios for the DEIS alternatives.	
6881	21	Fred Heutte	NW Energy Coalition	4.16 Conventional Least-Cost Portfolio The Replacement Power Analysis refers to the all-gas replacement scenario for MO3 as a least cost portfolio. However, an IRP analysis would not determine that a specific resource is least cost by assessing only one attribute, such as contribution to resource adequacy. Least cost resources are identified through replacement portfolio optimization, which was not accomplished in the DEIS. The blanket assumption that the specific type of natural gas generation chosen for the least-cost conventional portfolio is without technical merit and is inconsistent with economic conclusions from almost every recent Western Interconnection IRP process, which favor mixes of renewables, gas, energy storage and demand side resources.	The commenter suggests or questions why a competitive resource review, also known as an integrated resource plan (IRP), was not performed as part of the EIS analysis. An IRP is a resource planning tool that utilities use to plan for future resource builds and acquisitions to fulfill the utility's specific needs over a certain planning horizon, typically 20 years. Some utilities are required to conduct an IRP by their local or state utility commissions. Bonneville is not required to perform an IRP, but does perform resource planning to inform its decisions, including for this EIS. There are many different methods and tools that are used by utilities when performing an IRP. Furthermore, the output of an IRP is often driven by state energy policies, such as carbon emission requirements. Even if an IRP optimizes resource portfolios, the real costs of that portfolio are not known until a competitive request for proposal solicitation can be completed and evaluated. In selecting replacement resource portfolios, the EIS evaluated a variety of factors to determine the least-cost resource including how the resource affected costs related to regional imports, exports, fuel use and capital costs for the actual resource. These costs were then divided by the reliability benefit to determine the cost effectiveness. Natural gas was determined as the least-cost resource for improving reliability. The replacement resource analysis and assumptions are further described in Chapter 2 of Appendix H in the draft EIS. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS.
6881	22	Fred Heutte	NW Energy Coalition	4.17 Substantial Costs for Necessary LSR Powerhouse Upgrades Not Considered The Lower Snake River hydro generation facilities commenced commercial operation between 1962 and 1975. Since these facilities are assumed to have an engineering and economic life of 50 years, the risk of unforced outage and longer shutdown for extended maintenance, and even forced retirement, continues to grow as the 50-year anniversary approaches. The common language metaphor for this process is the bathtub curve 25 high maintenance costs when a facility is first put into place, followed by a long period of reliable and low-cost operation, and then increasing costs as parts begin to weaken and fail, followed either by refurbishment, replacement or retirement. The bathtub curve is a useful way to conceptualize the future of the LSR hydrogeneration facilities. Of the 24 generation units at the LSR dams, the first three at Ice Harbor dam are now undergoing a refurbishment and replacement program. In a news release in June 2019, the project manager stated, After 50 years of operation and increasing maintenance requirements, the need to replace the existing turbine runners at Ice Harbor presented the opportunity to pursue new turbine runner designs with fish passage improvement as a priority.26 The project cost is currently estimated at $92 million. The first 25 Sumereder, C. (2008). Statistical lifetime of hydro generators and failure analysis. IEEE Transactions on Dielectrics and Electrical Insulation, 15(3), 678685. doi:10.1109/tdei.2008.4543104 26 US Army Corps of Engineers Walla Walla District, New high-tech turbines at Ice Harbor improve safety for fish, produce more power. https://www.nww.usace.army.mil/Media/News-Releases/Article/1866445/19-067-new-high-tech-turbines-at-ice-harbor-improve-safety-for-fish-produce-mor/ Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 53 new turbine was placed in service in May 2019, about 57 years after the original equipment began commercial operation. If CRS operations continue in accordance with the DEIS Preferred Alternative, similar upgrade and replacements will be required at the other 21 LSR generating units starting in this decade. If the MO3 is adopted, these costs will be avoided. The first three generating units at Ice Harbor commenced operation in 1962, the second set of three units in 1976. Likewise, an initial and second set of generators commenced operation at Lower Monumental in 1969 and 1981, at Little Goose in 1970 and 1978, and at Lower Granite in 1975 and 1979, respectively. Thus, the 50th anniversaries for the various turbine groups began in 2012 (Ice Harbor 1-3) and will conclude in 2031 (Lower Monumental 4-6), with a substantial amount of powerhouse facilities reaching that anniversary in the mid to late 2020s. Lower Snake River Hydro Generation 50th Anniversary Dates Data source: US Army Corps of Engineers, Walla Walla Division It is reasonable to foresee that no later than the mid-2020s, the Army Corps of Engineers and BPA will need to agree on a refurbishment and modernization program for the 21 remaining generation units in Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 54 the four Lower Snake River dams if the Preferred Alternative or another option other than MO3 is pursued. Indeed, the first set of units at Lower Monumental and Little Goose have already passed the 50th anniversary. However, the CRSO DEIS steadfastly refuses to directly address this likelihood. Instead, the DEIS states, DEIS, Appendix Q, Annex A, Q-A-7 and 8 It appears from this language that the prospect for avoiding the future necessary refurbishment and modernization of the four Lower Snake River dam powerhouses is not considered in the DEIS energy analysis for MO3. Furthermore, on March 31, 2020, the Bonneville Power Administration issued a message by email that included the following statement: Major powertrain replacements for the Snake River Dam hydroelectric assets are not currently forecasted to occur within our 20-year system asset plan. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment health, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates. In fact, most of the optimal replacement Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 55 dates are spread between the 2040s and 2060s for the Lower Snake dams for turbine and generator replacements.27 To the knowledge of the Joint Commenters, this is the first statement made publicly by Bonneville that the LSR powerhouse upgrades can be delayed until the original equipment is 70 to 90 years old. As previously noted, current work on the first three generation units at Ice Harbor will cost about $92 million under contracts executed several years ago. Similarly, a major modernization project for the powerhouse at McNary dam on the Lower Columbia River is also in progress. The McNary project will cost approximately $340 million to upgrade 980 MW of generation. Together, the Lower Snake River dams have a combined nameplate capacity of over 3,000 MW, more than three times as much as McNary. While it is not possible to make a direct comparison, it seems likely that a complete Lower Snake River hydrogeneration upgrade could cost well in excess of $1 billion. Whether this occurs starting in the mid to late 2020s, or is mostly accomplished after 2040, the DEIS totally fails to address this crucial element affecting future CRS operations and costs.	The four lower Snake River dams are among Bonneville's lowest cost resources. Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary. Moreover, the average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1 in the Draft EIS) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1 in the Draft EIS). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $20 million and the benefit-cost ratio would fall to 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. The EIS estimates the costs to operate and maintain the CRSO, as well as the value of power, navigation, agriculture, and public water supply that would be adversely affected if the lower Snake River dams are breached under MO3. The EIS also estimates the effects of dam breach on anadromous fish species, but these are not explicitly quantified or monetized. The EIS considered multiple tradeoffs between potential effects, but an explicit cost benefit analysis for the EIS alternatives was not completed consistent with NEPA (40 C.F.R. 1502.23).
6881	23	Fred Heutte	NW Energy Coalition	1. The DEIS confirms that dam breaching and clean energy power replacement can maintain electric system reliability while providing the best chance for fish restoration. 2. The DEIS fails to meet energy industry resource planning standards, resulting in numerous inaccuracies and an exaggerated cost for clean energy power replacement. 3. Because the DEIS fails to provide the accurate information needed to make informed decisions, a new, more rigorous study is required. The preceding comments of the Joint Commenters demonstrate conclusively that the DEIS energy analysis failed to meet industry standards and did not achieve optimized, least cost/least risk outcomes for the energy resource portfolios for each of the DEIS alternatives, especially MO3, the dam breach/hydrogeneration retirement alternative. This has resulted in proposed replacement portfolios that are nearly certain to be substandard in performance and excessively high in cost, with 27 BPA Finances and Snake Dam hydroelectric information, G. Douglas Johnson, Senior Spokesman, BPA, March 31, 2020. Joint Commenters Comments on CRSO DEIS April 13, 2020 - Page 56 proportionally excessive costs for	The EIS describes the resource group options that could be used to return regional reliability to the No Action Alternative level available for replacing the capability and other operation changes proposed in MO3, which includes breaching the four lower Snake River dams. One of the resource options the EIS evaluated was a zero-carbon portfolio. The regional rate pressure associated with a zero-carbon resource portfolio ranges between 12 and 50 percent. See EIS, Section 3.7.3.5. The commenters concerns with the range of resource options, the data used to estimate the cost of those options, and the methodology used in the power replacement analysis, are addressed in detail in response to Comment 6881-4. An expanded discussion of the analysis is also provided in Appendix H, Section 2.2.2, of the Final EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				wholesale and retail electric rates. These failures directly result in the agencies selecting a preferred alternative without adequate justification. Thus, the CRSO DEIS fails to accomplish a hard look at the energy options to mitigate impact to protected species required by the National Environmental Policy Act and the Endangered Species Act. The Joint Commenters recommend that the entire energy analysis be redone for the final EIS, employing comprehensive long-term portfolio analysis consistent with standard industry practices.	
6881	24	Fred Heutte	NW Energy Coalition	The DEIS fails to meet energy industry resource planning standards, resulting in numerous inaccuracies and an exaggerated cost for clean energy power replacement. The errors stem from a failure to adequately consider a full range of possible replacement resources, a failure to optimize the selected replacement resources to achieve the most efficient outcome, and outdated and incomplete cost assumptions for replacement resources. These shortcomings were exacerbated by the use of inconsistent time frames for different elements of the analysis, the use of a static year rather than a multi-year analysis of the replacement portfolio, and by the arbitrary assumption of a 2022 implementation date. The result is an exaggerated estimate of clean energy replacement costs leading to a similarly exaggerated estimate of impacts to consumer electricity bills Because the DEIS fails to provide the accurate information needed to make informed decisions, a new, more rigorous study is required. A study that meets the standards of the regions utilities and the Northwest Power and Conservation Council for integrated resource planning (IRP) would examine energy and capacity needs over a span of 20 years, fully explore demand requirements and resource options, and test and optimize combinations of possible replacement resources. The result would be: Significantly lower costs to acquire wind, solar, storage, and demand-side resources. Less need for new generating and transmission resources because demand response and energy efficiency would make larger contributions than the DEIS assumes. A more efficient and cost-effective system that could improve region-wide reliability and greatly reduce the impact on customer rates.	The commenters concerns with the range of resource options, the data used to estimate the cost of those options, and the methodology used in the power replacement analysis, are addressed in detail in response to Comment 6881-4. An expanded discussion of the analysis is also provided in Appendix H, Section 2.2.2, of the Final EIS.
6885	1	jthompson@washingtonports.org	Washington Public Ports Association	Climate Impacts We request the action agencies to reconsider the centrality of climate impacts in their analysis. The DEIS does not adequately evaluate the climate-related consequences on salmonids listed under the Endangered Species Act. Scientific uncertainty is the likely reason for this omission. However, it seems clear today that the greatest single risk to the survival of these species in the mid- to long-term is climate change. We request the DEIS be modified to utilize climate risk as an organizing principle and critical factor used to evaluate competing alternatives and actions. Missteps on climate jeopardize the billions of dollars that have been invested as well as the resulting achievements.	The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with USACE climate change policy and guidance. The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. Water temperature modeling for each alternative is described in Chapter 3, however, as you note it was not conducted for conditions of future climate change. Information to develop, drive, and analyze specific projections of future water temperature and fish characteristics were not available on the timeline of this report.
6885	2	jthompson@washingtonports.org	Washington Public Ports Association	Social Costs of MO3 We urge the action agencies to re-evaluate the social consequences caused by removing facilities on the Lower Snake River considered in Alternative MO3. Social science literature establishes a causal link between profound personal and social costs that result from economic disruption on this scale. The toll includes increased suicide rates, increased addiction rates, increased domestic violence rates, increased incarceration rates and reduced lifetime earning potential. Sadly, effects of these disruptions are not limited to adults. Research conclusively demonstrates ongoing epigenetic consequences affecting generations far into the future. Preventing adverse childhood experiences is the central objective of state social service programs designed to break the cycle of abuse, neglect and the resulting cycles of violence and dysfunction. The out-migration of talent creates a self-reinforcing downward spiral in communities that cannot be staunched by short-term mitigation strategies. We recognize this pattern elsewhere in the Pacific Northwest and across the country as small communities have lost or had their economic bases eroded. Social science literature predicts shattering consequences for the small communities that rely on the river for their livelihoods. The DEIS must more fully account for these profound and long-lasting effects.	Section 3.10 of the Draft EIS describes the commercial and regional importance of the Snake River as part of the Columbia Snake Navigation System, as well as its relative efficiency, low costs for shippers, and relatively low air emissions relative to other transportation modes. The EIS also evaluates the additional transportation infrastructure investments that would be required, as well as the increases in air emissions that would occur. Additional regional economic impacts of these potential changes are discussed in section 3.10.3.5. Other social effects are described in section 3.10.3.5, including transitions of port communities that have evolved to be dependent on the current state of the river.
6885	3	jthompson@washingtonports.org	Washington Public Ports Association	Stranded Assets Resulting from MO3 Small communities have invested scare public resources to construct assets that form the core of their local economies. Public and private investments in marinas, parks and other public spaces, cruise facilities, storage terminals and transshipment infrastructure will be stranded, i.e. of no productive value. WPPA, in WPPA - CRSO Comments April 13, 2020 Page Three coordination with the Washington State Freight Mobility Strategic Investment Board completed the most recent update of the Marine Cargo Forecast & Rail Capacity Analysis (MCF) in 2017. Chapter 7 of the report identified and documented commercial infrastructure important to trade and goods movement in Washington including those facilities along the Snake River. We request the action-agencies modify the DEIS to more completely reflect the current and future economic value of these facilities that would be lost by dam breaching considered in MO3.	The EIS does broadly identify ports and recreation areas that are anticipated to be negatively impacted by MO3. If MO3 was selected and authorized by Congress, an implementation plan would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. The demand for waterway transportation is influenced by many factors, both related to the river operations and competing modes. In many cases, that demand is affected by private sector choices (investments by Class I railroads, construction of shuttle rail elevators by grain companies) that are largely difficult to predict into the future. The approach taken in the EIS is to utilize historical volumes as a barometer of what generally has been demanded and to provide impacts relative to that since it is known with certainty. That being said, in order to better characterize the level of uncertainty in which impacts should be considered, additional information has been added to the Navigation Appendix that puts the findings into context using recent historical highs and lows as a guide.
6885	4	jthompson@washingtonports.org	Washington Public Ports Association	Consequences for Tourism and Recreation of MO3 The MO3 analysis of Snake River recreation in the DEIS does not adequately recognize its importance to the Lower Snake River region. The analysis underestimates the number of facilities and the cost of mitigation that would be needed in this Alternative. The evaluation of land-based alternatives fails to understand important features of geography and climate. It is critical that the DEIS fully reflect mitigation needed to offset the impacts of this alternative, including: 1. Investment in new river access, including roadways and boat ramps. The DEIS does not specifically identify the costs or source of funding for these facilities. 2. Facilities abandoned by the U.S. Army Corps of Engineers will be orphaned and their economic benefits lost. Visitation at these locations totaled over 1.7 million visits in Fiscal Year 2018. The DEIS should identify the source of funding to preserve these facilities, including a plan that protects their future viability. 3. Prevailing winds will increase fugitive dust as a result of exposed sediments. The DEIS does not adequately evaluate the public health consequences nor does it identify a program or funding to eliminate the impact on any remaining river-based recreation. Absent a programmatic response the value of the recreation amenity will be reduced and local air quality will be degraded. 4. The DEIS overstates the potential for improved recreational and tribal fishing. The removal of facilities on the Lower Snake River will bring an end to mitigation funding from the Bonneville Power Administration and would curtail access to mitigation funding from this source, including support for hatchery facilities. 5. We ask the action agencies to modify the DEIS as it related to land-based recreation. The DEIS does not identify an ongoing source of funds to support a shift to this use. As a practical matter, the coincidence of the summer recreational season with summertime temperatures that often exceed 100 degrees and a lack of natural shade create an inhospitable environment for this purpose. 6. The DEIS should reflect an accurate assessment of the number of cruise boat passengers traversing the Lower Snake River and fails to mention Clarkston, Washington as an important location for embarkation/debarkation. This oversight would result in an underestimated economic and social value of this activity. 7. Finally, the DEIS would benefit from a more complete evaluation of the consequences of this alternative on nationally-designated recreation sites. These include the Clearwater & Snake River National Recreation Trail and the Hells Canyon National Recreation Area. The Clearwater Snake Trail hosts regional middle school, high school and college track meets, attracting thousands of visitors to the region to participate in or watch competitions. Accessible only by water, Americas deepest gorge attracts visitors from around the world.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. Mitigation by the co-lead agencies is not anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to implement the alternative. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands after the projects are deauthorized. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. Based on the evaluation in the Fish Section, which describes major and beneficial impacts to anadromous fish in the Snake River under MO3, a focus on salmon and steelhead fishing in this region was evaluated for the No Action Alternative and MO3 (see discussion in 3.11.3.2 and 3.11.3.5). The potential for visitation under MO3 in the lower Snake River in the long-term is predicated on that access would be developed for the resource. As described in Section 3.11.3.5, access to the river and its recreational opportunities will be paramount for the reestablishment of river visitation to the lower Snake River. For example, parking lots, boat launches, new trailheads, access roads, etc., would need to be developed to facilitate the drawing of visitors to the region. In addition, examples of the costs that would be incurred are provided. As described previously, further studies and NEPA would be conducted if MO3 were chosen for implementation. Regarding hatchery impacts associated with MO3, as described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels. Although Bonneville's funding of the Lower Snake River Comp Plan hatcheries would no longer be authorized under MO3, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries. Regarding cruise ships, this activity is addressed in Section 3.10 Navigation and Transportation. Clarkston, Washington, and its role as a primary point of debarkation, is described in Section 3.10.3.2. Impacts on the industry, including Clarkston, are described in Section 3.10.3.5.
6885	5	jthompson@washingtonports.org	Washington Public Ports Association	The DEIS incorporates state-of-the-art scientific evaluations of the tradeoffs among alternatives. WPPA is not qualified to comment of the substance of this ongoing work. However, we believe the DEIS should tell the story of what has been achieved through the investment of public resources. Billions of public dollars have been invested in order to restore the fish production capacity of the Columbia and Snake River systems. These investments have had a tremendous impact on the efficiency of fish passage through the dams on the Lower Snake River. As a result, juvenile passage at Ice Harbor (95% in 2007 study), Lower Monumental (99% in 2012 study), Little Goose (98% in 2012 study), and Lower Granite (97.5% in 2008 study) has shown dramatic improvement since the early 1990s (U.S. Army Corps of Engineers data). Hydropower system revenues have also supported considerable public investments in habitat restoration and hatchery production of salmon and steelhead to improve the restoration of runs in the Columbia and Snake Rivers. The public would benefit from a better understanding of what has been achieved as a result of their investments. We request this information is included in the DEIS. Much has been accomplished through enormous public investment. The successes that have been achieved are important context for the public and decision makers going forward. Much has been accomplished within the context of current operations.	Current and anticipated future fish and wildlife mitigation measures and operations are described under the No Action Alternative, Section 2.4.2. Many of the structural and operation measures are carried forward and proposed to be implemented or expanded under the Preferred Alternative (See Section 7.6). Funding of fish and wildlife mitigation actions and programs is described in Appendix Q, Section 6.1 and Table 6-1. Additionally, Section 5.2.1 describes the existing mitigation programs under the No Action Alternative and provides a high-level summary of some of the accomplishments stemming from the significant Federal investment to date. Since the 1990s, the Federal agencies have overhauled system operations and infrastructure, achieving juvenile dam passage survival that meets or exceeds performance standards of 96% and 93% for spring and summer migrants respectively, a marked improvement as compared to when Congress passed the Act and the estimated average juvenile mortality at each mainstem dam and reservoir project was 15%20% with losses recorded as high as 30%. Travel time improved for yearling Chinook and juvenile steelhead through the system, even in low flow years such as 2015, and total In-River survival has improved for migrating juvenile salmon and steelhead. Comparing two time periods reported in NOAAs reach study (19972007 and 20082016), there has been a 10% survival increase for hatchery and wild sockeye salmon, a 2% increase in hatchery and wild Chinook (4% for wild), and a 25% survival increase for hatchery and wild steelhead (13% for wild).
6885	6	jthompson@washingtonports.org	Washington Public Ports Association	Commercial Goods Movement & Transportation Infrastructure While the DEIS accounts for wheat that is transported on the Snake River, the alternatives analysis does not account for any other commercial goods movement today or in the future. Chapter 4 of the MCF highlights the historical trends and provides a 20-year forecast for movement on the Columbia/Snake River System. Under each of the growth scenarios performed for the	In 2018, 72 percent of overall freight volume on the Lower Snake system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the Lower Snake River was petroleum products that terminated below Ice Harbor Dam. These shipments do not utilize the Snake River locks and would not be directly affected by dam removal under MO3. This was unclear in some instances in the Draft EIS, and has been corrected and clarified in Section 3.10 and Appendix L. Other commodities that utilized the Snake River system included pulp and paper products (4 percent) as well as chemicals and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				study, tonnage using the Snake River, also known by its Marine Highway designation as M-84, is expected to grow. WPPA requests the DEIS more accurately account for commercial activity using the Columbia/Snake River System. WPPA believes the MO3 analysis significantly understates costs to maintain, modernize and in some cases rebuild alternative transportation infrastructure to replace goods movement along the Snake River. Many roads in the region are not all-weather and cannot accommodate increased freight shipment, particularly on a year-around basis. Furthermore, the states rail system has either insufficient capacity, significant backlog in maintenance or has been deemed surplus and abandoned. Again, Chapter 6 of the MCF highlights existing and future capacity, including expected constraints on the states Class I rail network through 2035. The report shows that while existing capacity is sufficient, even modest future growth will require new infrastructure capacity to accommodate future commercial activity and goods transport. The analysis conducted for the MCF does not contemplate conversion of tonnage currently being transported on the Snake River to all rail or truck-to-rail modes. This would most assuredly require immediate new Class I infrastructure to support increased tonnage as a result of MO3. In addition to the need for additional Class I railroad infrastructure, Class III, also known as shortline rail infrastructure has not been maintained adequately to allow for significantly increased tonnage brought on by MO3. Washington State Department of Transportation has documented the condition of the states shortline railroads in several plans, including the Washington State Rail Plan, the Shortline Inventory and Needs Assessment as well as well as the Palouse River and Coulee City Rail System Strategic Plan. These plans document millions in backlogged maintenance and preservation needs that would be required to support a modal conversion away from the current river transport. In certain cases, rail infrastructure may need to be rebuilt, as much of the rail system supporting the Palouse region of Washington has been abandoned. All WPPA - CRSO Comments April 13, 2020 Page Five told, the cost to increase capacity on Washington states road and rail network to support MO3 is vastly larger than that contemplated in the DEIS. WPPA requests the action agencies review the costs of infrastructure improvement associated with MO3. An area of significant concern to WPPA and our members is a lack of clarity around the analysis of transportation cost increases anticipated by MO3. Again, Chapter 4 of the MCF discusses the critical role the Columbia/Snake River System play in reducing shipping costs for all commodities and goods moved along the river system by providing competition between barge, rail and truck transportation modes. WPPA appreciates the DEIS considering multiple scenarios of cost increases but believes the analysis does not adequately incorporate the compounded impact that such increases (50% or higher increase in shipping costs) would have on the industries that rely on river transportation to manage costs. WPPA requests the action agencies more thoroughly analyze and model increases expected under MO3.	iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under MO3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5. In terms of forecasting freight volumes, the EIS recognizes that demand for waterway transportation is influenced by many factors, both related to the river operations and competing modes. In many cases, that demand is affected by private sector choices (investments by Class I railroads, construction of shuttle rail elevators by grain companies) that are largely difficult to predict into the future. The approach taken in the EIS is to utilize historical volumes as a barometer of what generally has been demanded and to provide impacts relative to that since it is known with certainty. That being said, in order to better characterize the level of uncertainty in which impacts should be considered, additional information has been added to the Navigation Appendix that puts the findings into context using recent historical highs and lows as a guide. Reviewing the MCF, it is noted that WPPA forecasts a range a 2.3 million metric tons to 3.1 million tons in 2035. This is consistent with the 2.4 million tons assumption utilized in the EIS TOM analysis in Section 3.10. Both the MCP and EIS under MO3 anticipated that some investment in rail, road and elevator capacity will be needed. The MCF does not indicate where or how much of such investment is warranted (Chapter 6). Their general statements about impacts and need for supply chain investments provide no further information on cost estimates than the most recent details utilized in the EIS. The impact on shippers was the focus of the models analysis, so industries that rely on river transportation to manage costs were considered. Capacity impact were discussed following the models findings. How rail rates would change without lower Snake River shallow draft barging can not bet known with certainty. Therefore, in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road maintenance costs may occur. It should be noted the co-lead agencies had discussions with WSDOT colleagues during the preparation and considered their information in developing road maintenance cost estimates. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. Ultimately, rail infrastructure investments would be at the discretion of the railroads. The EIS finds that average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled, depending on their specific location and other conditions.
6887	1	N/A	N/A	The DEIS doesnt mention load following operations or providing ancillary services; power peaking is mentioned only once (p. 26) and then wholly in the context of the dispatchable power that would lost with breaching ACOEs four lower Snake River projects. The DEIS totally fails to address any of the environmental impacts of the CRS most basic day-to-day operations on the environment.	This response assumes the comment is in regards to the Executive Summary, given the comment reference to page 26. While it is true that the Executive Summary does not discuss load-following, Chapter 2, Alternatives, specifically Section 2.4.2.1, subsection on Power System Operations, on pages 2-23 to 2-25 in the Draft EIS, discusses load following in the context of the No Action Alternative. Appendix J, Hydropower, Chapter 4.3, discusses the changes in system flexibility for following load and for integrating variable renewable energy generation. The impacts of load following and potential changes in load following on other resources are discussed in the respective sub-sections of Chapter 3, e.g., Section 3.6 on Vegetation, Wetlands, Wildlife and Floodplains.
6887	2	N/A	N/A	This glaring omission is also evident in all of the DEIS discussions of wind (and solar) integration. See Executive Summary, p.4, 21, 26, 27, 31.	See response to preceding comment, Comment 6887-1.
6887	3	N/A	N/A	ACOE, BOR and BPA should take a hard look at such impacts and reformulate their alternatives so as to avoid and/or mitigate the deleterious impacts of changes in projects discharges due to load following, power peaking and, now, integration of wind and solar resources.	The comment does not indicate what deleterious impacts of changes in project discharges are of concern. Grand Coulee ramping rates incorporate tailwater restrictions imposed by the Geological Survey Office in Denver, CO, to prevent bank sloughing below Grand Coulee dam. Other project ramping rates incorporate concerns around public safety for recreation downstream and other uses. Daily and hourly ramping rates may be exceeded during flood emergencies to protect health and public safety and in association with power or transmission emergencies. Otherwise, ramp rates are followed except when they would cause a unit(s) to operate in the rough zone. The rough zone is a zone of chaotic flow in which all parts of a unit are subject to increased vibration and cavitation that could result in premature wear or failure of the units. Impacts to resources affected by power operations, including ramping rates are included in Chapter 3 (e.g., Section 3.6 Vegetation, Wildlife, Wetlands and Floodplains). For additional information on ramping rates, see Chapter 2.
6894	1	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The attached comments are technical in nature and self-explanatory. However, the ability of the CTUIR to meaningfully participate in the CRSO process was materially hampered by the arbitrary shortening of the review period by the administration and Lead Agencies.	This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6894	2	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The CTUIR DNR looks forward to written responses to our concerns and resolution in the final document.	See response to Comment 6894-2.
6894	3	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Disclosure and Analyses of Significant Issues The process for assembling and analyzing the alternatives failed to distinguish truly significant issues from non-significant issues. There was also a failure of cooperative consultation, which should be emphasized in a NEPA process. 40 CFR 1501.1(b). As a Cooperating Agency, we were expected to raise questions about the environmental reviews and information gaps. 40 CFR 1503.3 (c). Questions we raised throughout the process, and comments submitted, were often disregarded or ignored by the staff of the co-lead agencies (US Army Corps of Engineers, Bureau of reclamation and Bonneville Power Administration) leading the EIS process. In the end, the co-leads provided effectively no feedback to cooperating agencies on whether our comments and suggestions were incorporated in the analysis or not, and why or why not. The timeline for the CRSO EIS also precluded transparent and meaningful analysis, review, dialogue and collaboration. The Trump administrations October 2018 Executive Memorandum on Promoting the Reliable Supply and Delivery of Water in the West, arbitrarily imposed an inadequate timeline on the development of the CRSO EIS, substantially shortening the timeline established by the United States District Court for the District of Oregon. The current comment deadline fell during spring First Foods ceremonies, the day after Easter, and during Passover.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The Draft EIS was subject to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6894	4	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Moreover, the tribes and other sovereigns in Pacific Northwest are prioritizing the health and safety of the people in responding to the COVID-19 emergency. Since February 28, almost 22,000 people within the United States have died as a result of COVID-19 infections. https://www.cdc.gov/coronavirus/2019-ncov/cases-updates/cases-in-us.html (last visited April 13, 2020). Adherence to the CRSO timeline and associated comment deadlines during the COVID-19 pandemic further compounded the flaws of the DEIS. As a result of the COVID- 19 pandemic, elected officials have little time for policy consideration of the DEIS. Mandated social distancing measures prevent meaningful government-to-government consultation on the DEIS. The broad disruption caused by the COVID-19 emergency frustrated the ability of the tribes and the public to provide input on the DEIS. Despite these complications, the federal government refused to suspend the CRSO EIS process or extend the public comment deadline, despite repeated requests by multiple sovereigns.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6894	5	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Structural Flaws Many of the structural flaws in the DEIS are broad and are programmatic or policy in nature. These flaws typically affect more than one chapter of the DEIS. These flaws include a narrow purpose and need statement, a failure to study all reasonable or viable alternatives, and a lack of rational explanations for alternatives not studied. Further, much of the DEIS suffers from a preference for technical detail over analysis of the programmatic issues, including but not limited to the Columbia River Fish Mitigation (CRFM) program, lamprey restoration program, and the analysis for Upper Columbia salmon and steelhead stocks. Another structural flaw is that the co-lead Agencies incomplete or inaccurate understanding of the CSS, COMPASS and HEC-WAT analytical models resulted in a confusing, albeit detailed, assemblage of model results without clear analysis of their implications, limitations and relevance to the objectives of each alternative. Additionally, the DEIS fails to analyze impacts to fishery management or harvest opportunity. The tribal harvest should be included in the baseline. The lack of harvest opportunity analysis runs counter to the Tribal Perspectives of the Columbia River Treaty Tribes, as well as the goals for non-Indian fisheries (and the corresponding economic effects of the non-Indian fisheries). The discussions in the Affected Environment sections do not meaningfully depict the nature and extent of the impacts that the Basins hydro system has had on the Columbia Basins anadromous fish. Meaningfully depicting these impacts cannot be avoided. Under NEPA, regardless of the selection of the baseline, all cumulative effects must be revealed.	As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives) as well as the objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 in the Draft EIS provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. To achieve a broad range of alternatives, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, the eight single objective alternatives (SOs), and then four Multiple Objective alternatives (MOs). After completing the effort to develop the SOs and MOs, the co-lead agencies evaluated all 12 alternatives against screening criteria of completeness and efficiency. Completeness was used to evaluate the extent to which a given alternative provides and accounts for all actions to meet most or all objectives, and thereby satisfying the Purpose and Need Statement. Efficiency was considered as how well (without duplication of effort) an alternative would meet objectives. Usually, cost effectiveness is part of this consideration, but costs were not available at the early screening of alternatives. In this case, efficiency was based on efficiency of analysis of measures and the elimination of duplication of effort. A detailed descriptions of the single objective alternatives and their measures are located in Appendix A, Alternatives Development. A description of the alternatives removed from further consideration is in Section 2.4. The co-lead agencies recognize the importance of Pacific lamprey and will continue to work with CRITFC, CRITFC member tribes, and regional entities through existing frameworks such as the Corps-Tribal Lamprey Work Group, the Pacific Lamprey Conservation Initiative and the Corps Regional Forum workgroups (e.g., FFDRWG) to implement ongoing programs, as well as the lamprey measures described in the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The analyses completed and described in this Draft EIS were for the purposes of comparing the effects of the multiple objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs related to lamprey, such as habitat restoration, reintroduction and translocation, and other efforts. Measures identified in the Draft EIS do not include all lamprey passage improvements that could be potentially implemented at the lower Columbia and lower Snake River dams, but the Corps believes that potential actions contemplated in preliminary lamprey program planning discussions with CRITFC staff and others related to the 2018 Accords Extensions are consistent with the measures and analyses included in the Draft EIS. Lamprey measures identified in the Draft EIS (and similar operational or structural measures) do not include research, monitoring or evaluation actions that may be needed to refine passage designs, inform operations, or address critical uncertainties. This includes the juvenile lamprey and adult lamprey migration behavior and fate studies identified in the 2018 Accords Extensions and in subsequent program planning and coordination discussions with CRITFC and others. For the purposes of the Draft EIS, measures must address known operational and structural issues, but this does not preclude development and implementation of future juvenile and adult lamprey studies. For Columbia River System dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is a result of significant investments in construction of components of the dams for the benefit of improved salmon passage. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps will continue to express capability in the annual budgeting process. Implementation of all measures including lamprey measures is dependent on funding availability. In 2020, the Corps did receive $20M in funding to implement actions contemplated in the 2018 Accords Extensions. As noted by CRITFC, and in similar comments from CTUIR, the Corps is currently refining cost estimates and developing a preliminary implementation plan for this $20M program. The Corps will continue to coordinate closely with CRITFC and other Accords tribes on prioritization of actions within this program and will continue to ensure consistency with measures identified and analyzed in the Draft EIS. Additional information on CRFM is included in Chapters 2, 5 and 7 of the EIS. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6894	6	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Poor Analysis of Mitigation The CEQ regulations concerning mitigation describe several types of mitigation actions at 40 CFR 1508.20. As pointed out in the DEIS, these include rectifying the affected environment and compensating for the impacts to resources of concern. The omission of ongoing mitigation from the DEIS and the limited scope of proposed mitigation are major issues that need to be rectified. Further, there is no alignment of identified impacts with proposed mitigation. Specific impacts are identified in Affected Environment, but there is no reference to those impacts in the mitigation chapter. The mitigation chapter does not reflect the significant input requested of, and provided by, the Cooperating Agencies. Finally, the DEIS uses the No Action Alternative (NAA) as a baseline for mitigation obligations. This NAA was already deemed inadequate by the District of Oregon. The DEIS fails to present any alternative with adequate mitigation measures.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. Ongoing mitigation is provided in Chapter 5 of the EIS. NEPA does not require identification of mitigation for the continuation of the No Action Alternative. The co-lead agencies, in coordination with technical teams, including the cooperating agencies, compiled lists of all potential suites of mitigation measures. Then, in comparison of the effects of each alternative to the No Action Alternative, highlighted where there were minor, moderate, and major adverse effects. If adverse effects were negligible or minor but otherwise not measurable, and the resource did not otherwise have institutional or legal significance (i.e. wetlands), then mitigation was not proposed. If, when compared to the No Action Alternative, there were moderate or adverse effects, the teams developed appropriate mitigation of type and scale. The suite of mitigation measures to select from were in the team's developed mitigation tool box (Appendix R, Part 3), which also presents rationales for not carrying forward mitigation measures.
6894	7	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Bias in Language and Model Results Improperly Influenced Results As noted above, the DEIS fails to adequately explain the differences between COMPASS and the CSS data and complexity, and what those differences mean for the model results. Further, the description of model effects is biased and inconsistent, in favor of uses and objectives other than fish and wildlife. This is also apparent in the level of detail given to various impacts. For example, the Executive Summary goes into great detail on impacts to power rates from the measures, but only gives a general discussion for other affected purposes.	The Comparative Survival Study model was run by the Fish Passage Center; and the COMPASS and Life Cycle models were run by NMFS's Northwest Fisheries Science Center for the co-lead agencies. Different models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5.
6894	8	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Failed Cooperation and Collaboration with Cooperating Agencies NEPA implementation should emphasize cooperative consultation among agencies. 40 CFR 1501.1(b). At a minimum, consultation is a dialogue where information is shared. As cooperating agencies, we were expected to raise questions about needing additional information to fulfill our environmental reviews. 40 CFR 1503.3 (c). Our cooperative agency experience was far from what these NEPA regulations envision. Exploration of issues during scoping, regardless of significance, were typically allocated five minutes for discussion on a conference call convened with more than 40 participants. There was little opportunity for collaborative dialogue among subject matter experts from the cooperating agencies and co-lead federal agencies. The process for assembling and analyzing the alternatives failed to discern truly significant issues from non-significant issues. This was due to the nature by which information was collected by the co-lead federal agencies, which seemed to have be based on accumulating detailed recommendations for actions, rather than collaboratively developing a shared understanding of the programmatically integrated suite of measures that have already been implemented and using these as a departure point for future plans. Multi-Objective Alternatives were developed and reworked (when Single Objective Alternatives were dropped) by the co-lead agencies with no input from the cooperating agencies. Questions throughout the process could not be asked in technical workgroups, but were directed to the NEPA policy team. We eventually came to understand that these were the designated NEPA leads for the co-lead federal agencies. When the cooperating agencies convened their own meetings for collaborative scientific discussion, the co-lead agencies issued a written admonishment directing that no cooperating agency should provide information, or collect, assemble, or analyze data related to the CSRO EIS unless specifically requested by the co-lead agencies. Technical input from individual cooperating agencies was directed to continue to be formatted into cells in an Excel spreadsheet, which aided input-tracking but did not create any dialogue with the cooperating agencies.	The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The CRSO EIS technical teams included experts from across over 30 cooperating agencies. Ultimately, the co-lead agencies are responsible for selecting and implementing an alternative. The rationale for doing so is presented throughout Chapter 7, which identifies a Preferred Alternative based on weighing the benefits in achieving the Purpose and Need Statement and EIS objectives while considering the potential adverse effects to the human and natural environment. With such large co-lead agency and cooperating agency teams, the co-lead agencies used spreadsheets to ensure the cooperating agency comments were captured accurately, so the co-lead agencies could respond appropriately. As for analysis conducted outside of the CRSO EIS process, any use of predecisional information developed as part of the CRSO EIS process is inappropriate and a violation of the MOU signed by cooperating agencies, as discussed in the letter sent to the cooperating agencies at the time. Team members from the cooperating agencies participated in the technical team meetings, in which alternative development, alternative analysis, and effects were discussed and presented for inclusion in the EIS. The co-lead agencies and cooperating agencies understood which measures the co-lead agencies would employ from the fish analysis, were part of the evaluation of the measures and alternatives, and were provided opportunities to comment on this analysis during development of the EIS. Development of alternatives and separate technical analysis outside of the co-lead agency process by select few team members does not meet the transparency required by NEPA. The co-lead agencies requested this work be conducted within the team, and not a separate effort. Finally, many cooperators asked questions in technical meeting related to a different resource aspect or analysis, or wanting to explore scopes of analysis outside the EIS. Technical team leads deferred these questions first back to the points of contact identified in the cooperating agency MOU, and then to policy leads if resolution was not reached. This followed the process established in the MOUs with each cooperating agency.
6894	9	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Scope and Foundation of the EIS A. The Purpose and Need Statement and Objectives are Improperly Narrow The co-lead agencies constructed improperly narrow Purpose and Need Statement and Objectives for the DEIS. As written, these essentially prescribe a status quo outcome. In doing so, the co-lead agencies effectively ignore the Order from the District Court for the District of Oregon Order, which affirmed that the CRS cries out for a major overhaul in terms of fish survival rates. The Objectives of the DEIS, or the statements of the desired outcome of the EIS, merely strive for the EIS to improve listed salmonids within the CRS: Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival within the CRS through actions including but not limited to project configuration, flow management, spill operations, and water quality management. (Improve Juvenile Salmon) Improve ESA-listed anadromous salmonid adult fish migration within the CRS through actions including but not limited to project configuration, flow management, spill operations, and water quality management. (Improve Adult Salmon) These objectives, by their explicit terms, do not include treaty rights, ESA, or NWPA compliance. As a result of these narrow objectives, probabilities of survival and recovery of listed salmonids (ESA compliance) were not analyzed in the DEIS. Its noteworthy that they are not analyzed in the draft BA either. Similarly, alternative "offsite mitigation" measures (a term of art under the Northwest Power Act in 16 USC 839b(h)(8)(A)) were not analyzed in the DEIS. The way the objectives are written create an implication that each objective needs to be balanced with the others.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Regarding the Preferred Alternative, this alternative is not simply a minor change to operations and maintenance of the CRS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The comment suggests that alternative offsite mitigation measures were not analyzed in the Draft EIS. Many of the mitigation programs funded by the co-lead agencies consist of offsite mitigation. Bonneville's Fish and Wildlife Program is primarily an off-site mitigation or enhancement program. See 16 U.S.C. 839b(h)(8)(A). In other words, Bonneville funds off-site enhancement, not mitigation at the dams. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and ongoing

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and the Northwest Power Act.
6894	10	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Current Conditions and Programs under the NAA are not Adequately Described or Analyzed Late in 2019, NOAA notified the region that Adaptive Management Implementation Plan (AMIP) safe-guards (low adult returns) had been meet for Snake River steelhead and were likely to be met for Upper Columbia River Steelhead. Yet, nowhere in the DEIS do they mention this. The PA and BA should at least acknowledge this and ensure that additional measures and safeguards to improve and protect adult returns be implemented. The tribes are working with NOAA to identify respective actions, such as more kelt collection and reconditioning, and avian hazing at Miller Rocks. We also repeatedly requested the Action Agencies to accelerate actions that they have existing authority to take to reduce avian predation on listed Upper Columbia and Snake River stock, such as implementing the John Day reservoir operation this year, 2020. The Action Agencies failed to act on any of these actions, nor have they included new actions in the DEIS Proposed Action. Notably, the DEIS PA identifies only two actions (the flex spill operation, and the John Day reservoir operations to reduce nesting at the Blalock Island) to improve the survival of all ESA listed species, including those that have already triggered the AMIP safe guards.	The co-lead agencies discussed current status of AMIP triggers on lines 7236-7243 in the draft CRSO EIS. The co-lead agencies reviewed the Rapid Response Actions identified in the AMIP and note that several actions were implemented in recent years that are likely to increase abundance and productivity. In particular, the co-lead agencies implemented spring juvenile fish passage spill operations that exceeded the performance standard spill operations developed in coordination with NMFS. These operations are part of the 2019-2021 Spill Operation Agreement with the states of Oregon and Washington and the Nez Perce Tribe to increase spill levels with the intention to benefit juvenile salmonids, while offsetting impacts to power generation and operational feasibility. Increased levels of spill were also implemented in 2020. The co-lead agencies have also started transport in 2018 and 2019 earlier than in the past, with the intended benefit of increasing the rates of Snake River steelhead transportation. Moreover, the co-lead agencies are also taking many steps to curtail predation of ESA-listed salmonids by a variety of predators, including pinnipeds, avian predators, and Northern pikeminnow. The co-lead agencies worked with regional stakeholders and enabled additional collection of Snake River steelhead kelts for subsequent reconditioning at Little Goose Dam. That operation was subsequently affected by access restrictions due to COVID-19 response, but has resumed. The co-lead agencies did not implement modifications to John Day pool operations as those are the focus of this Draft EIS review and are proposed for inclusion in the Preferred Alternative. If warranted, additional kelt collection may continue to be implemented after current the ESA consultation and NEPA analysis have been completed. Adaptive management to address these types of issues will continue to be a point of emphasis for the co-lead agencies. Finally, the agencies are continuing their efforts in funding hatchery programs to preserve and rebuild the genetic resources of ESA-listed salmon and steelhead in the Columbia and Snake River basins.
6894	11	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Alternative Selection Process was Flawed and Omitted Important Measures and Considerations from Disclosure and Analysis Section 2.3 suggests that cooperating agencies were collaborated with during the alternative selection process. This was not the case. While cooperating agencies were invited to suggest measures that may be included in alternatives, the development of the single and multipleobjective alternatives (MOs) was solely completed within the co-lead agencies; in no way was the process collaborative. Likewise, the decision to remove single-objective alternatives (SOs) and revamp the multi-objective alternatives was completed solely within the co-lead agencies. The slight exception was MO4, which was presented for consideration by the Nez Perce Tribe. However, here the agencies significantly amended MO4 from what the Nez Perce Tribe submitted without coordination with that or any other tribe. The co-lead agencies built their alternatives out of various measures upon the theory that the alternatives would then provide (1) bookends of impacts i.e., the extremes; and (2) modularity the ability to decipher which measures were driving various impacts. Ultimately, a preferred alternative could be built out of the various measures with known impacts. However, this effort failed for multiple reasons: 1. Focus on specific actions, or measures, fails to consider important programmatic efforts relevant to the CRSO (discussed more below). 2. Due to the time compaction for completing the EIS, the SOs were eventually dropped from review. These SOs would have presented a better bookend review. 3. MO combinations obfuscate any useful conclusions. All the MOs were formulated in a way that produce similar results. For instance, MO3 negates the benefits of breach by reducing spill in the lower river; MO4 takes away from reviewing the fish benefits of 125% TDG by reducing spring and summer flows through changed reservoir operation. 4. The effects analysis of the MOs does not evaluate the component measures within each of the MOs, making it difficult to identify which components of an MO provide benefits for fish versus which are a detriment. Additionally, some measures within MOs were written with biases that preclude a thorough comparison of the alternatives, because the measures all have different components: 1. MO4 is written to use a hard constraint for the McNary Flow target verses the target constraint used in NAA and MO1 and analyzed in previous biological opinions. Inclusion of the hard constraint masks and exaggerates the impacts of a max spill alternative. This makes MO4 look unreasonable due to significant cost, extensive reservoir drainage and increased impacts to resident fish. The description of the McNary flow target measure in MO4 is insufficient to explain the significant impact of that action in the alternative. 2. MO1, MO3 and MO4 all fail to limit spill at Bonneville to 150Kcfs.1 This is a structural limitation of the facility and it is unrealistic to assume that the Corps would exceed this spill level, and capricious then to include such in its modeling. Without this limit, the alternatives appear to spill a lot more in the alternatives, which make both the power cost and adult returns (SAR) effects artificially high. In this way, the alternatives are not reasonable, and the results biased. Moreover, the EISs reliance on bookends and modularity precluded evaluation of several reasonable alternatives: 1. A true breach or natural river alternative, as we believe was requested by the District of Oregon. MO3 the breaching alternative negates the fish benefits of breaching the Snake River Dams by, among other actions, decreasing spill in the lower river, precluding a true analysis of the potential benefits of breaching on Snake River stocks. A true breach/ natural river alternative would include spill in the lower river that supports juvenile fish passage, adequate spring flows, and optimized Dworkshak release schedules to regulate water temperature as was included in MO1. The agencies do not explain why they did not do this, particularly in light of the District Courts order. 2. A realistically implementable operation. As formulated, none of the four MOs provide a balanced, standalone operation or were ever intended to be considered as the final action as written. 3. An optimized spill operation. Such operation was requested during scoping and would have looked dam-by-dam at optimal and balanced spill operations that provide the best passage for fish while considering power needs. 4. The current Flex Spill operation. While the proposed alternative partially adopts the 2020 Flex Spill operation (with significant changes), a reasonable review of alternatives would have included the operation as an MO so the results were available for consideration in developing a preferred alternative. The EIS analysis was the chance to take a hard look at a new approach to CRS management and the opportunity to evaluate a practical suite of measures or reasonable alternatives for achieving the DEIS objectives. The DEIS does not provide a rational explanation for its failure to do so.	Section 2.2 of the Executive Summary of the EIS specifically states that the cooperating agencies contributed to the EIS by providing information, participating on technical teams, and reviewing draft documents. It does not state that the cooperating agencies collaborated in the alternative selection process. The MOU signed by cooperators specifically states that the co-lead agencies maintain responsibility for decisions. Regarding alternatives, the preliminary analysis of the Single-Objective (SO) alternatives informed the development of the Multiple-Objective (MO) alternatives. However, the SO alternatives were not developed as viable, complete solutions, as they were focused on only one resource objective and would not provide the comprehensive management strategy needed for the multi-purpose CRS nor would the SOs meet the Purpose and Need Statement. The SOs did provide bookends, as you noted, for example regarding effects of various spill regimes, and the team used them in that way. Ultimately, the range of alternatives needed to provide realistic options for meeting competing project purposes and congressional authorities. See Appendix A for more information. Finally, the co-lead agencies adequately evaluated breaching the four lower Snake River dams with 120% fish passage spill at the lower Columbia River Projects. The measure to adjust Dworshak releases under MO1 was ineffective as discussed in Section 3.4, and that was why it was not carried forward into the Preferred Alternative.
6894	12	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Important Potential Operational and Structural Modifications to the Hydrosystem Were not Analyzed In our initial scoping comments, we indicted that the EIS should consider a range of system operations and improvements with the goal of improving fish passage and whole system survival, including: 1. An optimized spill program under existing water quality waivers based on individual project characteristics and designed to maximize juvenile survival. 2. Permanent drawdown or seasonal drawdown at specific projects. 3. Altered flood control operations in low and mid-range water years to better support spring flow for migrating juveniles. 4. Replace drum gates at Grand Coulee Dam, or change the way the work is done on them, to eliminate or reduce the need for maintenance and associated reservoir draw down. 5. Additional turbines at certain reservoir projects to increase system and flood management flexibility and ensure delivery of flow augmentation when needed for migrating juvenile fish. 6. Additional predation control measures, such as additional bird wires and pinniped control measures. 7. Additional analysis to determine what additional options, either structural or operational, could be implemented to reduce thermal issues now and in the future. 8. Additional lamprey measures. See lamprey discussion below. The DEIS does not give these operations and improvements adequate consideration, and does not provide a rational explanation for its failure to do so.	Section 2.2 of the Executive Summary of the EIS specifically states that the cooperating agencies contributed to the EIS by providing information, participating on technical teams, and reviewing draft documents. The MOU signed by cooperating agencies specifically states that the co-lead agencies maintain responsibility for decisions. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in relevant literature. These alternatives represent a reasonable range of alternatives for the maintenance, configuration, and operation of the Columbia River System. Finally, the alternatives did include an evaluation of a wide range of spill levels, drawdown as part of MO4, drum gate maintenance at Grand Coulee as discussed in Section 2.4.2.1, predation measures, water temperature impacts from the various alternatives as described in Sections 3.4 and 7.3, including operational and structural measures, and lamprey measures as discussed in Chapter 7. Additional turbines may be evaluated as part of separate processes, as necessary.
6894	13	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Significant Programmatic Issues Are Obscured from Review by Measure-Based Alternatives The focus on specific actions, called measures, in the DEIS has overshadowed important programmatic issues of significance to the tribes. NEPA documents must concentrate on the issues that are truly significant to the action in question. Further, the following examples highlight that the DEIS appears to be a harbinger of the elimination of certain ongoing Corps programmatic efforts. Since the DEIS is intended to have a 25-year duration, the focus on specific measures to the exclusion of programmatic needs is troubling. 1. The DEIS does not meaningfully disclose and analyze the reductions in the CRFM program. The Corps Columbia River Fish Mitigation program (CRFM) has been a decades long endeavor supported by the Tribes, Pacific Northwest states and congressional delegation. The history, accomplishments and lessons learned from the CRFM are not described in the DEIS. Presumably one would expect to find a discussion of the CRFM in section 1.7 of the DEIS. Over $2 billion dollars has been appropriated by Congress to support this program and institutions such as the System Configuration Team (SCT) have developed around this program.2 While the NAA and MOs assume some continuing level of structural improvements at the CRS dams, the pace of CRFM activity is only revealed by Table 6.1 in Appendix Q (Costs), which identifies that CRFM funding will be reduced to $2 million per year. At its peak, CRFM funding was two orders of magnitude greater. There are two consequences related to the scope change of CRFM we wish to highlight at this time. First the CRFM program is more than just a collection of construction projects at the Corps dams. It represents the Corps ongoing programmatic support, including personnel, for Columbia River anadromous fish passage. The loss of staff capability represented by this budget contraction will impact ongoing working relationships between the Corps and CRITFCs member tribes. While providing repetitive detail about a limited list of structural measures in the NAA and MOs, the DEIS fails to address the programmatic consequences of the loss of the CRFM and the Corps ability to participate in regional decision making concerning its CRS dams. The DEIS should describe the effects of eliminating or drastically modifying the CRFM program. Second, the breadth of configuration measures for the CRS dams is limited and nonrepresentative of ongoing and planning actions. If the DEIS is intended to represent future structural measures for a 25-year period, the measures are far too narrow and too specific to portray a realistic range of activities currently envisioned by co-managers. For instance, collection and	The notion that the Columbia River Fish Mitigation (CRFM) program is being dismantled is not accurate. For CRS dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is because much of the major overhaul of the CRS for the benefit of improved salmon passage has already been constructed. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps will continue to express capability in the annual budgeting process. The analyses used in this Draft EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation and configuration of the CRS projects to the No Action Alternative. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs related to lamprey, such as habitat restoration, reintroduction and translocation, and other efforts. Implementation of all measures, including lamprey measures, is dependent on funding availability. In 2020, the Corps did receive $20M in funding to implement actions contemplated in the 2018 extension of the Columbia Basin Fish Accords. The Corps is currently refining cost estimates and developing a preliminary implementation plan for this $20M program. The Corps will continue to coordinate closely with the Columbia River Inter-Tribal Fish Commission and other Accords tribes on prioritization of actions within this program and will continue to ensure consistency with measures identified in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				reconditioning of steelhead kelts has shown significant benefits in the Yakima and Snake river systems. The discussion of steelhead kelts in the DEIS does not reveal either the scope of efforts now ongoing or planned actions such as expanded kelt trapping operations at CRS dams.3 The only kelt measures in the DEISs MOs are spill passage related. The kelt section of the DEIS should be expanded to address current knowledge concerning kelts and current and planned trapping at Corps dams and reconditioning actions be undertaken by the tribes.4 Similarly, the full suite of potential salmon and steelhead measures should be examined. Even in the near term, questions about the SCT project priority lists for 2018 and 2019 have been repeatedly addressed to the co-lead federal agencies by the Tribes. We have asked that the DEISs range of alternatives at least examine the full range of measures in the SCT project prioritization lists so as not to preclude their future management consideration and implementation. These actions are at least reasonably foreseeable, yet many of them are not mentioned at all in the DEIS. It would be appropriate for the co-lead agencies to answer whether the measures in the NAA and MOs fully include the SCT actions under active consideration by state, federal and tribal experts who participate in SCT, but may not have been involved in preparation of the DEIS.	
6894	14	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Following the 2008 Accords Agreement, the Corps developed a detailed programmatic approach to address the needs of Pacific Lamprey at CRS dams.6 Attached is the Corps Lamprey Program Prioritization Matrix (spreadsheet) identifying priority fixes for adult and juvenile lamprey at mainstem dams (Attachment B). The spreadsheet identifies relative costs and Corps and CRITFC Lamprey Tribal Task Force (comprised of representatives from CRITFC member treaty tribes) priorities as of March 2020. The priority actions matrix developed by the Corps is not a comprehensive list of all needed work for adult and juvenile lamprey at mainstem dams. It should be regarded as a starting point of known and immediate needs to be addressed in the near-term. From this list, the Lamprey Tribal Task Force identified a subset of high priority actions at recent meetings. Those included (1) a. Improving juvenile downstream passage and survival through Columbia and Snake river dams; b. Monitoring and evaluation of juvenile survival and passage success through mainstem Columbia and Snake river dams using juvenile lamprey acoustic tags, (2) Structural modifications to fishways at Columbia and Snake River dams to improve upstream adult passage efficiency and success, (3) Enhancement of the tribal translocation program through improvements to adult trapping systems, and improvements to existing and development of new adult holding facilities at Bonneville, The Dalles and John Day dams, and (4) Assessing the fate of adult lamprey in the lower Columbia River between Bonneville and John Day dams through acoustic telemetry. The Corps is currently working on revised cost estimates and timelines for the projects identified in the spreadsheet, which could alter priority rankings. These lamprey actions are funded through the CRFM. If the CRFM is dismantled as indicated by the cost assumptions in Appendix Q,and discussed above, how will the Corps participation in the lamprey passage program be accomplished? The Corps recently allocated $20 Million of workplan funding towards lamprey, which is great news, but that money in only available and will only fund lamprey efforts through about 2022. With a proposed 25-year term for the EIS, and the CRFM budget dwindling, the continuation of and support for needed lamprey effort is highly uncertain. Each of the MOs contains the same partial list of lamprey measures, which only address a portion of the lamprey priority list identified above. The EIS should include the whole priority list as possible actions for the 25-year term of the EIS. The lamprey measures seem to be focused at dams within the Portland District. For instance, with regard to adult passage modifications, the action list for McNary Dam and the Snake River dams upstream is limited to rounding 90-degree corners at fish ladders. Rounding ladder features is an inexpensive and short-term process, yet the scope of the DEIS, without further NEPA analysis, would preclude other adult passage measures at the Walla Walla District projects during the following 20-year period? Failure to return Pacific Lamprey throughout the Basin is unacceptable.	The co-lead agencies recognize the importance of Pacific lamprey and will continue to work with CTUIR, other Tribes, and regional entities through existing frameworks such as the Corps-Tribal Lamprey Work Group, the Pacific Lamprey Conservation Initiative and the Corps Regional Forum workgroups (e.g., FFDRWG) to implement ongoing programs as well as the lamprey measures described in the Draft EIS. The notion that the Columbia River Fish Mitigation program is being dismantled is not accurate. For Columbia River System dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is a result of significant investments in construction of components of the dams for the benefit of improved salmon passage. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps will continue to express capability in the annual budgeting process. The analyses used in this Draft EIS were for the purposes of comparing the effects of the multiple objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs related to lamprey, such as habitat restoration, reintroduction and translocation, and other efforts. Measures identified in the Draft EIS do not include all lamprey passage improvements that could be potentially implemented at the Lower Columbia and Lower Snake River dams, but the Corps believes that potential actions contemplated in preliminary lamprey program planning discussions with CTUIR staff and others related to the 2018 extension of the Accords are consistent with the measures and analyses included in the Draft EIS. CTUIR is correct that actions beyond the scope of the measures included in the Draft EIS or ongoing activities would potentially require further NEPA analysis. Lamprey measures identified in the Draft EIS (and similar operational or structural measures) do not include research, monitoring or evaluation actions that may be needed to refine passage designs, inform operations, or address critical uncertainties. This includes the juvenile lamprey and adult lamprey migration behavior and fate studies identified in the 2018 Accords Extensions and in subsequent program planning and coordination discussions with the CTUIR and others. For the purposes of the Draft EIS, measures must address known operational and structural issues, but this does not preclude development and implementation of juvenile and adult lamprey studies. Implementation of all measures including lamprey measures is dependent on funding availability. In 2020, the Corps did receive $20M in funding to implement actions contemplated in the 2018 Accords Extensions. As noted by CTUIR, the Corps is currently refining cost estimates and developing a preliminary implementation plan for this $20M program. The Corps will continue to coordinate closely with CTUIR and other Accords Tribes on prioritization of actions within this program and will continue to ensure consistency with measures identified in the Draft EIS.
6894	15	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS fails to disclose and analyze the need for a comprehensive predator control program. Both the Northwest Power and Conservation Council and Columbia River Treaty Tribes visions for predator management recognize the value of a coordinated and systematic approach to predator management which are described below: a. Wy-Kan-Ush-Mi Wa-Kish-Wit Since the publication of the Spirit of the Salmon Plan in 1995 (Wy-Kan-Ush-Mi Wa-Kish-Wit), we have witnessed an alarming increase in predation of salmon, lamprey, and juvenile sturgeon by birds, marine mammals, and other fish.7 In the basin, newly created habitat from navigation dredge spoils increased predacious bird populations; a lack of historical primary food sources brought more hungry sea lions upriver who congregated at Bonneville Dam to feed on Spring Chinook; and changes in the CRS flow regime and the explosion of exotic species in CRS reservoirs expanded predacious fish populations. These negative changes in avian, mammalian, and fish species population dynamics have tipped the predator/prey balance to the point that active management is required to rebalance predator populations and reduce salmon, lamprey, and sturgeon losses. Active management will keep predators at a level that is more in balance with the environment and reduce losses of Columbia River salmon and other native fish populations. Responding to these observations the tribes recommended the following actions in 2014: 1. Develop a common metric for fish, bird, and marine mammal predation (i.e ., adult equivalents) so that comparisons and impacts can be properly assessed . 2. Investigate, monitor, evaluate, and propose solutions to habitat changes at Columbia River tributary confluences where hydro-logic modifications have resulted in increased sediment deposition and potentially attracted predator responses. 3. Investigate indirect food web effects of predation. 4. Apply active, adaptive management practices to predation sources. 5. Pursue legislative solutions to barriers preventing active management. 6. Persuade co-managers to prioritize salmon management in anadromous waters and remove barriers to harvest non-native fish species. 7. Focus public outreach on benefits of native fish communities and balanced ecosystems. 8. Develop greater cross-agency cooperation and investigation opportunities. https://plan.critfc.org/assets/wy-kan-update.pdf A recent presentation by CRITFC to the NW Council is attached to these comments (Attachment C). b. NPCC Fish and Wildlife Program In its most recent Fish and Wildlife Program, the Northwest Power and Conservation Council also recognized the growing impacts of predators on the anadromous fish of the Columbia River Basin. Predator management is requiring more program resources and efforts year by year. Everyone involved in the program, including the Council, Bonneville, the Corps of Engineers, the fish and wildlife agencies and tribes, and others, must work together to continue developing a more effective systemwide, ecosystem-based approach for assessing and addressing the impacts of fish, avian, and pinniped predation on salmon and steelhead and other fish species important to the program. It is imperative to scientifically advance the understanding of predation impacts. It is important to understand which predator management actions have the greatest effect on adult returns and SARs and retarget efforts on those actions for cost-effective predation management. https://www.nwcouncil.org/sites/default/files/2020-1.pdf. The Program contains systemwide measures for predator control that are directed to Bonneville, the Corps, Bureau of Reclamation and others for their implementation. For example, the Program provides: Predation by double-crested cormorants, Caspian terns, and several other bird species continues to have a significant impact on ESA-listed juvenile salmon and steelhead in the Columbia and Snake rivers. A recent trend has been reduced support for this effort. The action agencies (Bonneville, Corps of Engineers, Bureau of Reclamation) working with state and tribal partners, should continue to provide adequate funding to implement activities, both in the estuary and inland, to reduce avian predation on listed juvenile salmon and steelhead. In contrast, the CRSO DEIS contains parsimonious mitigation measures for predators which are not responsive to the broader guidance from the tribes and the Council. Thoughtful analyses of the Northwest Power Act requirements and the obligations to implement Councils Program regarding predator management are not found in the DEIS. The DEIS should contain more programmatic responses, for instance committing to fund a Regional Predator Management Forum, with additional monitoring, that includes all funding and implementation partners to collaboratively and comprehensively evaluate and address predation (including piscivorous, avian, and pinniped predation) on salmon and steelhead from the river mouth to the spawning grounds.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. As for the suggestion that the three co-lead agencies (Corps, Reclamation, and Bonneville) develop a Regional Predator Management Forum, the species that are of concern due to their predation of anadromous fish in the Columbia River are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, and agreements. The three co-lead agencies (Corps, Reclamation, and Bonneville) have limited authority to manage predators of fish.
6894	16	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Preferred Alternative The Draft Preferred Alternative (PA) is based on 2021 operations under the Flex Spill Agreement, although it presents some significant changes. While increasing spill to a 125 TDG flex spill operation, numerous changes from the current Flex Spill Agreement threaten to make the PA operation worse for salmon and steelhead than the 2020 operations under the Flex Spill Agreement a change in the wrong direction. Below are further detailed comments on individual measures presented in the Draft PA, however, the following summary of our concerns paints a composite picture. In short, the benefits of a 125 Flex Spill Operation are systematically eroded by one power measure after another such that fish benefits are degraded to an unknown degree. In the end, the PA presents only slightly improved fish survival (if any) compared to the NAA, and those conclusions are based upon multiple layers of uncertainty. The PA reduces spring flows through altered water management operations at Libby, Coulee and Dworshak. This means less spring flow for Upper Columbia stocks, and this would occur in all years, not just high flow years. At Dworshak, the additional winter drawdown would be based on unreliable and uncertain early forecasts, which could similarly reduce spring flows in the Snake to the detriment of Snake River stocks. The impacts to the Upper Columbia stocks are especially troubling due to their current condition and the limited benefits provided to them from Flex Spill operations. In addition to the spring flow changes, the PA includes several other measures with detrimental or unknown effects on anadromous salmonids: 1. Options for unrestricted turbine flexibility outside of peak efficiency with unknown levels of impact and no mitigation proposed; 2. Fall zero generation (zero flow) in the Snake (effects unknown on adult fall chinook, steelhead, and coho, and on juvenile fall chinook) with no mitigation proposed; 3. Reliance on already implemented or phased out actions (structural and avian) with no commitment to ensure benefits of those efforts are implemented and maintained over time; 4. Options to reduce Fish and Wildlife Program with no metric or decision framework	Many measures have been included in the Preferred Alternative that benefit ESA-listed species in both the upper and lower Columbia River. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations. See Section 7.6.3 titled Preferred Alternative Operational Measures. In addition, a large number of structural changes are included to benefits salmonid species and Pacific lamprey. See Section 7.6.2 titled Preferred Alternative Structural Measures. The framework for the adaptive management process has been updated and is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the CRS EIS. The co-lead agencies intend to further refine the adaptive management approach with regional experts to more further define the decision making process, including those items that trigger the need for a decision to be made. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. It is the intention of the co-lead agencies to engage regional state, tribal, and federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams such as the Technical Management Team. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies will provide additional clarifying text in Appendix R to make these points more clearly.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				identified for evaluating that option; and 5. No additional fish mitigation, other than JDA operations for birds; almost all mitigation measures are for power flexibility that will result in negative impacts to fish. The PA action is then only set for one year, so all out year operations are highly uncertain. The PA points to the Adaptive Management Appendix for future year operations. This Adaptive Management Framework adds in significant additional uncertainty for fish benefits: 1. While written in the form of changes needed for fish, the appendix would allow for decreases in spill and other unknown actions that could have detrimental effect, with no real assurances that regional input will be adopted. Based on experience, it is likely that the Action Agencies will act in the interest of their primary agency missions (power, flood control, irrigation and navigation) without providing fish and wildlife equitable leverage in decision making. 2. A latent mortality test is required but unknown, with unknown effects on fish. If, for example, the previously discussed block study is implemented, this would significantly reduce spill from Flex Spill Agreement. It is not clear how that decision will be made. There are no fish goals stated in the PA to compare operational results to (to guide necessary change in operation), and no metrics have been provided to support future decision making. Moreover, the minimal fish benefits attributed to the PA rely on unknown benefits from reductions in latent mortality and are otherwise biased high. First, the base COMPASS model does not account for latent mortality and only shows benefit of the PA above the NAA when an arbitrary range of latent mortality rates are employed in the model. Second, the CSS model results are biased high due to the selected model inputs, (i.e.; daily time steps in operations data rather than hourly time steps consistent with PA operation, operations data sets did not include fully loaded powerhouse operations like we see in reality, so spill proportion is weighted higher than reality). The PA fails to mention this or take it into consideration. Based on the above, additional elements will be needed for the PA to cushion or otherwise address the inherent uncertainty in the action. This may include: 1. More mitigation to offset measures for hydro flexibility and unknown benefit of Flex Spill; 2. Maintained or increased Fish and Wildlife Program spending in order to improve from 2016/NAA baseline and not just maintain status quo survival statistics; 3. A charter identifying side boards on the Appendix Flex Spill Workgroup and clear definition for decision making framework within it; and 4. Check-ins and/or off-ramps. The PA rests on significant uncertainty and degrading fish populations; the availability of immediate and significant action is required.	
6894	17	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Preferred Alternative Does not Respect Tribal Rights and Interests, Including Fisheries and Cultural resources The statements regarding respecting treaty rights are unsupported by the PA. While there are numerous references to respecting treaty rights and tribal culture, the PA does not respect treaty rights as it reduces current actions to improve salmon and steelhead survival. It also suggests further future reductions to offsite mitigation based on results we will not see for 20 years. Finally, we find little or no evidence that our input has been incorporated within most sections of the DEIS. The PA needs to improve salmon survival from current conditions (not from 2016) and address whether these conditions will meet the tribal goals described in the Tribal Perspectives document provided in June 2019.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. The scope of the EIS focuses on the area affected by the alternatives presented for operation, maintenance, and configuration of Columbia River System Projects. The alternatives are evaluated in terms of change from the No Action Alternative, which is the baseline condition of 2016 when the development of the EIS began. The co-lead agencies defined the No Action Alternative consistent with NEPA and implementing regulations. In the case of an ongoing action, such as operation of the CRS, the no action alternative represents no change in current management direction or level of management intensity. The no action alternative thus assumes the existence of the CRS projects and does not attempt to hypothesize the direct and indirect costs of each of Congress's decisions to construct CRS projects. Under NEPA, the co-lead agencies are required to analyze a range of alternatives, including the No Action Alternative, to meet the purpose and need of the Project. The EIS analyzing the effects of the No Action Alternative on resources, environmental and socioeconomic, at present and into the future. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. The mitigation identified in the EIS is to offset impacts of each Multiple Objective alternative compared to the No Action Alternative, which was the scope of analysis for this EIS. NEPA does not require identification of mitigation for the continuation of the No Action Alternative. Each alternative, including the Preferred Alternative, has a number of proposed measures intended to benefit fish. Multiple Objective alternative 1, Multiple Objective alternative 3, Multiple Objective alternative 4 and the Preferred Alternative all meet the objectives for adult and juvenile ESA-listed fish, as well as resident fish, with an overall beneficial effect over the No Action Alternative, and did not have an overall adverse effect to fish; therefore additional mitigation was not warranted.
6894	18	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Water Management Measures Make the Preferred Alternative Worse for Fish Than 2020 Flex Spill Operation The PA proposes to move water from spring into January at Coulee, Libby and Dworshak, creating a worse situation for many salmon and steelhead stocks than we currently have with the 2020 Flex Spill Agreement. While different rationales are given, primarily, these operations provide more for power flexibility. This additional power flexibility was not part of the 2020 Flex Spill operations under the Flex Spill Agreement, and is detrimental to fish survival. The new drafting operations are not limited to high flow years but would occur in average and low flow years and would occur in 75% of all water years. At Libby, the operation states that they will draft deeper in January when inflow forecasts are less than 6.9 MAF, which is most years. From a fish perspective, this is backwards thinking. These new power flexibility operations will result in less spring flows for both Upper Columbia and Snake River stocks, likely resulting in higher water temperatures as well. Flow timing and volume have been proven to be two of the most important factors for juvenile migration, travel times and survival. Deeper drafts at Dworshak (DWR) are included as a measure to help protect TDG issues at nearby hatcheries. However, Total Dissolved Gas issues are only a concern during high flow events when large volumes of water need to be moved and units are not available, as was witnessed in 2017. A deeper draft would not have helped in 2017; units were needed to move the water. So, the DWR drawdown is really another operation to increase power flexibility, but at the risk of not refilling the reservoir and/or decreasing spring flows. Failure to reach full pool reduces summer flow augmentation and lower Snake water temperature management capacity. Moreover, the decision timeframe of December/January for determining whether to drawdown DWR is not implementable; adequate information is not available at that time. While the flow changes from each of the above measures may not be large, their combined effects could add up to significant flow reductions in the river. Moreover, the actions are changes from the power flexibility operations agreed to for 2020 under the Flex Spill Agreement, therefore representing power benefits and fish detriments from the 2020 operations that fulfilled the 3 pillars. Without more (explanations, limitations, mitigation), these measures are unacceptable.	Chapter 7, Section 7.7 in the Draft EIS analyzes the effect of the Preferred Alternative on flow relative to the No Action Alternative. While the commenter is correct in that the new water management measures will result in less spring flow, the reductions are relatively minor. For example, flows at McNary Dam (Table 7-17) show relatively minor decreases, the largest being 2% (4.4 kcfs) in May at the 99% exceedance probability. Other spring flows are within 1% of the No Action Alternative. Regarding Dworshak deeper draft, the comment is partially correct. The deeper early draft in large water years simply moves some of the draft into January and February, thus spreading it out and reducing TDG. It does help with power generation. In large snow pack years that start building early, there is information to base the deeper draft on. It can have a negative impact on refill, but the implementation rules would minimize that impact.2017 is not a reasonable year to base analysis on since Unit 3 was not available. In most years, we have three turbines available but are only running one small unit instead of full power house. The current drawdown moves most of the flood control water in March and April when we have little additional capacity, resulting in more spill which elevates TDG. The deeper draft would really be best described by an earlier draft as it moves part of the flood control draft into January and February. Before the operation could be implemented additional analysis, rule curves, and forecasting procedures would need to be approved for the reservoir. The commenter is likely correct in that a decision timeframe of December/January for determining whether to drawdown Dworshak may not implementable; and may require additional time prior to implementation if large uncertainty in annual forecasts remain...
6894	19	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Increased Turbine Operation Flexibility Needs Sideboards on Implementation. The PA includes operation of turbines outside of the 1% range. While some excursion is acceptable, the current way it is written is too broad and would allow excursions anywhere and for any reason. At some projects, operating outside of 1% has almost no impact since the turbines do not have capacity beyond 1%. However, other projects such as McNary could be operated 4-6 kcfs higher per turbine which equates to over 50 kcfs swing in flow moved from spill to the turbines. Meanwhile, the effects analysis assumes operation within the 1% bound. Specific sideboards are needed to minimize effects. The action agencies need to work with regional managers to come up with a mutually acceptable plan that considers individual project data and operations to create sideboards on turbine operations outside of 1% efficiency. Alternatively, this measure should be removed from the PA.	The co-lead agencies are coordinating guidelines and limitations for operations outside the 1% operating range. The overall level of spill at any given Project is determined not by the individual turbine unit capacity but by overall project operations management decisions. These decisions will occur through the Regional Forum and guided by the Adaptive Management Plan. Adaptive management strategies will be used to assure no detrimental impact.
6894	20	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Structural fish measures provide little benefit to anadromous salmonids. Many of the PA structural measures have little to no benefit for salmon and steelhead and should not be listed as beneficial to fish. Most of these fish measures appear to provide a hydro-power benefit instead, which is a step back from the Flex Spill Agreement. Those included in the PA are less than what was proposed in the multi-objective alternatives. For example, the Lower Granite Trap modifications and the Bonneville Serpentine Weir both have reduced scope providing almost no benefit above the NAA. In addition, most of the structural measures listed in the PA are already completed. Although they are additions to the NAA, their status towards completion should be clarified. The Columbia River Fish Management (CFRM) Program is characterized as being complete in 10 years since few new actions have been identified. The PA needs to accurately portray the minimal fish benefits associated with limited structural measures included in the PA and clearly identify that most have already been completed. Additional structural measures should be included in the mitigation toolbox to ensure NEPA coverage and to support advocating for increases in the CRFM budget. This should include (but not be limited to) all actions currently on the SCT list to assure EIS coverage and not foreclose on their funding. The scope of the DEIS must be sufficiently broad to provide NEPA coverage for all structural measures in the current Systems Configuration Team (SCT) spreadsheet analyses. The PA should provide for continued implementation of high priority measures from the SCTs analyses.	The co-agencies agree that the structural measures proposed in the Draft EIS provide small incremental benefits to fish survival when compared to increased spill or dam breach as modeled by CSS. There are two explanations for this: 1. Latent mortality, as modeled by CSS assigns a large survival benefit (Smolt-to-Adult) for large reductions in powerhouse passage; 2. the overhaul of the four lower Snake and Columbia River dams is near completion. All the big structural fixes, such as surface flow bypass, juvenile bypass systems and improvements, spillway improvements, avian predation deterrence, adult ladder improvements, have been constructed. What remains in the CRFM budget and SCT spreadsheet is completion of that construction effort. Funding for operating and maintaining the facilities that were constructed under this overhaul will continue into the future. The remaining actions on the SCT list are almost exclusively actions recommended in a BiOp, and as such are being carried into the Preferred Alternative from the No Action Alternative. Unless otherwise noted, all other actions that were planned or part of ongoing CRS operations and maintenance in 2016 when the EIS was initiated are included as part of the Preferred Alternative. Therefore the items in the SCT spreadsheet will have continued NEPA coverage.
6894	21	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department	The Preferred Alternative Fails to Meaningfully Disclose and Analyze That the Corps Reliance on O&M Funding to Meet its Fish Obligations Will be Increasing, but the Current Corps O&M Funding Trajectory is Declining The PA indicates that most of the Corps actions will shift to an O&M funding source, however Corps commitments to O&M funding are declining. Actions included in the PA that appear to rely on O&M funding include replacement and upgrades to existing system, continued implementation of existing management plans, and multiple lines of research, among others. Most of these items are hidden as continuing actions under the NAA, with continuing implementation assumed. The lack of certainty surrounding full implementation of these actions due to lack of funding is not acknowledged or factored into the effects analysis.	Section 7.2 describes that the No Action Alternative, MO1, MO2, and MO4 (described in Chapter 2) allow for the operation of the projects in furtherance of all of the congressionally authorized purposes to varying degrees. This includes flood risk management, navigation, irrigation, hydropower generation, fish and wildlife conservation, and recreation. Therefore existing funding mechanisms and congressional authorizations would continue under the Preferred Alternative. In addition, some programs are funded by Bonneville's electricity ratepayers as part of the rates Bonneville sets to recover its costs. However, under MO3, new congressional authority through the passage of new laws and associated funding would be required to implement the dam breaching measures. CRSO implementation and system requirements and associated costs, such as for project capital investments and operations and maintenance, were assumed to be fully funded to meet these requirements. Additional feasibility studies and engineering and design studies would be needed to implement the Preferred Alternative once this EIS is completed. The co-lead agencies are aware that potential funding challenges are a reality for all actions, but the assumptions for the EIS analysis are projects would be funded as implemented. The co-lead agencies also note Appendix R describes the Monitoring and Adaptive Management Plan. The agencies will also discuss the mitigation measures in their Record of Decision.

			of Natural Resources		
6894	22	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Fish Effects Analysis Depicts Minimal Improvements Based on High Levels of Uncertainty The analysis in the PA does not determine what benefits to salmon and steelhead are expected or needed, nor does it give a goal. The regional SAR goals are not discussed in the DEIS goals and are described as improvement without any quantitative goal. The analysis depicts almost little to no benefit for many of the stocks and when one considers confidence intervals (not shown in the summary chapters of the DEIS, only in the appendix) there is not a statistical difference between the PA and NAA (base case). Notably, the analyses do not indicate whether the measures result in increasing abundance trends towards the NPCC goal of 5 million salmon and increasing steelhead, and SARs between 2 and 6 percent. Progress towards achieving the NPCC goal should be one of the metrics to determine success of FCRPS hydro operations and mitigation measures.	Based on the analysis in the CRSO EIS, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals like those mentioned in this comment are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the 2-6%SAR target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
6894	23	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Preferred Alternatives Flex Spill Operation Relies on Unsupported Latent Mortality Assumptions to Show Fish Benefits The NOAA analysis performed in the PA relies heavily on assumptions regarding improvements in Latent Mortality to achieve any benefit when compared to the NAA (base case). Latent Mortality is associated with powerhouse passage. Analyses have shown that juvenile fish that pass through powerhouses experience a decrease in survival at later life stages compared to their spillway passed cohorts. Latent and delayed mortality refers to subsequent mortality at later life stages after the initial powerhouse passage experience. The CSS model is based on relationships built on SARs calculated from different passage routes from the long data time series of past years of adult returns (empirically based). CSS model analyses of CRSO-EIS do not require any assumptions regarding delayed mortality. Delayed/latent mortality that occurs is captured in the SAR metric. NOAAs Life cycle model, specifically the COMPASSS component does not include delayed/ latent mortality. Arrival time of juvenile salmon and steelhead to below Bonneville is the primary metric in COMPASS analyses used to access operational alternatives (including the PA) The CSS models do show a slight improvement in SARs for the PA when compared to NAA (base case) since the PA reduces Pit PH (powerhouse passages). Pit PH is an index to estimate the number of fish passing powerhouses. However, the improvement described in the DEIS of 35% is a relative improvement and the resulting absolute SAR with the PA is still small and below the regional 4% SAR goal. Conversely, the NOAA life cycle model does not show an improvement in the PA and actually shows it can be worse than the NAA (base case). NOAA modelers add a latent mortality adjustment factor into their model and arbitrarily used a range of values (0 50%). Once the Latent Mortality adjustment was used NOAAs Life Cycle Model did show a benefit when a 25% Latent Mortality reduction factor was added to the modeling, see appendix E. We agree that Latent Mortality is an important factor that needs to be considered, but the PA relies solely on this improvement to achieve even the modest improvements when compared to the NAA (base case). Any benefits of the PA in the NOAA analysis are questionable, because the NOAA latent mortality assumption lacks an empirical basis. If latent mortality improvements are less than this 25% threshold this could result in no benefit from the PA. The CSS analyses of the PA estimate that at low flow and poor ocean conditions, the predicted SAR with the PA is less than 1% which is less than population replacement levels. CSS analyses show that with implementation of the PA, predicted SARs are below the 1% SAR population replacement level 36% to 39% of the time. For these reasons we believe that additional mitigation actions are needed to ensure benefits are realized. Furthermore, additional monitoring and research should be conducted to evaluate how the PA operation is performing. See recommended addition mitigation and actions below.	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and COMPASS models predict that power house encounters would be cut in half relative to the No-Action Alternative for Snake River spring/summer Chinook salmon. The uncertainty lies in the hypothesis that reduced powerhouse encounters will result in increased adult returns. To address this uncertainty, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The model results presented in Section 3.5 and Section 7.7.4 address latent mortality and reservoir mortality. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results. Reservoir mortality is captured in the juvenile survival metrics presented in Chapter 3. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the Draft EIS.
6894	24	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Preferred Alternatives CSS Fish Benefits are Biased High All analyses by NOAA and the CSS were based on 80-year water record model generated data sets from the USACOE. The PA represents an operation that is based on an hourly operation, but the data sets provided to analyze the PA were based on daily average operations. The anomalies in the PA data sets were identified in a memorandum to the federal action agencies. The discussion of the benefits of the PA does not address the disparity of the data sets relative to the proposed operations. Specifically, the implications of analyzing an hourly operation (the PA) on the basis of a daily average operation (the PA data set), is not discussed in the DEIS. The PA analysis should account for the fact that the data sets provided to the CSS project were in daily average time steps, yet the proposed operation occurs on an hourly time step therefore raising doubts regarding the results. The CSS (memo January 24, 2020) highlighted their concern that the CSS predicted benefits are overestimates of predicted SARs. This creates a CSS analysis which shows more benefit to survival than is likely to occur (biased high). In addition, the hydraulic data sets has powerhouse operations that do not represent reality. Instead of fully loading the powerhouse when possible as is common practice, flow through the powerhouse is reduced, which results in more spill occurring then would actually occur. This would bias the fish models into predicting better survival then what would actually occur. The DEIS PA fails to mention this or take the biological effect into consideration.	In practice, model estimates may not overestimate PITPH due to day vs.. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of night time spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. This example of adaptive management will continue under the Preferred Alternative, as described in Appendix R.
6894	25	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The level of Improvement for new Turbines at Ice Harbor, McNary, and John Day are Unfounded and not Supported by Past Data and Research The PA includes installation of new turbines at John Day, Ice Harbor, and McNary dams. However, these actions are already planned to occur in the base case so it is misleading that they are identified as new fish benefits in the PA. Furthermore, the DEIS arbitrarily assumed that these turbines would have a 50% improvement in juvenile migrant survival. This assumption is not supported by any available studies. See detailed comments below in our comments on Effects Analysis modeling. Moreover, the PA indicates that generation capacity at John Day and McNary will increase hydraulic capacity. This increase in generation capacity was not included in the hydraulic modeling that was provided to the fish model or the economic models and would impact the results from both models. With more water going through the turbines, economic impacts would be reduced. More importantly, juvenile survival would be decreased (see detailed discussion below). This information needs to be considered against the unsubstantiated survival improvement accredited to the new turbines, something the analysis fails to do.	IFP turbines at John Day are not included in the No Action Alternative, only the Preferred Alternative. McNary and Ice Harbor (units 1-3) are part of the No Action Alternative because of the progress that has been made on these projects and the Preferred Alternative because work is yet to be done on implementing these projects. Survival estimates are based on the best available data. Once installed the new turbines will be tested and validated for fish survival. However, the turbine survival rates used in the model are based on empirical estimates, known to be biased low (Carlson et al 2012), but are unadjusted in the NMFS COMPASS model, as the magnitude of survival improvement is difficult to estimate. Only McNary turbines will have greater capacity. Project wide operations decisions determine the amount of water passing through turbines, not strictly turbine hydraulic capacity.
6894	26	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	There is Unaccounted for Bias or Uncertainty in the Preferred Alternative Analysis The following biases or uncertainties are not addressed or explained: a. Zero Generation in the Snake (as proposed for in the fall in the PA) has not been analyzed; b. Avian losses are not accounted for (see below); c. Significant uncertainty from the Adaptive Management Appendix is not considered and all risk is on the fish side of the equation while minimizing risk on the hydro-power system; and d. Looking at the PA data set in detail, spill plus powerhouse does not always come out the same as the daily average flow, by a large magnitude. Sometimes water disappears and sometimes there is a lot of extra water (more than fishway flows for instance). Due to the uncertainties and modeling biases, significantly more fish mitigation measures should be considered to counter these uncertainties and allow the PA to be consistent with the NPCC goals of 5 million fish and 2-6% SARs.	The co-lead agencies will implement the zero generation operation in a manner that has negligible effects to any salmon or steelhead present in the river. Nighttime operations will end prior to daylight hours and allow attraction flow to fish ladders to aid passage for fish that are attempting to pass the projects. Daytime zero generation operations would not be implemented until mid-December when juvenile and adult migration has largely ceased. These effects have been analyzed by the co-lead agencies and were also reviewed by National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) during the development of their respective Biological Opinions. Losses of salmonids due to avian predation is complex and is a function of species, location, timing, and habitat availability for birds. The Draft EIS describes avian predation on salmonids quantitatively when information is available and qualitatively when data is lacking. The current rates of predation are only known for certain species at certain locations, as described in the affected environment and No Action Alternative of Chapter 3 Section 5. For example, predation of juvenile steelhead from the upper Columbia River has been monitored at Crescent Island on the mainstem Columbia River and has declined from nearly 23% in 2009 to approximately 4% in 2017 (Draft EIS p. 3-290). Avian predation of juvenile steelhead at Crescent Island has been eliminated due to management actions (Draft EIS p. 3-290). Chapter 3, Section 6, describes effects to avian habitat availability at key locations on the mainstem Columbia River. Changes in operations affect the acres of available habitat for Caspian terns and cormorants, thus impacting the potential numbers of birds that may be nesting and foraging on salmonids. Where it is anticipated the alternatives would result in changes to avian predation from the No Action Alternative, Chapter 3, Sections 5 and 6, describe those effects. In addition, models used to describe effects to fish species include historical losses due to predation, so those effects are captured in the modeling. Chapter 7 includes measures to reduce avian predation and quantitatively describes effects to salmonids. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. The co-lead agencies acknowledge the uncertainty associated with the model outputs of both the CSS and the NMFS models. That is why we are implementing the adaptive management framework as part of the preferred alternative/proposed action. Outflows through the dams are divided into multiple different types, mainly comprised of the powerhouse turbine flow and the spill. The spill flow has several different components. There is fish spill, powerhouse bypass channel, attraction spill, lack of market spill and forced spill due to lack of turbine capacity. In addition there is miscellaneous flow, which includes lockages, leakage and other flows. For more information, see Appendix B, Part 2: Spill Analysis. As for the Northwest Power Act mandates and compliance, some context is necessary to understand where the Agencies stand with regard to the goals and objectives of the Northwest Power and Conservation Council (Council). For additional information, see response to Comment 31775-111. The Act anticipates a Columbia River Basin Fish and Wildlife Program (Program) based primarily on hydrosystem actions and identifies two mitigation priorities for anadromous fish, both of which the region has largely achieved. The Program must provide for improved survival of such fish at hydroelectric facilities and provide flows of sufficient quality and quantity between such facilities to improve production, migration, and survival of such fish. 1/ These goals and objectives apply to all hydroelectric projects in the Northwest. Appendix B to the Councils 2014 Program, which remains in effect, indicates the hydrosystem affecting anadromous fish in the basin includes 136 dams, some built even before Bonneville Dam. 2/ Congress required four agencies the Corps, Reclamation, and Bonneville along with the Federal Energy Regulatory Commission, which has regulatory authority over more than 100 dams in the basin to implement the substantive mitigation provisions of the Act. 3/ Four agencies and over 100 dams are thus needed to implement the Councils Program, because Congress mandated that Northwest Power Act mitigation be planned and implemented on a system-wide basis. 4/ Moreover, neither the Act nor the Councils Program has goals and objectives specific to the CRS (or the FCRPS). Suggesting that the co-lead agencies failed to meet Northwest Power Act mandates by falling short of the Councils Program goals conflates system-wide goals applicable to over 100 dams to the 14 hydroelectric projects comprising the CRS. In addition to applying to more than just the CRS projects, the Councils five million salmon goal can be influenced or even thwarted by factors other than the dams that have had adverse impacts on salmon, including population growth, habitat degradation, harvest, irrigation, and natural conditions including ocean conditions and climate. The Councils SARs goals suffer a similar shortcoming. Research shows that SARs are heavily influenced by factors other than in-river flows and spill

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					conditions, particularly ocean conditions that are beyond the control of CRS operations. For example, one study found a threefold difference in SARs for sockeye salmon that migrated downstream as juveniles in 2008 and 2010 despite nearly identical survival through the CRS from McNary to Bonneville dams. 5/ The researchers found the difference in sockeye SARs most closely correlated with ocean and climate indicators and concluded the large difference in SARs were the result of varying ocean conditions. The Councils SARs and adult fish goals do not reasonably apprise co-lead agency compliance with the Northwest Power Act because those goals are not tailored to the CRS specifically and do not meaningfully inform compliance with the Acts mitigation mandates. 1/ 16 U.S.C. 839b(h)(2)(A), (6)(E). 2/ See Council, 2014 Program, Appendix B, Compilation of Information on Salmon and Steelhead Losses in the Columbia River Basin, page 136 (Mar. 1986). 3/ 16 U.S.C. 839b(h)(11)(A). 4/ 16 U.S.C. 839b(h)(1)(A). 5/ Williams, J.G., Smith, S.G., Fryer, J.K., Scheuerell, M.D., Muir, W.D., Flagg, T.A., Zabel, R.W., Ferguson, J.W., and Casillas, E., INFLUENCE OF OCEAN AND FRESHWATER CONDITIONS ON COLUMBIA RIVER SOCKEYE SALMON ONCHORHYNCHUS NERKA ADULT RETURN RATES in Fisheries Oceanography (2014).
6894	27	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Preferred Alternative Fails to Disclose the Regional Importance of the Northwest Power Acts Fish and Wildlife Program, and to Analyze Whether the Actions Proposed in the DEIS are Consistent With the Program The DEISs discussion of the Northwest Power Acts Fish and Wildlife Program focuses on the cost of the program, fails to note its benefits, and does not disclose or analyze the individual measures within the Program for which the co-lead agencies have statutory obligations to take into account and implement. In various iterations the Program has been in existence since 1982. The region invests hundreds of millions of dollars in its implementation annually. Nevertheless, the DEISs discussion is essentially limited to the following point (DEIS, 7-39): Bonnevilles Fish and Wildlife (F&W) Program funds hundreds of projects each year to mitigate the impacts of the development and operation of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 (Northwest Power Act), 16 USC 839b(h)(10)(A), to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Each year Bonneville funds projects with many local, state, tribal, and Federal entities to fulfill its Northwest Power Act fish and wildlife responsibilities and to implement offsite mitigation actions listed in various Biological Opinions for ESA-listed species. Offsite protection and mitigation actions typically address impacts to fish and wildlife not caused directly by the CRS, but they are actions that can improve overall conditions for fish to help address uncertainty related to any residual adverse effects of the CRS. The benefits of the Fish and Wildlife Program are not disclosed or analyzed. Offsite mitigation is intended to replace survival benefits that cannot be fully addressed through modifying operations of the hydropower system alone. 16 USC 839b(h)(8)(A). Offsite protection and mitigation compensates for losses arising from the development and operation of the CRS hydroelectric facilities. The NAA alternative assumes the 2016 Program. However, the DEIS fails to disclose and analyze the fact that BPA has reduced Fish and Wildlife Program funding since 2016, cutting the budget by $30M in 2018 due to spill surcharge and negotiated reductions. This reduction in mitigation spending is not accounted for in the PA analysis and creates bias in cost analysis as well as assumptions about the benefits of current mitigation actions. In addition, the Co-Lead agencies discuss reducing the off-site fish and wildlife mitigation funding if the benefits to fish are as anticipated. The DEIS fails to disclose or analyze what level of benefit (abundance, SARs, etc.) will drive that discussion and decision. Nor does the DEIS disclose or analyze the process or timeline for consideration of that discussion and decision.	Funding decisions for the Bonneville Fish and Wildlife (F&W) Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W program costs are included to inform the broader cost analysis for each alternative in the EIS. In the case of the Preferred Alternative, Bonneville included a range of potential F&W program costs to acknowledge the possibility that the Preferred Alternative could provide biological benefits to anadromous fish species (see Chapter 7 of the EIS, Preferred Alternative) and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville F&W Program. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. As discussed in Section 7.7.21.1, in 2016, Bonneville's F&W Program budget was $267,000,000, and the Lower Snake River Compensation Plan (LSRCP) budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17%, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative. With regard to benefits of ongoing mitigation actions, Section 2.4.2 provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. The fish and wildlife mitigation projects that Bonneville funds have been recommended by the Northwest Power and Conservation Council (Council) and either derive from, or have been incorporated into, the Councils Columbia River Basin Fish and Wildlife Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria such as benefits to fish and wildlife. 16 U.S.C. 839b(h)(10)(D(iv). And for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Fish and Wildlife Program. See responses to Comments 31775-51, 6894-56, and 6894-49. With regard to the comments about the policies and mandates of the Northwest Power Act, the FEIS has been edited to provide more detailed discussion of those mandates and how the Agencies comply with them. See Chapter 5.1.2.
6894	28	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Mitigation Package Contained in the Preferred Alternative is Lacking There is very little offered in the PA in terms of fish mitigation. Most fish mitigation is ongoing, and the discussions regarding this ongoing mitigation do not disclose its extent or effects on listed and non-listed species. (See Fish and Wildlife Program and Avian Predation discussions.) With respect to new fish mitigation measures proposed in the DEIS, the only new operational measure with fish benefit is JDA pool operations to aid with predation dissuasion. Further, the off-season surface spill study for Steelhead overshoots (and bull trout migration) has been reduced to studies only. This is an important mitigation action that needs to occur as soon as possible under any alternative and not wait for additional studies. Tributary habitat restoration is also at a slower implementation pace than the NAA, due to budget cuts. Additional mitigation measures should be included; see below for some recommendations.	See response to Comment 31775-54. The Preferred Alternative includes actions that benefit fish species and habitat through additional measures, ongoing programs, mitigation measures, and ESA consultation. As described in Section 7.6.1, a number of measures that are carried forward, modified, or added from the alternatives in Chapter 2 are intended to improve survival of anadromous salmon and steelhead, lamprey, and resident fish. Some examples are structural measures for lamprey passage, juvenile fish passage spill operations, and predator disruption operations. Section 7.6.4.1 provides summaries of the ongoing programs that would be carried forwarded in the Preferred Alternative. The majority of those ongoing programs are mitigation currently being implemented. Additional mitigation measures identified to offset effects from measures in Section 7.6.1 are presented in Section 7.6.4.2 that include mitigation measures for fish effects (Plant Cottonwood Trees (Up to 100 Acres) Near Bonners Ferry for resident fish and Temporary Extension of Performance Standards Spill Operation for adult salmonid passage delays). Section 7.6.4.3 describes the measures incorporated into the Preferred Alternative as a result of informal and formal ESA consultation. The Bull Trout Access to Perched Tributaries in the Kootenai River measure includes both completing an assessment and two projects for upstream passage. The Surface Spill to Reduce Take of Overshooting Adult Steelhead measure would provide an operational method to address the overshooting steelhead. Chapters 2, 5, and 7 discuss the co-lead agencies' ongoing mitigation programs, and the co-lead agencies are unaware of the concern from the commenter that tributary habitat restoration is occurring at a slower pace currently.
6894	29	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Predator management actions identified for the PA, while continuing, are actually at a lower level than the NAA due to budget cuts and lack of commitment by COE. Recent avian predation rates indicate that avian predation continues to be a major source of fish loss in both CRS reaches and the estuary. The extent of this fish loss is not adequately portrayed or accounted for in the EIS analysis.	The co-lead agencies disagree that the extent of avian predation on fish in the CRS is not adequately portrayed. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
6894	30	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Inland avian predation management measures are insufficient. The AAs execution of the IAPMP has failed to keep colony specific avian predation rates less than 2% per ESU or to maintain breeding colonies at less than 40 pairs of nesting terns (e.g. Blalock Island). However, the greatest deficiency of the IAPMP is not in the execution of the plan, but the biological scope of the plan. At the time the IAPMP was written and implemented, we knew very little about other avian predator species and their impacts on ESA salmon and steelhead. The Action Agencies have funded research and continues to fund research that has added to our understanding of the impacts of avian predation and must be reflected in the IAPMP. For example, recent research has estimated Upper Columbia steelhead mortality by all species of avian predators to be as high as 53%. Gulls in the plateau region (e.g. Miller Island) are now known to contribute, largely, to the high steelhead and sockeye mortality estimates. For Miller Rocks, the 2007 to 2019 average Gull predation on Snake River Sockeye has been 6.2%, Snake River Steelhead 7.2% and Upper Columbia Steelhead 8.2%. Hence, the IAPMP must be broadened to include all predatory avian species, not just Caspian terns. This predation is occurring in the affected area of the DEIS. The majority of this predation takes place in the tailrace of the dams and is directly related to presences and operation of the dams. [letter contains graph figure here]. 2020 marks the first year that the Bureau of Reclamation (BOR) has funded dissuasion efforts on Goose Island. In 2019, the Priest Rapids Coordinating Committee funded all of the dissuasion and vegetation effort. It is our understanding that BORs work represents a 50% reduction in effort from 2019. Were skeptical that BOR will produce the same results as the PRCC with only half the effort. Furthermore, the DEIS states, Reclamation will continue passive and active dissuasion efforts on Goose Island. There are dozens of islands in the Potholes reservoir area. All of the islands are in BORs jurisdictional authority and any of them could host the next colony of Caspian tern or another avian predator. BORs avian predation responsibility to all the areas in their jurisdiction, not only Goose Island, should be clearly stated in the DEIS. a. Caspian Tern (CATE) predation management at East Sand Island. The USFWS will not issue egg taken permits for non-managed satellite colonies on ESI. This means that if an egg is laid outside the managed colony, the nest becomes protected under the auspices of the migratory bird treaty act. Terns are colonial nesters and if one nest becomes protected, it will likely result in a new colony. At a minimum, egg take permits must be issued. Until 2019, the AAs, researchers and the adaptive management team targeted 3,125 nesting pairs on terns on the managed colony. That target was a widely accepted but never achieved. In 2019, USFWS began citing the upper number in the range as the target (4,375) without explaining its rationale. This was a departure from the widely accepted management goal of 3,125. The CATE Predation Plan has not met its biological goals for nesting numbers in most years nor has it met its original biological goals, as stated in previous BiOps, of reducing CATE predation on steelhead to less than 6%. The COE has not moved to further reduce habitat at ESI to achieve the nesting pair goal and has moved funding away from this program to Operation and Maintenance, which has a negative funding trajectory. This calls into question the certainty of the future support and funding of these management operations. b. Double-crested Cormorant predation management at East Sand Island. The DEIS predation section essentially restates the Corps responsibility to the DCCO ESI management plan. After modifying the terrain on ESI in a way that was consistent with the management plan, the COE stated that they have met the management objectives of this plan and are phasing this program out. However, the COE did not meet its biological goals of nesting pairs on ESI prior to making terrain modification. This has caused a majority of the colony to move further upstream and enhance and create new incipient colonies at such sites as Astoria- Megler Bridge, a location known as The Towers, various Navigation Markers, and the Longview Bridge. The COE can say they are closing out their management plan, but their actions to date have not meet the biological goals of reducing DCCO predation. Rather, they have moved the birds further upstream which will likely increase their predation impacts on listed salmon and steelhead stocks. Like the tern management plan, future funding for this program has been moved to the Corps of Engineers Operation and Maintenance budget which has a negative funding trajectory. This calls into question the certainty of the future support and funding of these management operations. [letter contains graph figure here]	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Columbia Plateau Response: The Inland Avian Predation Management Plan (IAPMP) has been focused on reducing predation by Caspian terns with initial efforts being implemented at Goose Island (Potholes Reservoir near Othello, WA) and Crescent Island (McNary Reservoir near Burbank, WA). The objectives of the IAPMP have been met at these two locations in recent years and as of 2019, there has been a 49% reduction in the total number of Caspian terns nesting on the Columbia plateau region since implementation of the IAPMP begun (Collis et al. 2020; http://www.birdresearchnw.org/2019%20GPUD%20Final%20Report.pdf). Adaptive management efforts to dissuade incipient colonies that have formed following implementation of the IAPMP have been implemented where the co-lead agencies have authority and management responsibilities which includes Potholes Reservoir including at the NW Rocks starting in 2014 and at small islands in the northern portions of Potholes Reservoir starting in 2015. The co-lead agencies continue to monitor and adaptively manage all of Potholes Reservoir to dissuade terns from nesting on co-lead agency managed lands in the area and this is anticipated to continue as described in the Draft EIS. However, the co-lead agencies recognize that some Caspian terns have moved to other locations and that some of these locations are managed by other entities outside of the co-lead agencies current management abilities. The co-lead agencies will continue to work closely with these other entities in the region who have authorities and obligations to mitigate the impacts from avian predators to benefit ESA-listed salmonids as well as implement a new reservoir management operation for the John Day reservoir to dissuade nesting Caspian tern as described in the Draft EIS. The IAPMP was developed with the best information available at the time and gulls were not identified as warranting directed management efforts at nesting colony locations by the co-lead agencies at agency-managed properties at that time. The co-lead agencies propose to continue, under the Preferred Alternative, predation reduction measures such as hazing at the agencies' CRS facilities as described in the Draft EIS to ensure the operation of the CRS does not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The co-lead agencies can only address certain types of predation by gulls, such as when they are foraging within the direct footprint of the co-lead agencies' CRS facilities where the agencies have management abilities. Other entities in the region have authorities and obligations to mitigate the impacts from avian predators as well and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Management of gulls at Miller Rocks just upstream of Miller Island is not feasible by the co-lead agencies as they do not own or manage this property and therefore do not have the authority or abilities to manage avian predation at this location. The Bureau of Reclamation has been engaged with and funding actions associated with management of piscivorous waterbirds on the Columbia River plateau including at Potholes Reservoir since 2010. Starting in 2014 when the implementation of the IAPMP begun, BOR began funding their respective commitments associated with implementation of the IAPMP in coordination with the other co-lead agencies. While the Priest Rapids Coordinating Committee has funded additional avian predation efforts in the region, and agreed to fund all 2019 activities at Potholes Reservoir, the Bureau of Reclamation intends to continue implementing and funding future actions necessary to implement the IAPMP where they are the responsible agency. CATE RESPONSE: The goal of the CATE management plan was to reduce habitat at East Sand Island to a minimum of 1.0 acre following the creation/enhancement of habitat at alternative sites outside of the Columbia River basin. Habitat creation/enhancement was completed and habitat at East Sand Island reduced to 1.0 acre preceding the 2015 breeding season. The number of breeding pairs nesting on East Sand Island was used as a proxy to assess predation rates, but the stated goal of the plan was defined as an acreage of habitat and not the number of pairs in the estuary. Depredation permits are issued to alleviate some form of damage, not to achieve population control. As a result, depredation permits are issued only if the requested lethal take of birds is consistent with the conservation of the species (e.g., the species remains at a healthy and sustainable level). (From USFWS DCCO FAQ website: https://www.fws.gov/pacific/migratorybirds/pdf/DCCOQ_A_USFWS03212016.pdf). The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. DCCO RESPONSE: The management goal of the DCCO plan was a reduction of the breeding colony at East Sand Island via lethal and non-lethal means to no more than 5,380 5,939 breeding pairs nesting. As described in the DCCO management plan, an average 3-year peak estimate of the breeding colony would be used to assess management objectives after implementation of Phase II activities (i.e. habitat modification). Actions would be considered successful when the average 3-year peak colony size estimate does not exceed 5,380 5,939 breeding pairs while no management activities are conducted. In coordination with USFWS, the Corps defines no management activities to mean non-lethal activities described in Chapter 5 of the FEIS. Specifically, Phase II activities are intended to consist of lower maintenance, non-lethal hazing and dissuasion actions that reduce the amount of human presence needs on East Sand Island to ensure colony size objectives are not exceeded.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Hazing and dissuasion activities would be implemented as needed, and would continually transition to methods that are most effective, least impactful to non-target species, and require the least management effort and cost. Pending evaluation of the peak colony size during the 2020 breeding season, if the average 3-year breeding colony is less than 5,939 breeding pairs, management objectives will be met and actions will transition long-term operation and maintenance of the colony. Similar to the CATE management plan, the co-lead agencies support efforts to offset adverse effects to listed species from CRS operations, through funding, direct implementation, and other means.
6894	31	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The extent of sea lion predation is unclear. While the California Sea Lion program has been successful (and presumedly continues), it is unclear if a Stellar Sea Lion program is included in the EIS.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure that operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped (California and Steller sea lion) and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Under the Preferred Alternative, actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with ESA as described in Section 7.6.4.1, Ongoing Programs, including ongoing measures to haze and monitor pinniped predators. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped (both California and Steller sea lions) and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
6894	32	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	A comprehensive Columbia River predator control program should be considered as a mitigation measure to address predation through the freshwater migration of juvenile salmon and steelhead. This should include at least the following: 1. Increased predation control both inland and in the estuary for avian, expand to include other species such as gulls; 2. Measures at dams, hatchery outfalls, hatchery release locations, and river mouths must have active hazing during periods of hatchery and volitional releases. These control actions must have some lethality incorporated to maximize effectiveness of reducing losses from avian predators. 3. Improved avian deterrence at projects (e.g. wires, enhanced hazing and lethal deterrence for all species), most notably in those areas immediately downstream of dam tailrace and forebays. 4. Sea Lion Predation control to include Stellar as well as California Sea Lions. 5. Maintain options to manage river levels during the spawning periods for walleye and smallmouth bass to limit recruitment of these invasive non-native fish.	The Endangered Salmon Predation Prevention Act authorizes NOAA to issue permits to states and Tribes to kill sea lions in the lower Columbia River and some tributaries in order to protect certain fish from sea lion predation. The co-lead agencies do not have authorities to administer the Act. However, the co-lead agencies have supported actions to mitigate adverse effects to listed species from CRSO operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue as described in Chapter 7.
6894	33	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Lamprey measures in the Preferred Alternative are incomplete and funding unclear. The lamprey measures listed in the have been identified since 2016. They have not been implemented due to lack of funding commitment by the co-lead agencies. The lamprey measures disclosed in the DEIS represent only a portion of the list of needed lamprey actions even as identified in the Corps Lamprey Priority Matrix, which is itself just a start, and does not cover all lamprey needs. Recent funding commitments only provide funding through about 2022, and it unclear how that funding relates to this EIS and implementation of the lamprey measures identified for the DEIS. Future lamprey actions through the 25-year term of CRS EIS have not been identified, nor has their funding. With the reduction/phase out of the CRFM budget (also discussed above), funding for additional and future lamprey measures is uncertain. Including all actions in the matrix would demonstrate the importance of the actions, provide NEPA coverage, and assist with future funding requests.	See response to Comment 3894-13. Measures identified in the Draft EIS do not include all lamprey passage improvements that could be potentially implemented at the Lower Columbia and Lower Snake River dams, but the Corps believes that potential actions contemplated in preliminary lamprey program planning discussions with the Columbia River Inter-Tribal Fish Commission (CRITFC) staff and others related to the 2018 extension of the Accords are consistent with the measures and analyses included in the Draft EIS. CRITFC is correct that actions beyond the scope of the measures included in the Draft EIS or ongoing activities would potentially require further NEPA analysis.
6894	34	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Preferred Alternative should include additional measures. The following list includes potential mitigation actions that could be implemented to mitigate for fish impacts. These actions were identified and suggested during the development of the mitigation toolbox but are not currently identified in the Draft EIS as potential mitigation. As a Cooperating Agency, we were never told the disposition of our recommendation to add these items to the toolbox. With the uncertainty of the action moving forward, and the reliance on an adaptive management framework as identified in the Adaptive Management Appendix, it is important that these actions be included somewhere in the EIS analysis to provide the NEPA coverage for quick implementation and to assist with identifying funding. As noted above, at least some of these should be add as mitigation to the PA as currently drafted. 1. Predation actions noted above; 2. Adult ladder temperature cooling pumps for McNary and John Day; 3. Vertical slot weir gates for adult steelhead fallback post spill make operation more cost effective; 4. Evaluate options to increase the number of RSW/TSW at dams to create the best possible surface passage attraction flow and increase the number of surface passage routes. (This alternative would require modifications of existing spill patterns and would need to be modeled); 5. Evaluate potential options to increase Kelt collection at projects in both Snake and lower Columbia; 6. Replace/place Cells at Little Goose Dam North Shore adult entrance; 7. Replace trunnion pin and wire ropes at The Dalles spillway; 8. Install additional Spillway Pit Detection (Ice Harbor, work collaboratively with Mid-Col to get detection there, possibly Wannapum, and location in lower Columbia); 9. Increase Pit Barges and other detection arrays below and at Bonneville Dam; 10. Implement shad reduction measures; 11. Look at ways to fund/implement 10-year Lamprey Plan (Strong need to get juvenile active tag study going); 12. During times when no adult ladders in operation, (ie LWG and LGS) run the RSW to assist overshot steelhead; 13. Work to increase funding through CRFM and O&M to ensure actions and maintenance will be completed; and 14. Continue to address measures under consideration in SCT analyses. 15. Monitoring of adult migration may assist in the development of actions to increase survival or reduce overshoot.	Appendix R, Part 3 presents the mitigation toolbox including rationale for not carrying forward mitigation measures. Potential actions as listed in this comment, especially the structural actions, may require further refinement for site-specific analysis including NEPA and other applicable laws. The commenter's proposed mitigation measures do not appear to offset impacts associated with implementing the Multiple Objective alternatives (MOs), including the Preferred Alternative. These mitigation measures were proposed in the workshop process and not selected as they did not offset identified effects of the MOs, and were not carried forward into the Preferred Alternative.
6894	35	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Adaptive Management Appendix Does not Adequately Address Future Fish Survival The following aspects of the Adaptive management Appendix need to be corrected. 1. Flex Spill is only for one year, and the Flex Spill Workgroup is problematic. The Adaptive Management Appendix essentially reduces the proposed actions flex spill to a single year, with uncertainty of operation for the rest of the term of the EIS. The Flex Spill operation should be a defined 15-year commitment. The adaptive management process should require consensus from all parties to deviate from that fixed operation. It is unclear how the Flex Spill Workgroup will be organized and what the decision-making process will be. As written, the Workgroup would consult and inform regional interest, but leaves the decisions to the action agencies with uncertain limitations. The process also has the potential to undermine the TMT and FPAC groups. Based on experience there is not enough assurance that non-Federal parties input will be given due consideration. The Flex Spill Workgroup needs set sideboards and a clearly defined decision-making framework. 2. The Fourth Pillar to test latent mortality opens wide uncertainty. Appendix X unilaterally adds a Fourth Pillar to the Flex Spill Agreement pillars to require testing for latent mortality. Previous discussions have looked at a block study as this test. A block study would decrease the PAs spill operation and cause unanalyzed fish effects. Other potential tests could do the same. Any latent mortality test should have regional consensus and mitigation for any possible fish effects. 3. There is uncertainty regarding any future Spill Surcharge. Our current understanding is that future spill surcharges will be taken completely out of the BPA fish and wildlife budget, and not shared by all parties. BPA needs to model uncertainty and adaptive management to include all costs in rates cases and prevent future spill surcharges.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. The co-lead agencies do not feel that the short-term nature of this operation is an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies will provide additional clarifying text in Appendix R to make these points more clearly. Regarding the spill surcharge, it was removed from power rates in BP-20. See BP-20-E-Bonneville-19 Power and Transmission Rate Policy Testimony. Fredrickson et. al, page 15-17. The spill surcharge was included in BP-18 rates due to the significant cost recovery risk the court-ordered spill injunction created with little ability for Bonneville to model the impact without speculation. In BP-20, the circumstances surrounding the spill assumptions changed and allowed Bonneville to model planned spill in its rates, removing the need for the Spill Surcharge for cost recovery in the same way it did for BP-18 power rates. Regardless, the outcomes of the funding decisions for the Bonneville F&W program are not being made as part of the CRSO Draft EIS. Future spending level decisions and rate provisions would be made in consultation with the region through Bonneville's processes and other appropriate forums.
6894	36	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The Affected Environment Sections and Analyses are Inadequate The discussions in the Affected Environment sections and the analyses of effects do not meaningfully depict the nature and extent of the impacts that the Basins hydro system has had on the Columbia Basins anadromous fish. Meaningfully depicting these impacts cannot be avoided. Under NEPA, regardless of the selection of the baseline, all cumulative effects must be revealed. At a minimum, the DEIS should be revised to incorporate and analyze the nature and extent of the impacts described in the Tribal Perspectives document that was submitted to the colead agencies at their request.	Consistent with the Council on Environmental Quality's June 24, 2005 guidance and interpretation of CEQ Regulations for Implementing the Procedural Provisions of NEPA, 40 C.F.R parts 1500-1508, "Agencies are not required to list or analyze the effects of individual past actions unless such information is necessary to describe the cumulative effect of all past actions combined... Generally agencies can conduct an adequate cumulative effects analysis by focusing on the current aggregate effects of past actions without delving into the historical details of individual past actions." However, the analysis of current conditions includes the ongoing effects of the existence of the system, inclusive of a host of other factors influencing natural and cultural resources of concern to potentially affected tribes. System operations are the focus of the EIS, not the existence of the system (and to the extent the analysis considers the existence of the system, i.e. breach, the effects analysis captures the cumulative effect of project existence). Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Chapter 7 provides the effects analysis on Cultural Resources and Indian Trust Assets, Tribal Perspectives, and Tribal Interests, in Sections 7.7.18 and 7.7.19 in the Draft EIS, respectively.
6894	37	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Tribal Cultural Resources are not Adequately Addressed The CTUIR continues to have fundamental disagreements with the action agencies regarding the scope of the analysis of the CRSO DEIS for impacts to cultural resources. By selecting an arbitrary distance of one mile from the reservoirs, the agencies are taking an impermissibly narrow view of the human environment under NEPA, and failing to interpret it comprehensively to include the natural and physical environment and the relationship of people with that environment. 40 CFR 1508.14. As noted, this is a fundamental flaw in the analysis, a concern the CTUIR raised in our scoping comments of February 7, 2017 and our comments to the draft Cultural Resources Chapter in the email of Catherine Dickson on March 27, 2019. In conference calls and comments the CTUIR raised this concern again and again and yet the agencies retained the one-mile limitation on the analysis and even refused to acknowledge in the DEIS that there was a disagreement on this issue among the cooperating agencies. To quote the National Preservation Institute: NEPA's concern is with the "human environment," defined as including the natural and physical (e.g., built) environment and the relationships of people to that environment. A thorough environmental analysis under NEPA should systematically address the "human" social and cultural aspects of the environment as well as those that are more "natural," and should address the relationships between natural and cultural. Culturally valued aspects of the environment generally include historic properties, other culturally valued	Regarding the definition of cultural resources, the co-lead agencies used a property-based definition of cultural resources based on Federal laws, regulations and policies. This includes the definition of historic property provided in the National Historic Preservation Act, the definition of archaeological resources provided in the Archaeological Resources Protection Act, the guidance provided by the National Park Service regarding traditional cultural properties, and the definition of sacred sites provided in Executive Order 13007. The co-lead agencies acknowledge the holistic perspective of Tribes when it comes to management of resources. Tribal interests and perspectives were addressed throughout the Draft EIS by inclusion of statements from the Tribes, consideration in applicable resource sections of tribal views, and in Section 3.17, Tribal Perspectives. The co-lead agencies selected the size of the study area based on the area where the effects from the proposed structural and operational measures are expected to occur. This study area is sufficient for the agencies to understand the effects of the different alternatives and to enable the agencies to make an informed evaluation of the alternatives. The co-lead agencies focused on the locations where there were understandable direct and indirect effects, as opposed to third and fourth order effects, which are harder to predict, require speculation, and thus difficult to evaluate, as a part of the NEPA process. Finally, the co-lead agencies analyzed the entire range of property-based cultural resources in the EIS, which included the built environment and traditional cultural properties, as well as archaeological resources. The analysis was based on over 20 years of data accumulated as a part of the Federal Columbia River Power System (FCRPS) Cultural Resource Program, which engages closely with Tribes on traditional cultural properties. Please see Section 3.16 (Table 3-289, in the Draft EIS), which documents the inclusion of over 1,300 traditional cultural properties in the analysis and Section 7.7.18 for the effects of the Preferred Alternative on cultural resources.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				pieces of real property, cultural use of the biophysical environment, and such "intangible" sociocultural attributes as social cohesion, social institutions, lifeways, religious practices, and other cultural institutions. These impacts are usually analyzed either as impacts on "cultural resources," or as "social impacts," or as both but many such impacts actually fall into the cracks between the "cultural resource" and "social impact" categories as usually defined.8 As noted in our comments, the easiest way to address cultural resource impacts is to use the whole basin as the study area. If the agencies will not do that, the agencies will need a carefully crafted argument as to why the study area selected meets each of the project purposes/changes proposed in the alternatives. The study area for irrigation and environmental justice are both much larger than the cultural resources study area, accounting for job losses for irrigation changes and impacts to communities distant from the projects themselves. Because changes to river operations affect cultural resources (farming practices impact native plants and animals for example), the study area should be broad as well. Similarly, the EIS suffers from insufficient analysis when certain study areas are broad if that furthers certain goals (such as keeping the dams because of importance to local farmers/shippers), but other study areas are small when it seems a larger area might highlight other goals. Fish are a cultural resource (in and of themselves, under NEPA, as opposed to fishing sites which are considered under the NHPA) and from Judge Simon's perspective, the primary point of this NEPA study is to determine impacts to the fish populations. Those fish migrate well beyond one mile from the edge of the reservoirs. The study area for aquatic habitat is virtually the whole basin. Figure 3-109, page 3-287, lines 6767-6768. The narrow scope of the CRSO DEIS study area is further impaired by a focus on archaeological resources while ignoring cultural resources (in the NEPA sense rather than archaeological resources under ARPA and the NHPA). From our participation as a cooperating agency in the teams reviewing drafts of the documents, it appears that the agencies were thinking only about archaeological sites (cultural resources team), TCPs (cultural resources team), Sacred Sites (likely cultural resources team, but possibly tribal liaison team), and Trust Assets (tribal liaison team). The other types of cultural resources we brought up in our scoping comments, such as cultural values (identity, traditional practices, first foods), social resources (community), and economic activity of tribal importance (by resource or geographic area) appear to have been relegated to the socioeconomics team. Yet from our position on the socioeconomics team, we know that they exclusively focused on economic impacts, did not do work specific to tribes, and failed to consider social impacts at all. We feared that separating cultural resources into three different teams increased the likelihood that some concerns would be lost altogether, and further that all cultural resources would not get the thorough consideration they need and deserve. This is exactly what happened. The CTUIR believes this is in part because the Action Agencies cultural resources team consisted exclusively of archaeologists; the agencies representatives should have had the benefit of additional expertise in other types of cultural resources.	
6894	38	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The analysis in the DEIS of sacred sites focuses exclusively on Executive Order 13007 and does not address the obligation to examine these sites under NEPA or other laws as cultural resources. Significantly, the DEIS does not address sacred sites under the NHPA as historic properties of importance to tribes. By focusing narrowly on the authority of EO 13007, the agencies precluded open and honest discussions about sacred sites with tribes because information sent to agencies under EO 13007 does not have specific statutory protections from release under the Freedom of Information Act as does information sent under the NHPA or ARPA. The CTUIR specifically raised this concern about confidentiality of sacred site info in a December 6, 2018 call with the agencies. The CRSO addressed the concern by stating [w]here appropriate, agencies will maintain the confidentiality of sacred sites. CRSO DEIS page 3-1355, lines 6098-6099. Tribes will not share sensitive sacred sites information if the agency will only commit to protect the confidentiality of that information as appropriate. Additionally, when the CTUIR identified the Columbia River as a sacred site, the agencies made no response. We learned in the DEIS [t]he co-lead agencies believe this does not meet the definition in the Executive Order as it is not discrete or narrowly delineated. CRSO DEIS page 3-1355, lines 6116-6117. No discussion with the CTUIR on this subject was held. The CTUIR believes the site we identified meets the definition in the Executive Order. The agencies position also ignores the potential for analysis of this designation under either the NHPA or ARPA, both of which authorize the designation of lands of significance to the tribe. The CTUIR incorporates by reference all comments we have previously provided to the agencies.	The co-lead agencies requested information from Tribes to identify sacred sites consistent with Executive Order (EO) 13007. While data collected to identify historic properties under the National Historic Preservation Act (NHPA) may be similar in nature to the data or information related to sacred sites, Federal agencies cannot make the assumption that this information can be used interchangeably without specific information provided by Tribes. The traditional cultural property (TCP) information and data used to conduct the impact analysis described in the cultural resources Section 3.16.2.6 was largely derived from co-lead agencies efforts to comply with Section 106 of the NHPA through the ongoing efforts of the Federal Columbia River Power System (FCRPS) Cultural Resources Program. This information was gathered by the co-lead agencies in part to identify historic properties of importance to Tribes. Because of the requirements of EO 13007 the co-lead agencies could not make the assumption that any of the TCPs used in the Draft EIS analysis were also sacred sites and instead relied on information requested from the Tribes regarding sacred sites during the CRSO EIS process. The co-lead agencies determined that all Federal land within 1 mile of the lower Snake River and lower Columbia River Projects is neither discrete nor narrowly delineated, as required to meet the definition of sacred sites in EO 13007.
6894	39	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS Fails to Analyze Harvest Opportunities for Treaty and Non-Indian Fisheries The DEIS repeatedly states that [d]ue to the complexity of fishery management, it is not possible to predict changes in fishery management that may result from changes in fish abundance. This statement is inconsistent with the reality of fishery management. Coastwide, harvest managers in the United States and Canada regulate salmon fisheries based on abundance predictions. West coast ocean fisheries are for the most part managed based on one of two approaches, either aggregate abundance-based management or Individual stock-based management. Both approaches manage harvest based on anticipated salmon abundance.9 In the Columbia Basin, harvest is managed in accordance with the US v. OR 2018-2027 Management Agreement that sets forth harvest schedules from which changes in fisheries harvest regulations are regularly predicted and adopted.10 These harvest schedules have been analyzed for the effects on abundance, productivity, spatial structure and diversity of affected salmon and steelhead populations.11 The lack of harvest opportunity analysis runs counter to the Tribal Perspectives of the Columbia River Treaty Tribes. The lack of harvest opportunity analysis also runs counter to the goals for non-Indian fisheries and the corresponding economic effects of these fisheries. No rational explanation is given for the failure of the DEIA to analyze impacts to harvest opportunity.	The EIS recognizes the value of commercial as well as tribal and recreational fishing to the region. Section 3.15 describes the values associated with fisheries in the Pacific Northwest. Section 3.11 characterizes recreational fishing activities in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively.
6894	40	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS Analysis of Hatchery Impacts is Incomplete The DEIS asserts without basis or support that the Lower Snake River Compensation Plan hatchery production will terminate is Snake River Dams are breached. The DEIS discloses no legal or factual analyses to support this position. The effects of the Snake River dams will persist in future populations of Snake River lamprey, sturgeon, salmon and steelhead. Tribal analyses indicated that hatchery production must continue until the impact of the dams has been mitigated, well beyond the 25-year scope of this EIS. The DEIS failure to disclose the facts regarding hatchery mitigation generally and the LSRCP specifically leaves the tribes with no reasonable analysis or factual basis to consider the veracity of the DEIS statements. With respect to the other hatchery production occurring in the Columbia River Basin, including the mitigation and supplementation programs, the DEIS should provide for fully funding hatcheries, current operations as well as deferred maintenance and repairs, to meet their hydro system mitigation goals according to the recent U.S. v. Oregon hatchery assessment. Hatchery facilities authorized to mitigate for the hydro system are rapidly aging, with inadequate funding identified for capital upgrades, repairs, and maintenance. Estimated costs for deferred maintenance of the Lower Snake River Compensation plan facilities alone is over $100,000,000. 1. Non-operational conservation measures for ESA-listed salmon and steelhead. This section highlights a small sub-set of Action Agency (AA) funded hatchery programs in the Columbia Basin, of which there are more than 170, and includes comments on the Biological Analysis released with the DIES. By not accounting for all of the hatchery programs in the Basin, the future of the hatchery programs that have not been identified herein is opaque and should be elucidated. The AAs fund hatchery programs that have the primary purpose to mitigate for impacts to fish from construction/operation of hydropower dams. Above Bonneville Dam, the AAs fund annual target releases of ~66 million salmon and steelhead. Regardless of how individual hatchery programs are managed (i.e., for harvest, supplementation, and/or reintroduction), every single program funded by the Action Agencies serves the purpose of mitigation including the programs identified in table 2-18 of the Biological Analysis (which only add up to a target release of 3.35 million). See Attachment D for an overview of Columbia River Basin Hatchery Programs. The six programs identified in table 2-18 represent only ~5% of the hatchery production funded by the Action Agencies (above Bonneville Dam). The AA-funded hatchery programs include both ESA-listed and non-listed salmon and steelhead. Of only ESA-listed production that the AAs fund (~17 million annually), table 2-18 represents only 20% of those programs that are managed to supplement natural populations and use local broodstock (do these not count as conservation and safety net hatchery actions?). If the purpose of this section and table 2-18 is to identify only the ESA-listed programs that are managed as supplementation programs (i.e., conservation/safety net), then the table does not come close to capturing the number of existing programs that should be listed.	The CRSO EIS acknowledges that with breaching of the Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, other mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer be possible. The rationale for this, as stated in the Draft EIS, is that Bonneville's funding is directly tied to the operation of the LSR dams. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. A summary of this qualitative discussion is provided for the reader for each Snake River species. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. The scope of this Draft EIS is the operation and configuration of CRS projects; a complete analysis of all hatchery programs and the status of maintenance/operations of each one is beyond this scope.
6894	41	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The following errors, omissions and inadequacies relate to modeling and underlying analysis of biological effects and apply to all MOs and the Preferred Action. The current status of the fish is not adequately considered. For example, the upper Columbia stocks triggered the AMIP. Ironically, upper Columbia spring Chinook are used as a surrogate for upper Columbia sockeye for system survival; yet, the same data is not provided for upper Columbia spring Chinook. Only McNary to Bonneville survival is presented for chinook. The data also ignores similar CSS results from previous studies. All models used in the DEIS are required to have a third-party review. We understand that this is ongoing as of the time of DEIS release, but the public will not be given a chance to see the third-party review for consideration in our comments. A. Issues With the CSS and Compass Modeling Discussion and Results 1. The DEIS fails to adequately explain the differences between COMPASS and the CSS data and complexity. Broadly, COMPASS makes a large number of predictions that are not directly observed, and breaks survival into multiple individual route of passage survivals for each reach (spill, bypass, turbine, and other configuration routes for each dam), whereas the CSS models treat the entire hydrosystem as an aggregate of 2 routes of passage (number of powerhouses passed vs spilled on average). The CSS models are thus "cumulative effects" sensitive, whereas COMPASS looks for effects that may not be noticeable incrementally unless they are added up to full "accumulation". 2. When comparing the predictions of the CSS models and the COMPASS	Rock Island to Bonneville survival rates are reported in Appendix E for COMPASS model results from the Upper Columbia Chinook ESU. Take note, that when comparing levels of change in major metrics between the MOs vs. the No Action Alternative, adding the Rock Island-to-McNary segment doesn't seem to significantly change the level of effect that one would interpret from changes in operations. This is a fair description of distinctions between the two modeling approaches, except instead of calling this 'error,' we consider this to simply be distinctions due to differences in model construction. All models must make assumptions which led us to use both modeling approaches . The NMFS COMPASS/LCM models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival, and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of hydrosystem operation with respect to flow and spill. The Fish Technical Teams for the EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. CRS survival rates are not necessarily that different between the models, and any difference could potentially be explained by a different composition of hatchery and wild fish entering into the PIT data used to calibrate each model. In annual observations, Chinook and steelhead tagged in the CSS study do show higher survival rates than smolts tagged at Lower Granite Dam by the NOAA juvenile survival study. The differences in SAR are due to the different assumptions of carryover effects or delayed mortality of the model systems. There is not necessarily a problem with the CSS models having more variability in hydrosystem survival. COMPASS was calibrated with PIT survival and travel time data and properly captures the observed variability.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				model, the EIS draws attention to the fact that CSS models and COMPASS predict similar hydrosystem survivals, but do not predict similar SARs. This is misleading for two reasons. First there are two CSS models, which are different in nature, yet those two predict similar hydrosystem survivals and SARs. Secondly, both CSS models predict more variability in hydrosystem survival than the COMPASS model. (see Sec. 3.5) 3. The DEIS states in "Critical data" (Sec. 3.5) that anomalous years are driving the trend, yet it contradicts the point. The DEIS states effectively that ocean survival was high when the ocean was cold and fewer fish went through powerhouses in 1999 and 2000, and subsequently low when the ocean was cold and more fish went through the powerhouses in 2001, which corroborates that powerhouses have a negative impact on survival, yet the DEIS takes issue with including data that have a strong influence on the result because the COMPASS model is not responsive to that contrast. The DEIS should perhaps instead draw attention to the fact that COMPASS is failing to detect a signal in the data. 4. The DEIS subjectively states that excluding thermal exposure in the CSS models "likely overestimates" powerhouse effects. This ignores the positive relationship between the implementation of the hydrosystem and temperatures. 5. The DEIS fails to mention that the two CSS models make statistical estimations of the effect of the freshwater hydrosystem on latent ocean mortality. 6. In the COMPASS (NOAA) model, NOAA used data from one Upper Columbia River (UCR) Spring Chinook population, as a surrogate to model UCR sockeye. However, they did not then use these data to model the actual, larger UCR Spring Chinook population. This begs the question: If this one population is not adequate to represent the entire UCR Spring Chinook how can it be used as a surrogate for UCR Sockeye. The selection of data seems seems arbitrary, and no explanation for the discrepancy is provided in the DEIS. 7. Water Temperature in COMPASS. The DEIS notes that the water temperature models that use flow relationships in COMPASS were not used for the CRSO scenario runsinstead water temperature predicted by the Corps was used in COMPASS. No rationale was given for this change or any analyses or validation as to whether not this change to the COMPASS model runs decreased or reduced the efficacy or reliability of the COMPASS evaluations. B. Latent Mortality in CSS and COMPASS 1. The COMPASS life cycle model was expanded/revised to include latent mortality effects in the 2018 CRSO Biological Opinion and in this DEIS. This revision has not undergone extensive peer review and was the subject of debate within the CRSO anadromous technical team. The COMPASS modeling results include four arbitrary levels of assumed latent morality reductions (0, 10, 25, and 50%). The exploration of potential latent mortality impacts, in the COMPASS modeling, is positive; however, the COMPASS modeling does not link these latent mortality effects to specific CRS operations or fish powerhouse passage experience and is aspect open for criticism. There is ample research that fish that pass powerhouse experience some level of latent mortality. 2. The Executive Summary describes delayed or latent mortality as a key factor in explaining different predictions between the models. While this is accurate, the write-up fails to acknowledge the COMPASS model runs included variable latent mortality reduction levels of 10%, 25% and 50% which result in increased adult abundance, if true. 3. Furthermore, the models were informed by common hydrological datasets provided by the Action Agencies. These datasets were not open to cooperating agency review and appear to have received insufficient validation. For example, the MO1, MO3 and MO4 dataset fails to apply the 150kcfs spill cap constraint associated with stilling basin structural integrity (ie. rock entrainment and erosion). This inaccuracy in datasets will result in overestimates of SARS and underestimates of power generation. C. Other Problems with the Modeling 1. COMPASS SAR results need further explanation for MO3 and MO4 alternatives. COMPASS SARs are similar for MO3-4 compared to MO1-2 because fish migrate inriver at a more natural rate of migration. The method COMPASS used for calculating SARs is heavily reliant on date of ocean entry. Therefore, in-river fish in MO3-4 enter the ocean a few days later than transported fish in MO1-2, so they are assumed to have is not obvious that transported fish would survive better in the ocean than in-river fish migrating at a more natural rate, based entirely on entry date into the ocean. 2. There is CSS data available that was not incorporated in this report. Even though it was not generated specifically for this EIS, it represents the NAA and should be used as a reference. For example, CSS has calculated system survival for Upper Columbia stocks and could be used qualitatively to demonstrate potential impacts under each of the MOs. 3. The Action Agencies do not consistently include confidence intervals throughout the DEIS and appendices. Confidence intervals (standard deviation) are provided in Appendix E but not in Chapter 3, the Preferred Alternative, or the BA. This omission means that it is impossible to evaluate the statistical significance of the data and, by extension, and the benefit asserted by the Lead Agencies. 4. The DEIS states (Appx E Sec. 1.4.2) that summary statistics for SARs and return abundances for the CRSO were calculated differently that under the CSS modelers (McCann et al. 2017). For the CRSO, the action agencies picked somehow (not stated how) random averages over the 80 year historical flow period for the two metrics, while the CSS modelers used the average of the last 10 flow years in the historical period. The CRSO authors do not provide a rationale for this change, however, given the overall reduction in flows over the last 10 years, the CRSO appears to bias for higher flows and thus higher survival rates. In any case, the CSS flow choice methodology should have remained for CRSO analyses for consistency.	An 80-year historical water record with flows and water quality variables was generated with the HYDSIM and ResSim models for use in the CRSO EIS. The models were able to simulate the effects of hypothetical operations included as measures in the MOs, such as monthly irrigation diversions, reservoir elevation changes, spill and so forth. Climate change was also included as an additional trend. The co-lead agencies used temperature data sets that were developed by the water quality team as part of the CRSO EIS development. Sensor fish successfully identified and played in a significant role in solving spillway passage injuries at both The Dallas and Ice Harbor. Although certainly not an analogy for a fish, their motions are controlled by the hydraulics of the water and structure the impact and do provide a measure of the physical environment fish are passing through. Less violent sheer and turbulence is obviously a benefit for fish. Balloon tags, do best represent the potential for trauma to passing fish and not total mortality. Certainly, fewer traumatic injuries would lead to a lower mortality rate. The magnitude of the survival rate increase for naturally passing fish is unknown. The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Relying on the best available science, the co-lead agencies assumed mortality would be halved. Turbine intake screens would not be removed, unless a telemetry based survival study demonstrates survival would not be decreased. The most recent 10 years in the 80-year water record have a below average number of 'dry years' falling in the lowest 20th percentile of snowpacks or water supply. It might be a mistake to interpret the most recent years as being representative of a progressive linear trend of climate change. There may have been periods of acceleration of the rate of change during the past 80 years, as well as periods of drought or high rainfall that were caused by shorter term decadal cycles. For the EIS, the technical teams chose to represent the best available information about future climate impacts in Chapter 4.
6894	42	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Modeling of High Capacity Turbines High Capacity turbines are included as a measure in several of the DEIS alternatives. However, the data sets provided by BPA did not include increases in flow through the powerhouses due to the installation of high capacity turbines. The assumptions of increased survival through new turbines at John Day dam, McNary and Ice Harbor (fish friendly turbines) are not supported by any available studies. Survival estimates are, at best, equal to those of older turbine units (Skalski and Townsend 2005, Deng et al. 2019, Heisey et al. 2019). However, the higher flow through these turbines will cause higher absolute turbine passage, leading to lower overall dam survival and larger impacts of latent mortality. In Turbine Improvement Assumptions Final, the document used to justify increased survivals in the DEIS modelling based on bead strike studies, the underlying assumption is that 50% of fish would experience mortality due to both low pressures and strike/shear. While this number is useful for design it is not based on any biological study, data, or other form of evidence and should not be used in any survival estimates. The same document assumes equal improvements in direct and indirect turbine mortality. There is also no evidence provided for this assumption and it seems to be an example of optimistic estimate not based in reality. Further, the interpretation of bead strike studies has resulted in an assumption of a 50% decrease in turbine mortality. This assumption has not been backed up by increased survival in studies with live fish at Wanapum or Ice Harbor Dams, both of which showed no detectable increase in survival. Additionally, any increase in turbine capacity will increase the total number of smolts passing via the powerhouse. This will have impacts not only on concrete survival, but cumulative negative impacts throughout the hydrosystem. The PA assumes reduced turbine mortality with the installation of new turbines. The DEIS stated that these new turbines will improve fish passage conditions, lower TDG, and improve turbine efficiency and capacity. Turbine passage can directly cause fish mortality through blade strikes, rapid pressure changes, and other physical stresses. Turbine and powerhouse passage is also associated with delayed mortality, manifesting in the estuary or first year of ocean life. While direct mortality due to turbine passage has been studied primarily with models, sensor fish, and bead strike studies, tests with live smolts are relatively uncommon. Indirect and delayed mortality have been associated with powerhouse and turbine passage in a wide range of work demonstrating reduced estuary and first-year ocean survival for individuals who passed via one or more powerhouses during their outmigration (Haeseker et al. 2012, Petrosky and Schaller 2010, Tuomikoski et al. 2010, FPC 2010, FPC 2011a, FPC 2011b). There are few studies available to test the assumptions of increased turbine survival. In 2005, a comparison of turbine survival was done at Wanapum Dam, comparing one high-capacity turbine to single turbine of the old design (Skalski and Townsend 2005). In this study, balloon and radio-tagged smolts were released into the turbines under a range of conditions, making it difficult to interpret the results of the tests. Both balloon and radio tags have a number of methodological problems, including: a) requiring a minimum size that does not represent the runat- large, b) releasing fish via tubes into turbines that cause large pressure differences that do not approximate actual passage conditions, and c) tag burdens that significantly impede swimming ability and, therefore, affect the probability of blade strikes and other injuries. For extensive comments on the difficulties of interpreting the results of balloon tag studies, see FPC (2004), FPC (2012), JTS (2004), and JTS (2005). Additionally, a complicated study design makes determining a biologically significant difference between turbines virtually impossible to detect. A significant three-way interaction effect between turbine type, flow, and entry depth means that any difference in survival between the turbines cannot be separated from the other factors in the study. Although the study results have been described as showing equal survival between the turbines, the study design makes it impossible to determine if this result is a product of study design or if direct mortality is equal between the two turbine designs. In 2019, sensor and balloon fish were deployed through the new turbine in Unit 2 of Ice Harbor Dam. The reports from these studies have not yet been made available, so a full review of their ability to address assumptions and interpretation of the results is not possible. However, the presentations at AFEP 2019 showed that severe shear or strike events were reduced only in two of four tested flows, and a reduction of 50% was only observed under one tested flow (Deng et al. 2019). Survivals of balloon-tagged fish were not significantly different under any of the tested conditions (Heisey et al. 2019). These studies indicate the increases in survival developed from bead strike studies and physical modelling efforts are overstated. Modifications to the hydrosystem must be thought of in the context of the entire salmonid lifecycle, not just the concrete survival at each project. Even if the direct mortality of highcapacity turbines is shown to be no higher than that of the existing turbines, the increased turbine flow will lead to increase powerhouse passage of the run-at-large. This effect, compounded over multiple dams, will have a net negative impact on the smolt-to-adult returns. If the increased powerhouse flows are not included in the modeled datasets provided to the fish modelers, the increase in powerhouse passage will be lost.	The measures for Ice Harbor and McNary IFP turbines were included in the No Action Alternative based on the progress made in design, environmental compliance, and implementation. These measures were carried forward in the Preferred Alternative along with the John Day IFP turbine measure. Sensor fish have successfully identified and played a significant role in solving spillway passage injuries at both The Dalles and Ice Harbor. Although certainly not a perfect analogue for a fish, their motions are controlled by the hydraulics of the water and structure impact and do provide a measure of the physical environment fish are passing through. Less violent sheer and turbulence is obviously a benefit for fish. Balloon tags do best represent the potential for trauma to passing fish and not total mortality. Certainly, fewer traumatic injuries would lead to a lower mortality rate. The magnitude of the survival rate increase for naturally passing fish is unknown. Relying on the best available science, the co-lead agencies assumed mortality would be halved. The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Again, the magnitude is uncertain. Turbine intake screens would not be removed, unless a telemetry based survival study demonstrates survival would not be decreased. The opinion that more fish would pass the turbine because of the increase hydraulic capacity is not accurate. The amount of water passing through the powerhouse is actually controlled by operation decisions on spill levels, and is not solely dependent on the hydraulic capacity of the turbines. It should be noted that only turbines at McNary would have increased hydraulic capacity.

6894	43	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Water Temperature Effects Analysis High summer water temperatures in the Columbia River System are known to have detrimental outcomes on fish survival and recovery. These losses will only be intensified by a warming climate. It is essential to project how each EIS alternative will impact water temperature and thus fish survival in the Columbia system. Numerical modeling was used by the Action Agencies to simulate the impacts of each EIS alternatives on water temperature and quality. The DEIS Executive Summary summarizes findings from the modeling efforts and recognizes that MO3 would have major benefits for anadromous fish survival: Model estimates for MO3 showed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the alternatives.12 In addition, DEIS Chapter 3 on Affected Environment and Environmental Consequences details results of the extensive modeling effort and analyses done to evaluate MO3 and reports significant improvements in water quality: Water temperature differences (up to 8.8 degrees Fahrenheit) between impounded (No Action Alternative) and non-impounded (MO3) river conditions would be greatest in the fall.Over the long term, MO3 would have moderate to major beneficial effects on water quality in Region C through the restoration of natural, river, and water quality processes; a substantial cooling effect in the fall; greater nighttime cooling and respite from warm water temperature conditions in the summer; and a reduction in overall system TDG.13 Yet despite the predictions of significant benefits to fish SARs and water quality, MO3 actions were not identified in the Preferred Alternative. DEIS Chapter 3 presents the framework that was used to define the overall level of impact of water temperature outcomes for each CRSO EIS alternative. For water temperatures, the level of impact (negligible, minor, moderate, or major) was defined based on the absolute change in the maximum and minimum water temperatures as averaged over the 5-year simulation period (2011-2015)14. Taking a 5-year averaged approach to determine a single impact of each alternative fails the public by obscuring predictions of the numerical modeling effort which predicted hourly temperature changes for a wide range of hydrologic (wet, dry, average) and weather conditions (hot, cold, average). Appendix D presents more detailed predictions of MO3 actions on water temperature in graphics that clearly show between 2-10 F water temperatures improvements for the Snake River during the critical summer and fall seasons for a wide range of hydrologic and weather conditions (Appendix D, Figures 6-23 to 6-27). In their decision framework, the DEIS defines water temperature changes of >2 degrees Fahrenheit to be a major impact15. In addition to the predicted cooling, diel temperature conditions are predicted by the numerical models. The DEIS reports Average diel temperature differences seldom exceed 1 degree Fahrenheit under the no Action Alternative.Average differences would range from 2.5 to 3.5 degrees Fahrenheit for the same time period if MOE was implemented (Figure 6-29).16 Diel temperature fluctuation could provide thermal refuge for migrating adults even in the lower river. There is no rational explanation for why the thermal benefits predicted by the numerical modeling for a free-flowing river were not part of the preferred alternative solution. EPA used an alternative one-dimension model, RBM10, to evaluate the Columbia River system as part of the temperature TMDL process and also developed a model of a free flowing river scenario. The DEIS reports EPA modeling results in Appendix D, Annex A that detail daily average temperature predictions with no Lower Snake River dams17. EPA also presented modeling results using RBM10 during the TMDL process18. The DEIS and EPA water quality models overlap geographically and temporally, and although the results may not be directly comparable, EPAs analysis offers comparison between a free flowing and impounded scenario that offers insights that supports the benefits of MO3: A. The free-flowing scenario results in a significantly cooler Lower Snake River by 1-2C during the period when the Snake River currently typically exceeds 20C (mid-July mid September). B. The free-flowing scenario significantly reduces the number of days that exceed a daily average of 20C. C. The cooler daily average temperatures in the summer and fall under the free-flowing scenario as noted above will result in cooler temperatures for a few migrating adult sockeye in July, for a significant number of adult steelhead in July, August, and September , and for a significant number of adult Fall Chinook in August and September19. Currently, in July and August the Snake River is warmer than the Columbia River by 2-3C at a time when Snake River temperatures exceed 20C. Adult steelhead may delay migration up the Snake and hold in the cooler Columbia River. In the MO3 scenario, the predicted cooling and migration. The cooler summer and fall temperatures would provide less stressful migration conditions for adult steelhead and fall Chinook salmon migrating up the Lower Snake River.	The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in the Draft EIS Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Predicted water temperatures under MO3, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. All water quality data, in addition to data from the other resource teams (fish, wildlife, navigation, hydropower, cultural resources, etc.) were used to select the Preferred Alternative. The system water quality model is limited by available data and run times, so modeling long-term record sets was not possible for EIS analysis. Instead, a 5-year period (20112015) that represent a wide range of environmental response to hydrology (wet, dry, average) and weather conditions (hot, cold, average) were selected to model each EIS alternative against. The co-lead agencies feel that this 5-year period of data represents a good range of conditions to compare EIS alternatives against. The CRS is a complex system with multiple, sometimes competing, congressionally-authorized purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. This EIS was developed to evaluate the operation and maintenance of the CRS system over the next 20 years, with the expectation that the co-lead agencies will continue to meet the multiple, authorized purposes until directed differently by Congress. Although fish and wildlife conservation is one of the authorized purposes, it is not the only purpose, and the co-lead agencies must balance all resources. The analysis of the multiple objective alternatives reflect these trade-offs and have allowed the co-lead agencies to understand the effects of emphasizing some purposes over others in order to find the most acceptable balance for future operations. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapter 3, summarized by resource and alternative in Table 3-1, and once again presented for comparison in Table 7-1. Effects from the Preferred Alternative are discussed in Chapter 7. Effects specific to anadromous fish are described in Section 3.5.3. Table 3-61 compares expected survival by alternatives, and Table 3.62 provides a comparison of the alternatives specific to anadromous fish.
6894	44	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Finally, the DEIS process should have included an alternative that combined optimized Dworshak releases to regulate water temperature with a free free-flowing Lower Snake River. The options that were only evaluated in MO1 which proposed releasing more Dworshak water in June/July, less in August, and more again in September/October. This schedule would release cold water during the peak of the sockeye and S/S Chinook migrations in June/July and again during the peak of fall Chinook and steelhead migrations in September and October. This option should have been combined with an evaluation of a free-flowing lower Snake River to fully evaluate the best options for fish survival.	As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Tables 7-1 and 7-55 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. During the formulation of the Preferred Alternative, Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams, was not selected due to the inability to meet other objectives (e.g., irrigation, recreation, transportation), and therefore was not evaluated in combination with the Dworshak releases. Finally, as described in Section 3.4, adjusting the timing of Dworshak releases did not provide water temperature benefits, and thus, was not included in the Preferred Alternative. To achieve a broad range of alternatives, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single-objective alternatives (SOs), and then four Multiple Objective alternatives (MOs). After completing the effort to develop the SOs and MOs, the co-lead agencies evaluated all 12 alternatives against screening criteria of completeness and efficiency. Completeness was used to evaluate the extent to which a given alternative provides and accounts for all actions to meet most or all objectives, thereby satisfying the Purpose and Need Statement. Efficiency was considered as how well (without duplication of effort) an alternative would meet objectives. Usually, cost effectiveness is part of this consideration, but costs were not available at the early screening of alternatives. In this case, efficiency was based on efficiency of analysis of measures and the elimination of duplication of effort. A detailed descriptions of the SOs and their measures are located in Appendix A, Alternatives Development. A description of the alternatives removed from further consideration is in Section 2.4.
6894	45	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Power/Economics: The DEIS Power And Economics Analyses Are Flawed and Fail To Incorporate and Analyze Important Information Sources Early in the DEIS development process, tribal staff urged the Co-lead Agencies to adapt their power analyses to recognize the rapid evolution of western energy markets and the role of the CRS in this setting. The ever-increasing integration of the Western electricity grid creates opportunities and threats for both fish and power. Independently from the DEIS process the co-lead agencies, state and tribal parties entered into a Flex Spill Agreement for an interim period of three years. Unlike the DEIS, the process for developing the Flex Spill agreement was forward-looking, innovative and collaborative. It was not and is not a comprehensive agreement and its limits are clearly described within the Agreement itself. Nevertheless, the Agreement was founded on innovations in analytical methods that assisted the parties collaborative dialogue. For instance, the Flex Spill Agreement is based on hourly spill operations in attempt to accommodate time-of-day pricing that occurs in Western energy markets. The selection of analytical methods in these analyses was carried out solely by the co-lead agencies, despite offers of assistance from the tribes. As an example, CRITFC has extensive capability to perform analyses with a HYDSIM based analytical tool it developed for just this kind of setting. Called CIS, the analytical tool is capable of modeling and comparing multiple operation scenarios for CRS projects, quickly and easily. It has been used by the 15 tribes in the U.S. portion of the Columbia Basin to analyze the potential effects of modernizing the Columbia River Treaty. An explanation of CIS was provided to the co-lead agencies. CRITFCs offer went into a void. In the case of anadromous fish, the development of future system scenarios were not iterative. Rather it was based on a one-way information flow. Energy is important to certain economic sectors in the region, but overall the economy of the region is highly dependent on the natural capital provided by the Columbia River and its tributaries and other factors that is far larger than CRS energy outputs and which the DEIS failed to disclose or analyze. The DEIS should have disclosed to the public the broader natural capital values of the Columbia River Basin, which are described in The Value of Natural Capital in the Columbia River Basin: A Comprehensive Analysis by Earth Economics. https://ucut.org/wpcontent/uploads/2017/12/ValueNaturalCapitalColumbiaRiverBasinDec2017.pdf. This broader context of natural capital management is important economic context for changes in CRS configuration and operations, which are minor in comparison. The DEIS also fails to consider the effects of built capital resources on the natural capital of the Basin. In many cases, such as the CRS, the built capital has degraded the natural capital of the basin. This degradation is described in the Earth Economics report, the 1999 Tribal Circumstances report and the 2019 Tribal Perspectives document. The loss of the Basins natural capital has profoundly damaged the tribes cultures and economies. Restoring the natural capital lost to the tribes is not disclosed or analyzed in the DEIS. Moreover, future sustainability of the natural capital of the Columbia River Basin is not analyzed in the DEIS. Our prior comments urged the co-lead agencies to consider the Tribes Energy Vision for the Columbia River. It was originally published in response to the energy crisis of 2001, when the federal dams violated their ESA operation requirements.20 Those violations were the result of regional utilities assumptions that spot market power supplies would be adequate to address the regions needs. Those faulty assumptions cost BPA hundreds of millions of dollars. The 2003 Energy Vision for the Columbia River described solutions to address conflicts between peak power production and Columbia Basin salmon. Against the backdrop of fish problems associated with serving loads, the plan identified less harmful and less expensive ways to provide electricity for peak loads. The CRITFC 2013 Energy Vision for the Columbia River builds on the recommendations made in 2003. Like its predecessor, the 2013 plan recommended measures to reduce the pressures of the regions energy demands on the Columbia River and its ecosystem and included recommendations that would benefit the DEIS. The DEIS fails to disclose and analyze the tribes concerns and recommendations to evolving nature of the regions energy demands and the pressures they place on the Columbia Rivers ecosystem, including its anadromous fish. It also	The comment suggests that the EIS should have adapted its power analysis to recognize the rapid changes occurring in the western energy markets. The comment is not clear, though, as to what aspect of the western energy market the EIS omitted. The EIS recognizes that the energy market is constantly changing. To that end, the EIS included updated information concerning coal retirements, demand response, resource integration, and other factors that could affect the power analysis. See Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, pages 3-829-841 in the Draft EIS. In addition, in response to comments, the EIS will update the data used in estimating replacement resources costs for solar and batteries using publicly released draft information from development of the 8th Power Plan; this information is included as rate sensitivities in the Final EIS. The Final EIS will also include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will likely be used by the Council in the 8th Power Plan. The EIS analysis also considers emerging technologies in the resources analysis, though it recognizes that most of these new resource options have not reached the scale needed in the EIS to be cost-effective. See Section 3.7.3.5, Replacement Resource Options, pages 3-907-910 in the Draft EIS. The co-lead agencies are proposing an adaptive implementation framework for juvenile fish passage spill operations, which builds off the lessons learned from the 2019-2021 Spill Operation Agreement. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the CRSO EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Regarding the selection of modeling tools in the EIS, the analysis uses high quality resource information and a variety of industry-standard, robust models to analyze the effects of the alternatives on hydropower generation and Western energy markets. See Appendices H, I, and J. Bonneville is familiar with the CIS comparison tool developed by CRITFC and used during the Columbia River Treaty Review (CRTR). Specifically, the Tribes used the modeling portion for their analytical work while Bonneville used HYDSIM. The display feature of the Tribes tool was used for the Sovereign Review Team work with the Tribes and the Federal agencies. For the EIS, Bonneville chose to use its own staff for hydropower modeling with HYDSIM because staff have the necessary expertise with HYDSIM, using the tool for decades in many different areas. While cooperating agencies are invited to supply specialized technical expertise to assist the co-lead agencies, the co-lead agencies had sufficient expertise to run models and perform the necessary operations required for the EIS. CRITFC was not a cooperating agency, though later in the EIS process they were utilized for technical assistance by the Confederated Tribes of the Umatilla Indian Reservation who were a cooperating agency. Bonneville did host several meetings with the cooperating agencies who expressed an interest in hydropower, describing the plan progress and outcomes of modeling, soliciting feedback along the way. Bonneville's modeling on HYDSIM was closely coordinated with the Corps hydroregulation modeling in ResSim. The teams used a parallel modeling process, with weekly or even daily check-ins, to effectively peer-review the two models and analyses. The EIS recognizes the environmental, social, and economic values of the natural resources of the Columbia River Basin and the focus is on how the CRSO EIS Alternatives affect these resources. For example, Section 3.5 evaluates effects of the alternatives on fish and Section 3.15 describes the values that people hold for salmon, including for commercial fishing, ceremonial and subsistence purposes, and passive use (e.g., existence values); Section 3.11 describes the effects on recreation (including fishing and other types of recreation); and Section 3.17 provides information on the cultural significance of the salmon to regional Tribes. Beyond the effects on fish, the EIS additionally evaluates potential effects on wildlife species and habitats (Section 3.6), agricultural productivity (Section 3.12), and air quality (Section 3.8). The EIS also recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The Fisheries analysis (Section 3.15 as well as Section 3.17), in particular, includes discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries section 3.15.2.1, which includes information on ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				does not provide a rational explanation for its failure to do so. We are pleased that the DEIS recognizes the NW Councils regional energy plan, but the tribes Vision goes beyond the Councils regional energy planning. We specifically incorporated by reference herein the power and economics comments of the Yakama Nation. The analyses reported by the Yakama Nation were developed with input and support from the technical staff of CRITFC, as delegates of the CTUIR in the Cooperating Agency process. Rather than repeat this content here, we are specifically incorporating the Yakama Nations power and economics analyses by reference.	
6894	46	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	There are also additional effects that were not considered in the DEIS but should be. These include but are not limited to different flood risk management regimes that may result from the ongoing Columbia River Treaty negotiations.	The current operations of the Columbia River System, including current Treaty-related operations, are included in the EIS analysis. Section 2.5.10 of the Draft EIS explains why re-evaluating system flood risk management was screened out from further consideration in this EIS. Section 2.5.10 also explains that while the U.S. Entity Regional Recommendation stated support for the pursuit of Congressional authorization and appropriations for a region-wide public process to assess potential changes to the current level of flood risk protection, no such authorization or appropriation was provided. As such, a study for this purpose was determined to be outside of the scope of this EIS. If CRT-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary.
6894	47	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Similarly, analyses of reservoir ecology should be included in the EIS.	Please see Section 3.5 Aquatic Habitat, Aquatic Invertebrates, and Fish; and Section 3.6 Vegetation, Wetlands, Wildlife, and floodplains for information on reservoir ecology. Additional information is also available in associated Appendices E and F.
6894	48	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Climate Change The DEIS lack of quantitative regulated flow and river operations modeling based on the RMJOC II 160 climate change projections is a significant flaw. The DEIS states that the BPA approach used to examine four of the RMJOC II climate change scenarios does not, meet the policies or technical guidance of the Corps or Reclamation under the time frame of the EIS. This is a significant failing of the DEIS to adequately evaluate the DEIS alternatives for climate change impacts as required by ESA and NEPA. We anticipate that Phase II of the RMJOC II project will contain the Phase I climate change scenarios with regulated flows and river operations based on updated flood risk and irrigation data is necessary to fill this inadequacy. The DEIS notes that having quantifiable understanding how future climate may impact EIS alternatives is important to BPAs understanding of impacts to generation and revenue in the future. It is no less important and is vital to understanding the other metrics examined in this EIS such as flood risk, ecosystem function with respect to anadromous and resident fish, water quality, recreation and water supply. In this section, the DEIS notes that the four climate change scenarios BPA chose to evaluate for power generation provide a general spread of future climate scenarios, but they are not adequate considering the full suite of 160 climate scenarios in the RMJOC II study. Further, the approach BPA used to estimate and compare power generation and review four RMJOC I unregulated climate change scenarios by regulating them through HYDSIM runs is an interesting preliminary first look but lacks adequate daily flood risk rule curves and appears to lack validated modified flows. The details of how BPA established data sets used to replace the 80-year modified flow data set and the volume forecast data sets used in all of the alternatives are not provided. Assumptions are provided as to how BPA established URCs for the four climate change scenarios, but they are not the approach that is required for robust flood risk evaluations. The revised URCs are based on the HYDSIM 14 period time step and do not have the precision of the daily time steps that the Corps uses when generating flood risk curves and URCs. In addition, the four climate scenarios chosen were based on the spread of 160 scenarios, culled down to 19 scenarios and based on annual runoff. It would much more informative to examine a fuller suite of scenarios culled by seasonal volumes for each metric considered (i.e. spring and early summer volume forecasts for fish; winter volume forecasts for flood risk). In Appendix J Hydrogeneration, the summary section that provides the results of the BPA model comparisons between historical climate (80-year historical record) and the four RMJOC II climate scenarios for all of the DEIS alternatives. These results indicate there were negligible differences between historical climate and future climate change scenarios for all DEIS alternatives with respect to power generation and revenue. Dynamic changes to potential load demand and market shifts from winter generation to summer generation, new generation resources and conservation technologies are all important uncertainties under current examination by BPA and the Northwest Power and Conservation Council. These uncertainties need to be assessed, weighed and accounted for in revised EIS modeling to establish a more robust approach to examining climate change effects on future power needs.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6894	49	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Continuing Mitigation Actions are not Adequately Described or Considered Within the Affected Environment and Analytical Framework The Northwest Power Acts Fish and Wildlife Program (BPA/Council) is noted as an existing mitigation program under Section 5.2.1 (p. 5-5). There are also extremely high-level discussions of the program in Chapters 2 (Measures Previously Committed to By The Co-Lead Agencies to Benefit Endangered Species Act-Listed Fish, 2-29 through 2-34) and Chapter 7 (Ongoing Programs, 7-39 through 7-43). The most complete discussions of the Fish and Wildlife Program is contained Appendix Q, which discusses costs which seems to be the primary point of consideration in the EISThere is no discussion of the Programs goals, objectives and measures. The Affected Environment chapter fails to mention that the NPCC, consistent with the Northwest Power Act, has identified a regional goal of 5 million salmon and steelhead with SARs in the 2-6% range. These are important benchmarks that the DEIS should be measuring their analysis against. While the DEIS NAA assumes a 2016 Baseline, the discussions in the Affected Environment sections do not meaningfully depict the nature and extent of the cumulative impacts that the Basins hydrosystem has had on the Columbia Basins anadromous fish. The NAA carries with it substantial unmitigated salmon and steelhead losses due to the CRSO dams configurations and operations. The broad scope of these impacts are described in multiple sources, including the Tribal Perspectives submitted by Warm Springs, Umatilla, Nez Perce and Yakama tribes in June 2019. In an effort spanning multiple years with numerous public hearings in a notice and comment style, the NW Power Planning Council considered the extent of hydropower related salmon and steelhead losses and concluded by adopting Program goals in 1987. The effort is described in multiple volumes. https://www.nwcouncil.org/reports/2014-columbia-river-basinfish- and-wildlife-program/appendix-b-estimates-hydropower-related-losses. Costs for Implementing the Fish and Wildlife Program are approximately $300 million annually, recently reduced to $282M. Program implementation is a key factor in the overall balance of activities that fulfills the equitable treatment mandates that apply to the co-lead agencies pursuant to 16 USC 839b(h)(11). The cost analysis in Appendix Q suggests reducing Fish and Wildlife Program funding and proposes funding cuts that are so substantial that they represent major shifts in regional governmental activities and policies. Table 12 in Appendix Q describes a $105 million/year (37%) reduction of Program spending associated with MO3 and MO4. Appendix Q describes a metric, benefits, that would evidently justify this 37% reduction in Program funding. There is, however, no actual appraisal in the DEIS of the biological benefits of the BPA actions implementing the Fish and Wildlife Program, let alone an analysis placing such benefits in the context of the full extent of the CRS dams effects. Without more, it is simply irrational to assume that co-lead agencies statutory obligations under the Northwest Power Act can be met using such gross assumptions. Unless the DEIS contains a thorough, accurate and meaningful discussion of the Fish and Wildlife Programs implementation, including progress toward its goals and mitigation objectives, there is no basis to assume a 37% funding reduction in Program implementation should accompany MO3 and MO4 While federal agencies are given latitude in establishing their objectives in a NEPA analysis, that latitude does not relieve the agencies from considering cumulative actions, cumulative impacts as well as direct and indirect effects. In this regard, the DEIS fails to accurately consider the context and intensity of the dams historic and long-term effects as well as this context for establishing appropriate mitigation measures. This situation is again symptomatic of the structural flaws that flow from an inadequate analysis of the CRSO dams cumulative baseline effects and a DEIS scope that only seeks improvement in juvenile and adult passage. Since reductions in Fish and Wildlife Program funding are beyond the stated scope of the DEIS objectives, the DEIS should not purport to analyze such measures.	Consistent with CEQ's June 24, 2005 guidance and interpretation of CEQ Regulations for Implementing the Procedural Provisions of NEPA, 40 C.F.R parts 1500-1508, "Agencies are not required to list or analyze the effects of individual past actions unless such information is necessary to describe the cumulative effect of all past actions combined... Generally agencies can conduct an adequate cumulative effects analysis by focusing on the current aggregate effects of past actions without delving into the historical details of individual past actions." However, the analysis of current conditions includes the ongoing effects of the existence of the system, inclusive of a host of other factors influencing natural and cultural resources of concern to potentially affected tribes. System operations are the focus of the EIS, not the existence of the system (and to the extent the analysis considers the existence of the system, i.e. breach, the effects analysis captures the cumulative effect of project existence). The comment further notes an absence of the goals and objectives established by the Northwest Power and Conservation Council, in particular the 5 million fish goal and the 2% to 6% SAR objective. These goals and objectives apply to the entire federal and non-federal hydroelectric system in the Columbia River basin, not the CRS dams specifically. For more on this issue, see response to Comment 6929-8. In a similar vein, the comment contends the co-lead agencies omitted discussion of unmitigated salmon and steelhead losses documented by the Council. The No Action Alternative, however, reflects conditions existing when the CRSO EIS was drafted. As such, the No Action Alternative reflects full compliance with the Northwest Power Act and other laws with regard to mitigating salmon and steelhead losses as described in the Accord Extension agreements signed in 2018. For more on this issue, see response to Comment 6894-56. The comment also overstates the nature of the co-lead agencies Northwest Power Act responsibilities under section 839b(h)(11). That provision applies to management and operation of the CRS only, not Bonneville's overall mitigation funding effort undertaken to comply in large part with section 839b(h)(10), as described in greater detail in the response to Comment 5962-3.The comment also questions the analysis of reduced Fish and Wildlife Program funding under MO3 and MO4. Funding decisions for the Fish and Wildlife Program are not being made as a part of the CRSO EIS process. However, a range of potential Fish and Wildlife Program costs are included to inform the broader cost analysis for each alternative in the EIS. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments to the Fish and Wildlife Program would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. In the case of MO3 and MO4, Bonneville included a range of potential Fish and Wildlife Program costs to acknowledge the possibility that the alternatives could provide biological benefits to anadromous fish species and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville Fish and Wildlife Program. For MO3 and MO4, Bonneville's Fish and Wildlife Program costs are estimated to range from no change from No Action Alternative to a decrease of approximately 37 percent, or approximately $105 million, annually (see Section 3.19.2). With respect to anadromous fish, the Northwest Power Act calls for improved survival at the dams and flows of sufficient quality and quantity . . . to improve [their] production, migration, and survival. The co-lead agencies demonstrate throughout the EIS how they meet these statutory objectives. The Columbia River Basin Fish Accord Extensions (Fish Accords) and Bonneville's comments to the Council on its 2020 amendment process also highlight the actions the Agencies have taken to fulfill the anadromous fish mandates of the Act.1/ Under MO3 or MO4, operational, structural and mitigation measures would substantially benefit anadromous fish. This could potentially necessitate reductions in off-site mitigation funding. The funding decrease modeled in MO3 results because substantially more mitigation would be provided on-site at the dams, thus reducing the need for off-site mitigation; and the power purpose at the four lower Snake River dams is eliminated under MO3 when four dams are breached. Section 3.19 discusses these effects in more detail. Moreover, the co-lead agencies note that through the 2008 Fish Accords and the 2018 Accords Extensions, six tribes, one tribal association, and two states voluntarily affirmed the legal and biological adequacy of CRS operations as well as the off-site mitigation done through Bonneville's Fish and Wildlife Program. Several of the Accord partners published a 10-year review of its Accord-related mitigation accomplishments and the biological benefits obtained. In that report, the entity found Bonneville's $261 million annual funding level during the Accords and mitigation effort was consistent with the Northwest Power Act. For additional information, see the response to Comment 31775-51. Finally, the comment suggests the draft EIS needed to examine the biological benefits of the actions implementing the Bonneville Fish and Wildlife Program with an analysis placing such benefits in the context of the full extent of the CRS dams effects. Bonneville's Fish and Wildlife Program is primarily an off-site mitigation or enhancement program. See, 16 U.S.C. 839b(h)(8)(A). In other words, Bonneville funds off-site enhancement, not mitigation at the dams. Therefore, it is unrealistic to expect the benefits of these off-site enhancement actions to be placed in the context of the CRS dams effects as the comment suggests. For further information on the effectiveness of the co-lead agencies mitigation actions, see the response to Comment 6894-56. 1/ See Bonneville, Recommendations to the Council on Amending the 2014 Fish and Wildlife Program (Dec. 13, 2018) https://app.nwcouncil.org/uploads/2018amend/recs/765/Bonneville%20Recomendations%20to%20Council%20FW%20Program%20Amendment%2012.13.2018.pdf; Final Comments on Draft Addendum Part II (Oct. 18, 2019) https://app.nwcouncil.org/uploads/2018amend/comments/1341/Final%20Bonneville%20Comments%20on%20Draft%20Council%20Addendum%202019.10.18.pdf
6894	50	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian	For MO1, the summary tables of anadromous fish effect in Table 6-20 indicate that MO1 would be similar to the base case which was found to not be sufficient to meet jeopardy standards. However, MO1 has little to no additional mitigation actions. The mitigation proposed for salmon and steelhead is to revert backwards to the operation proposed in the NAA for Little Goose Dam and continue existing predator management programs. No other mitigation is proposed. As discussed with the PA, continuing existing predator management programs at NAA funding levels is not an improvement	The co-lead agencies proposed mitigation actions for MO1 that addressed the potentially negative effects of that alternative. The agencies, in evaluating the range of alternatives for how well they each met the Purpose and Need Statement and the eight objectives, incorporated measures from the multiple objective alternatives to form the Preferred Alternative. This alternative avoids jeopardizing ESA-listed species and does not adversely modify designated critical habitat.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
			Reservation Department of Natural Resources	over the NAA. Rather than reverting to NAA spill levels to encourage adult migration, at the expense of juvenile migrants, the co-lead agencies should propose improvement of the adult fish ladder at Little Goose Dam or construction of a second ladder. This mitigation action was recommended by the tribes for the mitigation toolbox.	
6894	51	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	For MO2, the co-lead agencies propose no mitigation actions for salmon and steelhead because even though the alternative is stated to decrease survival for both juveniles and adult abundance. If the NAA poses jeopardy for salmon and steelhead, there should be a significant mitigation package attached to this alternative.	The mitigation package for MO2 is described in Chapter 5, Section 5.4.2 and Chapter 2, Section 2.4.2.1 and includes many actions carried forward from the No Action Alternative. The Preferred Alternative includes a mitigation package that the co-lead agencies expect to offset potential negative effects.
6894	52	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	For MO3, the co-lead agencies propose short term mitigation to offset short term impacts caused by breaching the lower Snake dams. They propose constructing or improving trap and haul facilities to get fish out of the river and transport them around the zone of breaching. They also propose to rear more hatchery fish during the construction phase of breaching to replace two lost year classes of salmon and steelhead. The effect of this mitigation action does not offset the impact but reduces the number of fish impacted. No other mitigation is proposed.	The trap and haul facilities and hatchery fish mitigation is to provide fish during the short-term impacts associated not with the demolition, but the flushing of stagnant water and sediments, anticipated to drop dissolved oxygen levels significantly, and potentially cause 2-7 years of no biological productivity and aquatic losses. Description of these impacts are in the Multiple Objective alternative 3 analysis for water quality and fish in Chapter 3.
6894	53	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	For MO4, again the co-lead agencies propose to revert backwards to the operation proposed in the NAA for Little Goose Dam and rely on existing predator management programs as described under MO1. No other mitigation is proposed. As with MO1, with adult passage identified as a concern, a second fish ladder at Little Goose (and possibly Lower Granite) should be considered as an appropriate mitigation action.	A second fish ladder entrance at Little Goose was considered. Ultimately, the "Temporary extension of performance standard spill levels in coordination with the Regional Form" was carried forward as mitigation in Multiple Objective alternative 4.
6894	54	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	For All MOs and the PA, the DEIS proposes continuation of current (NAA) predator control measures without addition or enhancement, however this fails to recognize: avian predation measures are not meeting biological goals, or have been deemed complete without meeting such goals. (See discussion under PA comments) likely increase in Northern Pike Minnow predation, which the DEIS does recognize but keeps the program at current levels. increases in pinniped predations, which the DEIS also recognizes as likely or uncertain, but fails to mitigate. Many examples exist for additional Affected Environments (e.g.; Water supply, Navigation, etc.) but due to time constraints we have limited our comments to salmon and steelhead.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from the CRS operations, through funding, direct implementation, and other means. Sea lions are protected under the Marine Mammal Protection Act. With the exception of continuation of the pikeminnow program, the co-agencies are not proposing additional predator management actions in the Preferred Alternative. The avian management plan encourages birds to nest in alternate locations outside of the Columbia River Basin. As analyzed in Section 7.7.7, the Predator Disruption Operations measure in the John Day reservoir could delay nesting water birds, forego nesting, or relocate to other areas, reducing avian predation on migrating juvenile salmonids. As discussed in Section 3.6.3.2, Caspian terns are highly mobile during the breeding season and move between breeding colonies in a given year and between years, demonstrating a willingness to nest away from the Columbia River while still foraging on juvenile salmonids (Corps 2014, 2018, 2019). Under the Preferred Alternative, actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with ESA as described in Section 7.6.4.1, Ongoing Programs, including ongoing measures to haze and monitor pinniped predators. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators. The co-lead agencies will continue to work closely with and assist NMFS, States and tribes efforts to benefit ESA-listed salmonids, including pinniped removal efforts near Bonneville Dam.
6894	55	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Offsite Mitigation is lacking The Offsite Mitigation Package (p. 5-29, 5-33) is lacking in several areas: 1. RM&E. This section is inadequate with regards to habitat condition, implementation of habitat restoration, and evaluation of biological responses. Tributary habitat restoration projects are implemented to reduce the impacts of limiting factors and increase the survival and productivity of focal species of interest. There should be a strong commitment to protecting and improving tributary habitat and implementing monitoring programs for assessing the impacts of limiting factors and effectiveness restoration actions. This will help to inform critical additional habitat improvement needs. The DEIS does not discuss significant regional habitat strategies in progress: the Habitat RM&E Strategy and the Habitat Implementation Strategy. Both strategies are attempting to synthesize standardized metrics (or indicators) of habitat conditions, habitat implementation and the impact on biological response. In addition, the DEIS fails to discuss the Northwest Power Planning Councils Research Plan regarding tributary habitat uncertainty research (2017-4). The following are key RM&E questions or uncertainties from this document. These should be referenced in the EIS with support for implementation. At a minimum, it should be recognized that the tribes should have the autonomy to implement a tributary habitat research program to address these uncertainties. Question 1. Do investments in tributary habitat restoration mitigate for degraded mainstem habitat and passage conditions? 1.1. To what extent do tributary habitat restoration actions improve the survival, productivity, distribution and abundance of native fish populations? 1.2. How much does improving habitat and eliminating barriers (removing dams and culverts, or transporting migrating fish above dams) increase carrying capacity and contribute to recovering important fish populations? 1.3. To what extent is an increase in carrying capacity usurped by non-native invasive species, preventing recovery of native fish and wildlife populations? 1.4. To what extent do restoration efforts provide resilience to buffer against climate events and recover native species of interest? Question 2. What additional habitat restoration projects should be implemented to benefit fish and wildlife? 2.1. Are the cumulative suites of restoration actions benefiting populations of fish and wildlife in tributary watersheds? 2.2. How can habitat restoration actions support or enhance cold water habitat to provide thermal refuges? 2. Habitat Restoration. Offsite mitigation should include increased floodplain restoration actions in tributaries. CRITFC member tribes and others are aggressively assessing and addressing primary limiting factors which are causing significant juvenile fish loss in tributaries. The degree of stream channelization in some Columbia Basin tributaries exceeds 75 percent therefore floodplain restoration must be aggressively embraced as offsite mitigation in the DEIS. Recent Columbia Basin Partnership Task Force modeling determined that tributary juvenile fish mortality in the mid- Columbia sub-region accounts for the highest level of fish mortality in all salmon and steelhead life history phases. The DEIS should recognize and be informed from this effort. For instance, CTUIR is implementing a science-based approach to restore floodplains to naturally functioning and sustaining ecosystems. It is paramount that this work be maintained or increased to continue address the most limited fish life history stages. 3. Lamprey Restoration. See lamprey discussions in sections IV.E.2. and V.M. above. 4. Hatchery Programs. Current hatchery programs are frequently not meeting mitigation requirements and are not fully funded. Offsite mitigation must include increased hatchery fish production to meet mitigation goals and address facility delinquencies such as water supplies and critical capital improvements. This will provide valuable harvest and assist with fish recover by supplementing natural fish production. Additionally, the Affected Environment chapter fails to mention that the NPCC, consistent with the Northwest Power Acts statutory requirements, has identified a regional goal of 5 million salmon and steelhead with SARs in the 2-6% range. These are important benchmarks that the DEIS does not disclose or analyze.	This comment identifies concerns related to: 1) RME, 2) habitat restoration, 3) lamprey restoration, and 4) hatchery programs. In regards to the first two areas, the comment identifies three primary concerns related to tributary habitat condition, habitat project implementation, and the evaluation of biological responses. The 2020 CRS Biological Assessment and proposed action, Appendix V to the EIS, specifically addressed these issues as documented below. 1/ In addition, the co-lead agencies offer the following responses. With regard to tracking habitat conditions from tributary enhancement and restoration projects, Bonneville tracks broad-scale changes in select habitat status and trends information, including stream temperature and flow, across the Columbia River Basin. Bonneville also is exploring opportunities for programmatic integration of temperature and flow data within regional data display and modeling efforts (e.g., the USFS NorWeST stream temperature platform). A subset of watersheds within the Snake River, Upper Columbia and Mid-Columbia ESUs would continue to implement regional habitat data collection to support existing long-term habitat monitoring efforts. Bonneville is also working with regional partners to develop additional monitoring for habitat or fish status and trends as part of the forthcoming Columbia River Basin habitat research, monitoring and evaluation strategy. Bonneville intends to leverage existing efforts capturing habitat or fish status and trends information funded by regional partners and entities wherever possible to address additional or unmet needs. The co-lead agencies, with the Northwest Power and Conservation Council and National Marine Fisheries Service (NMFS), began developing the strategy under the NMFS 2019 CRS BiOp and have committed to finishing it with assistance from the commenting entity and other fisheries managers. With regard to concerns about implementing habitat enhancement and restoration projects, the co-lead agencies have invested heavily in non-operational measures supporting their compliance with applicable laws. The Preferred Alternative and associated ESA consultations continue this practice by including a strong tributary habitat restoration commitment affirmed and detailed in the appendix Supplemental Narrative for Tributary Habitat Actions for listed Salmon, Steelhead and Bull Trout.2/ The co-lead agencies would continue to work with various agencies and project sponsors on prioritization and implementation of restoration actions that provide the greatest benefit to aquatic species and promote resilience with respect to climate change, including improving tributary fish passage and floodplain conditions. To address and evaluate the biological responses of tributary habitat actions, the co-lead agencies proposed monitoring and evaluation using fish status and trend data along with site and watershed-scale effectiveness monitoring. The Proposed Action detailed in the Biological Assessment specifies that, [c]onsistent with the 2018 proposed action, the Action Agencies will continue to support fish status and trend monitoring for one population per major population group (MPG) for the following life stages: returning adult fish (e.g., PIT arrays in fish ladders, tributary PIT arrays and weirs, redd surveys for Chinook), smolt outmigration abundance and condition (e.g., screw traps), and smolt movement and survival (e.g., PIT tagging and associated arrays). Moreover, the co-lead agencies would address habitat restoration effectiveness with monitoring related to their habitat mitigation efforts at a range of scales including the site and watershed scales. This monitoring would serve multiple purposes, including determining if habitat actions are meeting their physical or biological objectives (limiting conditions and relative abundance in ESA-listed species), as well as revealing the benefit of actions on larger scales. To date, many key management questions have been addressed through a variety of regional effectiveness monitoring efforts including site-scale programmatic monitoring intensively monitored watersheds (IMWs). At the site-scale, Bonneville would continue to fund site and project-scale action effectiveness monitoring (AEM) through completion of this programmatic project study design in 2023 to provide a comprehensive, consistent, efficient, and cost-effective approach to monitor and evaluate salmon and steelhead tributary habitat improvement actions (e.g. fish passage, instream wood structures, floodplain enhancement and riparian improvement). The majority of Bonneville's implementation partners conduct site-scale effectiveness monitoring through the AEM Programmatic effort, including multiple habitat actions distributed across the Snake River, Upper Columbia and Middle Columbia ESUs/distinct population segments (DPSs). Results from this work are available on a rolling basis as action categories monitored in the AEM program are completed and evaluated. At the watershed scale, the co-lead agencies intend to complete a summary analysis and synthesis report for the Columbia Habitat Monitoring Program to guide management decisions on habitat priorities funded by Bonneville. The co-lead agencies intend to continue supporting fish status and trend monitoring within the Entiat, Lemhi, and John Day basins, all of which were identified as pilot IMWs in the 2008 BiOp. These monitoring results can inform future effectiveness monitoring called for in the Columbia River Basin tributary habitat RM&E strategy. Moreover, the co-lead agencies also would continue supporting ongoing habitat monitoring for a subset of readily available and high value habitat variables, including stream temperature and flow. The results of this monitoring would be evaluated for integration into regional data display platforms through collaborative efforts with regional experts, including the USFS Rocky Mountain Research NorWeST team. Bonneville intends to continue to fund the development of stream habitat linear networks to display habitat attributes (e.g., stream temperature and flow) in GIS-based data displays and maps in select priority watersheds. Additionally, biologically based fish metrics (e.g., salmon densities) are being explored for use in conjunction with stream habitat metrics to help guide future habitat improvement efforts. Results of site and watershed-scale effectiveness monitoring would continue to be used to guide future habitat action implementation to ensure the co-lead agencies are investing in effective habitat improvement actions designed to help address uncertainty related to any residual adverse effects of CRS management. Additionally, results can help evaluate improvements in habitat and fish status resulting from completed habitat actions in the Columbia River Basin through coordination with the Tributary Technical Team, and evaluation in regional science-based processes such as lifecycle modeling. The development of the regional habitat RM&E strategy is planned to include considerations and recommendations for future effectiveness monitoring. With respect to research on tributary habitat uncertainty and the Northwest Power and Conservation Councils Research Plan, which informs Bonneville's habitat project implementation, the Preferred Alternative provides the following commitment. The co-lead agencies recognize the value of focused, cost-effective, time-bound research and validation monitoring that increases understanding of the cause and effect relationships between habitat actions and biological fish responses. The forthcoming habitat RM&E strategy is proposed to include recommendations for future research priorities consistent with regional critical uncertainties (e.g. Independent Scientific Advisory Board [ISAB] Critical Uncertainties report and the Councils Fish and Wildlife Program Research Plan). In collaboration with NMFS and when necessary to inform management decisions, the co-lead agencies intend to fund fish and habitat research projects with regional partners as priorities and Agency funding availability allows. Lastly, the Agencies would continue to address key research, monitoring, and evaluation questions or uncertainties through the CRS mitigation commitments cited above. Bearing in mind the questions posed are complex and technical in nature, they are best addressed by fisheries and habitat managers, not the managers of the CRS. That such questions persist after decades of work shows their complexity and hints at the additional time and investment necessary to resolve them and resolving them is not within the scope of this EIS, which focuses on CRS operations, maintenance and configuration. Regarding lamprey, the Preferred Alternative includes several measures to improve lamprey passage. Finally, regarding hatchery programs, the co-lead agencies fund the operation and maintenance of safety net, conservation, and mitigation hatchery programs to mitigate for the impacts of CRS operations. The mitigation goals for these hatchery programs are either established by Federal agencies or by state or tribal co-managers in consultation with regulatory agencies. Salmon and steelhead hatchery program goals are formalized in in the Biological Opinions issued by NOAA fisheries. BPAs Fish and Wildlife Program funding of hatchery programs is consistent with the Northwest Power Act and conservation strategies established in regional salmon and steelhead recovery planning processes. The co-lead agencies recognize there are

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					hatchery maintenance and infrastructure needs in the region, and that these needs extend beyond Federally funded hatchery programs. This is a regional issue that is being worked through a variety of public and regional forums that are broader than the scope of the CRSO EIS. 1/ See FEIS Appendix V, 2020 CRS Biological Assessment at 2-94 through 2-103, Section 2.6.1.4 Habitat Improvement Actions. 2/ See FEIS Appendix V, 2020 CRS Biological Assessment, Appendix D, Supplemental Narrative for Tributary Habitat Actions.
6894	56	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	The DEIS Omitted Analysis of ESA and NWPA Compliance Without Rational Explanation Based on multiple communications with the co-lead agencies, including review of the DEIS and its draft components, it is clear that the DEIS, its actions and objectives are framed in terms of the co-lead agencies NEPA objectives, not their obligations under the ESA or the Northwest Power Act. Notably, the objectives for the DEIS for ESA-listed anadromous fish are improvement, not survival and recovery required by the ESA or for equitable treatment required by the Northwest Power Act or other federal legal obligations as described in the Tribal Perspectives report. It is worth reading the objectives for the EIS carefully. The two related to ESA-listed anadromous fish read as follows: Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival within the CRS through actions including but not limited to project configuration, flow management, spill operations, and water quality management. (Improve Juvenile Salmon) Improve ESA-listed anadromous salmonid adult fish migration within the CRS through actions including but not limited to project configuration, flow management, spill operations, and water quality management. (Improve Adult Salmon) DEIS Page 18 (Executive Summary). The introduction to the Mitigation chapter of the DEIS describes the NEPA framework of the DEIS, including the mitigation requirements specific to NEPA. Throughout the DEIS development process the foregoing objectives framed the analysis conducted by the co-lead agencies as well as the mitigation considered in the DEIS. NEPA and the case law interpreting it do not require this constrained analysis. As part of the NEPA process, Federal agencies consider appropriate mitigation measures to avoid, minimize, rectify, reduce or eliminate, and/or compensate for specific impacts (CEQ 2011). The mitigation measures summarized in this chapter are intended to reduce the duration and severity of impacts from implementing a specific action. DEIS Page 5-1. Importantly, mitigation measures are only proposed in the DEIS in those instances where the proposed alternative worsens or impacts juvenile survival or adult migration in the CRSO from where it was estimated to be under the No Action Alternative. E.g. DEIS, page 5-24, section 5.4.2.2. As a related matter, effects are categorized to include minor, moderate and major effects for NEPA purposes. As a result, the analyses segmented conditions and effects occurring before and existing in 2016 from those that would occur as a result of the actions contained in the DEIS alternatives. This segmentation is akin to the existence versus operations segmentation that was contained in NOAAs 2004 BiOp for the FCRPS and that was struck down by Judge Redden in May 2005. Appendix V, which is the Biological Assessment for ESA compliance is framed somewhat differently, but it acknowledges the different statutory frameworks as follows: It is important to note that NEPA and the ESA establish different standards for legal compliance and have different approaches to the analysis of the effects of the action. Because of these differences, the analyses performed in the draft EIS and in the BA are tailored to the requirements of each regulatory process. The mitigation chapter of the DEIS includes conclusory discussions of Bonnevilles Fish and Wildlife Program funding commitments under the Northwest Power Act in subsection 5.2.1.1 as well as a similar conclusory statement of the Northwest Power Acts equitable treatment requirements in section 5.2.1. The mitigation discussion fails to disclose and analyze the effectiveness of the ongoing mitigation actions required by the Northwest Power Act, Endangered Species Act or other federal laws. Compared to the narrow improvement and mitigation framework of the DEIS, the June 2019 Tribal Perspective document describes a much different set of objectives that should have framed at least some of the analyses in the DEIS. It includes discussion of tribal plans to effectuate treaty reserved fishing rights as well as the Northwest Power Acts fish and wildlife obligations. Its frame of reference is based on tribal well-being, as opposed to improvement from the status quo. The DEIS fails to disclose and analyze whether the alternatives would achieve those objectives described in the tribal Perspectives report. The EIS omitted analysis of ESA and NWPA compliance and other plans. Contrary to the assertions in the DEIS, there is no evidence that the Co-lead Agencies considered the NPCCs Fish and Wildlife Programs specific goals, objectives and measures with regard to anadromous fish. While some disclosure and analysis of wildlife Program obligations is set forth in the DEIS, such disclosure and analysis does not occur for anadromous fish. Without that disclosure and analysis there is no evidence in the DEIS that the Co-Lead agencies have provided equitable treatment for fish and wildlife. Similarly, neither the DEIS nor the Biological Assessment in Appendix V contain a holistic analysis of whether any of the alternatives would meet ESA requirements. Many federal ESA jeopardy analyses on the CRS (or FCRPS) have preceded the DEIS. They are the subject of many technical and legal publications, but this history not disclosed in the DEIS. There is also no disclosure and analysis of survival metrics or recovery metrics from previous BiOps. Nor does the DEIS contain a discussion of the survival and recovery metrics from NOAA Recovery Plans or the Interior Columbia Technical Review Team. Perhaps the most salient disclosure is contained in a paragraph in Chapter 3 and it does not bode well for future salmon and steelhead returns: On February 4, 2020, the co-lead agencies viewed a presentation prepared by NMFS regarding returns for the 2019 fish passage season and the Adaptive Management Implementation Plan. Although not all returns occurred prior to the presentation, NMFS utilized current return numbers to project return numbers if current return rates continued in 2020 and 2021. These projections signaled that returns are low, especially for Snake River steelhead. The co-lead agencies are currently evaluating the information provided by NMFS and will have a more detailed discussion of this information in the final EIS, including any updates that NMFS may provide once all returns have occurred, if appropriate. DEIS Page 3-301. Notably, the information disclosed by NMFS to the co-lead agencies on February 4, 2020 is not disclosed in the DEIS. The discussion of recovery plans in the Biological Assessment (Appendix V) is only aimed at ensuring the consistency of tributary habitat programs and safety net hatcheries with recovery plans. There is no analysis of recovery per se or its likelihood under any of the alternatives. The absence of such analysis frustrates public consideration of the alternatives and their consequences.	Chapter 8 of the EIS demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and Northwest Power Act. Regarding the ESA, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat and are included as an appendix to the EIS. Regarding Northwest Power Act compliance, the comment asserts inadequate analysis in the EIS as to the efficacy of mitigation funded through Bonneville's Fish and Wildlife Program. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that would continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and present, ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. Although the Northwest Power Act requires Bonneville to fund mitigation consistent with the Northwest Power and Conservation Councils (Council) Columbia River Basin Fish and Wildlife Program (Program) and the purposes of the Act, no statutory provision requires the co-lead agencies to undertake separate analyses regarding the efficacy of such mitigation. Rather, the structure and processes of the Act create a presumption that mitigation measures and projects recommended for implementation by the Council are indeed an effective means for addressing mitigation under the Act. First, the Council develops its Program based largely on the recommendations and expertise of fish and wildlife managers. The mitigation projects that the Council recommends to Bonneville for funding derive from their Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria that, for example, include examining whether projects are based on sound scientific principles and benefit fish and wildlife. 16 U.S.C. 839b(h)(10((D)(iv). These statutory processes for vetting and reviewing implementation of mitigation projects provide a reasonable basis for the co-lead agencies to rely on these projects being effective. In addition, for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Program, the underlying assumption being that the mitigation projects address appropriate obligations under the Council Program, and do so effectively. The comment also asserts that the agencies did not consider the Councils Program goals, objectives, and measures for anadromous fish. First, the co-lead agencies note that the Councils Program goals, objectives, and measures have been under a revision process for a substantial portion of this EIS analysis, and that revision remains ongoing. Bonneville submitted comments in the Councils amendment process, including fundamental questions about the legal basis of many of the Programs goals and objectives. 1/ However, even under the Councils prior 2014 Program, the overarching anadromous fish goal includes a smolt-to-adult return of 2-6%. The EIS analyzed SAR implications of the various alternatives. In addition, the CSS model predicts that certain smolt-to-adult return rates under the Preferred Alternative would increase from 2.0% to 2.7%, within the range included in the Council Program goal for anadromous fish. The comment further claims that there is no evidence in the EIS of the agencies adherence to the equitable treatment mandate of the Act. The equitable treatment provision of the Act directs the agencies management and operation of the Columbia River System provide equitable treatment for fish and wildlife with the other authorized purposes for which the system is managed, such as flood risk management, hydropower generation, irrigation, navigation, and recreation. See 16 U.S.C. 839b(h)(11)(A)(i). The co-lead agencies provide fish and wildlife with equitable treatment on a system-wide basis. See NW. Envtl. Def. Ctr. v. Bonneville Power Admin., 117 F.3d 1520, 1533-34 (9th Cir. 1997) (While each power marketing action that affects the system implicates the equitable treatment provisions, Bonneville may properly exercise its obligation by insuring equitable treatment for fish on a systemwide basis.); Confederated Tribes of the Umatilla Indian Reservation v. Bonneville Power Admin., 342 F.3d 924, 931 (9th Cir. 2003) (The equitable mandate of [the Northwest Power Act] does not require every Bonneville decision to treat fish and wildlife equitably. For example, Bonneville may make some decisions that place power above fish, so long as on the while, it treats fish on par with power.). Through this EIS process, the co-lead agencies have considered management and operation of the Columbia River System for its multiple authorized purposes. And, as noted above, CSS analysis of the Preferred Alternative predicts an increase in smolt-to-adult return rates as compared to the no action alternative. The co-lead agencies inclusion of alternatives MO3 and MO4 which are focused on benefiting fish, plus the incorporation of measures specifically designed for improved benefits to fish and wildlife, as balanced against other purposes, reflects equitable treatment of fish and wildlife consistent with the Northwest Power Act. 1/ See Bonneville Power Administration Comments on Draft 2020 Addendum to the Columbia River Basin Fish and Wildlife Program (Oct. 18, 2019), available at https://app.nwcouncil.org/uploads/2018amend/recs/765/Bonneville%20Recomendations%20to%20Council%20FW%20Program%20Amendment%2012.13.2018.pdf; Bonneville Power Administration Comments on Revised Part One of the 2020 Addendum to the Columbia River Basin Fish and Wildlife Program (Jun. 22, 2020) available at https://app.nwcouncil.org/uploads/2018amend/comments/1392/Final%20Council%20Addendum%20Pt%201%20Cover%20Ltr%20and%20Comments%202020.06.22.pdf. See also response to 31775-119 and 6929-8.
6894	57	ericquaempts@ctuir.org	Confederated Tribes of the Umatilla Indian Reservation Department of Natural Resources	Under its Treaty of 1855, 12 Stat. 945, the CTUIR reserved for itself and its members the right to take fish at all usual and accustomed areas. Tribal members have fished on the Columbia River for subsistence, ceremonial and commercial purposes since time immemorial. The Supreme Court of the United States has repeatedly recognized the significance of the treaty reserved right to fish at off-reservation usual and accustomed places, holding that the right is not much less necessary to the existence of the Indians than the atmosphere they breathed. Washington v. Washington State Comml Pass. Fishing Vessel, 443 U.S. 658, 680, 99 S. Ct. 3055, 3071-3072 (1978), quoting United States v. Winans, 198 U.S. 371, 380 (1905). This treaty right to fish is a property right, protected by the Fifth Amendment to the Constitution of the United States. See Muckleshoot Indian Tribe v. United Sates Corps of Engineers, 698 F.Supp. 1504, 1510 (W.D. Wash. 1988), citing Menominee Tribe of Indians v. United States, 391 U.S 404, 411-412, 88 S.Ct. 1705, 1710-1711 (1968). The Treaty also creates a federal trust responsibility under which the federal government maintains an affirmative obligation to safeguard the subject matter of federal treaties. Thus, federal agencies must use their authorities in a manner that will protect and enhance-- not degrade -- the fish species that underlie treaty fishing rights. Further, [i]n carrying out its fiduciary duty, it is the government's, and subsequently the Corps', responsibility to ensure that Indian treaty rights are given full effect. NW Seafarms v. US Army Corps, 931 F.Supp. 1515, 1520 (W.D.Wash. 1996), citing, Seminole Nation v. United States, 316 U.S. 286, 296-97, 62 S. Ct. 1049, 1054-55, 86 L. Ed. 1480, 86 L. Ed. 1777 (1942) (finding that the United States owes the highest fiduciary duty to protect Indian contract rights as embodied by treaties). This duty does not cease once a fish run becomes viable. Tribal members must be allowed to achieve their enjoy the "same level of exclusive use and exploitation" they had at the time the treaty was signed. United States v. Adair, 723 F.2d 1394 (9th Cir. 1984) cert. denied, 467 U.S. 1252 (1984). In short, the Tribe has an absolute right to a fair share of the fish destined to pass tribal fishing places. U.S. v. Oregon (Sohappy v. Smith), 302 F. Supp. 899 911 (D.Or. 1969). These fish include those artificially propagated for rebuilding, mitigation and enhancement purposes. United States v. Washington, 759 F.2d 1353 (9th Cir. 1985)(en banc) (holding that hatcheryreared fish are fish within meaning of treaty fishing clause and subject to allocation thereunder). The harvest rights and federal fiduciary obligations properly cabin any consideration of the Treaty right to harvest to the environmental baseline. Including Treaty harvest in the baseline is consistent with the purpose of the CRSO EIS, which is to examine different hydrosystem operation configurations. All alternatives studied in the CRSO EIS should have been analyzed for their effect on Columbia River fisheries and their ability to contribute to the recovery of stocks to harvestable levels that support tribal fisheries and communities.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6899	1	Kari Kostka	The Nature Conservancy of Idaho	TNC supports improvements to anadromous fish passage and survival on Columbia mainstem rivers. Actions identified in the Preferred Alternative, however, are likely not aggressive enough to keep ESA-listed fish stocks from near-term extinction. Moreover, TNC recognizes the alternatives in the DEIS were developed prior to the implementation of flex spill agreement in 2018 and the development of the fish operations plan for 2019. These efforts have led to new information regarding spill for juvenile fish passage and potential benefits to downstream migration. TNC supports these types of efforts to improve fish passage and other survival benefits through the hydro system and continued study of various strategies for long-term benefit.	The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waivers had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. That result, however depends upon the latent mortality hypothesis central to the CSS model being correct. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
6899	2	Kari Kostka	The Nature Conservancy of Idaho	Integrating the array of actions necessary to restore abundant anadromous fish populations requires coordinated effort across the entire CRS. TNC believes the DEIS and Preferred Alternative falls short in comprehensively addressing impacts to anadromous fish in the following ways: 1. The DEIS does not include an analysis of the watershed upstream of Hells Canyon Dam and the ecological linkages and aspects of water use and impacts to fish survival downstream. Understanding and recognizing current conditions, how water is used, and identifying opportunities to improve uses and water	The operation, maintenance, and configuration of the 14 dams in the CRS were analyzed in this EIS because they are operated as one system for multiple purposes. The dams not included are operated by others or operated independent of the CRS, so the effects related to these dams are outside of the scope of this EIS. Upper Columbia operations were consistent among the alternatives.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				quality to benefit conditions throughout the Snake River system and downstream is critical to the overall CRS; 2. The Preferred Alternative does not go far enough identifying actions to substantially move toward NOAAs Recovery Level goals for anadromous fish (and may regress if latent mortality effects are not reduced); and 3. The Preferred Alternative does not provide guidance and provisions to take more aggressive action, such as analyzed in MO3 and MO4, if fish populations continue to decline.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their designated critical habitats. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Furthermore, the NMFS Northwest Fisheries Science Center recently identified a mechanism for latent mortality related to how bypasses on the Columbia select for smaller downstream migrants with an overall lower chance of survival at sea. The survival estimates for those fish represent a non-random sampling that is a function of the configuration of structures at dam, not a realized deleterious impact that is expressed at later life stages due to passage through a dam (see Faulkner, J. R., Bellerud, B. L., Widener, D. L., & Zabel, R. W. (2019). Associations among Fish Length, Dam Passage History, and Survival to Adulthood in Two At-Risk Species of Pacific Salmon. Transactions of the American Fisheries Society, 148(6), 1069-1087.). The Corps relies on a comprehensive evaluation of the Preferred Alternative by NOAA in order to determine if and when additional actions are required to avoid jeopardy of the species, and does include an Adaptive Management Framework, and rigorous monitoring program to proactively react to SAR and abundance into the future.
6899	3	Kari Kostka	The Nature Conservancy of Idaho	To achieve lasting stability in the region and to maintain viable, abundant populations of anadromous fish, CRS federal managers must continue to work with stakeholders to implement new strategies in the coming decade (near-term strategies) while determining a path forward to manage the CRSO over the long-term (10+ years). Near-Term Strategies Include: Implement permanent land and water protection projects that catalyze restoration activity in CRS basins by completing biologically significant projects supporting anadromous fish recovery objectives. Ensure prioritization processes for tributary habitat restoration and protection efforts are in place to select the best possible projects. Ensure funding from mitigation programs is applied to projects with high return on investment. Support coordination among states, tribes, and communities across the CRS to identify actions and investments needed to recover abundant anadromous fish populations, honor and protect tribal needs and cultural identity, and strengthen the energy and food production services the region depends on. Long-Term Strategy: To successfully restore abundant anadromous fish populations while balancing needs across the CRS, the region needs to come together to comprehensively identify the actions and investments required. In addition to continued efforts to implement near-term solutions, a well-designed regional strategic vision and plan that moves all interests forward together, while underscoring the importance of tribal and treaty obligations, is the best way to solve such interconnected challenges. This includes continuing to discuss and consider the more aggressive fish survival benefitting actions described in MO3 and MO4 as new information becomes available. We need to work toward fundamentally changing the investment paradigm of public and private partners and improve coordination among management entities from headwaters to the sea.	The co-lead agencies look forward to further opportunities to work with stakeholders to advance common near- and long-term objectives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery as compared to the No Action Alternative. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Finally, the Preferred Alternative carries forward habitat restoration actions.
6903	1	Ben Enticknap	Oceana	As recognized in the Council on Environmental Quality regulations, [a]ccurate scientific analysis, expert agency comments, and public scrutiny are essential to implementing NEPA.2 We find the DEISs consideration of impacts on Southern Resident orcas insufficient and request the Action Agencies consider the best available science regarding Columbia Basin Chinook salmon and endangered orcas in the DEIS. 1 40 C.F.R. 1500.1(c). 2 Id. at 1500.1(b). April 13, 2020 CRSO DRAFT EIS Page 2 of 6 For Southern Resident orcas, the close connection between salmon and dependent wildlife could not be clearer or more pressing. Perhaps the single greatest change in food availability for Southern Resident orcas has been the decline of Chinook salmon in the Columbia River basin (NMFS 2008). Rebuilding Chinook populations in the Columbia-Snake system is a critical need for the recovery of these orcas. This distinct orca population has relied on Columbia basin Chinook for thousands of years, but the orcas are now dangerously nearing extinction just as many Chinook populations are threatened with extinction and not meeting recovery goals. In November 2005, NOAAs National Marine Fisheries Service issued a final rule listing Southern Resident killer whales as endangered (70 Fed. Reg. 69,903 (November 18, 2005)). Primary threats to the orcas recovery include reductions in the quantity or quality of prey (principally Chinook salmon), contaminants, and sound and disturbance from vessel traffic. As of January 24, 2020, with the disappearance of L41, there are now only 72 Southern Resident orcas in the population (figure 1). The Southern Resident orca recovery goal of an annual average 2.3% growth rate over 28 years is not being met. To meet Southern Resident orca recovery goals and prey requirements, Chinook abundance needs to increase by at least 75 percent (Williams et al. 2011). Southern Resident orca births and deaths are closely linked with coastwide Chinook abundance. Diet studies show that 99% of their diet is salmonids, with roughly 80% being the largest and fattiest of fish, the Chinook (Ford et al. 2016). With lower Chinook abundance, Southern Resident orca fecundity decreases and mortality increases (Ward et al. 2009, Ford et al. 2010). Recent low Chinook salmon returns have been perilous for the Southern Residents. There were no successful Southern Resident orca births from 2016 to 2018 and half of the ten orcas born in the 2014-15 baby boom later died. Some orcas have visibly starved to death. In 2018, 3-year old Scarlet, or J50, died after she became so emaciated that she lost the fat at the base of her head - what scientists call "peanut head. [Text contains figure that does not transition to database.] Figure 1. Number of Southern Resident killer whales, 1990 to January 2020. Center for Whale Research. April 13, 2020 CRSO DRAFT EIS Page 3 of 6 Columbia River basin Chinook including Lower Columbia Springs, Lower Columbia Fall, Snake River Spring, Snake River Fall, Middle and Upper Columbia Spring, and Middle and Upper Columbia Summer Chinook are considered among the priority Chinook stocks for increasing abundance to help Southern Resident orca recovery (NOAA and WDFW 2018). The science confirms Southern Residents feed on Columbia River basin Chinook, often in late winter and early spring months when they are foraging near the mouth of the Columbia River. Analysis of fish scales and Southern Resident fecal samples collected on the outer coast indicate that Chinook are the primary species consumed and that over half the Chinook consumed by the Southern Residents are from the Columbia River basin (NMFS 2019).	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.
6903	2	Ben Enticknap	Oceana	In the face of persistent threats to salmon and orca recovery, we support the removal of the lower Snake River dams with increased spill to 125% TDG at the remaining hydro projects in the middle Columbia river. While significant, this proposed approach is not new, and it is grounded in science. It is based on available scientific information which affirms that dam breaching is the most probable option for achieving Snake River Chinook rebuilding goals and recovery. Increased spill and lower Snake River dam removal should occur in concert with other actions such as reintroduction of Chinook above the Hells Canyon dam complex on the Snake River and above the Chief Joseph and Grand Coulee dams on the Columbia. Dam removal should also be done without sudden changes to hatchery production, which should continue to augment wild salmon runs until the historic impacts of the dams has been mitigated. There is likely also tremendous restoration potential in the Columbia River Basin by increasing passage above currently blocked areas and providing salmon access to high quality habitat in the upper reaches of the basin. In its 2017 and 2019 Comparative Survival Study (CSS) Annual Reports, the Fish Passage Center evaluated the effects of various levels of spring spill, as well as removal of the four lower Snake River dams on smolt-to-adult return rates (SARs) for Snake River spring/summer Chinook (McCann et al. 2017, McCann et al. 2019). Using more than twenty years of empirical data on dam passage survival and SARs, the CSS Reports conclude that dam removal on the lower Snake River and spilling to 125% tailrace TDG limits at the remaining four middle Columbia River dams would result in Snake River Chinook SARs and return abundances four times higher than under 2014 BiOp spill levels (McCann et. al. 2019). In terms of an overall increase in adult Chinook, up to a million adult Spring Chinook could return to the mouth the Columbia with lower Snake River dam removal and spill at 125% TDG depending on variable ocean conditions (all runs, originating above Bonneville Dam, hatchery and wild) (figure 2). Modelling efforts consistently show removing the four lower Snake River dams and increasing spill would provide the greatest benefits to Chinook recovery. April 13, 2020 CRSO DRAFT EIS Page 4 of 6 Figure [Text contains figure that does no transfer to database.] Figure 2. Spring Chinook returns and expected spring Chinook returns to the mouth of the Columbia River under the 2014 federal Columbia River hydropower system spill management framework (BiOp) and under revised spill and Lower Snake River (LSR) dam breach management scenarios (Adapted from, M. DeHart 2018).	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed by the co-lead and cooperating agencies. The co-lead agencies used high quality data and the best available science in the analysis of the CRSO EIS. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict different outcomes, depending on assumptions used for decreased latent mortality. To address this uncertainty, the Preferred Alternative will be implemented using a robust monitoring plan.
6903	3	Ben Enticknap	Oceana	While comprehensive salmon recovery efforts are needed throughout the West Coast region, the Columbia River basin is critical to the regions orca recovery efforts. Historically the Columbia River basin produced 9 to 16 million salmon per year, including 3.54 million Chinook per year on average (CPB 2019). Todays runs are only a small fraction of their former abundance. The available science suggests lower Snake River dam removal and increased	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				spill would significantly advance salmon recovery goals toward healthy levels, which, in turn, will greatly benefit endangered orcas and other wildlife by increasing available prey. This action should be coupled with other actions including passage above blocked areas and habitat restoration. Ultimately, we need to see real, meaningful and comprehensive change throughout the Basin to benefit salmon, orcas and people. The DEIS fails to address these broader issues and the needs of the region such as a path forward for sustainable commerce, clean energy production, communities, fisheries, and the overall health of the ecosystem. Importantly, the DEIS fails to consider the best available science on the effects of CRSO operations on Southern Resident orcas.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.
6905	1	anjeet@nezperce.org	Nez Perce Tribe	I At this point, it is self-evident that NEPA's core public involvement and comment requirements will not have been met with a 45-day comment period, for a 7,000 page DEIS, during a public health crisis unprecedented in the history of NEPA itself, given the disruptive effects COVID-19 is having on nearly all members of the tribal public and general public.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6905	2	anjeet@nezperce.org	Nez Perce Tribe	On June 1 1, 1 855, at Pdasx'pa (Walla Walla, Washington), the Nez Perce Tribe (Tribe) reserved by Treaty, and the United States secured to the Tribe, rights that Nez Perce people have exercised since time immemorial, including the right to take fish at all usual and accustomed places, and the rights to hunt, gather, pasture, and travel (12 Stat. 957). These were not merely "rights." For the Nez Perce they were and are a guarantee of our ability to preserve our culture and identity that is inextricable linked to the reserved rights. These Treaty rights are the "supreme law of the land." (U.S. CoNsr., art.YI, cl.2).	The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS.
6905	4	anjeet@nezperce.org	Nez Perce Tribe	Physical manifestations of the Nez Perce relationship to the Land that are evident and have survived the cataclysmic transformation of the landscape include: camp/village sites, fishing stations, gathering areas, burials/cemeteries, legend/origin sites, sacred sites, ceremonial locations, wdeyekinlsupplication areas, petroglyph/pictograph sites, etc. These sites and many others, are currently being impacted on an hourly basis by the CRS. From its beginning, the CRS grew dam by dam and increasingly overwhelmed and destroyed the Nez Perce relationship with the Land. Today for example, as salmon continue to be imperiled in the river that bears their name and throughout the rest of the Snake River basin, nearly no lamprey are found in the present-day town of Asotin on the Snake River that borrows its name from the Nimiipuutimt word for the place of eels or lamprey. And CRS impacts and injuries have become interconnected and compounded with other harms. Even now, as our people experience the COVID- I9 crisis, we know we are at a higher health risk, and that our health is not what our ancestors' was, precisely because we no longer have - no longer canhave under the present hydrosystem - the healthy diet ofour ancestors.	Many of the cumulative effects and past actions referenced in this comment are included in the affected environment (Chapter 3) and Cumulative Effects (Chapter 6) sections of this EIS. Additionally, the co-lead agencies explicitly acknowledge the magnitude of impacts to tribal culture, interests, and resources from development in the Columbia River basin. These acknowledgements and discussions are primarily contained in the Cultural Resources (3.16) and Tribal Perspectives (3.17) sections as well as the associated Appendix P which includes the perspectives as provided directly by the Tribes.
6905	5	anjeet@nezperce.org	Nez Perce Tribe	The Tribe is providing the attached "High Priority Concerns" with the DEIS. Several of the Tribe's concerns, including concerns about the alternatives and the environmental effects analyses that we have expressed repeatedly during this process, require foundational changes to the EIS. These are not mere "disagreements." They correlate to recognized NEPA legal flaws. We urge you to make these changes. Otherwise, the EIS will not withstand legal scrutiny and will simultaneously undermine meaningful discussions about implementing the actions that salmon, steelhead, and lamprey - and their ecosystems - need.	The co-lead agencies appreciate the Tribe's concerns, and have accordingly responded to each specific comment. The co-lead agencies disagree, however, that the analysis suffers from legal flaws or requires foundational changes. See response to Comment 6905-44.
6905	6	anjeet@nezperce.org	Nez Perce Tribe	The Publics Draft Participation And Comment Period During COVID-19 Public Health Crisis: As of this date, April 13, 2020, it is self-evident that NEPAs core public participation and comment requirements for a draft EIS will not have been met with a 45-day comment period, for a 7,000 page DEIS, during a public health crisis unprecedented in the history of NEPA itself, given the overlapping disruption of the COVID-19 crisis for nearly all members of the tribal public and general public. It is not too late for the action agencies to extend or suspend the public involvement period, and they should think very carefully about doing so. The way the agencies have treated public involvement during this draft comment period violates the spirit and purposes of NEPA public participation in ways that may well invalidate an EIS finalized from this DEIS. And as a matter of permanent legacy, an EIS finalized from this DEIS, after an obliterated public participation period during a historic public health crisis, may go down legal consequences aside as a dishonor to the agencies and the United States they represent.	See response to Comment 6905-1.
6905	7	anjeet@nezperce.org	Nez Perce Tribe	Chapter 1, Introduction:1 Section 1.3.1, Geographic and Temporal Scope (and affecting Chapter 3 throughout): o Geographic Scope is defined in Chapter 1 only as a reference to the general geography of 14 FCRPS projects. Section 1.3.1. A defined or presumptive EIS action or analysis area is not provided. This leaves particular analysis areas to be defined and employed in Chapter 3 resource by resource in arbitrary, inconsistent ways that appear manipulated for each resource so as to optimize analysis outcomes and conclusions that were pre-desired for those resources. Two examples of the consequences of arbitrary, inconsistent effects analysis areas (see Chapter 3 comments below for others): o Section 3.17.1, Indian Trust Assets: An arbitrarily narrow Indian Trust Asset (ITA) analysis area, 1-mile adjacent to project reservoir edges only, is used for the 19 Indian tribes affected by the FCRPS. This results in a conclusion that almost no ITAs are even present in the study area; then no analysis is described or conducted; and a single-sentence conclusory statement is made that, for ITAs for the 19 Indian tribes, No direct or indirect effects to ITAs were identified for any of the alternatives. And insult to injury, Chapter 6 Cumulative Effects then circularly exempts the ITA resources from any cumulative effects consideration -- when in fact the cumulative adverse effects of the CRS for over 80 years have been more devastating for Indian tribes and Indian people than any other group because no effects were found in Chapter 3. o Section 3.18, Environmental Justice: Suddenly an arbitrarily enormous 7-Western-state EIS analysis area is employed, including 139 Western counties across those states, and finding the broadest possible non-Indian Environmental Justice effects with respect not to environmental quality but to (purportedly) power rates across that expanded Western geography. This expanded analysis area conveniently marginalizes the Environmental Justice effects of the CRS on the Indian tribes and other people directly affected, historically and presently, by the location and operation of the dams and reservoirs.	The co-lead agencies selected the size of the study area based on where the effects from the proposed structural and operational measures are expected to occur. This study area is sufficient for the agencies to understand the effects of the different alternatives and to enable the agencies to make an informed evaluation of the alternatives. The co-lead agencies focused on the locations where there were understandable direct effects, as opposed to third and fourth order effects, which are harder to predict, and thus evaluate, as a part of the NEPA process. The co-lead agencies have analyzed ITAs consistent with applicable statutes, regulations, and guidance. Neither the rights of fishing, hunting, and gathering, nor the resources subject to those rights, are "assets held by the federal government" within the meaning the Interior Department Manual, 303 DM 2.5(c). As a result, the co-lead agencies do not consider the rights or resources to be ITAs. The agencies' analysis nevertheless considers effects to the resources subject to the Tribe's rights, as well as the cumulative effects to those rights as a result of effects to underlying resources.
6905	8	anjeet@nezperce.org	Nez Perce Tribe	Section 1.6.2, Resource Concerns: o The Resource Concerns list in this section appears to represent a misunderstanding or mischaracterization of the purposes of NEPA and an EIS, and the nature of the Human Environment that is to be considered under NEPA and CEQ regulations as distinct from 1 The DEIS Executive Summary (ES), in its entirety, misleads the public and decision-makers both as to the impacts of the CRS and as to the (defective) contents of the DEIS. As but two examples, the ES contains no mention or description of reservoir passage survival, instead emphasizing 96% dam passage survival at the eight federal projects on the mainstem Columbia and lower Snake River (and does not explain that this equates to a 28% cumulative mortality rate). And, while the ES states that it is important that tribal perspectives have a prominent place in this document as well as in the management of the CRS (ES at 12), the DEIS does not actually analyze the effects of the action alternatives on tribal perspective information and concerns, including Treaty rights (repeatedly and recently affirmed by the United States Supreme Court), the federal Trust responsibility, etc. 3 the project purposes of the CRS and the agencies non-NEPA considerations of those project purposes, or a mere public popularity list of resources which may or may not align with the Human Environment that is the proper statutory and regulatory purpose of NEPA. The original, and current, purposes of NEPA are fundamental: The purposes of this Act are: To declare a national policy which will encourage productive and enjoyable harmony between man and his environment; to promote efforts which will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of man; to enrich the understanding of the ecological systems and natural resources important to the Nation; and to establish a Council on Environmental Quality. 42 U.S.C. 4321. The term Human Environment as defined in CEQ regulations, after introduction and use in the NEPA statute, is first and foremost, the natural and physical environment and the relationship of people with that environment. 40 C.F.R. 1508.14. Economic and social effects are only considered when they are interrelated with natural or physical environmental effects. Id. Alone they do not trigger NEPA. Id. And even	Regarding reservoir passage survival, the metric "dam survival rate" is an empirical estimate (or modeled based on empirical data) of the survival rate of a specific group of fish from the immediate forebay through the structures and tailrace, or the inverse of the mortality rate induced by passing through the immediate forebay, structures, and tailrace. It is the most sensitive metric for assessing effects of operations or configuration of a dam and, therefore, is frequently used. When first mentioned at line 7247 on page 3-301 in the Draft EIS, in the Affected Environment section, it is presented clearly as just at-dam survival and not including system or latent mortality. The next section discusses reach survival rates, which do include all mortality from passing the dams, the reservoirs and any other source. Further, the No Action Alternative refers to recent survival rates for discussion purposes; with survival rates through these routes ranging from 97 to 99% (Ploskey et al 2012) on page 3-369 of the Draft EIS. Recent actual reach survivals (incorporating all sources of mortality) are also presented for context in each ESU/DPS in the No Action Alternative, Section 3.5.3.3. However, the juvenile metrics used to evaluate alternatives compared to the No Action Alternative and to one another in the Environmental Consequences chapter were all modeled reach-specific (either from Lower Granite to Bonneville dams, or from McNary to Bonneville dams, depending on ESU/DPS) and included juvenile reach survival, travel time, proportion destined for transport, and powerhouse passage events, as well as discussion of Total Dissolved Gas (TDG) exposure. See Section 3.5.3.1 Methodology for more information, and specifically the list of indicators and primary metrics on page 3-359, in the Draft EIS. See also results for each ESU/DPS for each alternative. Additionally the EIS properly analyzes impacts to power generation and transmission since changes in operations affect generation (i.e. a direct effect) and changes in power generation and transmission could affect the natural environment leading to indirect effects (e.g. reservoir elevation changes potentially causing erosion; changes in generation resulting in building renewable resources). Changes in CRS generation may also affect decisions made by other energy producers leading to cumulative effects on affected resources (e.g. changes to Mid-Columbia project generation). Thus, the EIS properly considers the direct, indirect and cumulative effects to power generation and transmission in Chapters 3, 6 and 7. Regarding Tribal perspectives, the co-lead agencies invited a number of entities (including Tribes, states, and local agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River System.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				when economic effects are properly considered in a NEPA analysis, as they are here, it is only because of their interrelation with the natural and physical environment which is the heart of NEPA. The point here is that the DEIS appears to reveal, in Section 1.6.2, as in Section 1.2, Purpose and Need, and then as a consequence in several of the environmental resources of Chapter 3, a misunderstanding of the purpose of NEPA and the need for this specific EIS. This EIS should not be in fact driven by a presumed need to consider the effects of various action alternatives on FCRPS project purposes such as, for example, Power Generation and Transmission. Power effects are secondary they can and should be considered here only in their role as a type of economic and social effect that is related to the effects of the action alternatives on the natural and physical environment that is the purpose of NEPA and an EIS. This DEIS does not explain or reflect that understanding and appears in fact to invert the purposes for which EIS analyses are properly conducted, and therefore reaches conclusions that have been driven by an inverted understanding of the actual ecological purposes of NEPA and the proper purpose of a NEPA EIS.	
6905	9	anjeet@nezperce.org	Nez Perce Tribe	Biased content throughout: Language and content of the DEIS is arbitrarily power-centric (including analyses that highlight adverse outcomes for power and do not highlight adverse outcomes for fish), biased against fish, biased against tribal interests, biased against fishingdependent economies that are important economic drivers of rural communities, and biased against the Comparative Smolt Survival (CSS) modeling. o Major revisions are needed to balance the level of detail across resource areas and to evaluate effects findings (including weighting for context and intensity) relative to EIS standardized categories of no, negligible, minor, moderate, and major effect.	The co-lead agencies used high-quality information to analyze the effects of the Multiple Objective alternatives on the human environment and, therefore, disagree that the analysis is biased. Section 3.1 describes how the effects determinations in the EIS relate to the context and intensity factors in the Council on Environmental Quality's NEPA regulations. The Comparative Survival Study model was run by the Fish Passage Center; and the COMPASS and Life Cycle models were run by NMFS's Northwest Fisheries Science Center for the co-lead agencies. Different models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5.
6905	10	anjeet@nezperce.org	Nez Perce Tribe	Dworshak Dam and Reservoir information is incomplete throughout: DEIS descriptions of Dworshak Dam do not mention that the dam blocked and provides no anadromous fish passage. Descriptions of other CRS dams recite numbers of fish ladders, while the Dworshak Dam 4 description remains silent on the lack of fish passage.	Section 1.9.7.2 p. 1-41 states that "Dworshak Dam blocks upsteam migration on the North Fork of the Clearwater River." Table 1.2 indicates Dworshak does not include fish passage.
6905	11	anjeet@nezperce.org	Nez Perce Tribe	Also, the DEIS does not describe or consider the location of Dworshak Dam on Nez Perce tribal trust land.	The Final EIS will acknowledge the DOI Solicitor's January 16, 2016 Opinion regarding "Status of the Bed of the Clearwater River within the 1863 Treaty Boundaries of the Nez Perce Reservation," which concluded the bed of the Clearwater River within the boundaries of the NPT Reservation is held in trust by the United States for the benefit of the NPT. However, title to the lands encompassing the bed of the Clearwater River within the boundaries of NPT Reservation are not identified in the BIA records as trust lands and are, therefore, not considered as an ITA in the EIS.
6905	12	anjeet@nezperce.org	Nez Perce Tribe	Chapter 2, Alternatives: The DEIS fails to evaluate all reasonable alternatives. As encapsulated by Judge Simon: One of the benefits of a comprehensive environmental impact statement, which requires that all reasonable alternatives be analyzed and evaluated, is that it may be able to break through any logjam that simply maintains the precarious status quo. A comprehensive environmental impact statement may allow, even encourage, new and innovative solutions be developed, discussed, and considered. The federal agencies, the public, and our public officials then will be in a better position to evaluate the costs and benefits of various alternatives and to make important decisions. The Federal Columbia River Power System remains a system that cries out for a new approach and for new thinking if wild Pacific salmon and steelhead, which have been in these waters since well before the arrival of homo sapiens, are to have any reasonable chance of surviving their encounter with modern man. Perhaps following the processes that Congress has established both in the National Environmental Policy Act and in the Endangered Species Act finally may illuminate a path that will bring these endangered and threatened species out of peril. Natl Wildlife Fedn v. Natl Marine Fisheries Serv., 184 F. Supp. 3d 861, 876 (D. Or. 2016). All reasonable alternatives, against this backdrop for this EIS, must include alternatives that maximize benefits for salmon, steelhead, and Pacific lamprey. The two primary CRS actions colloquially referred to as the big swings for fish are readily identified as breaching the four lower Snake River dams or providing maximum spill at the CRS dams. Because of the shorthand used for MO3 (breach alternative) and MO4 (high spill alternative), at first glance it might seem that the DEIS included alternatives for evaluation that maximize benefits for fish. In fact, no alternative in the DEIS maximizes benefits for fish. And, both the MO3 and MO4 alternatives are constructed to neutralize or undermine the benefits for fish associated with breaching the four lower Snake River dams or maximizing spill at the CRS dams. For example, among other things, MO3 caps spill at the (remaining) four lower Columbia River projects, and without an explicit description within the alternative itself immediately terminates hatchery production at the Snake River basin hatcheries collectively referred to as the LSRCP hatcheries, that provide important fishing opportunities to non-Indians and tribes and represent a significant economic driver for rural communities.2 Nor does MO4 maximize fish benefits; rather it identifies a high 2 MO3 itself does not set forth immediate termination of the hatcheries that are collectively referred to as the Lower Snake River Compensation Plan (LSRCP). Instead, the DEIS introduces this in the NAA: LSRCP would be continued, consistent with the No Action Alternative, under all of the Multiple Objective Alternatives except for MO3. (2-37). The subsequent rationalization, set forth in the effects analysis, is Upon the breaching of the LSR dams, Bonneville would no longer have an obligation to fund US Fish and Wildlife Service for the operations and maintenance of the LSRCP facilities. Bonnevilles funding authority is directly tied to the operation of the LSR dams. 3-548; 3-753; see also 3-831; 3-913; 3-1466; 6-48 (incorrectly stating These fish account for 80 to 90 percent of all juvenile Snake River fish passing CRS projects. The actual percentage is around 65%). 5 spill alternative that is applied before and after the spring migration period and adds (costly, power-centric) actions, for example, powerhouse surface passage structures in the lower Columbia and increased water diversion from the upper Columbia. Bottom line: the alternatives in the DEIS do not comply with NEPAs requirements or the opportunity identified in the Courts ruling in Natl Wildlife Fedn. v. Natl Marine Fisheries Serv.	As stated in Chapter 2, the co-lead agencies developed alternatives to meet the objectives and the Purpose and Need. Certain alternatives and measures were designed to emphasize one particular aspect of the Columbia River System, while still meeting the Purpose and Need Statement and objectives. The Purpose and Need Statement includes the need for action as well as the resource and legal and institutional purposes. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Regarding hatchery production under MO3, Bonneville directly funds the U.S. Fish and Wildlife Services annual operations and maintenance of the Lower Snake River Compensation Plan (LSRCP). Congress authorized the LSRCP as part of the Water Resources Development Act of 1976 (90 Stat. 2917) to offset fish and wildlife losses caused by construction and operation of the four lower Snake River dams. A major component of the authorized plan was the design and construction of fish hatcheries and satellite facilities. The LSRCP is administered through the USFWS. The LSRCP hatcheries and satellite facilities produce and release more than 19 million salmon, steelhead and rainbow trout each year as part of the programs mitigation responsibility. Upon the breaching of the lower Snake River dams as analyzed in MO3, Bonneville would no longer have an obligation to fund US Fish and Wildlife Service for the operations and maintenance of the LSRCP facilities. Bonneville's funding authority is directly tied to the operation of the LSR dams. The co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. The co-lead agencies, note as well that there are other hatcheries in the Snake River basin that would continue to produce fish not tied to LSRCP. Bonneville would continue to fund the LSRCP under all of the other alternatives, including the Preferred Alternative. The co-lead agencies disagree MO4 is constructed to neutralize or undermine the benefits for fish associated with maximizing spill at the CRS dams. The co-lead agencies proposed this alternative as bookend to determine potential benefits to anadromous from maximized spill and flow levels. MO4 resulted in potential substantial improvements to anadromous fish.
6905	13	anjeet@nezperce.org	Nez Perce Tribe	The precise combination of actions (referred to in the DEIS as measures) that make up each of the four MO alternatives are the basis for the subsequent effects analysis conducted at the alternative level. This approach has precluded an understanding, analysis, and meaningful comparison of component actions effectiveness and cost.4 This does not allow for refinement of MO alternatives or the development of a new alternative without a full and complete environmental effects analysis at the alternative level.	The development of the MO alternatives was informed by preliminary analysis of Single Objective alternatives as well as additional analysis conducted on the MOs. Cost estimates were prepared for each of the measures; thus, allowing for comparison among the alternatives and to the No Action Alternative. Whether or not a refinement of a new alternative would trigger additional environmental effects analysis would hinge on whether the existing effects analysis captured the effects of the refinement. The co-lead agencies agree that if a new alternative is developed, it would need likely need additional environmental effects analysis.
6905	14	anjeet@nezperce.org	Nez Perce Tribe	Incomplete Description of Alternatives: o The DEIS does not completely and accurately describe the no action alternative (NAA), which the DEIS uses as a baseline condition for comparing the environmental effects of the MO alternatives and for identifying cumulative effects. The NAA does not disclose the legal inadequacy of operation and the biological deficit situation that operation has imposed on salmon, steelhead, and lamprey as reflected in their imperiled status. Put simply, the NAA represents in large part a system operation that was invalidated under the ESA in federal court in 2016. For example, the NAA does not identify measures that are occurring (e.g., the Northwest Power Acts Fish and Wildlife Program, protective measures for Pacific lamprey), the status of implementation of these measures, the status of funding necessary to implement these measures (e.g., measures that have been identified but This rationale is deceptive and incorrect as a matter of law as it does not acknowledge that only Congress is and would be responsible for decisions associated with the continuation of the important benefits that these hatcheries provide for non-Indian and tribal fisheries, and the benefits these fisheries provide to rural economies. This unsupported assertion of an immediate cessation of the LSRCP hatcheries is also incorrect given that the adverse effects of the impacts of the lower Snake River dams accumulating in total over nearly 60 years will continue to occur for a significant period of time after the dams are breached. No rational breach plan would conceivably terminate a system mitigating fish hatcheries immediately upon breach. 3 The NEPA problems with the alternatives and their subsequent evaluation are independent from the process used to produce them (such as concerns that alternative development was guided by objectives to merely improve fish performance and conditions; objectives that are inaccurate (carbon-free as opposed to low carbon), etc. 4 The Fish and Wildlife Managers matrix of measures, provided in the Cooperating Agency process but not used in the DIES, demonstrated the benefits of conducting an analysis that allows for a meaningful comparison of the effectiveness of actions (measures). 6 have not been implemented because of a lack of funding). (As noted below, these concerns with the NAA are not addressed in Chapter 5 as a matter of mitigation.) For example, the NAA states that Specific operations for fish and wildlife are designated in the following paragraphs and would continue as described under the No Action Alternative, yet the sections entitled Measures Previously Committed to by the Co-Lead Agencies to Benefit Endangered Species Act-Listed Fish and Bonnevilles Fish and Wildlife Program and Direct Funding Agreements with the Corps and Reclamation (and habitat actions and hatchery actions subsections) are vague, opaque, and entirely devoid of detail (2-29 to 2-34). For example, the NAA does not disclose the decrease in the level of funding for the Fish and Wildlife Program that has occurred since 2016, nor identify and confirm the level of commitment to funding for future years. For example, the NAA contains a vague, indecipherable reference to hatchery mitigation (2-31). The NAA does not identify hatchery mitigation commitments in addition to the Fish and Wildlife Program, that Congress authorized to mitigate for dams that are part of the CRS, such as Grand Coulee Fish Mitigation, Dworshak Mitigation, John Day Mitigation. (Nor are these identified as a matter	The co-lead agencies developed the No Action Alternative consistent with regulations implementing NEPA, which allow agencies to use the "status quo" from the time of the Notice of Intent to Prepare the EIS. Funding decisions for the Fish and Wildlife Program are not being made as a part of the CRSO EIS process. However, a range of potential Fish and Wildlife Program costs are included to inform the broader cost analysis for each alternative in the EIS. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments to the Fish and Wildlife Program would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. As discussed in section 7.7.21.1, in 2016, Bonneville's F&W Program budget was $267,000,000, and the Lower Snake River Compensation Plan (LSRCP) budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17%, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative. In the case of MO3, for example, Bonneville included a range of potential Fish and Wildlife Program costs to acknowledge the possibility that the alternatives could provide biological benefits to anadromous fish species and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville Fish and Wildlife Program. For MO3, Bonneville's Fish and Wildlife Program costs are estimated to range from no change from No Action Alternative to a decrease of approximately 37 percent, or approximately $105 million, annually (see section 3.19.2). With respect to anadromous fish, the Northwest Power Act calls for improved survival at the dams and flows of sufficient quality and quantity . . . to improve [their] production, migration, and survival. The co-lead agencies demonstrate throughout the EIS how they meet these statutory objectives. The Columbia River Basin Fish Accord Extensions (Fish Accords) and Bonneville's comments to the Council on its 2020 amendment process also highlight the actions the Agencies have taken to fulfill this anadromous fish mandates of the Act.1/ Under MO3, operational, structural and mitigation measures would substantially benefit anadromous fish. This would allow, if not necessitate, reductions in off-site mitigation funding. The funding decrease modeled in MO3 results because significantly more mitigation will be provided on-site at the dams, thus reducing the need for off-site mitigation; and the power purpose at the lower Snake River dams is eliminated under MO3 when four dams are breached. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Section 3.19 of the FEIS discusses these effects. Upon the breaching of the LSR dams, Bonneville would no longer have an obligation to fund US Fish and Wildlife Service for the operations and maintenance of the LSRCP facilities. Bonneville's funding authority is directly tied to the operation of the LSR dams. The co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, tribal, and federal entities, would be reviewed and potentially adjusted. The comment asserts inadequate analysis in the EIS as to the efficacy of mitigation funded through Bonneville's Fish and Wildlife Program. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. The fish and wildlife mitigation projects that Bonneville funds have been recommended by the Northwest Power and Conservation Council (Council) and either derive from, or have been incorporated into, the Councils Columbia River Basin Fish and Wildlife Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria such as benefits to fish and wildlife. 16 U.S.C.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				of mitigation in Chapter 5). These programs produce almost 30 million juvenile salmon and steelhead annually about of the hatchery fish produced above Bonneville Dam. For example, the NAA does not reveal that adult spring and summer Chinook salmon returns have never met their compensation goals under the existing Lower Snake River Compensation Plan. [Text contains figure that does not transfer to database.] For example, the NAA does not disclose measures occurring for Pacific lamprey, and does not disclose that measures identified for lamprey have not been implemented because they have not been adequately funded. For example, the NAA does not disclose that while hundreds of millions of dollars are annually spent upgrading the CRS dams ($238 million in capital infrastructure at CRS dams in 2020 alone is identified by BPA in the 2018 Integrated Program Review Close Out Report, of which $40.5 million is allocated to the four lower Snake River dams), and which is expected to increase to $340 million in 2029), $0 (zero) dollars are identified for capital hatchery upgrades (and the large and ballooning costs of deferred maintenance) at federally funded hatchery facilities that mitigate for federal CRS dams. (For private dams, like the mid-Columbia PUD dams or Idaho Power Company dams, mitigation hatchery upgrades, repair and maintenance are a requirement of their FERC operating licenses). For example, the NAAs mention of habitat actions consists of two brief paragraphs which are vague and devoid of detail, precluding any meaningful understanding of the actions and level of effort that is being evaluated in the NAA. There is no acknowledgement that these habitat actions are part of the federal agencies approach to filling existing gaps for ESA species. There is no acknowledgement of the law of the case in Natl Wildlife Fedn v. Natl Marine Fisheries Service governing habitat actions, including requirements that such actions must be reasonably certain to occur. Further, there is no acknowledgment and differentiation between actions necessary to address existing conditions and actions necessary to address climate change.	839b(h)(10)(D(iv). And for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Fish and Wildlife Program. See responses to Comments 31775-51, 6894-56, and 6894-49. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. Finally, the commenter conflates what is required under ESA for reasonable and prudent actions with what is required under NEPA for mitigation. Chapters 2, 5 and 7 discuss existing and proposed additional mitigation whiles Chapters 4 and 7 discuss the climate effects of the various alternatives.
6905	15	anjeet@nezperce.org	Nez Perce Tribe	The MOs include measures for Pacific lamprey, without disclosing that these measures have long been identified (see, e.g., Pacific Lamprey Conservation Agreements) but have not been implemented because of a lack of funding, and do not identify a commitment to the funding necessary to implement these measures. Any additional certainty resulting from a multiyear funding commitment does not address the reality that there is no increase or additional funding.	Federal funding for any measure included in an alternative is dependent upon fiscal appropriation from Congress and is not guaranteed, or in the case of Bonneville, availability of ratepayer funding. The Co-lead agencies can request finding to implement the Preferred Alternative and the measures identified within it. The co-lead agencies will designate the Preferred Alternative and adopt appropriate mitigation in their Record of Decision.
6905	16	anjeet@nezperce.org	Nez Perce Tribe	Chapter 3, Affected Environment and Environmental Consequences: Section 3.1, Introduction and Background: o The time scale for analysis is variable: It is 25 years for some aspects, and 50 years for other aspects. See 3-1. It is unclear how the time scale is employed and how it impacts/informs affected environment modeling and analyses. Fish analysis does not specify time frame, identify duration of impacts on fish or realization of benefits for fish.	The time frame associated with the CRSO EIS analysis was dependent on the level of confidence each modeling team had in long range predictive capability of their data sets. As noted in the comment, that time frame typically varied from 25 to 50 years depending on the resource are being analyzed. The temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives (with the exception of the socioeconomic-related resource analysis - 50 years). Economic effects are longer to capture the annualized costs of long investments, such as construction, and maintenance costs. While many of the effects associated with the preferred alternative are expected to accrue over time, the co-lead agencies also worked with National Marine Fisheries Service and US Fish and Wildlife Service to have consistent analysis frameworks as they developed the Biological Opinions that are included as Appendix V.
6905	17	anjeet@nezperce.org	Nez Perce Tribe	Considerations of Context and Intensity (page 3-3): Never applied to fish and tribal resources in determining the significance of effects on those resources, as required under the NEPA CEQ regulatory definition of Significantly. The DEIS states statements of significance are supported by text describing the context and intensity of the impact, however this is lacking in the actual resource effects sections. All nine factors described (3- 3) have some relation to fish and/or tribal communities; yet, the DEIS does not in fact consider the context and intensity the severity of impacts to precisely these resources.	The co-lead agencies' analysis of current conditions includes the ongoing effects of the existence of the system, and a host of other factors influencing natural and cultural resources of Indian Tribes. The focus of the EIS is system operations, not the construction of the system. To the extent the analysis considers the existence of any system projects, e.g., breach, the effects analysis nevertheless captures the cumulative effects of Congress's decision to construct the projects and, thus, project existence. Regarding intensity, the co-lead agencies respectfully disagree. The co-lead agencies used high-quality information in their analysis and made sure to identify and describe effects to Tribal interests. See Section 3.17.2, which provides Tribal perspective summaries, and Section 3.17.3, which provides a review of Tribal interests. This is in addition to consideration of Tribal perspective contributions provided by many of the 19 involved Tribes. The Federal agencies factored in this information in their evaluation of the alternatives. The intensity, or potential level of effect, on any resource analyzed across the suite of alternatives is characterized on page 3-3 of the Draft EIS. The characterization of effects for any resource with a Tribal interest nexus is disclosed throughout the EIS, including in the fish analysis sections. Finally, tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
6905	18	anjeet@nezperce.org	Nez Perce Tribe	Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish: o Some data reported in DEIS tables is inconsistent with the CSS cohort-specific model predicted SARs and juvenile travel times for MO3. The SARs (CSS) data reported for MO3 in the DEIS (Table 3-89) does not match the SARs (CSS) results provided in the FPC April 29, 2019 memorandum or the FPC updated January 24, 2020 memorandum (that is substantially similar). In addition, Table 3-89 reports SARs (CSS) as LGR-LGR when similar tables for the other Alternatives present LGR-BON and the FPC reported SARs (CSS) as LGRBON. Juvenile travel time reported forMO3 in DEIS Table 3-88 is also inconsistent with FPC analysis (11.3 days depicted in the DEIS compared to 12.5 in both FPC memorandums). It appears the DEIS 11.3 day content may be a FPC generated wild fish only estimate. However, line 9781 in Chapter 3 states wild fish only estimates were not reported in Chapter 3, and these estimates were limited to Appendix E. o Effects analysis of each alternative in DEIS is modeled for a subset of populations in the Upper Columbia and Snake basins; DEIS does not apply the modeled population outcomes to all populations across the entire affected environment. o The DEIS Tables 3-68, 3-76, 3-83, 3-89, 3-97, and 7-25 report CSS LCM-based abundance as a single metric for the six populations that were modeled. That single number is generated by summing the six predicted abundance responses, the subsequent percent change from NAA reflects an aggregated response of the Grande Ronde/Imnaha MPG (does not include Lookingglass Creek) and is disproportionality influenced by the larger populations in the MPG. The DEIS acknowledges that COMPASS and CSS modeling of SARs and abundance is done on a subset of populations but states the percent change is considered indicative of the Snake River population [sic should be ESU] for the purpose of comparing between MOs. The variation between the six modeled populations is important (CCS LCM MO3 variation across the six populations is 108% to 197%). Accurate abundance response would base the abundance response on an average percent change of the six populations (144%), this would standardize for population size. The resulting abundance response for MO1 would be 6% vs 5% reported in the DEIS; MO2 would be 45% vs 43% reported in the DEIS; MO3 would be 144% vs. 103% reported in the DEIS; MO4 would be 108% vs 99%; and the PA would be 62% vs 58% reported in the DEIS. The MO3 difference in abundance response of 144% vs. 103% reported in the DEIS is significant. o Effects analyses on zero nighttime flows are not conducted. Current zero nighttime flow operations are implemented no earlier than December 1 and only after low adult steelhead abundance criteria are met. The Preferred Alternative proposes zero nighttime flows starting October 15. Analyses must cover impacts to adult migration (not only steelhead, but also fall Chinook and coho salmon) and juvenile migrants (fall Chinook).	Thank you - we did catch errors in Table 3-89 of Chapter 3, in which the SAR for Snake River Chinook had been inaccurately transcribed for MO3; this has been corrected and the reach for SAR has now been labeled. Also, travel time for MO3 in Table 3-88 has been corrected. The co-lead agencies will implement the zero generation operation in a manner that has negligible effects to any salmon or steelhead present in the river. Nighttime operations will end prior to daylight hours and allow attraction flow to fish ladders to aid passage for fish that are attempting to pass the projects. Daytime "zero-generation" operations will not be implemented until mid-December when juvenile and adult migration has largely ceased. These affects have been qualitative assessed by the co-lead agencies and will also be reviewed by NMFS and USFWS during the development of their respective Biological Opinions. The Biological Opinions will be appended to the FEIS.
6905	19	anjeet@nezperce.org	Nez Perce Tribe	Section 3.5.3.6, MO3 effects do not identify beneficial effects of breaching on adult fish migration for Snake River Spring/Summer-Run Chinook Salmon and Snake River Steelhead. (Compare Snake River Coho Salmon, Adult Fish Migration/Survival Long term effects of MO3 on Snake River adult coho would include a lower risk of delay, and fallback because four of the dams would be breached.)	The Fish Technical team are not aware of any existing models that are capable of estimating the change in adult salmon travel time or survival through the hydrosystem as a function of variables such as spill and flow that will change under alternative operations. That said, the cited documentation for the CSS lifecycle and cohort models in the CSS Annual Reports (Appendix b) and memos do report SAR both back to Bonneville and Lower Granite for Snake River ESUs under current conditions. An additional multiyear study has used radiotagging to estimate conversion and travel time of adults through reservoir, tailrace, and ladder passage portions of the hydrosystem (Keefer et al. 2017). We agree that this data should be used in the future to attempt to fit an adult upstream model that uses dynamic inputs related to dam operations. United States. Army. Corps of Engineers. Portland District, Keefer, M. L., Jepson, M. A., Clobough, T. S., Caudill, C. C., Bjornn, T. C., ... & Stuehrenberg, L. C. (2017). Migration of adult salmonids in the Federal Columbia River hydrosystem: a summary of radiotelemetry studies, 1996-2014.
6905	20	anjeet@nezperce.org	Nez Perce Tribe	The DEIS also does not address adult migration through the Lower Snake River in the NAA or any of the other MO alternatives.	The EIS evaluates the effects to adults (and juveniles) in Sections 3.5 and 7.7.4, and the Preferred Alternative includes measures intended to benefit adult fish migration and survival in the Snake River and the Columbia River.
6905	21	anjeet@nezperce.org	Nez Perce Tribe	MO1, MO2, and MO3 include summer spill reductions at the lower Columbia River projects that would impact fall Chinook juveniles; effects on upper Columbia River fall Chinook not identified or discussed in the effects on Upper Columbia fish species.	Agreed. Approximately 50% of the summer Chinook run originating between Priest Rapids and Wells dams could experience a very minor adverse effect from reduced spill between August 15 and August 31. River flow levels through August are unchanged by the Preferred Alternative. Upper Columbia River fall Chinook are discussed in Chapter 7 for the Preferred Alternative (lines 2573-2610).
6905	22	anjeet@nezperce.org	Nez Perce Tribe	Inaccuracies exist in flow datasets applied to effects modeling of all resources, impacting predicted fish impacts and power generation potential. MO4 dataset fails to apply the 150kcfs spill cap constraint associated with stilling basin structural integrity (i.e., rock entrainment and erosion). This inaccuracy in datasets results in overestimates of SARs and underestimates of power generation. Appendix B, Part 2: Spill Analysis graphics (Figure 4-17) of Dworshak flows have incorrect max powerhouse or misallocation between Lack of Market (LOM) and forced spill Full powerhouse flow is 10.5kcfs. Figures 4 -1, 2, 3, 4, 7, and 8 associated with Bonneville, The Dalles, and McNary dams flows have incorrect max powerhouse or misallocation between Lack of Market (LOM) and forced spill. These inaccuracies misrepresent spill due to power demand limitations or project capacity constraints as being done intentionally for fish benefit (overestimates cost of fish spill operations). Spill analysis (Appendix B, Part 2) apply different flow datasets for MO4 and PA at Bonneville, The Dalles, and John Day dams as evidenced by unique flow spikes in MO4 in late March and in PA in mid June. Spill analysis (Appendix B, Part 2) inconsistently apply powerhouse bypass channel flow. Generally, powerhouse bypass channel flow appears in the MO4 graphics but no others.	Thank you for your comment. Outflow through the dams are divided into multiple different types, mainly comprised of the powerhouse turbine flow and the spill. The spill flow has several different components. There is fish spill, powerhouse bypass channel, attraction spill, lack of market spill and forced spill due to lack of turbine capacity. In addition there is also miscellaneous flow, which includes lockages, leakage and other flows. For more information see Appendix B, Part 2: Spill Analysis. The detailed description of the measures for MO4 included spill to 125%, but a spill cap at Bonneville Dam to limit spillway erosion was not included. The perspective used in designing the alternatives was that these should serve as "bookend" scenarios. MO4 was intended to capture the high-end range of spill. The co-lead agencies can then interpret that a real world operation with a modified set of measures or limits such as the Bonneville 150 kcfs spill cap would modify economic costs or survival rates from the modeled bookend scenario.
6905	23	anjeet@nezperce.org	Nez Perce Tribe	Analytical omissions and inaccuracies as to water temperature and water quality: The DEIS does not apply commonly accepted EPA temperature modeling to assess impacts to mainstem temperatures and the TMDL. EPAs 2018 draft report entitled Assessment of Impacts to Columbia and Snake River Temperatures using the RBM10 Model includes a simulation of the impacts of removing the Lower Snake River dams on river conditions. EPAs assessment was made using the RBM10 model which has been peer-reviewed, documented, and applied in the region and elsewhere since 2001. The EPA 2018 report requires careful inclusion and consideration in the EIS because it projects significantly different temperature outcomes for a free-	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				flowing river, especially when daily average temperature metrics, under specific low, moderate, and high hydrologic conditions are taken into consideration. Further analysis and consideration of adult fish ladder temperature impacts and management options to alleviate temperature differential between ladder and tailraces at John Day, Ice Harbor, and Lower Monumental is warranted.	As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
6905	24	anjeet@nezperce.org	Nez Perce Tribe	Description of fish behavior repeatedly does not acknowledge CRS projects as the reason (mechanism) for the described behavior. For example: While Dworshak Reservoir and the North Fork Clearwater River contain healthy populations of bull trout, there is no documented evidence that these fish regularly reach the Snake River (Page 3-349 lines 2434-2436). This statement specifically does not mention that Dworshak Dam does not 10 have juvenile or adult fish passage facilities; as such upstream and downstream passage of bull trout and other species are blocked and precludes them from reaching the Snake River.	Throughout the Draft EIS it is made clear that Dworshak does not have fish passage facilities. Section 1.9.7.2 p. 1-41 States that "Dworshak Dam blocks upstream migration on the North Fork of the Clearwater River." Table 1.2 indicated Dworshak does not include fish passage. Some example text includes: Within this subbasin there are five Columbia River System projects, including one storage dam, Dworshak Dam on the North Fork Clearwater River, and four run-of-river dams on the Snake River. These include Lower Granite, Little Goose, Lower Monumental, and Ice Harbor Dams. All four of the lower Snake projects are equipped with fish passage facilities and Under the No Action Alternative, migration of bull trout to the North Fork Clearwater River Subbasin from the rest of the Clearwater Basin would continue to be blocked by Dworshak Dam, as the dam has no fish ladders or other means of passing fish upstream.
6905	25	anjeet@nezperce.org	Nez Perce Tribe	The DEIS incompletely identifies and underplays the number and scope of hatchery programs that mitigate for impacts of hydrosystem. DEIS asserts that hatchery fish are negatively impacting the productivity of wild fish, while ignoring the effects of the CRS on the productivity of wild fish. BPA/Corps/Reclamation are responsible for producing 61% of the hatchery fish released above Bonneville Dam about 60 million juveniles annually. (The effects of these hatchery release on wild fish are covered under existing Biological Opinions for hatchery operations). There is a suggestion with no citation that hatchery fish may be a major factor in reducing steelhead productivity. This statement Implies that a lot of hatchery fish are spawning naturally in the Snake which is not correct, because the vast majority of steelhead are harvested or return to a hatchery. At the same time, there is no disclosure that a major factor that is actually reducing wild fish productivity is the 57% mortality rate caused by the operation of the CRS dams. Widener et al. 2019 reported survival from Lower Granite Dam to Bonneville Dam for natural-origin Snake River steelhead has averaged .43 from 1999 to 2018. Appendix V (Biological Assessment) is even more misleading. (E.g., 3-40, 3-124). No reference is made to existing Biological Opinions for federal hatchery programs mitigating for federal CRS dams. And there is no disclosure of the 30-50% mortality of juveniles caused by the CRS before they have a chance to get to the ocean and become adults.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. The Draft EIS analyzes the effects of the configuration, maintenance, and operation of the CRS projects in Chapters 3.4 and 7. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. The statement that the 57% mortality rate of juvenile natural-origin steelhead is caused by the dams is inaccurate and misleading because the estimate includes mortality from multiple sources such as passage mortality, natural mortality, and predation. Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS.
6905	26	anjeet@nezperce.org	Nez Perce Tribe	Section 3.5.3, Tribal Interests: This description is overly-generalized and does not include accurate, complete information for decision-maker and public consideration; it neither documents nor analyzes the substantial differences in effects of the action alternatives on tribal interests; as a result it does not include the complete effects of the alternatives on tribal interests here or anywhere else in the DEIS. (It specifically lacks any reference to the destruction of fish runs, fish passage, and Nez Perce culture, health, and economic welfare, from the construction and operation of the Dworshak Dam and Reservoir on the North Fork Clearwater River, and the Nez Perce Reservation and Nez Perce tribal trust land.)	The tribal interest sub-sections within each resource analyzed in Chapter 3 are not intended to be comprehensive, but are included as a way to highlight tribal interests within that resource. In Section 3.17 and the submitted Tribal perspectives there are additional discussions on Tribal interests and perspectives related to the alternatives and information on Nez Perce Tribal trust land.
6905	27	anjeet@nezperce.org	Nez Perce Tribe	Section 3.7, Power Generation and Transmission: There is a flaw in the 179-page Power Generation and Transmission section that is so fundamental, as a matter of the legislative purposes of NEPA as originally enacted by Congress, that it can be stated relatively briefly here. At core, NEPA is about promot[ing] efforts which will prevent and eliminate damage to the environment and biosphere and stimulate the health and welfare of man[.] 42 U.S.C. 4321. The term Human Environment is then defined under CEQ regulation, after introduction and use in the NEPA statute, as first and foremost, the natural and physical environment and the relationship of people with that environment. 40 C.F.R. 1508.14. Economic and social effects are only considered when they are 11 interrelated with natural or physical environmental effects. Id. Alone they are not the subject of NEPA and do not trigger NEPA review. Id. As a result, when economic effects are properly considered in a NEPA analysis, as they are in fact here, it is only because of their interrelation with the natural and physical environment which is the core purpose of NEPA. Despite this basic NEPA purpose and framework, the DEIS treats Power Generation and Transmission in Section 3.7 (and throughout the DEIS) as essentially a distinct resource area that merits effects analysis based on its own independent significance. But, again, under NEPA, power effects are secondary and only considered for interrelation with the natural human environment: they are to be considered only in their role as a socioeconomic effect that is related to the effects of the action alternatives on the natural and physical environment that is the purpose of NEPA and an EIS. For the agencies to consider power generation and transmission as an aspect of whether an alternative meets the very purpose of the CRS as a federal project would be legitimate. But that is not what the environmental consequences section of an EIS is for. For the agencies to treat power generation and transmission effects as environmental effects within an EIS, beyond their socioeconomic consequences, is a misconstruction of the purposes of NEPA and an EIS. Here Section 3.7 reads as an analysis of the effects of the alternatives on a key project purpose of the CRS for the agencies, rather than on the natural and physical environment. That is a fundamental error in consideration and analysis in the DEIS that would be not in accordance with law under Administrative Procedure Act review.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for multiple purposes, including hydropower generation and transmission. An underlying need to which the co-lead agencies are responding is to review and update the management of the CRS, including evaluating measures to avoid, offset, or minimize impacts to resources affected by managing the CRS in the context of new information and changed conditions in the Columbia River Basin since the prior systemwide EIS was released. The CRSO EIS evaluates actions within the current authorities of the co-lead agencies, as well as certain actions that are not within their authorities, based on the District Courts observations about alternatives that could be considered and comments received during the scoping process. The EIS also allows the co-lead agencies and the region to evaluate the costs, benefits, and tradeoffs of various alternatives as part of reviewing and updating the management of the CRS. The EIS properly analyzes impacts to power generation and transmission since changes in operations affect generation (i.e. a direct effect) and changes in power generation and transmission could affect the natural environment leading to indirect effects (e.g. reservoir elevation changes potentially causing erosion; changes in generation resulting in building renewable resources). Changes in CRS generation may also affect decisions made by other energy producers leading to cumulative effects on affected resources (e.g. changes to Mid-Columbia project generation). Thus, the EIS properly considers the direct, indirect and cumulative effects to power generation and transmission in Chapters 3, 6 and 7.
6905	28	anjeet@nezperce.org	Nez Perce Tribe	Section 3.11, Recreation: Incomplete resource information is provided and no analysis is conducted with respect to positive/beneficial effects on recreation from MO3 over a complete, comprehensive geographical area of salmon and steelhead restoration, as affecting both Indian and non-Indian communities, and including tourism and related economic benefits. Effects analysis must include beneficial fishing and recreational effects in areas including but well upstream and downstream of merely the breached lower Snake River area.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objectives alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The potential effects to recreational fishing is based on the description of effects to resident and anadromous fish in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The potential for increases in recreational fishing under MO3 in the Snake River Basin is described in Section 3.11.3.5, which would support jobs, income, and social benefits in Tribal and rural river communities. The effects to anadromous fish under MO3 in other locations would have negligible to minor changes from the No Action Alternative. For the effects on recreational fishing under MO3, see Section 3.11.3.5. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Sections 3.5 and 7.7.4.
6905	29	anjeet@nezperce.org	Nez Perce Tribe	Section 3.16, Cultural Resources: The Cultural Resources section of the DEIS does not include complete and accurate information on the impact of the CRS dams and particularly the four Lower Snake River dams on Tribes including the Nez Perce Tribe, and does not completely and accurately evaluate the effects on tribes and tribal cultural resources of the action alternatives. The highest priority Cultural Resources flaws are: o The DEIS attempts to exclude analysis of any actions taken before 2016, accepting the ongoing impacts from almost a century of federal action on innumerable Tribal cultural resources as status quo and therefore not to be considered under NEPA. This constitutes a serious injustice to the Tribes and these resources, and does not provide complete and accurate resource information to inform a complete and accurate evaluation of the effects of the action alternatives on these resources. 12 o The Area of Analysis for Cultural Resources defined as one mile in all directions from the reservoirs at full pool elevation to include the tailrace of each dam is arbitrary and grossly inadequate to a complete and accurate identification of the impacts of the dams on cultural resources and an evaluation of the effects of the alternatives on those resources. This narrow Area of Analysis severely restricts the cultural resources identified: it excludes cultural resources outside Reservoirs, including those on the Clearwater River between the Dworshak and Lower Granite Reservoirs; it ignores the much larger resource concerns identified by the Tribes; and, it does not even cover all the property used by the action agencies, both for ongoing operations and for mitigation of resource impacts.	In the Purpose and Need Statement (Section 1.2 of the Draft EIS), the co-lead agencies identified September 30, 2016, as the baseline date for analysis of effects coincident with the Notice of Intent to Prepare the EIS. This is consistent with NEPA regulations for an ongoing action, including the action analyzed here, where the focus of analysis is changes in operations and maintenance of the existing system. The co-lead agencies selected the size of the study area based on where the effects from the proposed structural and operational measures are expected to occur. This study area is sufficient for the agencies to understand the effects of the different alternatives and to enable the agencies to make an informed evaluation of the alternatives. The co-lead agencies focused on the locations where there were understandable direct and indirect effects, as opposed to third and fourth order effects, which are harder to predict, speculative, and thus difficult to evaluate, as a part of the NEPA process. The co-lead agencies would conduct separate environmental compliance to implement mitigation of resource impacts in many cases that would provide better site specific information for these efforts. With regard to mitigation of resource effects, the co-lead agencies conduct site-specific environmental compliance processes, such as NEPA, ESA and NHPA, as appropriate. Chapter 8 includes review of compliance with applicable laws and regulation.
6905	30	anjeet@nezperce.org	Nez Perce Tribe	The DEIS focuses on archaeological resources to the exclusion of traditional cultural properties and other ethnographic resources that are significant to the culture and lifeways of the Tribes and continue to be impacted by the CRS dams (for example, the four lower Snake River dams inundated areas of cultural and spiritual importance, traditional gathering areas, fishing and fish processing sites, camping sites, burial locations, travel and trading routes, and village sites).	The co-lead agencies respectfully disagree there is an exclusion of Traditional Cultural Properties (TCPs) in the Draft EIS. For example, Section 3.16.2.6 provides an overview of TCPs. In the Draft EIS, Impact analysis to TCPs is provided in Sections 3.16.3.3 through 3.16.3.7 for the No Action and the Multiple Objective alternatives. In addition, in the Draft EIS, Section 7.7.18 provides an impact analysis to TCPs for the Preferred Alternative. Section 3.16.2.1 of the Draft EIS provides ethnohistory including settlement, subsistence, habitation and material cultural. Within this section numerous references are provided to ethnographic resources which were considered in the analysis.
6905	31	anjeet@nezperce.org	Nez Perce Tribe	The DEIS omits and/or fails to consider critical information concerning the significant positive/beneficial effects that breaching the four lower Snake River dams would have on cultural resources, traditional cultural properties, and other ethnographic resources that are significant to the culture and lifeways of the Tribes that have been and continue to be impacted by the CRS dams. This information was provided by the Nez Perce Tribe, the Confederated Tribes of the Umatilla Indian Reservation, and other tribes both in the Meyer Report for use in the 1999/2002 Lower Snake River Juvenile Salmon Migration Feasibility Study, and was provided again for use in the present DEIS. o As a result of these flaws, the evaluation of the action alternatives on cultural resources is arbitrary, inaccurate, and incomplete. It is worth noting that Tribal representatives in the Cultural Resource Technical Team communicated these flaws and omissions repeatedly to the agency representatives in that group. Also, these flaws and omissions are particularly	The co-lead agencies respectfully disagree the Draft EIS omits the positive or beneficial effects of breaching the four lower Snake River dams. Section 3.16.3.6 discusses impacts from the MO3 to the cultural resources property types, including Traditional Cultural Properties. In the Draft EIS, lines 7054-7060 describe the benefits of MO3 on Traditional Cultural Properties, such as increased access to the river and the ability to experience the river in a pre-inundation condition. The co-lead agencies state on page 3-1388 in the Draft EIS, "In the long term, this would be expected to have a beneficial effect to TCPs."

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				troubling here, given the United States Treaty and trust relationships with Tribe, and where NEPA dictates the consideration and dissemination of complete and accurate information to the public and decision-makers.	
6905	32	anjeet@nezperce.org	Nez Perce Tribe	Section 3.17, Tribal Issues: Summary observation: Only 21 pages of resource information, over three distinct tribal resource issues, with no genuine effects analyses conducted at all, out of approximately 7,000 EIS pages, are provided for the 19 Indian tribes that live within the core geography of the CRS and have been directly impacted by the CRS in nearly every aspect of their social, economic, and 5 As the recently released draft Lower Snake River Dams Stakeholder Engagement Report (Report) illustrates, a candid identification of the ongoing impacts of the CRS dams and particularly the four lower Snake River dams on the tribes is a prominent consideration with respect to any evaluation of alternatives. (See Report, Section 2, Tribal Connections to the Lower Snake River Dams, highlighting Treaty-reserved fishing rights, the loss of salmon, and the loss of access to land and cultural sites relative to the four lower Snake River dams). 13 cultural lives for over 80 years. This is inexplicable and unacceptable, and glaringly fails the hard look at the environmental effects of action alternatives that is fundamentally required in a NEPA EIS.	The co-lead agencies respectfully disagree. The co-lead agencies used high-quality information in the analysis and made sure to identify and describe effects to Tribal interests. See Section 3.17.2, which provides Tribal perspective summaries, and Section 3.17.3, which provides a review of Tribal interests. This is in addition to consideration of Tribal perspective contributions provided by many of the 19 involved Tribes. The Federal agencies factored in this information in their evaluation of the alternatives. Finally, tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
6905	33	anjeet@nezperce.org	Nez Perce Tribe	Section 3.17.1, Indian Trust Assets (ITAs): The ITA analysis area is arbitrarily and irrationally narrow: limited to one mile from project reservoir edges. This results in a conclusion that almost no Indian Trust Assets are even present in the study area; then no analysis is described or conducted in the DEIS; and a single-sentence conclusory statement is made that, for ITAs for all 19 Indian tribes, No direct or indirect effects to ITAs were identified for any of the alternatives.	The co-lead agencies selected the size of the study area based on the area where the impacts from the proposed structural and operational measures are expected to occur. This study area is sufficient for the agencies to understand the effects of the different alternatives and to enable the agencies to make an informed evaluation of the alternatives. The co-lead agencies focused on the locations where there were understandable direct effects, as opposed to third and fourth order effects, which are harder to predict, and thus evaluate, as a part of the NEPA process. The analysis of Indian Trust Assets in 3.17.1 follows this approach.
6905	34	anjeet@nezperce.org	Nez Perce Tribe	Section 3.17.2, Tribal Perspective Reports: No geographical analysis area is provided or employed for consideration of environmental effects. Tribal Perspective Reports are attached as an EIS appendix, but there is no genuine consideration of the effects of the EIS action alternatives on the information and concerns provided by the multiple tribes that submitted Tribal Perspective Reports. Slightly more than one (1) page in total is provided for descriptions of the five EIS action alternatives in relation to the Tribal Perspective Report information provided by 11 Indian tribes located within the core geography of the CRS. This is not a meaningful consideration of the effects of the alternatives on the information provided by the tribes.	The scope of the Columbia River System Operations Environmental Impact Statement is described in Section 1.3. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6905	35	anjeet@nezperce.org	Nez Perce Tribe	Section 3.17.3, Tribal Interests / Treaty Rights: No area of analysis information is provided for any of the Indian treaty rights of any of the 19 affected Indian tribes. Incomplete treaty information is provided in an abbreviated table; no actual treaty rights information or detail is provided or employed. No effects analysis is conducted with respect to any action alternative as to effects on any regional Indian treaty rights, in this section or in any of the other environmental resource sections the reader is then directed to. In the unlikely event that the agencies believe Indian treaty rights are not a mandatory environmental effects consideration under a NEPA EIS, the recent D.C. District Court opinion in the ongoing case of Standing Rock Sioux Tribe v. U.S. Army Corps of Engineers provided a reminder, in passing within the opinion, that consideration of impacts on Indian tribal treaty rights is an agency obligation under NEPA. (March 25, 2020 Mem. Op. at 7, citing Standing Rock III, 255 F.Supp 3d 101, 132-34 (D.D.C. 2017).	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty-specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision-making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16, Cultural Resources, and Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests and Chapter 7, Preferred Alternative. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6905	36	anjeet@nezperce.org	Nez Perce Tribe	Section 3.18, Environmental Justice: Similar to the geographic point made above regarding Section 1.3.1, but additionally: Section 3.18 arbitrarily employs an enormous seven-Western-state, 139-county Environmental Justice analysis area, marginalizing Northwest Indian tribe Environmental Justice effects, and the cumulative effects history of the CRS on the Indian tribes who live within the core river geography of the CRS and have experienced the direct adverse effects of the CRS dams at every moment of dam development and expansion over 80 years. Among multiple failures to consider relevant information, Section 3.18 provides no analytical consideration of the Tribal Perspective Reports submitted by 11 Indian tribes, to inform the required Environmental Justice analysis.	The commenter is concerned that the information provided in the tribal perspectives submittals included in Appendix P have not been adequately considered in the Environmental Justice analyses. Based on public comments, the co-lead agencies revised the Environmental Justice analysis (Section 3.18) to provide additional discussion of the potential effects to environmental justice populations. The commenter is also concerned about the geographic area used in the analysis. The study area for the environmental justice analysis is intended to include areas where minority populations, low-income populations, or tribes may be affected by CRSO EIS alternatives. The study area for power effects is larger than the study area for other resources because the potential effects from changes in power and transmission rates are broader. For more detail see Section 3.7.1.3, Area of Analysis.
6905	37	anjeet@nezperce.org	Nez Perce Tribe	Chapter 4, Climate: Climate change was a critical flaw the Federal District Court identified in its opinion and order in Natl Wildlife Fedn v. Natl Marine Fisheries Serv. and thus serves as an important backdrop with respect to a full and complete analysis of climate change and its impacts: The best available information indicates that climate change will have a significant negative effect on the listed population of endangered or threatened species. Climate change implications that are likely to have harmful effects on certain of the listed species include: warmer stream temperatures; warmer ocean temperatures; contracting ocean habitat; contracting inland habitat; degradation of estuary habitat; reduced spring and summer stream flows with increased peak river flows; large-scale ecological changes, such as increasing insect infestations and fires affecting forested lands; increased rain with decreased snow; diminishing snow packs; increased flood flows; and increased susceptibility to fish pathogens and parasitic organisms that are generally not injurious to their host until the fish become thermally stressed. A single year with detrimental climate conditions can have a devastating effect on fish. . . . Similarly, in late July 2013 low flows and high temperatures caused adult sockeye and summer Chinook salmon and steelhead to refuse to enter the fish ladder at Lower Granite Dam for approximately one week. 184 F. Supp. 3d at 914. An analysis of climate change, whether in an ESA or NEPA context, must apply the best available science, address all important aspects of the problem, analyze the effects of climate change, including its additive harm, and how it may reduce the effectiveness of CRS mitigation actions, particularly habitat actions that are not expected to achieve full benefits for decades, and how it increases the chances of a catastrophic effect. Id. at 917. The magnitude of Chapter 4 Climate effects is not used to adjust the absolute NAA baseline conditions against which Chapter 3 effects analysis of multi-objectives are analyzed. (And Climate effects are not considered in Chapter 3.) The qualitative assessment of climate effects on anadromous fish within the NAA describes a likely Major Effect. While the relative impacts of Climate across alternatives may not change, absolute outcomes may become inadequate when NAA baseline conditions are adjusted for future Climate conditions. A quantitative analysis is only provided for Hydropower (in Appendix J); full and complete analysis should be provided for all resources, especially anadromous fish. The hydrology and hydraulics historical data sets (80-year water record) do not include anticipated climate impacts; as a result, the analysis must acknowledge that limitation and the analysis must account for anticipated climate impacts.	The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with USACE climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in USACE Engineer Technical Letter 1100-2-3, "Guidance for Detection of Nonstationarities in Annual Maximum Discharges." The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the Tribes. While individual years can have substantial negative impacts to returning salmon and steelhead, their life history strategy of a single brood year returning over multiple years helps to reduce the potential negative impact from any one single year. Habitat improvements can help improve resiliency to changing river conditions. Many of the types of habitat improvement actions implemented by the co-lead agencies can provide improved conditions for many fish species. Habitat mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. The same is true for projecting changes to TDG. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6905	38	anjeet@nezperce.org	Nez Perce Tribe	Chapter 5, Mitigation: As set forth above, the NAA, the four MOs, and the PA do not describe measures that are occurring (e.g., the Northwest Power Acts Fish and Wildlife Program, protective measures for Pacific lamprey); do not evaluate the adequacy or inadequacy of these measures; and do not 15 describe the status of the funding associated with these measures. Chapter 5 does not address these issues as a matter of mitigation. With respect to the Fish and Wildlife Program, Chapter 5 contains a reference to existing mitigation programs that states [u]nder the No Action Alternative, mitigation currently implemented would continue but then describes that certain programs would move forward with certain modifications, suggesting that more information on the Fish and Wildlife Program is provided Chapter 6 (where there is no additional detail on the Program or any modifications). The information that is provided on the Program in the DEIS (in Appendix Q) focuses on some costs without discussion of funding assumptions and trajectories, the Programs goals, objectives, measures, relationship to the CRSO EIS, etc. For example, all alternatives, as part of the alternative or as part of mitigation, must address hatchery compensation goals established under the existing Lower Snake River Compensation Plan authority and address the fact that adult spring and summer Chinook salmon returns have never met their mitigation goal under existing authority. Mitigation measures that are identified in the DEIS do not contain sufficient detail to meaningfully analyze them. For example, mitigation measures associated with MO-3 include a statement that [t]he co-lead agencies propose raising additional hatchery fish to offset two lost year classes prior to start of breach of the Lower Snake River (5.3.3.2); this statement contains insufficient detail to analyze the adequacy of this proposed mitigation.	Bonneville's Fish and Wildlife Program is summarized in Chapters 2, 5, and 7. Since Bonneville's Fish and Wildlife Program is part of the No Action Alternative and carried into the Multiple Objective and Preferred Alternatives, this program along with the other ongoing programs are analyzed for each resources for each alternative as part of that alternative. As described in Appendix Q, the costs to operate the system are funded through multiple mechanisms including federal tax dollars appropriated to cover system costs, as well as revenue generated through the marketing and sale of hydropower. The baseline cost estimates are based on both recent historic costs or cost requirements based on discussions with agency program or financial experts. Additional studies would be required prior to implementing the Preferred Alternative, including feasibility studies and NEPA along with congressional authorization and appropriations, to assess the requirements of the project. Specific funding requirements, including mitigation measures, would be part of these studies. In addition as described in Section 6.1.1. of Appendix Q, funding decisions for the Bonneville F&W Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W Program costs are included to inform the broader cost analysis for each alternative in the EIS. To make the most of available funds, investments in fish and wildlife mitigation would be prioritized based on biological and cost effectiveness and their connection to mitigating for impacts to the FCRPS. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. The co-leads disagree that the mitigation measures do not contain sufficient detail to meaningfully analyze them. In Chapter 5, the mitigation measures are identified to the scale and resource type appropriate based on the scale and severity of effects detailed in Chapter 3, per each MO, and brought forward for the Preferred Alternative. Additionally, the Tables in Chapter 5 identify the mitigation measure proposed to offset each impact, and the cumulative effect after implementing the measures. The resource teams went through a thoughtful analysis of all potential measures using the mitigation toolbox compiled by co-lead agency and cooperating agency expertise, discussing resource effects, severity, location, and methods to mitigate, before proposing mitigation measures appropriate to the effects. Finally, funding decisions for the Bonneville Fish and Wildlife (F&W) Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W program costs are included to inform the broader cost analysis for each alternative in the EIS. In the case of the Preferred Alternative, Bonneville included a range of potential F&W program costs to acknowledge the possibility that the Preferred Alternative could provide biological benefits to anadromous fish species (see Chapter 7 of the EIS, Preferred Alternative) and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville F&W Program. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. As discussed in section 7.7.21.1, in 2016, Bonneville's F&W Program budget was $267,000,000, and the Lower Snake River Compensation Plan (LSRCP) budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17%, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					With regard to benefits of ongoing mitigation actions, section 2.4.2 provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. The fish and wildlife mitigation projects that Bonneville funds have been recommended by the Northwest Power and Conservation Council (Council) and either derive from, or have been incorporated into, the Councils Columbia River Basin Fish and Wildlife Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria such as benefits to fish and wildlife. 16 U.S.C. 839b(h)(10)(D(iv). And for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Fish and Wildlife Program. See responses to Comments 31775-51, 6894-56, and 6894-49. With regard to the comments about the policies and mandates of the Northwest Power Act, the FEIS has been edited to provide more detailed discussion of those mandates and how the Agencies comply with them. See Chapter 5.1.2.
6905	39	anjeet@nezperce.org	Nez Perce Tribe	Chapter 6, Cumulative Effects: Section 6.2, Cumulative Actions Scenario: No cumulative effects analysis is conducted with respect to any Indian Trust Assets, for 19 affected Indian tribes, based on the no-analysis Section 3.17.1 conclusion that there are no direct or indirect effects on ITAs, and so, in Section 6.2, that a cumulative effects analysis is not required.	The reasoning behind the level of analysis of cumulative impacts in Chapter 6 is discussed in6.3.1.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests and states "Since the CRSO EIS alternatives are not expected to have direct or indirect effects on Indian Trust Assets, there would likely be no change in effects to these assets, and thus there would be no likely cumulative effects to Indian Trust Assets."
6905	40	anjeet@nezperce.org	Nez Perce Tribe	Chapter 6 also appears to omit any consideration of cumulative effects on Tribal Interests/Treaty Rights, for 19 affected Indian tribes, as should have occurred in connection with Section 3.17.3 of the DEIS.	Chapter 6 includes RFFA7, Fishery Management, which discusses the 20182027 United States v. Oregon Management Agreement. The purpose of the agreement is to rebuild weak runs to full productivity and fairly share the harvest of upper river runs between treaty Indian and non-treaty fisheries in the ocean and Columbia River Basin. RFFA7 was included in the cumulative effects analysis in Chapters 6 and 7. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Chapter 7 provides the effects analysis on Cultural Resources and Indian Trust Assets, Tribal Perspectives, and Tribal Interests, in Sections 7.7.18 and 7.7.19 in the Draft EIS, respectively.
6905	41	anjeet@nezperce.org	Nez Perce Tribe	And while there is a table reference to Tribal Perspective Reports, there also appears to be no DEIS consideration or evaluation of cumulative effects that employs the information provided by the 11 Indian tribes who provided those reports for analytical consideration in this DEIS.	The information included in Table 6-44 "Reasonably Foreseeable Future Actions Relevant to Tribal Interests" considered information received from the tribal perspectives submissions, located in Appendix P and was included in the cumulative effects analysis in Chapters 6 and 7. Additionally, tribal input, and their concerns, interests and especially treaty rights were considered throughout this EIS. Please see the treaty rights discussed in the Tribal Perspectives section of 3.17 and discussion of tribal consultation in sections 1.5, 3.5, 3.15 and Chapter 9.
6905	42	anjeet@nezperce.org	Nez Perce Tribe	Original and cumulative adverse effects from the construction and operation of the CRS (which is presently a continuing federal action) are not fully disclosed or addressed. Setting the baseline condition for effects comparisons through establishment of a NAA of 2016 operations, results in a failure to consider or evaluate the enormous historical and cumulative impacts of the CRS, particularly on the natural and cultural resources of affected Indian tribes, including the Nez Perce Tribe.	Consistent with the Council and Environmental Quality's (CEQ) June 24, 2005 guidance and interpretation of CEQ Regulations for Implementing the Procedural Provisions of NEPA, 40 C.F.R parts 1500-1508, "Agencies are not required to list or analyze the effects of individual past actions unless such information is necessary to describe the cumulative effect of all past actions combined... Generally agencies can conduct an adequate cumulative effects analysis by focusing on the current aggregate effects of past actions without delving into the historical details of individual past actions." However, the analysis of current conditions includes the ongoing effects of the existence of the system, inclusive of a host of other factors influencing natural and cultural resources of concern to potentially affected Tribes. System operations are the focus of the EIS, not the existence of the system (and to the extent the analysis considers the existence of the system, i.e. breach, the effects analysis captures the cumulative effect of project existence). Moreover, the No Action Alternative appropriately is the date of the Notice of Intent to Prepare the EIS (September 30, 2016) consistent with CEQ's treatment of ongoing actions (i.e. the No Action Alternative for ongoing actions is the status quo of the date of the Notice of Intent to Prepare the EIS). Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Chapter 7 provides the effects analysis on Cultural Resources and Indian Trust Assets, Tribal Perspectives, and Tribal Interests, in Sections 7.7.18 and 7.7.19 in the Draft EIS, respectively.
6905	43	anjeet@nezperce.org	Nez Perce Tribe	The DEIS should be amended to address multiple particular cumulative effects embedded in the NAA, including but not limited to: o Reduced harvest opportunities and connection to traditional fishing areas due to hydrosystem related mortality and reduced adult returns. 16 o Inundation and blocked access to treaty-reserved Usual and Accustomed places, including both active use and archeological sites. This includes reservoir areas of the Lower Columbia, lower Snake, North Fork Clearwater river, and Ahsahka community areas. o Visual landscape alteration by Dworshak Dam and Reservoir. o Coldwater releases from Dworshak Dam during summer months that preclude swimming and social gathering along Clearwater River. o Unmet LSRCP hatchery mitigation.6 o Increased presence of invasive species and resulting impacts to native species. o Dworshak hatchery production.	Justification and identification of the Reasonably Foreseeable Future Actions are discussed in 6.1.3 Identification of Past, Present, and Reasonably Foreseeable Future Actions. Moreover, the No Action Alternative analysis is the date of the Notice of Intent to Prepare the EIS (September 30, 2016) consistent with Council on Environmental Quality's treatment of ongoing actions (i.e. the No Action Alternative for ongoing actions is the status quo of the date of the Notice of Intent to Prepare the EIS). The past and present effects to fish, cultural resources, visual resources, hydrology and hydraulics, and invasive species are discussed in the respective sections of Chapters 3 and 7. Actions such as hatchery production goals are outside the scope of the CRSO EIS.
6905	44	anjeet@nezperce.org	Nez Perce Tribe	Chapter 7, Preferred Alternative: Unacceptable Preferred Alternative: o The Tribe has previously conveyed that given the status and trends of salmon, steelhead, and lamprey in the Snake River Basin, the 2020 and 2021 flex spill operation set forth in the 2019-2021 Spill Operation Agreement (Agreement) is not an acceptable operation for a long period of time (such as a 10 year time frame often examined in a biological opinion or an even longer time frame often examined in a NEPA document). (Here, Appendix V (Biological Assessment) seeks 15 years of ESA coverage, the longest ever sought in the history of the CRSs efforts to comply with the ESA.) o The Tribe entered into the 2019-2021 interim Agreement, agreeing to forbear from pursuing litigation until completion of the EIS, and intending to incrementally benefit juvenile salmon passage in 2020 and 2021, as the Tribe continues working to address the significant fish mortality from the dams and ensure a full analysis of lower Snake River dam breaching. Tribes Press Release, December 17, 2018. o The 2019-2021 Spill Operation Agreement identifies that the principle and objectives of the Agreement (often referred to as the pillars of the Agreement) were solely for the purposes of this Agreement and that no Party makes any concessions regarding the legal validity, scientific validity, or economic cost/benefit of the spill operations contemplated in this Agreement which encompasses the entirety of the Agreement including its principles and objectives. Natl Wildlife Fedn v. Natl Marine Fisheries Serv., Docket 2298-1, 2019-2021 Spill Operation Agreement, at Sections III, IX. 6 Neither the NAA nor any other part of the DEIS reveals that the impacts of the four lower Snake River dams began occurring in 1961 with the construction of Ice Harbor Dam and that all of four lower Snake River Dams were constructed long before in some cases decades, in all cases years before the hatcheries commonly referred to as the Lower Snake River Compensation Plan were implemented; it does not reveal the delay in meeting some compensation goals (Snake River fall Chinook not met until 2008). 17 o The PA fails to identify specific continued actions that would occur, the reduction in fish and wildlife funding that has occurred since 2016, the commitment to fish and wildlife funding that would occur in the future, projects (reasonably certain to occur) that will be implemented, etc., all of which are critical to an informed understanding of the PA. The PA asserts that Additionally, ongoing actions are being carried from the No Action Alternative which includes measures committed to in the past to benefit ESA-listed species. These include actions under Bonnevilles Fish and Wildlife (F&W) Program, Corps Columbia River FIsh Mitigation Program and Reclamations Tributary Habitat Program. 7-22. As noted above in the Tribes comments on Chapter 2, the NAA contains vague references that preclude a meaningful understanding of what actions are continuing. Chapter 7 does not alleviate, and perpetuates, that flaw in its brief description of Ongoing Programs. 7.6.4.1 (7-39 through 7-43). Major hatchery programs (Grand Coulee Mitigation, Dworshak Mitigation, John Day Mitigation) are omitted. The PA contains only vague references to habitat actions that are devoid of detail, precluding any meaningful understanding of the actions and level of effort that is being evaluated in the PA. No mention is made of these habitat actions being part of the federal agencies approach to filling existing gaps for ESA species, the law of the case in Natl Wildlife Fedn v. Natl Marine Fisheries Serv.with respect to habitat actions, and requirements that such actions must be reasonably certain to occur. And the description makes no differentiation between actions necessary to address existing conditions and actions necessary to address climate change. Information in an EIS must be of high quality and must allow for accurate scientific analysis, expert agency comments, and public scrutiny. Here, the Tribe, as a co-manager and partner, is actively implementing habitat projects in watersheds including the Snake, Salmon, Clearwater and watersheds in Northeast Oregon. The information presented in the DEIS7 7 The vagueness Chapter 2 and 7 is compounded in Attachment V (Biological Assessment BA). The Habitat Improvement Actions section starts with the assertion that habitat actions are included to help address uncertainty related to any residual adverse effects of CRS management on ESA-listed migrating salmon and steelhead, including uncertainty regarding such effects. (Appendix V, 2.6.1.4 pages 2-94 through 2-114). The BA does not disclose that these habitat actions are part of the federal agencies approach to filling existing gaps for ESA species, the law of the case in Natl Wildlife Fedn v. Natl Marine Fisheries Serv.,, and requirements that such actions must be reasonably certain to occur. Funding levels and commitments are not identified. This BA asserts that A more detailed description of the Action Agencies proposed tributary habitat actions can be found in Appendix D to the BA, yet neither the BA nor its Appendix D provides any greater detail. The accomplishments table (D-5, Table D.1) does not identify that actions may benefit multiple species (leaving the impression that these accomplishments are always additive); and the very broad accomplishment metrics–the table cites Bonneville 2019 and the references state Tributary habitat metrics taken from [unknown] Bonneville report – appear to be disconnected from Section D.12 (Population Specific Accomplishments Metrics 2007-2018) and the work the Tribe is most familiar with. While the Priorities section properly acknowledges Snake River spring Chinook being a focus priority (D.7, D-11), there is no acknowledgment that Snake River steelhead status has triggered NOAAs significant decline trigger and that continued and additional habitat work for Snake River steelhead is a necessary and high priority. The 5 year metrics set forth in Appendix	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Chapter 8 of the EIS demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and Northwest Power Act. Also, the co-lead agencies relied on high quality, current information in the development of the CRS. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKWs), along with vessel traffic and noise, and toxic contaminants. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. The FEIS includes additional information on SRKWs in Section 3.6 and 7.7.8. Finally, funding decisions for the Bonneville Fish and Wildlife (F&W) Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W program costs are included to inform the broader cost analysis for each alternative in the EIS. In the case of the Preferred Alternative, Bonneville included a range of potential F&W program costs to acknowledge the possibility that the Preferred Alternative could provide biological benefits to anadromous fish species (see Chapter 7 of the EIS, Preferred Alternative) and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville F&W Program. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements.

				V (Table 2-19, 2-98) and the fifteen year metrics for 2021-2036 (Table 2-20, 2-99) are broad and general. The information presented does not satisfy the reasonably certain to occur standard or the law of Natl Wildlife Fedn v. Natl Marine Fisheries Serv. for the first five years much less the fifteen year period for which ESA coverage is being sought. These metrics 18 precludes meaningful analyses by the Tribe, by the tribal and general public, and by decision-makers. o Most of the measures in the PA improve non-fish objectives and many of the fish measures in the PA are measures that are ongoing under the status quo. Of the thirty nine measures, 34 target non-fish objectives, one is juvenile fish passage spill, and the remaining four fish measures, while important and good to do, provide modest fish benefits relative to SARs and adult abundance.8 Non-fish objective measures in the PA (e.g., spring flow volumes) appear to reduce existing protective measures for salmon, steelhead, and lamprey. An especially problematic measure in the PA is earlier initiation of Zero NighttimeFlows, as and the work necessary to achieve these metrics have not been coordinated with the Tribe as an onthe- ground implementer of projects. These metrics do not allow for meaningful analyses by the Tribe which is most familiar with these efforts, much less the general public. No information is presented that assures that the highest priority limiting factors are being addressed, that projects are feasible to implement, funding is adequate and committed, etc. This stands in stark contrast to the Action Agencies and NOAAs approach to habitat actions following Judge Reddens rulings in Natl Wildlife Fedn v. Natl Marine Fisheries Serv.. The remainder of the habitat discussion consists of identifying (additional) processes in the form of a Tributary Habitat Improvement Program structure, a Tributary Habitat Steering Committee with a Science Committee, etc. that appear to be disconnected from the Councils Fish and Wildlife Program. The flaws in the DEIS and the PA in disclosing status quo actions and limitations on actions are exacerbated in Appendix V (BA). For example, the Snake River kelt program identified as an ongoing, existing action (Chapter 5), yet Appendix V (BA) treats the kelt program as a potential emergency contingency action (In years of low steelhead returns, reconditioned kelts can help boost abundance of steelhead on the spawning grounds. The Action Agencies could make this program available as a contingency measure should steelhead numbers show significant declines.) Kelt programs are already implemented for Snake and upper Columbia steelhead. And, significant steelhead declines have already triggered NOAAs significant decline analysis. Appendix V (BA) suggests safety net hatchery programs as a potential emergency contingency (The Action Agencies could discuss with hatchery operators potential reprogramming of certain hatchery programs to safety-net hatchery programs to address declining status issues.). This cannot be squared with reality / feasiblity within a time frame that could be impactful. (See, e.g., NOAAs recent exercise related to Southern Resident Killer Whales in seeking to find additional space and water to grow salmon and steelhead). As a further example, omissions and vague references in DEIS exacerbate confusion in BA. Required prior mitigation actions and required actions in reasonable and prudent alternatives not identified/included, resulting in random lists of and reference points for projects. This is true for both hatchery actions (see, e.g., 2-89 and Table 2-18) and habitat. 8 See Table 7-2, 7-23. Of these measures, Lower Granite Trap Modifications should occur as normal operation and maintenance, and will not significantly impact SARs and long-term abundance; Bonneville Ladder Serpentine Weir Modifications would benefit salmon (though may stack up shad in fish ladder) and would improve lamprey passage but will not significantly impacts SARs and long-term abundance; Early Start to Transportation may provide a moderate benefit to steelhead and hatchery Chinook with a likely decrease to no effect on wild Chinook; and Predator Disruption Operations have implementation /effectiveness questions associated with estimating their benefit. 19 effects analyses on this operation have not been conducted.9 The Dworshak Flow reprogramming proposal in the PA contains a TDG justification and a high now pack implementation criteria that are not accurate and not implementable (infeasible implementation due to highly uncertain water supply forecasts in December and January). o The PA does not identify actual spill operations beyond 2021 and leaves spill operations for the duration of the EIS undefined and uncertain, deferring to an adaptive management10 construct (that does not preclude significant reductions in spill from 2020 levels). The PA is grounded in a principle and objective developed solely for the purpose of the 2019-2021 Agreement without any acknowledgment of that limitation or acknowledgment of the governing legal framework. It should come as no surprise the Tribe views this PA as unacceptable. o As noted elsewhere, the DEIS does not contain an analytical construct that allows a measure-specific effects analysis of the PA. o Modelling tools in the EIS are based on daily or monthly averages; PA operation is an hourly operation. o All alternatives, including the PA, must contain a full NEPA effects analysis, to inform decision-makers and the public. The PA fails this requirement. 9 Current Zero Nighttime flow operations are implemented no earlier than December 1 and only after low adult steelhead abundance criteria are met. The PA proposes Zero Nighttime flows starting October 15. Analyses of this operation must cover impacts to adult migration (fall Chinook and coho in addition to steelhead) and juvenile migrants (fall Chinook) 10 The associated Adaptive Implementation Framework set forth in Appendix R proposes formalizing the Flexible Spill Working Group in a way that appears to be duplicative of existing regional forums (TMT and RIOG). In the summer of 2017-winter 2018, the Flexible Spill Working Group, against the backdrop of almost-certain further litigation including injunctive relief if the Action Agencies did not reach agreement with the fish managers and many parties desire to focus on the EIS process ordered by the Court, organically developed and reached the 2019-2021 Spill Operation Agreement. Natl Wildlife Fedn v. Natl Marine Fisheries Serv., Dkt 2298 and 2298-1 (December 18, 2018). This proposal seeks to co-opt the Flex Spill Working Group to implement a flawed PA set forth in a flawed DEIS, while simultaneously, among other things, adding an additional pillar to pillars agreed to solely for the purpose of that Agreement (with no concession that these pillars were consistent with or satisfy any legal requirement under NEPA, the ESA, the Northwest Power Act or any other law).	As discussed in section 7.7.21.1, in 2016, Bonneville's F&W Program budget was $267,000,000, and the Lower Snake River Compensation Plan (LSRCP) budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17%, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative. With regard to benefits of ongoing mitigation actions, section 2.4.2 provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. The fish and wildlife mitigation projects that Bonneville funds have been recommended by the Northwest Power and Conservation Council (Council) and either derive from, or have been incorporated into, the Councils Columbia River Basin Fish and Wildlife Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria such as benefits to fish and wildlife. 16 U.S.C. 839b(h)(10)(D(iv). And for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Fish and Wildlife Program. See responses to Comments 31775-51, 6894-56, and 6894-49. With regard to the comments about the policies and mandates of the Northwest Power Act, the FEIS has been edited to provide more detailed discussion of those mandates and how the Agencies comply with them. See Chapter 5.1.2.
6906	1	joseph@wildsalmon.org	Wild Salmon	Indeed the parties to the current, short-term Flexible Spill Agreement made this explicit and respected regional scientists have confirmed that the flexible spill included in the Preferred Alternative will NOT deliver salmon the survival benefits through the hydrosystem they need. The changing climate will further erode any benefits of flexible spill as a long-term approach and only underscores the urgency for meaningful action. The draft plan includes little to address these intensifying impacts.	The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waivers had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. That result, however depends upon the latent mortality hypothesis central to the CSS model being correct. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
6906	2	joseph@wildsalmon.org	Wild Salmon	Finally, a dramatically new approach is urgently needed to develop the comprehensive plan the people of the Northwest and nation require and deserve one that (1) recovers salmon abundance, (2) invests in fishing and farming communities to provide them a healthier future, and (3) supports a reliable, affordable and increasingly decarbonized regional energy system.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA species is the purview of NMFS and the U.S. Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery as compared to the No Action Alternative. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Socioeconomic effects were analyzed in the Draft EIS. Investing in fishing and farming communities, however, is outside the scope of this project and outside the authorities of the co-lead agencies. The U.S. Government supports the development of alternative forms of energy through many different programs and policies. For example, the Bonneville Power Administration also has a robust conservation program, from which about 90 aMW in conservation are saved a year. Further, when acquiring long-term resources, the Bonneville Power Administration statutory directives give priority to conservation and renewable resources.
6910	1	kberquist@earthjustice.org; ttrue@earthjustice.org	Earthjustice	Because the federal agencies have failed to take a comprehensive approach for more than 20 years and do not propose one in the DEIS, we need an entirely new approach. We must develop a comprehensive plan to restore abundant salmon and steelhead, invest in fishing and farming communities to provide them a more prosperous future, honor our commitments to Native American tribes, and support the development of a reliable, affordable, and clean Northwest energy system.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA species is the purview of NMFS and the U.S. Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives of the study for resident fish, hydropower, water management, water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. Socioeconomic effects were analyzed in the Draft EIS. Investing in fishing and farming communities, however, is outside the scope of this project and outside the authorities of the co-lead agencies. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

					With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, including protecting Native American treaty and reserved rights and trust obligations for natural and cultural resources throughout the environment affected by CRS operations. The U.S. Government supports the development of alternative forms of energy through many different programs and policies. For example, the Bonneville Power Administration also has a robust conservation program, from which about 90 aMW in conservation are saved a year. Further, when acquiring long-term resources, the Bonneville Power Administration statutory directives give priority to conservation and renewable resources.
6913	1	N/A	N/A	As fish populations continue to drop, our window of opportunity to have a meaningful impact on their recovery is closing. Increased hatchery production is not the answer and only leads to dwindling wild populations of fish. I would like to suggest that you consider yet another alternative- one that includes both breaching the lower Snake River dams AND increasing spill in the meantime to 125% total dissolved gas. This alternative is clearly discussed as MO34 proposed by the Fish Passage Center.	Improving anadromous fish conditions was one of the eight multiple objectives of the CRSO EIS. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
6919	1	nsarmie2@gmail.com	N/A	The DEIS executive summary states New congressional authority and funding would be required to implement the dam breaching measures in MO3 on page 24 of the executive summary. As a federal project owned and operated by a federal agency, this is incorrect. Army Corps of Engineers headquarters in DC down to individual divisions, such as the Northwest Division, follow the same authorization procedures for federal projects. These procedures are in accordance with the public trust doctrine, assuring that approved projects will benefit the public with a positive investment return, or cost-to-benefit ratio. Once built, these projects must maintain their benefits or be economically viable to continue operation. When a project is no longer economically viable, it is time for the Corps to stop spending money on it, and the Corps has decommissioned (Aka mothballing, care-taker, non-operational status) hundreds of projects in U.S. history under their own authority. It would be an inappropriate precedent to set if all future projects must be decommissioned by a vote of congress, not to mention congesting our legislative bodies. The corps being a federal agency, under governance of the US Army, has the right to uphold its authority on the Lower Snake River Dam projects, like any other. An example of the CORPs authority over projects was during the decommissioning of Willamette Dam in 2011 without the use of congressional authorization. The project quickly went from caretaker status (could be reestablished) to non-operational status (will never operate again). The water behind the dam began moving over the low spill-way and the CORPs became free of their duty to manage and maintain it. Years later, a section 216 Study was initiated to decide what to do with the remaining structure. Similarly, the CORPs could put the Snake River Dams into a caretaker or non-operational status by removing the earthen berm, and allowing water to flow around the concrete structure, absolving them of any future operation and maintenance costs. While the decision process for decommissioning is simple, authorization for changing the purpose of a project was made more multipart, because headquarters did not want projects to change their purpose without congressional authorization. This makes sense, because projects were authorized for a certain reason, and changing that reason, requires approval outside the District. Securing a project for non-operational status is mutually exclusive to changing its purpose, because its purpose is no longer needed. For the Snake River Dams in MO3, their purposes (Navigation and hydropower) would cease with a change in status, and there is no way to put the projects in non-operational status without breaching. Breaching as a means of securing the projects does not need the approval of congress because they will no longer be serving any purpose.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
6922	1	brad@lrecoop.com	N/A	Preferred alternative must not drastically impact consumer rates The 2020 DEIS addresses customer wholesale power rates in each of the 5 Multiple Objective Alternatives. The viability of any preferred alternative terms must include serious consideration for impact on consumer rates. Rate increases associated with MO3 and MO4 are without question, outside the scope of meeting the providing adequate or economical power supply. Modest rate increases, such as the lower end of estimates provided in the DEIS MO1 of 4.5-8.6% could be acceptable, if there would be significant reduction of fish mortality. Provided that these mortality reduction objectives were met, a potential offset in litigation expenses should be sought to recover these additional costs.	The statements in the comment about hydropower generation and wholesale power rate effects under MO3, MO4, and the Preferred Alternative are consistent with the findings of the EIS (See Sections 3.7.3.5 and 3.7.3.6, Electricity Rate Pressures, as well as Section 7.7.9, Power Generation and Transmission, under the Preferred Alternative). The EIS recognizes that increases in utility costs can adversely affect vulnerable groups. The Environmental Justice analysis (Section 3.18.3 and Section 7.7.20 of the EIS) provides further detail on the potential disproportionate effects to Tribal, low-income and minority populations. Note that the power estimates presented in the EIS are a comparison to the No Action Alternative, rather than the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement. In addition, as noted in the EIS, the rate pressure associated with the Preferred Alternative may be offset by cost reductions. See EIS Section 3.7.3.1, at 3-817, in the Draft EIS. Consistent with the comment, the co-lead agencies developed a Preferred Alternative that strives to balance the multiple objectives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6923	1	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	The Columbia River includes resources of critical cultural importance to the Tribe, including but not limited to water quality, water quantity, aquatic and riparian habitats, native anadromous fish runs, native aquatic species and wildlife, spiritual values, place-based traditional knowledge, archaeological resources, and aesthetic values. The ongoing CRSO has impacted and will likely continue to impact these resources; the Tribe finds it critically important that the Tribes voice be heard and considered in any decision making process for the CRSO. For this reason, Grand Ronde offers the following comments on the dEIS. Please note that the Tribe considers these to be interim comments only, as the Grand Ronde Tribal Council has officially requested an immediate extension of time for Tribal participation on all projects or processes potentially impacting resources of Tribal importance.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6923	2	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	Through a Memorandum of Understanding (MOU) signed with the CoLeads, Grand Ronde has been a Cooperating Agency for the dEIS since 2017. As such, Tribal leaders and staff have actively participated in the scoping, development, and review of the EIS and its elements. CoLead staff have communicated frequently seeking Tribal input on the EIS, and for this the Tribe is grateful and appreciative. However, that said, we would be remiss in our responsibilities if we did not also comment on the shortcomings of the NEPA process as applied to the CRSO-EIS thus far. Timeframes have been too compressed to provide meaningful review periods The Tribe has not yet experienced true Tribal Consultation in this process When the Tribe has provided detailed input, such as on the Tribal Perspectives section, it has been obvious that CoLead staff did not read it, much less consider it Process steps such as meetings and review periods have failed to correct for the Tribes limited capacity and costs of participation Delays in releasing sections of the dEIS for review, and lack of communication on those delays, exacerbated an already hurried timeline.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as Cooperating Agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subject to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 and additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource.
6923	3	Torey.wakeland@grandronde.org	The Confederated	The Tribe has reviewed and provided comments at several points along the path of development of the dEIS, and greatly appreciates those opportunities to be heard. However, that said, there are some Tribal comments that we feel have either not been addressed or not been addressed adequately by the CoLeads; we repeat such comments below. There are additional Tribal comments on the dEIS for parts the Tribe either has not seen	The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change. For this EIS, the No Action Alternative describes the operation, maintenance, and configuration of the CRS, from September 30, 2016, the date the Notice of Intent to complete the CRSO EIS was published in the Federal Register. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 Code of Federal Regulations [CFR] 1502.14). The co-lead agencies assume that, to the extent possible, all ongoing, scheduled, and routine maintenance activities for the Federal infrastructure and all structural

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
			Tribes of Grand Ronde	before this public version, or has not commented on due to limited capacity given restricted timeframes and other constraints. For resources that existed prior to construction of the CRSO dams, the proper baseline metric is the Pre-System Condition (PSC) There should be equity in the rigor of analyses applied to all resources in the dEIS Any additional impact to tribal resources should be considered significant, as those resources are already impacted. Mitigation being carried forward from other commitments should not be considered mitigation for impacts imposed by the proposed action. Mitigation for fish should be basin-wide for all alternatives, as fish are highly impacted throughout the system. The magnitude of the effects is misleading. For example, a finding of No Effect implies that the resource will not be impacted. Current operations already have a Major Effect on resources. The Tribe places the most value on conservation of resources, not maximization of revenue. Fish populations and culturally significant resources need to be highly prioritized.	features, including those recently constructed or reasonably foreseeable, are included in the No Action Alternative. The No Action Alternative provides a baseline condition for comparing environmental effects of the action alternatives, or MOs and the Preferred Alternative. The No Action Alternative assumes the CRS will continue to be operated for all congressionally authorized purposes, requiring a balancing of operations across the 14 projects within the CRS. Current operations include actions agreed to in previous ESA consultations among the co-lead agencies, National Marine Fisheries Service (NMFS), and U.S. Fish and Wildlife Service (USFWS). The focus of the EIS is system operations, not the construction of the system. To the extent the analysis considers the existence of any system projects, e.g., breach, the effects analysis nevertheless captures the cumulative effects of Congress's decision to construct the projects and, thus, project existence. Chapter 2 discusses existing mitigation, while Chapters 5 and 7 specifically discuss additional mitigation proposed for the Multiple Objective Alternatives (Chapter 5) and the Preferred Alternative (Chapter 7).
6923	4	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	The inclusion of Pacific lamprey in the dEIS is greatly appreciated. In many cases lamprey are not analyzed as they are not an ESA listed species. The Tribe appreciates measures to enhance lamprey passage in the basin.	The co-lead agencies recognize the value of considering these important native fish and plan to continue ongoing work in coordination with regional stakeholders through frameworks such as the Pacific Lamprey Conservation Initiative to implement ongoing programs as well as the lamprey measures described in the Draft EIS.
6923	5	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	There is an under reporting of Tribally based Traditional Cultural Properties (TCPs), sacred sites, properties of traditional religious and cultural significance, and properties of traditional religious and cultural importance by Tribes to the Agency/ies due to the sensitivities of the cultural practices and their locations.	The co-lead agencies acknowledge the sensitivity of the information related to Traditional Cultural Properties, sacred sites, and properties of religious and cultural significance by Tribes. The co-lead agencies were able to conduct analysis on the data available from previous studies. Out of respect for the sensitivity of this information, the co-lead agencies minimized the publication of location specific information as they completed the impact analysis to cultural resources. In the Draft EIS, the co-lead agencies discuss these concerns in Section 3.16.2.7 upon the introduction of sacred sites; and also in Section 3.16.3.1, Traditional Cultural Properties.
6923	6	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	1.5.2.3 It is felt by the Tribe that meaningful tribal government-to-government consultation was greatly lacking. In many instances it is felt the Tribes voice was not considered.	The co-lead agencies have engaged in a three-tiered process for engaging Tribes at technical, policy, and leadership levels to ensure all Tribal comments and perspectives are carefully considered. Tribal input has been critical and important to improving the quality of this EIS.
6923	7	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.4 As this is the first time the water quality section has been available in a completed form, it is a concern that any input the Tribe has will not be considered in the final EIS.	The water quality sections of the EIS have been available for review throughout the EIS process. The Confederated Tribes of the Grand Ronde (CTGR) was provided documents and invited to conduct reviews at every step of the way. Some of these reviews included: (1) review of No Action - March 2019; (2) review of MO1 - March 2019; (3) review of MO2 - May 2019; (4) review of MO3 - May 2019; (5) review of MO4 - April 2019; (6) review of the Adminstrative Draft EIS (including the Preferred Alternative) - January 2020; (7) review of the CRSO model and model documentation reports - February 2019. In addition, the co-lead agencies met with the CTGR one-on-one, via webinar, on March 03, 2020, to discussed EIS results and answer specific questions that the Tribe may have. To suggest that this is the first time that the water quality sections of the EIS have been available in completed form for review is therefore puzzling.
6923	8	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.4 There is no mention of turbidity being evaluated for water quality impacts, which can have a significant impact on aquatic species.	Turbidity is discussed where data is available and relevant. Additional water quality information for each CRS project can also be found on the CRSO website: https://www.nwd.usace.army.mil/CRSO/#top.
6923	9	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.5.2.3, 7214-7230 This section is very misleading. It paints a picture that anadromous fish populations are doing well in the basin. The fish populations in the basin are highly impacted by current operations.	The co-lead agencies do not feel that Figure 3-111 on page 3-300 or the text between 7214-7230 is either inaccurate or misleading. This figure and associated text is part of general overview of anadromous fish in the study area. The later Sections of the report do break out analyses and discussion by species and origin. An additional figure detailing cumulative in-river survival from Lower Granite to Bonneville Dam will be added to the FEIS.
6923	10	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.5.3.3, 10201 Upstream passage survival estimates are not generated. This seems like an easy model to run and would help the reader understand upstream passage impacts.	The Fish Technical Team was not aware of any existing models that are capable of estimating the change in adult salmon travel time or survival through the CRS as a function of variables such as spill and flow that will change under alternative operations. That said, the cited documentation for the CSS Life Cycle and cohort models in the CSS Annual Reports (Appendix B) and memos do report Smolt-to-Adult returns (SAR) both back to Bonneville and Lower Granite for Snake River ESUs under current conditions. An additional multiyear study has used radiotagging to estimate conversion and travel time of adults through reservoir, tailrace, and ladder passage portions of the CRS (Keefer et al. 2017). We agree that this data should be used in the future to attempt to fit an adult upstream model that uses dynamic inputs related to dam operations, but since that model is not currently available, the co-lead agencies could not use it in the CRSO EIS. U.S. Army. Corps of Engineers. Portland District, Keefer, M. L., Jepson, M. A., Clobough, T. S., Caudill, C. C., Bjornn, T. C., ... & Stuehrenberg, L. C. (2017). Migration of adult salmonids in the Federal Columbia River hydrosystem: a summary of radiotelemetry studies, 1996-2014.
6923	11	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.5.3.4, 14829-14823 Any increase in impact should be considered a Major Impact as anadromous fish species are already highly impacted in the basin.	In the analysis of the effects of the alternative approaches of operation, maintenance, and configuration of the CRS, the EIS compared the effects of each alternative to the No Action Alternative. The magnitude of effect was used in this comparison; otherwise the analysis would not be meaningful and allow for informed decision making. The Preferred Alternative was determined to provide substantial benefits to ESA-listed salmon and steelhead (see Chapter 7, Section 7.7.4). The co-lead agencies then submitted the action as described in the Preferred Alternative to the US Fish and Wildlife Service and NMFS to analyze under the Endangered Species Act to ensure that the actions do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. These analyses can be found in Appendix V of the EIS.
6923	12	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.5.4, 20277-20282 The wording of this paragraph is concerning. The message conveyed here is that adverse impacts caused by dams are merely the opinion of tribes. Impacts from dams are well documented and studied; this should be re-worded.	Text will be edited in FEIS.
6923	13	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.6.4 Any loss of culturally significant plants should be included in the replanting effort.	Suggestion noted. Impacts to vegetation are discussed in Sections 3.6 and 7.7.7. Vegetation mitigation for areas that would be replanted are discussed in Chapter 5, Mitigation.
6923	14	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.15.4 Same comment as made for 3.5.4. The wording makes the Tribes stance seem ill-informed. The Tribes stance is supported by best available science.	Text will be edited in FEIS.
6923	15	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	3.17.1.3 Any adverse effect to fish populations is a direct affect to tribal trust assets.	The co-lead agencies have analyzed ITAs consistent with applicable statutes, regulations, and guidance. Neither the rights of fishing, hunting, and gathering, nor the resources subject to those rights, are "assets held by the federal government" within the meaning the Interior Department Manual, 303 DM 2.5(c). As a result, the co-lead agencies do not consider the rights our resources to be ITAs. The agencies' analysis nevertheless considers effects to the resources subject to the Tribe's rights, as well as the cumulative effects to those rights as a result of effects to underlying resources.
6923	16	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	5.4.1.2 Mitigation can occur above Chief Joseph Dam in the form of reintroduction and management. Passage can be added here to mitigate for the loss of habitat.	Measures to reintroduce salmon above Chief Joseph Dam and Grand Coulee were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
6923	17	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	7.6.2 Passage at Chief Joseph dam should be considered as part of the alternative.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6923	18	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	7.7.4, 2358-2363 Modifying the intake to increase power production in the form of removing protective fish screens is irresponsible and cuts against the core values of the Tribe. 7.7.4 This section is misleading as it does not consider the major impacts on the species under current conditions.	The co-lead agencies do not intend to remove screens in front of turbine units until a process is in place to confirm that salmon and steelhead dam passage survival is not negatively impacted.
6923	19	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	7.9.7 Cumulative impacts to anadromous fish are extensive. This section does not hold up to the type of analytical rigor the Tribe would expect to see.	The co-lead agencies recognize both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Chapters 6 and 7 incorporate the past and present effects described in Section 3.5 into the cumulative effects analysis for fish as described below. Moreover, the cumulative action analysis methods are based on the policy guidance and methodology originally developed by CEQ (1997a). This method includes identifying affected resources and associated direct/indirect effects; establishing the geographic and temporal boundaries of the analysis; identifying the cumulative action scenario; and analyzing the cumulative effects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The Environmental Consequences sections of Chapter 3 present the direct and indirect effects of the Columbia River System Operations (CRSO) Environmental Impact Statement (EIS) Multiple Objective Alternatives (MOs) on each resources affected environment as presented in the Affected Environment sections of Chapter 3. The resource conditions described in those sections account for the effects to resources related to past and present actions. Chapter 6, Cumulative Effects, further considers the cumulative effects of each alternative combined with reasonably foreseeable future actions and conditions for all resources. RFFAs are considered in the cumulative effects analysis for each resource in chapter six. RFFAs are proposed activities that could cause similar effects in the same space and time as the MOs, but that are proposed by an outside entity. RFFAs are not yet implemented. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. The evaluations are clear, transparent, and repeatable based on the best available information.
6923	20	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	7.9.20 This section states there are no cumulative impacts to tribal trust assets. This is woefully inaccurate. In section 7.10 there is mention of unavoidable affects to resources considered trust assets.	Resources identified as Trust Assets are identified in Section 3.17. Section 3.17.1.1 Introduction and Background provides the legal definition of an Indian Trust Asset. That Section states: "Treaty-reserved rights, for instance, fishing, hunting, and gathering rights on and off reservation, are usufructuary rights that do not meet the Department of Interior (DOI) definition of an ITA." Given the importance to the Tribes of these resources that do not meet the Department of Interior's definition of an Indian Trust Asset, effects to those resources are discussed in Section 3.17.2, Tribal Perspectives Summaries.
6923	21	Torey.wakeland@grandronde.org	The Confederated Tribes of Grand Ronde	NOTICE: The Confederated Tribes of the Grand Ronde Community of Oregon (Grand Ronde or Tribe) has declared an ongoing Tribal state of emergency as of March 18, 2020, due to the effects of the COVID-19 pandemic. The Tribe has taken numerous measures to protect Tribal members, employees, and the general public from the novel coronavirus. These measures include but are not limited to a partial shutdown of Tribal government operations. As a result, normal Tribal government procedures are largely disrupted; many reviews, approvals, communications and other processes involving non-life-threatening topics have been suspended at this time, severely reducing Tribal capacity in responding to the Tribes partner governments on such topics. This is expected to continue for as long as the pandemic continues to pose a risk to the community. For this reason, the Tribe respectfully requests from its partner governments an immediate extension of time for all applicable deadlines on proposed actions potentially impacting resources of Tribal importance. In order to be fair and effective, avoiding any prejudice to or bias against the Tribe, the extension currently must be indefinite; upon the return to normal Tribal government operations, the Tribe should be able to determine the time needed to respond meaningfully to each proposed action. Whether or not this extension request is granted fully and immediately, Grand Ronde acknowledges and reserves the right to take steps it deems necessary for protection of Tribal resources. These steps may include but are not limited to: submitting interim Tribal comments within the comment period that may be later modified by official comments from Tribal Council; submitting technical comments while reserving the Tribes right to later submit policy comments; requesting Tribal consultation on the proposed action upon a return to normal Tribal operations; or choosing not to comment within the comment period while reserving the Tribes right to comment later. The Tribe respectfully notifies its partner governments that such is the case until further notice. Please see language from the Tribal Council Resolution passed at the regularly scheduled meeting of April 1, 2020 (attached). In the case of this proposed action, at this time the Tribe will submit interim comments that may later be modified by official comments from Tribal Council. The Tribe reserves the right to take additional steps or change course at any time, with or without notice. hayu-masi (Many thanks), Torey Wakeland Environmental Policy Analyst Attachment: Tribal Council Resolution No. 106-20	Thank you for your comment. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6924	1	bertbowler@mac.com	N/A	he Federal Draft Environmental Impact Statement (DEIS) for the Columbia River System Operation (CRSO) is seriously flawed. The Preferred Alternative (PA) if adopted will diminish the persistence of Snake River wild salmon and steelhead that have survived for thousands of years. Returns of several hundred thousand were common in the 1950s -1960s reinforced by Idahos plentiful quality habitat. Wild Snake River salmon and steelhead are running out of time. Twenty years since the last EIS is too long. The Northwest deserves a final EIS/ROD with a more aggressive salmon restoration plan and mitigation strategy protecting other river users. A process that accurately schedules removing the four lower Snake River dams using an adaptive management policy is defensible.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The Preferred Alternative includes several new mitigation measures as well as continuing long-standing mitigation programs managed, funded, or implemented by the co-lead agencies. he co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion.
6925	1	Citizenthad@gmail.com	N/A	WREC concurs with the comments submitted by the National Rural Electric Cooperative Association (NRECA), the Public Power Council (PPC), Northwest Requirements Utilities (NRU) and Northwest River Partners. We share their concerns as well. In addition, WREC is concerned that some of the socio-economic analysis seemed to focus on communities in proximity to the LSRD, possibly to the exclusion of more distant communities. While communities adjacent to the LSRD will certainly bear the brunt of any misguided effort to breech the LSRD, communities such as Pine Valley and Shanty Town, which are approximately 125 miles south of the Idaho-Nevada border will also be impacted by any rate increase that would be necessary to implement any of the other alternatives. WREC also serves West Wendover, Nevada and Wendover, Utah which are approximately 70 miles south of the Idaho-Nevada border.	The retail electricity rate estimates in Section 3.7.3, Chapter 7, and Appendix H, are for the entire Northwest region, not only for the locations around the lower Snake River dams. The figures under Residential Effects in Sections 3.7.3.3, 3.7.3.4, 3.7.3.5, 3.7.3.6, and Section 7.7.9 in the Draft EIS show generation by county, including Elko County in Nevada. Exhibit 1 in Appendix H contains a table of retail rate pressure for each alternative by county, also including Elko County. Note the figures of retail rate pressure in Chapter 5 of Appendix H were inadvertently mislabeled and out of order in the Draft EIS, but are corrected in the Final EIS. Please also see the co-lead agencies comment response to National Rural Electric Cooperative Association (NRECA), the Public Power Council (PPC), Northwest Requirements Utilities (NRU) and Northwest River Partners.
6926	1	ASIHcons@gmail.com	N/A	We have reviewed the Draft EIS and have concluded that the proposed alternatives fail to meet the objective of recovery of anadromous salmonids in the Columbia River basin. Specifically, we find the EIS analysis is fundamentally flawed based on: Inaccurate, selective and misleading use of data to assert that salmon and steelhead abundance is improving. o Analyses that selectively emphasize data from 1990-2015 and ignoring data from 1957 to 1990 hide, unintentionally or intentionally, massive declines in salmon and steelhead populations. o The EIS inappropriately combines salmon and steelhead return to Bonneville Dam from 1938-2019. Unless data are plotted separately by species and origin (hatchery vs. wild fish), the combined data lead to the false conclusion that returns are robust. Declines in wild fish abundance is hidden by including the numbers of hatchery fish.	The co-lead agencies disagree that information provided in the EIS can be characterized in the way this comment conveys. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The time span of the graphs mentioned in this comment were intended to show trends in fish populations since they were listed under the ESA; there was no intent to ignore previous data. Figure 3-111 on page 3-300 is neither inaccurate nor misleading. The title is "Combined Annual Returns of Salmon and Steelhead to Bonneville Dam 1938-2019." The caption reads: Figure 3-111. Combined Annual Salmon and Steelhead Returns (all species) to Bonneville dam from 1938-2019. These returns are a combination of hatchery and natural origin fish. (data Source: University of Washington-Data Access Real Time (DART) tool). This figure is part of a more general overview of anadromous fish in the study area. The later sections of the CRSO EIS do break out analyses and discussion by species and origin. The comment incorrectly implies that hatchery fish are not relevant to the CRSO EIS. However, hatchery-origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS.
6926	2	ASIHcons@gmail.com	N/A	o The economic and social analyses favor the port of Lewiston and minimize or ignore the tremendous recreation and traditional subsistence economies.	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The effects of MO3 on recreation is described in Section 3.11.3.5 and on commercial fisheries is described in Section 3.15.3.5. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries subsection and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries subsection of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Most sections of Chapter 3 include a Tribal Interests Section at the end that attempts to summarize issues by topic. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
6926	3	ASIHcons@gmail.com	N/A	Inaccurate statements about smolt survival, using a per dam survival metric, ignores the cumulative effects of delayed mortality and reservoir mortality. Overestimate of improvement in operations impacts on smolt to adult survival ratios (SARs) that result in a failure to meet the goal of 4% SAR survival. Missing information and incomplete or inadequate analyses that fail to represent the full range of alternatives, have no quantitative discussion of the effect of climate change on Snake River salmon and steelhead and understate the importance of maintaining wild populations. The 465 miles of the lower Snake and Columbia rivers to the ocean include a series of eight dams and reservoirs that create an almost continuous set of slack water reservoirs. Water travel times from Lower Granite to Bonneville Dam increased from 2 days to about 40 days. Many of the critical ecosystem features required for successful smolt migration have been lost, resulting in slower migration, increased stress, direct mortality and prolonged exposure to predators. Transit time to the sea for smolt migration has slowed from 2 days before mainstream dams were constructed, to an average of 20 days today. This increased travel time for out migration increases loss of smolts due to increased exposure to predation and compromises the necessary physiological changes that enable smolts to adapt to saltwater. The warmer impounded water often creates a thermal barrier to upstream migration. Sockeye Salmon are particularly sensitive to this warmer water. This belies the flaw in using the per dam survival metric. That approach claims >96% survival per dam; the Fish Passage Center (2019) reports that smolt survival from the Snake River to below Bonneville Dam averages about 50%. An estimated 76% of juvenile salmon that pass through the Columbia River hydrosystem died as a result of injury or stress incurred while migrating. The critical importance of SARs is well-recognized 80% of the variation in salmon survival is explained by SARs. It is linked to achieving NOAA interim survival and recovery standards in the 2000 FCRPS BIOP, is an established standard of the Northwest Power Planning Council Fish and Wildlife Program and was recognized by the Independent Science advisory Board as a 1st-order objective for restoring stocks. The recognized standard for survival is a mean SAR of 4% and range of 2%-6%. SARs ranged from 3.5 6.5% in the 1960s when only four dams existed. By the time the eight dams were completed, SARs had fallen below 1% on average. A natural river option is the only alternative that can attain recovery standards providing 2-6% smolt to adult survival ratios (SARs) [IDFG 1997, Limiting Factors and Recovery Options for Anadromous Fish Stocks in Idaho]. The recovery objectives identify a SAR of 2% associated with about 35% of historical productivity (1950-60s BEFORE completion of most of the federal dams), 4% SAR with about 70% of historical productivity and 6% SAR with about 105% historical productivity. The current SARs of Snake River Spring/Summer Chinook average about 1% or less, a ratio consistent with continued population declines. This is in stark contrast with mean SARs of John Day River Chinook (above 3 dams) of about 4% and Yakima River Chinook (above 4 dams) of about 2.5% recently. Snake River SARs are below 1%. Wild Steelhead SARs show a similar pattern. Migrating fish in the Columbia River basin, whether they spawn in the John Day, Yakima, or Snake River experience the same treaty and non-treaty fisheries, pinniped predation, and ocean conditions; the primary differences among them are the number of dams they pass. A 4-fold increase in SARs will be necessary to meet survival standards and reduce extirpation risks for Snake River stocks. We conclude that the more dams and reservoirs migrating fish need to negotiate, the greater the toll on anadromous fish. The final EIS must evaluate each alternative based on its ability to substantially improve SARs and meet the 4% goal.	Travel times under the No Action Alternative and MO1-4 are shown in Appendix E. Under MO3, the CSS model estimates travel time from LGR-BON would be 11-12.5 days for steelhead and Chinook. The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past 10 years has been shown to contribute to improvements in total in-river serval of smolts migrating through the CRS especially for steelhead. These figures were used to provide context in the Affected Environment Section. The focus of this EIS and the analysis presented throughout this EIS in Chapters 3.5 and 7 utilized total in-river survival, travel time, powerhouse passage rates, and Smolt-to-Adult return rates. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. These improvements are expected to benefit all of the stocks listed in this comment if latent mortality is reduced through higher spill levels. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for the Preferred Alternative. With the uncertainty associated with climate change, it is important that we establish methods for adapting and increasing flexibility on the system. There are measures in the Preferred Alternative that are adaptive to emerging changes in climate and ensure there is flexibility to respond to future changes. One example of this is the habitat restoration program that counters increased stream temperature with deeper pools and more shaded areas.
6926	4	ASIHcons@gmail.com	N/A	The No Action Alternative is unacceptable. SARs are so far below the threshold for survival that extinction is almost assured. Multiple Objective Alternative 1 (spill and transport) will not meet minimum recovery standards. Multiple Objective Alternative 2 maximizes power production and degrade conditions for salmon and steelhead populations, further accelerating the path to extinction. Multiple Objective Alternative 3 would breach the four Lower Snake River dams. Models suggest that salmon and steelhead populations would increase approximately 170%. Multiple Objective Alternative 4 increases spill throughout the spring/summer smolt out-migration. Models suggest population increases between 70-75 %. The Preferred Alternative uses flexible spill but fails to achieve recovery. Even the most optimistic projections fail to meet the 2% SAR for Spring Chinook. It is not satisfactory.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The 2% SAR target referenced in this comment refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4 for the Preferred Alternative, it will make a meaningful contribution towards recovery, but the Councils broad sense recovery goals are beyond the scope of this EIS which is limited to those effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6927	1	N/A	N/A	Specific Comments The CRSO DEIS was designed to deceive the public and decision-makers. The following information essential to decision-making was concealed. Federal District Court Judge Simon ordered a National Environmental Policy Act analysis of, in effect, removing the four lower Snake River dams. The COE previously produced a NEPA analysis that concluded, in effect, the dams were salmon doomsday devices; they could not be fixed to restore salmon, only removal would accomplish that. Instead of doing what the court ordered, the agencies pulled their usual con of hiding the four lower Snake River dams in the forest of an analysis of the entire Federal Columbia River Power System. The agencies compounded the deception, and fatally corrupted their analysis, by using as a premise of the DEIS that the dams authorized purposes must be met. This is not required by NEPA, and would defeat its intent of a wide-open and comprehensive evaluation of alternative ways to achieve the objective of restoring Snake River salmon. The DEIS did not reveal that the authorizing legislation for the dams required that they provide safe passage for Snake River salmon. The DEIS did not reveal that in 1946, decades before the first dam was built, the U.S. Fish and Wildlife Service warned the COE that if the dams were built they would pose an existential threat to Snake River salmon. The DEIS did not reveal that the COE also ignored the catastrophic failure of fish passage facilities just upstream at Idaho Power Company's three-dam Hells Canyon Project built in the late 1950s-early 1960s. There, as predicted, juvenile salmon were unable to pass through the reservoirs; salmon and steelhead were made extinct in the vast upper Snake River Basin. The DEIS did not reveal that the COE design for the lower Snake River dams negligently made no provision whatsoever for juvenile salmon to migrate through the reservoirs and past the dams. The DEIS does not reveal that the preferred alternative does not comport with the following laws, in addition to the legislation authorizing their construction: – Fish and Wildlife Coordination Act. –Laws establishing Snake River Basin Wilderness Areas, Wild and Scenic Rivers, National Recreation Areas and federal land management policies. Within the Snake River Basin is the largest contiguous wilderness and roadless land complex and largest expanse of pristine and near pristine salmon habitat in the coterminous United States. This 14 million-acre area includes more than 4.4 million acres in 6 Wilderness Areas, more than 700 miles in 12 Wild and Scenic Rivers, and nearly 1 million acres within 2 National Recreation Areas. Protecting wild salmon was a primary purpose of the laws creating all these areas. –Lower Snake River Compensation Plan, a contract obligating the federal government to replace with hatchery fish the wild fish estimated (corruptly underestimated) that would be lost due to construction of the dams. –The Pacific Northwest Electric Power Planning and Conservation Act of 1980 (Northwest Power Act). The Power Act requires that Snake River salmon be restored. Salmon were to get equitable treatment with other uses of the Federal Columbia River Power System.	Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the Fish and Wildlife Coordination Act, Wild and Scenic Rivers and the Northwest Power Act. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The Northwest Power Act does not require restoration of Snake River salmon, as the comment suggests, or of any other fish or wildlife. While the Northwest Power and Conservation Council and others, use terms such as rebuilding and restoring when discussing fish and wildlife mitigation, the Northwest Power Acts legal mandates do not. Instead, the Act consistently uses the terms protect, mitigate and enhance when discussing fish and wildlife. 16 U.S.C. 839 b(h)(1), (2), (5), (10), and (11). For example, a purpose of the Act is to protect, mitigate and enhance the fish and wildlife, including related spawning grounds and habitat, of the Columbia River and its tributaries, particularly anadromous fish which are of significant importance to the social and economic well-being of the Pacific Northwest and the Nation and which are dependent on suitable environmental conditions substantially obtainable from the management and operation of Federal Columbia River Power System and other power generating facilities on the Columbia River and its tributaries. 16 U.S.C. 839(6). This language is also reflected in the Purpose and Need Statement for the EIS. Under the Act, the co-lead agencies responsibilities to protect, mitigate, and enhance fish and wildlife apply to the effects of development, management, and operation of the federal dams, including the CRS, 1/ but not to more general restoration of fish and wildlife, which implicates numerous other factors including non-federal dams, population growth, habitat degradation, harvest, and ocean and climate conditions. The comment is correct that the Northwest Power Acts equitable treatment provision directs the co-lead agencies management and operation of the Columbia River System to provide equitable treatment for fish and wildlife with the other authorized purposes for which the system is managed, such as flood risk management, hydropower generation, irrigation, navigation, and recreation. See 16 U.S.C. 839b(h)(11)(A)(i). The co-lead agencies provide fish and wildlife with equitable treatment on a system-wide basis. See NW. Envtl. Def. Ctr. v. Bonneville Power Admin., 117 F.3d 1520, 1533-34 (9th Cir. 1997) (While each power marketing action that affects the system implicates the equitable treatment provisions, Bonneville may properly exercise its obligation by insuring equitable treatment for fish on a systemwide basis.); Confederated Tribes of the Umatilla Indian Reservation v. Bonneville Power Admin., 342 F.3d 924, 931 (9th Cir. 2003) (The equitable mandate of [the Northwest Power Act] does not require every Bonneville decision to treat fish and wildlife equitably. For example, Bonneville may make some decisions that place power above fish, so long as on the while, it treats fish on par with power.). Through this EIS process, the co-lead agencies have considered management and operation of the Columbia River System for its multiple authorized purposes. CSS analysis of the Preferred Alternative predicts an increase in smolt-to-adult return rates as compared to the no action alternative. The co-lead agencies inclusion of alternatives MO3 and MO4 which are focused on benefitting fish, plus the incorporation of measures specifically designed for improved benefits to fish and wildlife, as balanced against other purposes, reflects equitable treatment of fish and wildlife consistent with the Northwest Power Act. Regarding the Lower Snake River Compensation Plan, Bonneville directly funds the U.S. Fish and Wildlife Services annual operations and maintenance of the Lower Snake River Compensation Plan (LSRCP). Congress authorized the LSRCP as part of the Water Resources Development Act of 1976 (90 Stat. 2917) to offset fish and wildlife losses caused by construction and operation of the four lower Snake River dams. A major component of the authorized plan was the design and construction of fish hatcheries and satellite facilities. The LSRCP is administered through the USFWS. The LSRCP hatcheries and satellite facilities produce and release more than 19 million salmon, steelhead and rainbow trout each year as part of the programs mitigation responsibility. Upon the breaching of the lower Snake River dams as analyzed in MO3, Bonneville would no longer have an obligation to fund US Fish and Wildlife Service for the operations and maintenance of the LSRCP facilities. Bonneville's funding authority is directly tied to the operation of the LSR dams. The co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. The co-lead agencies, note as well that there are other hatcheries in the Snake River basin that would continue to produce fish not tied to LSRCP. Bonneville would continue to fund operation and maintenance of the LSRCP under all of the other alternatives, including the Preferred Alternative. 1/ See 16 U.S.C. 839b(h)(10)(A); 839b(h)(11)(A).

6927	2	N/A	N/A	The preferred alternative put forth in the DEIS is merely more of the agencies past fanatical betrayal of the public trust, dressed up in the rouge of balance and the mascara of adaptive management, what in August 2011 U.S. District Court Judge James Redden characterized as . . . a cynical and transparent attempt to avoid responsibility for the decline of listed Columbia and Snake River salmon and steelhead. The agencies have succeeded in driving Snake River salmon to the cusp of extinction. The DEIS makes it clear they intend to finish the job.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6929	1	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	The DEIS does not meet the legal requirements of NEPA. The Action Agencies prepared this DEIS to review and update operations, maintenance, and configuration of the 14 CRS multiple purpose dams and related facilities. DEIS, Executive Summary, p.7. Section 101 of NEPA declares a broad national commitment to protecting and promoting environmental quality.5 In furtherance of this commitment, NEPA requires federal agencies to analyze the environmental impact of their proposed actions by preparing environmental impact statements for actions significantly affecting the environment.6 The purpose of this requirement is to assure that agencies take a hard look at environmental consequences, and provide for broad dissemination of relevant environmental information.7 All impacts must be considered, whether direct, indirect, or cumulative, so long as they are reasonably foreseeable.8 The DEIS is legally insufficient because it: a) fails to clearly articulate what best available science is informing its effects determinations and selection of a preferred alternative; b) fails to adequately analyze the impacts and benefits of the proposed alternatives on aquatic resources and c) articulates a preferred alternative that is likely to jeopardize the continued existence and recovery of listed salmonids and is therefore inconsistent with existing laws.	NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement of NEPA, after evaluating scoping comments from the public, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to get to the range of alternatives. The Draft EIS considered the environmental consequences of the alternatives, including impacts to aquatic resources and disclosed to the public those consequences. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The effects analysis of each resource is based on current, high quality information in Chapters 3, 4, 5, 6 and Chapter 7. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat and are included as an appendix to the EIS.
6929	2	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	The Vague Purpose and Need Statement and Accompanying Objectives Guiding the DEIS Analysis Enable the Selection of a Legally Inadequate Preferred Alternative 5 Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 348 (1989) (Robertson) (citing 42 U.S.C. 4331). 6 42 U.S.C. 4332(2)(C). 7 Biodiversity Conservation Alliance v. BLM, 404 F.Supp.2d 212, 216 (D.D.C.2005). 8 See 42 U.S.C. 4332(2)(C); 40 C.F.R. 1508.7, 1508.8. April 13, 2020 Page 5 The vague objectives accompanying the purpose and need statement misguide the DEIS analysis from the beginning resulting in selection of a preferred alternative that is inconsistent with ESA requirements and the direction articulated by the National Wildlife Federation v. National Marine Fisheries Service court (hereinafter Court).9 NEPA requires federal agencies to articulate the purpose and need for a proposed action for which environmental review is required.10 The articulation of a purpose and need statement is critical for a properly framed and robust alternatives analysis– the heart of NEPA – because only a sufficiently broad statement will allow full development of an adequate range of alternatives which enables the EIS to provide a clear basis for choice among options by the decision-maker and the public.11 The purpose and need statement should be drafted in such a manner to not curtail a full assessment of alternatives.12 Purpose and need statements are often accompanied by objectives. Importantly, an agency may not define the objectives of its action in terms so unreasonably narrow that only one alternative from among the environmentally benign ones in the agencys power would accomplish the goals of the action.13 The Action Agencies declined the opportunity to articulate a broad purpose and need statement that would facilitate a robust, comprehensive analysis of alternative actions that could offset the impacts of the FCRPS, enable timely recovery of Columbia Basin salmon and steelhead, and be responsive to the deficiencies of the 2016 biological opinion as articulated in Court decision. Instead, the Action Agencies purpose and need statement focuses on reviewing and updating the management of the [FCRPS] System, including evaluating measures to avoid, offset, or minimize impacts to resources affected by the management of the System while ensuring that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat. DEIS, Executive Summary, p. 16. 9 National Wildlife Federation v. National Marine Fisheries Service, 184 F.Supp.3d 861 (D. Or. 2016). 10 40 CFR 1502.13. 11 See, e.g., Simmons v. U.S. Army Corps, 120 F.3d 664 (7th Cir. 1997); Davis v. Mineta, 302 F.3d 1104, 1118 (10th Cir. 2002); see also 40 CFR 1502.14. 12City of Carmel-by-the-sea v. United Dept of Transp., 123 F.3d 1142, 1155 (9th Cir. 1997). 13 Friends of Southeasts Future v. Morrison, 153 F. 3d 1059, 1066 (9th Cir. 1998) (quoting Citizens Against Burlington, Inc. v. Busey, 938 F. 3d 190, 196 (D.C. Cir. 1991). April 13, 2020 Page 6 In effect, the Action Agencies have assumed the lowest possible bar for species protection by indicating that the purpose of the DEIS is to comply with ESA and then interpreting that obligation throughout the document in an unacceptably narrow manner. Accordingly, there is little acknowledgment that, as part of their obligation under ESA, the DEIS must analyze whether or not proposed actions impede listed species prospects for recovery. The Action Agencies could have provided needed direction and clarification as part of the purpose and needs objectives but declined that opportunity as well as noted in more detail below. Accordingly, the DEIS does not articulate a plan that will help ensure both the survival and recovery of listed salmon and steelhead. Nor does it attempt to reach bolder goals that will rebuild abundant, resilient and harvestable levels of salmon and steelhead which is the goal the region is seeking to attain, as confirmed by the Columbia Basin Partnership.14 With such a low bar for species protection guiding its analysis, the DEIS leaves itself little room for uncertainty or error before running afoul of both NEPA and ESA requirements and the Court decision.15 Unfortunately, as detailed infra, the DEIS conclusions and analysis are underpinned by significant uncertainty providing little assurance that the Preferred Alternative will achieve even the low bar it has set for listed salmonids. a. The stated objective of improving fish populations is insufficient to meet applicable laws, including the Endangered Species Act. TU appreciates that the DEIS includes objectives to identify how the Action Agencies aim to achieve their purpose and need. DEIS, Executive Summary, p. 17. When clearly constructed, project objectives allow a measurable mechanism for decision-makers and the public to assess whether and to what degree the stated alternatives meet the purpose and need. In particular, objectives can help quantify how project alternatives will fulfill ESA obligations and further species recovery objectives. Regrettably, the DEIS objectives, especially for fish species, are too vague to be meaningful. This, in combination with the fact that objectives for other non-fish purposes (i.e., power supply) 14 See Phase 1 Recommendations, Columbia Basin Partnership available at https://www.fisheries.noaa.gov/west-coast/partners/columbia-basin-partnership-task-force. 15 National Wildlife Federation v. National Marine Fisheries Service, 184 F.Supp.3d 861 (D. Or. 2016). April 13, 2020 Page 7 contain more detail, enables an unbalanced DEIS analysis where more environmentally robust alternatives cannot meet the objectives for other purposes yet alternatives with more robust measures for non-fish purposes can still meet the fish objectives with minimal environmental safeguards. For instance, the DEIS contains objectives to improve adult and juvenile salmon and resident fish populations. DEIS, Executive Summary, p. 19. No definition, information or metrics are provided regarded what constitutes improvement. Without direction or metrics to provide meaning to this term, the DEIS analysis appears to be mostly guided by the objective to comply with environmental laws. DEIS, Executive Summary, p. 18. This objective, of course, requires compliance with ESA but does not include any metrics to inform how the Action Agencies will determine that proposed actions are meeting both the survival and recovery prongs of ESA. Section 7 of the ESA requires federal agencies to "insure that any action authorized, funded, or carried out by such agency ... is not likely to jeopardize the continued existence of any endangered species ...."16 To "jeopardize the continued existence of" a species means "to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species."17 The survival and recovery aspects of this obligation are distinct.18 A species may be jeopardized even "if there is no appreciable reduction of survival odds" because "a species can often cling to survival even when recovery is far out of reach."19 In other words, proposed actions cannot appreciably impede species survival or recovery prospects.20 Accordingly, the Action Agencies must analyze project effects on recovery as well as survival.21 16 16 U.S.C. 1536(a)(2). 17 50 C.F.R. 402.02 (emphasis added). 18 While they are not necessarily mutually exclusive, recovery and jeopardy are two distinct concepts. Cascadia Wildlands v. Thrailkill, 806 F.3d 1234, 1244 (9th Cir. 2015). In making a jeopardy determination, fish agencies are required to assess both the survival and recovery of a listed species. 50 C.F.R. 402.02. The agency is not permitted to resolve the difficulty of distinguishing between survival and recovery by ignoring recovery needs and focusing entirely on survival. Natl Wildlife Fedn, 524 F.3d at 932. 19 See National Wildlife Federation v. National Marine Fisheries Service, 524 F. 3d at 931. 20 Id. at 932. 21 Id. April 13, 2020 Page 8 Unfortunately, the DEIS does not provide sufficient metrics to track whether and in what magnitude and timeframe the alternatives assist the species to hit survival or recovery targets. Such targets (both high end recovery goals and numeric goals required to remove ESA protections for Columbia stocks) have already been articulated by the Columbia Basin Partnership and should have informed this effort. Without targets and metrics, the sufficiency of the alternatives in meeting legal requirements under the ESA and other federal laws cannot be determined. b. The purpose and need facilitates a DEIS analysis that does not conform to the Courts directives in National Wildlife Federation v. National Marine Fisheries Service, 184 F.Supp.3d 861 (D. Or. 2016). The Action Agencies were compelled into the NEPA process pursuant to the Federal District Courts directives in National Wildlife Federation v. National Marine Fisheries Service, 184 F. Supp.3d 861 (D. Or. 2016). The Court ordered that they conduct a NEPA analysis before they adopt and implement a NMFS biological opinion for listed Columbia River	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Additionally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia Basin. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat and are included as an appendix to the EIS.

				salmon and steelhead. Supporting its order, the Court noted: For more than 20 years, NOAA Fisheries, the Corps, and BOR have ignored the admonishments of Judge Marsh and Judge Redden to consider more aggressive changes to the FCRPS to save the imperiled listed species. The agencies instead continued to focus on essentially the same approach to saving the listed speciesminimizing hydro mitigation efforts and maximizing habitat restoration. Despite billions of dollars spent on these efforts, the listed species continue to be in a perilous state. One of the benefits of a NEPA analysis, which requires that all reasonable alternatives be analyzed, is that it allows innovative solutions to be considered and may finally be able to break through any bureaucratic logjam that maintains the status quo. The agencies, public, and public official will be able to evaluate the costs and benefits of various alternatives. The FCRPS remains a system that cries out for a new approach. A NEPA process may elucidate an approach that will finally move the listed species out of peril. National Wildlife Federation v. National Marine Fisheries Service, 184 F.Supp.3d at 876. The Action Agencies indicate that the DEIS is intended to be responsive to the Courts direction. The co-lead agencies assessment also addressed the need to respond to the Opinion and Order issued by the U.S. District Court for the District of Oregon to evaluate how the system can be operated in compliance with Section 7(a)(2) of the ESA. April 13, 2020 Page 9 DEIS, p. 7-3 However, the Action Agencies did not embrace the direction of the Court when structuring the DEIS analysis around a purpose and need statement and accompanying objectives that effectively ensured that the same unproductive path of the previous plans (which were all rejected in federal court) would persist without measures adequate to meet ESA and other legal obligations. Ensuring that the survival and recovery of ESA-listed anadromous fish species is not appreciably reduced by the FRCPS should have been the foundation for the DEIS purpose and need statement and its objectives. The Court recognized the value of objectives, particularly to identify whether and how actions meet ESA obligations.22 Specifically, the Court noted that without metrics tied to any estimated recovery abundance levels and the timeframe needed to achieve those levels, even roughly it cannot be rationally concluded that an alternative will be sufficient to avoid appreciably reducing a species chance of recovery.23 The Court also emphasized the particular importance of metrics when encountering species with low abundance levels recommending the identification of any metric or goal that considers whether the incremental improvements to the currently low abundance levels [of listed fish populations] are sufficient to avoid creating a "new risk of harm" by decreasing the chances of recovery of the listed species.24 The Court further suggested that an analysis of Viable Salmonid Populations (VSP) parameters such actual abundance, spatial structure and diversity should inform a jeopardy analysis.25 As noted above, however, the purpose and need objectives do not identify any metrics that can enable the Action Agencies and members of the public to determine whether the proposed actions meet ESA standards or otherwise benefit fish populations. Instead, vague objectives unmoored to the ESAs legal requirements and fish requirements in other federal laws, including 22 Nat'l Wildlife Fed'n v. Nat'l Marine Fisheries Serv., 184 F. Supp. 3d at 892. 23 Id. at 894. 24 Id. at 892. 25 Id. at 887-890; See also McElhany, P., M.H. Ruckelshaus, M.J. Ford, T.C. Wainwright, and E.P. Bjorkstedt. 2000. Viable salmonid populations and the recovery of evolutionarily significant units. U.S. Dept. Commer., NOAA Tech. Memo. NMFSNWFSC-42, 156 p (identifying four broad categories for VSP parameters: diversity, spatial structure, abundance, and productivity. These factors have been identified as a means to assess populations, establish delisting goals, and provide guidelines for relating viability at the population level and broader levels.) April 13, 2020 Page 10 treaties with Native American tribes, results in a preferred alternative that does little more than preserve the status quo; an outcome which is directly contrary to the Courts direction.	
6929	3	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	The DEIS Effects Analysis for Aquatic Resources is Incomplete and Unclear Under NEPA, the analysis in an EIS must consider direct, indirect, and cumulative effects of the proposed alternatives. Effects include ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative. 40 C.F.R. 1508.8. Unfortunately, the DEIS effects analysis is insufficient because of its reliance on multiple, sometimes conflicting, modeling tools that fail to adequately capture the alternatives range of impacts, including the beneficial impacts of LSDR included in Multiple Objective (MO) Alternative 3. TUs specific comments on the DEIS effects analysis are set forth below. a. The DEIS fails to disclose model limitations and does not adequately explain how divergent model results are used to evaluate alternatives The DEIS uses quantitative results from COMPASS, CSS and the Life Cycle Model (LCM) to predict juvenile and adult survival metrics for focus populations of salmon and steelhead. DEIS, p. 3-358. The DEIS notes that, in some scenarios, the models produce very divergent predictions and attributes these to a few critical assumptions. While the models apply different assumptions and predict survival with different environmental variables on different temporal scales, the divergent predictions are the result of only a few critical assumptions. DEIS, p. 3-360. The most significant assumption being attribution of cause for changes in latent mortality. An EIS is required to clearly present information and analysis of the environmental consequences that form the scientific and analytic base for consideration of reasonable alternatives.26 In so doing, it must identify the methodologies used, and must explicitly refer to the scientific sources of information relied upon for the conclusions it sets forth. The DEIS clearly acknowledges and describes the divergent results of the different models. However, the DEIS is less clear about which of the results it is relying upon to reach its effects 26 40 C.F.R. sections 1502.14, 1502.16. April 13, 2020 Page 11 analysis conclusions. The DEIS notes that the models different assumptions produce different results related to the magnitude of benefit and significance of impact of all alternatives. Without additional analysis, inclusion of the results of both models mainly serves to highlight the inherent uncertainty that exists in terms of fish outcomes with implementation of any of the alternatives. The one exception is that all models unequivocally find the most improvement for salmon and steelhead with implementation of MO3, and, despite uncertainty as to the magnitude of benefit, MO3 is in fact the only alternative that ensures the continued existence of salmon and steelhead in the basin. Beyond divergent results, the models each have inherent limitations not adequately identified in the DEIS. For instance, the fact that the models focused only on a subset of stocks for which sufficient data were available. For most stocks, assessment was qualitative; based on application of general findings from empirical models without direct analysis. This shortcoming is not explored or described sufficiently in the DEIS. Additionally, germane questions posed by independent subject matter experts about the models limitations are not addressed. For example, the Independent Science Advisory Board (ISAB) questioned the insensitivity of COMPASS model to differential spill. The DEIS is unclear if this insensitivity, relative to the findings of the CSS model, is due to truly mechanistic/empirically based differences in impact of spill or a lack of variability in the data used to evaluate spill.27 Given the limitations and the wide range of results presented by the different models regarding effects to salmon and steelhead populations, it is necessary for the Action Agencies to disclose what specific model results (and other scientific information) they are relying upon to inform their effects conclusions and selection of a preferred alternative. To the extent there is significant uncertainty in the modeling, the DEIS must account for that by considering the impact on listed fish populations in the event that the worse-case outcome materializes and concrete actions or processes that are recommended to mitigate against that uncertainty. This analysis should be guided by a recognition that the Action Agencies ESA obligation to insure against a likelihood of jeopardy requires that the benefit of the doubt be given to listed species 27 Independent Scientific Advisory Board (ISAB). 2017. Review of NOAA Fisheries Interior Columbia Basin Life-Cycle Modeling (May 23, 2017 draft). Available at https://www.nwcouncil.org/fish-and-wildlife/fw-independent-advisory-committees/independent-scientific-advisory-board/review-of-noaa-fisheries-interior-columbia-basin-life-cycle-modeling-draft-report. April 13, 2020 Page 12 and the burden of protecting against risk and uncertainty on the agency. See Ariz. Cattle Growers Assn v. Salazar, 606 F. 3d 1160, 1166 (9 th Cir. 2010). b. The benefits of LSDR are not adequately captured in the DEIS NEPA requires the consideration of both beneficial and adverse effects of the proposed alternatives.28 It is absolutely essential to the NEPA process that the decisionmaker be provided with a detailed and careful analysis of the relative environmental merits and demerits of the proposed action and possible alternatives, a requirement that we have characterized as "the linchpin of the entire impact statement", Monroe County Conservation Society, Inc. v. Volpe,472 F.2d at 697-98. Natural Resources Defense Council v. Callaway, 524 F.2d 79, 92 (2d Cir. 1975) Despite this requirement, the DEIS does not adequately capture the benefits of MO3. As noted above, the divergent model results highlight the risk of uncertainty present from implementation of the alternatives, but neither is sufficient to capture the benefits of LSDR in MO3. For instance, the presented models do not address the following benefits of dam removal: (1) a much more productive food web (due to the shift to lotic habitat and influxes of marine-derived nutrients) providing increased food sources for salmon and steelhead; (2) habitat complexity and the water temperature, foraging and predator avoidance benefits it provides; (3) improved fitness of smolts due to the fact that they would not have to actively migrate and could ride the current through the lower Snake; (4) reductions in predator populations; 5) improvements in life history and genetic diversity that would be developed and maintained in a complex, free-flowing river; 28 40 C.F.R. 1502.23 ([T]he weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis.); but see e.g., Sierra Club v. Sigler, 695 F.2d 957, 978-79 (5th Cir. 1983) (holding that NEPA mandates at least a broad, informal cost-benefit analysis, and so agencies must fully and accurately and objectively assess environmental, economic, and technical costs); Chelsea Neighborhood Assns v. U.S. Postal Serv., 516 F.2d 378, 387 (2d Cir. 1975) (NEPA, in effect, requires a broadly defined cost-benefit analysis of major federal activities.); Calvert Cliffs Coordinating Comm. v. U.S. Atomic Energy Commn, 449 F.2d 1109, 1113 (D.C. Cir. 1971) (NEPA mandates a rather finely tuned and systematic balancing analysis of environmental costs against economic and technical benefits); Natl Wildlife Fed. v. Marsh, 568 F. Supp. 985, 1000 (D.D.C. 1983) (The cost-benefit analysis of NEPA is concerned primarily with environmental costs. . . .). April 13, 2020 Page 13 and 6) positive and	The co-lead agencies used current high quality data and the best available science in the analysis of the CRSO EIS. Where data was not available to model effects to certain species, the co-lead agencies explained that lack of data and qualitatively evaluated the effects to those species. More detail on the analytical approach and modeling is captured in Appendix E. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. Results from both models were used by the co-lead agencies to bookend potential effects of the No Action Alternative, the 4 MO's, and the Preferred Alternative. The results of third-party review, both the Corps' Independent Expert Peer Review as well as a recently released ISAB review of the CSS results have been included in the Final EIS and provide more technical review of these models. This review included the use of wild and hatchery fish for both the CSS and the NOAA models. Both modeling approaches consider the effect of transportation on both downstream juvenile migrants as well as returning adult salmon and steelhead. Initial review of the results of the peer review do not indicate fundamental flaws in either the CSS or NMFS approach and both models will continue to frame the potential outcomes associated with all MOs and the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In relation to the comment that fish passing few dams have higher SARs and survival, the co-lead agencies follow the guidance from the Independent Science Advisory Board, and to not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons. The 2 to 6 percent Smolt-to-Adult return rates (SARs) target referenced in this comment refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. Based on the analysis, the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. Regarding MO3 analysis, different models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Life Cycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict the alternative that includes the measure of dam breaching will have the highest benefit for several species of salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

				interactive feedback loops that would continue to increase the synergistic benefits of each of these effects. Together, these benefits would be expected to provide a huge boost to Snake River stocks, but the benefits are not addressed in the modeling. This is a major omission. Even if, at this time, there is not sufficient empirical information to robustly capture these beneficial effects in the model, a comprehensive effort to capture them qualitatively should have been made. Additionally, assumptions were made in the models that likely serve to under-estimate the benefit of dam removal. For instance, the LCM model used information about smolt survival taken from free-flowing sections of the Snake River upstream of Lower Granite Reservoir and applied those to downstream reaches to evaluate smolt survival through a free-flowing river below the lower Snake dams. However, upstream migrants are smaller and less mature than a downstream fish would be and therefore downstream fish survival estimates from the LCM are likely under-estimated. c. The effects analysis fails to adequately analyze impacts to wild fish The DEIS notes that, in most cases, quantitative results from COMPASS, CSS, and the Life Cycle Model (LCM) are based on a combination of hatchery and natural origin fish. DEIS, p. 3-358. This fact, along with the existence of large numbers of hatchery fish in certain systems, such as the Snake, confound attempts to estimate impacts to wild fish from implementation of the alternatives. This is problematic as it serves to mask the imperiled status of ESA-listed wild stocks of salmon and steelhead, many of which are experiencing sharp downward population trends, and over-emphasizes solutions that are more tailored for hatchery fish. The Action Agencies must evaluate and disclose how the high number of hatchery fish effect the modeling results and conclusions with respect to wild fish. d. The models fail to adequately capture the full range of impacts from the alternatives and disclose relevant shortcomings NEPA requires the up-front disclosures of relevant shortcomings in the data or models relied upon in environmental documents. Lands Council v. Powell, 395 F. 3d 1019, 1032 (9th Cir. April 13, 2020 Page 14 2005). In some cases, the assumptions used in the models fail to capture the effects to fish populations from certain actions, yet these limitations are not disclosed. As one example, the LCM shows a benefit to MO4s proposal to barge late migrating smolts because such an action allows the smolts to avoid lethal high-water temperatures, particularly in the lower Columbia. However, the model does not account for the fact that adult salmon and steelhead (particularly steelhead) that were transported as juveniles often have a higher tendency to stray into rivers other than their river of origin. Additionally, the model does not contextualize its findings to note that smolt transportation programs that have occurred to date have not met regional SAR goals identified by the Northwest Power and Conservation Council (2% to 6% SAR range, average 4% for ESA-listed Snake and Columbia salmon and steelhead populations).29 For instance, Comparative Survival Study (CSS) data shows the 24 year average SAR of transported wild Snake River Spring Chinook was 0.98%, indicating not only are these fish not approaching the 2% SAR needed to ensure population maintenance, but are declining despite transport.30 Additionally, hatchery Spring Chinook originating from Dworshak, Sawtooth, Catherine Creek and Clearwater hatcheries, that were transported as juveniles all have SARs far less than 1% indicating population decline.31 As stated in the CSS 2019 Annual Report, [f]or Snake River populations, none of the passage routes (in-river or juvenile transportation) have provided SARs within the range of the NPCC objectives.32 Further, [u]nless a minimum level of survival is maintained for listed species sufficient for them to at least persist, the issue of the effect of transportation is moot.33 Accordingly, the benefits from this action (transport) are likely over-stated especially given the precarious state of many of the stocks. 29 Columbia River Basin Fish and Wildlife Program, Northwest Planning and Conservation Council, 2014 Program and Part II of 2020 Addendum available at https://www.nwcouncil.org/reports/2014-columbia-river-basin-fish-and-wildlife-program. 30 Mccann, J., et al. 6929	4	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	iii. The DEIS Fails to Analyze Lower Snake River Compensation Plan Hatchery Impacts as a Direct Effect of the Project as Required by NEPA NEPA defines direct effects of a proposed action as those that are caused by the action and occur at the same time and place. 40 C.F.R. section 1508.8(a). The DEIS notes that the Lower Snake River Compensation Plan (LSRCP) was created to mitigate the loss of salmon and other fish and wildlife affected by the construction of the four Lower Snake River dams. The LSRCP required construction of eight fish hatcheries. Currently, Bonneville directly funds USFWS for the annual operation and maintenance of these LSRCP facilities. DEIS, p. 2-32. LSRCP hatcheries and satellite facilities produce and release more than 19 million salmon and steelhead as part of the programs mitigation responsibility. Id. The LSRCP is included as part of the No Project Alternative and the DEIS notes it would be continued under all of the alternatives except MO3. DEIS, p. 2-37. Despite the direct relationship between operation of the CRSO and LSRCP hatchery operations, the DEIS does not treat LSRCP hatchery effects as direct effects. Instead, its effects analysis notes that anadromous fish are influenced by many factors unrelated to the operations and configuration of the CRS and include competition and interbreeding with hatchery stocks. DEIS, pp. 3-446, 447. In fact, the LSRCP hatcheries are directly related to the operations and configuration of the FCRPS and must be analyzed as such.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. This Draft EIS analyzes the effects of configuration, maintenance, and operation of the CRS projects in Section 3.4 and Chapter 7. The operation of the hatchery programs in the basin are included in the Affected Environment and, as expected to continue, were evaluated as part of the No Action Alternative evaluation in the Environmental Consequences. In MO3, the effects of discontinuing the LSRCP program was considered qualitatively because the fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. The analyses used in this Draft EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. The scope of this Draft EIS is the operation and configuration of CRS projects; a complete analysis of all hatchery programs is beyond this scope. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
6929	5	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	iv. The DEIS Fails to Adequately Analyze the Impacts of Hatchery Fish on Wild Salmon and Steelhead Using the Best Available Science The best available scientific information is clear that hatchery fish do not address the factors limiting wild fish and have, in many cases, contributed to the decline of wild populations. In its 2015 report to Congress, the congressionally-appointed Hatchery Scientific Review Group (HSRG) stated: Hatcheries cannot replace lost habitat and the natural populations that rely on it. It is now clear that the widespread use of traditional hatchery programs has actually contributed to the overall decline of wild populations. Annual Report to Congress on the Science of Hatcheries, 2015, Hatchery Scientific Review Group, (July 2015), p. 2. April 13, 2020 Page 16 This fact is corroborated by the 2015 finding of the Independent Scientific Advisory Board (ISAB) that density dependence (i.e., overcrowding of available habitat) reductions in wild population productivity in the interior Columbia basin is becoming evident and that too many hatchery fish spawning in the wild is a major and pervasive problem.34 In addition to these demographic effects, hatchery fish also jeopardize the genetic integrity and life history diversity of wild fish when they interbreed, threatening their ability to adapt to a changing environment. Unfortunately, these effects are not meaningfully captured in the DEISs effects analysis or in the cumulative effects analysis. Accordingly, the DEIS fails to give more than a cursory analysis to this topic despite the existence of ample research that clearly demonstrates that the productivity of wild populations decreases when hatchery fish spawn in the wild. ISAB at 141. A 2016 study by the Independent Science Advisory Board found that [s]trong density dependence is now evident in at least 25 of 27 spring/summer chinook populations, the Snake River fall chinook population, and all 20 steelhead populations examined upstream of Bonneville Dam. ISAB at 139. As the ISAB points out, this is likely due in part to supplementation programs that result in large numbers of adult hatchery fish on the spawning grounds: 35-80% of chinook spawners and 15-80% of steelhead spawners per ESU and DPS, respectively. ISAB at 141. The Action Agencies analysis of hatchery impacts on wild salmon and steelhead is badly out of step with the best available science. It utterly fails to account for the ISABs reports and the large and growing body of peer-reviewed literature establishing the harmful genetic and ecological impacts of hatcheries on wild populations. Instead, the Action Agencies suggest that hatcheries are beneficial to wild populations without providing a scientific basis for such conclusions. For example, the DEIS says that the preferred alternative includes measures to benefit ESA-listed fish including fish hatchery production (DEIS, p. 7-22), yet offers no scientific support for that conclusion. In other places, the analysis of hatchery impacts is woefully incomplete. For example, in its analysis of MO3, there is a brief qualitative analysis suggesting that the reduction of hatchery fish by as much as 85 percent would result in lower survival rates of wild Chinook as they navigate through the predators inhabiting the migratory 34 Density Dependence and Its Implications for Fish Management in the Columbia Basin, Independent Scientific Advisory Board (ISAB) (February 25, 2015). April 13, 2020 Page 17 corridor DEIS, pp. 3-548, 549, 558. This conclusion is not supported by any quantitative analysis. The DEIS fails to round out this analysis by adequately analyzing the expected predation benefits from dam removal, such as the concomitant reduction in lentic predators that would occur with removal of the reservoirs or the increased ability of salmon and steelhead to avoid predation in a free-flowing river. TU acknowledges that there are benefits to hatchery production, such as maintaining populations on the brink of extinction and reintroducing extirpated populations. But the scientific evidence about the harmful genetic and ecological effects of hatcheries on wild populations is clear. A much more robust analysis, based on the best available science, on the effects of hatcheries on wild salmon and steelhead is required.	The Draft EIS uses current high quality information and best available science to describe and acknowledge the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. This information and science was used to analyze the effects of the configuration, maintenance, and operation of the CRS projects in Section 3.4 and Chapter 7. The operation of the hatchery programs in the basin are included in the Affected Environment and, as expected to continue, were evaluated as part of the No Action Alternative evaluation in the Environmental Consequences. In MO3 the effects of discontinuing the LSRCP program was considered qualitatively because the fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. The analyses used in this Draft EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. The scope of this Draft EIS is the operation and configuration of CRS projects; a complete analysis of all hatchery programs is beyond this scope. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
6929	6	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	v. The DEIS Fails to Explain How Maintaining Suboptimal Temperature Conditions Meets the Purpose and Need and Requirements of Federal Law The DEIS fails to adequately analyze how maintaining severely degraded temperature conditions, especially considering climate change projections, supports the conclusion that the preferred alternative meets the purpose and need and legal obligations, such as ESA and the Clean Water Act. The DEIS acknowledges the degraded status quo temperature condition and the role that the proposed action has in maintaining that condition. Water temperatures in many reaches do not meet the regulatory standards in the summer and early fall. System operations can impact both water temperature and TDG in the Columbia River Basin DEIS, p. 3-236 Under the No Action, the State water quality standard for temperature is violated on average (for the five years simulated) 57, 71, 71 and 58 days downstream of McNary, John Day, The Dalles and 2207 Bonneville dams, respectively. As comparison, under the Preferred Alternative, the State water quality standard is violated (on average for the five years simulated) 63, 71, 72, and 59 days downstream of McNary, John Day, The Dalles and Bonneville dams, respectively. The differences in tailwater temperatures under the No Action	The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperature. The EIS results indicate that the operations of the CRS do impact water temperature, but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. The Draft EIS indicates that some CRS dams can lead to heating and cooling, while other CRS dams have little to no influence on the water temperatures. For example, the Draft EIS references historical temperatures in the lower Snake River basin prior to the construction of the four lower Snake River facilities and the Hells Canyon Complex. This data shows that temperatures in the pre-dam, free-flowing lower Snake River often exceeded 68F (20C) in July and August and occasionally exceeded 25C. These measurements were taken near the mouth of the Snake River from 1955 to 1958. (source: Peery, C. A. and T. C. Bjornn. 2002. Water Temperatures and Passage of Adult Salmon and Steelhead in the Lower Snake River. Technical Report 02-1. U.S. Geological Survey, Idaho Cooperative Fish and Wildlife Research Unit, University of Idaho, Moscow, Idaho.) Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Drier and warmer years such as 2015, as summarized in NMFS' 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage

				Alternative and the Preferred Alternative are considered negligible. DEIS, p. 7-86. April 13, 2020 Page 18 As noted above, the water quality standard for temperature will be violated at a slightly higher rate under the preferred alternative as compared to the no-action alternative. The DEIS does not explain how essentially maintaining status quo temperature conditions (or worsening them) meets its obligations under federal law. ESA requires that the preferred action not be likely to result in destruction or adverse modification of designated critical habitat of listed species.35 Critical habitat includes areas with the physical or biological features essential to the conservation of listed species and includes elements such as adequate water temperature.36 Critical habitat includes the juvenile and adult migration corridors of the Snake and Columbia Rivers. The Court gave direction on this point noting that [s]imply maintaining the status quo when there is severely degraded habitat that does not serve its conservation role and will be adversely modified unless changes are made to the operations of the FCRPS does not suffice [to meet ESA obligations].37 Accordingly, the preferred alternative, which would maintain harmful water temperatures in contravention of federal law, is legally deficient.	ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the Draft EIS (see Chapters 2 and 8). In addition, the co-lead agencies are actively working on implementing the recommendations identified in NMFS' 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision making and reduce, to the extent practicable, the adverse impacts of high summer temperatures on migrating salmon, including adult sockeye salmon. The water temperature analysis specific to MO3, which includes breaching the four lower Snake River Dams, utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-dimensional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. Specifically, 2016 No Action Dworshak operations were used in the MO3 analysis. Results were provided to the fish team for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. The models are also not available at the required resolution (river-scale vs. regional- or global-scale). Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3 and Section 7.8.4). EPA is the lead agency on developing a water temperature TMDL for the Columbia and Snake Rivers, and in doing so will evaluate the impact of all anthropogenic and natural sources of heat in the Columbia and Snake rivers. In contrast, the Draft EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. Thus, the Draft EIS did realistically and clearly analyze, to the extent practicable, whether the hydrosystem is causing or contributing to compliance with the water quality standards as compared to historic river temperatures. In addition to investigating the operational impacts on water temperature, the co-lead agencies have taken other actions to address water temperature impacts on fish passage. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with all applicable laws such as Clean Water Act and ESA. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4., the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6929	7	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	vi. The Affected Environment Omits Necessary Information Central to Understanding Status and Trends of Key Fish Species The Affected Environment section omits information that is central to understanding the status and trends for the relevant salmon and steelhead stocks. The description of each species does not include information expressed in the metrics that the Court found lacking in or missing from the biological opinion. For instance, the DEIS should have displayed relevant information for each stock at the (Evolutionarily Significant Unit or Distinct Population Segment) level regarding both the survival prong and the potential for recovery elements of the jeopardy standard including analysis of the levels of abundance, distribution and life history diversity that are necessary to ensure the likelihood of recovery is not appreciably diminished. This is essential for being able to understand the current status of each species because the minimum population levels needed to ensure survival are found at the ESU/DPS level and not the aggregate species level. 35 16 U.S.C. section 1536(a)(2). 36 16 U.S.C. section 1532(5)(A). 37 Natl Wildlife Fedn, 184 F. Supp.3d at 875. April 13, 2020 Page 19 At a minimum, the final EIS (or revised DEIS) should contain information in tabular or graphic form regarding the three quantitative measures that are part of the trend towards recovery analysis: abundance trend, the median annual change in population in four year running sums, and the recruit per spawner ratios. While necessary, these three measures are not sufficient. There should also be information on the abundance of each of the 27 populations. This information will better inform decision-makers and the public about which populations are at alarmingly low numbers where survival may be in question, or where the low abundance numbers are trending at a level that diminishes the likelihood of recovery.	The metrics and citations provided in this comment are relevant to ESA consultation, not the NEPA process. The co-lead agencies are currently in consultation with NMFS and the U.S. Fish and Wildlife Service. The biological opinions that conclude that consultation process will be appended to the FEIS. In the CRSO EIS, the co-lead agencies focused on utilizing current high quality information and metrics that will enable the co-lead agencies to analyze the effects of the operation and maintenance of the CRS projects and that provide meaningful assessment of information for the comparison between the range of alternatives and the No Action Alternative. This information and analysis has and will inform the public and the decision makers in selecting an alternative in the Record of Decision.
6929	8	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	vii. The Action Agencies Preferred Alternative Does Not Include Necessary Actions to Meet ESA and Northwest Power Act NEPA requires agencies to: study, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources. This requirement seeks to ensure that each agency decision maker has before him and takes into proper account all possible approaches to a particular project which would alter the environmental impact and the cost-benefit balance. 42 U.S.C. 4332(2)(D).38 A viable but unexamined alternative renders [the] environmental impact statement inadequate.39 As part of the alternatives analysis, the DEIS must examine whether and how the alternatives meet legal obligations including ESA, the Northwest Power Act and treaty obligations. Relevant ESA obligations are discussed more fully in section II(a)(i)(a) supra. The Northwest Power Act requires Action Agencies to take the Fish and Wildlife Program adopted by the Northwest Power 38 Calvert Cliffs' Coordinating Committee, Inc. v. U. S. Atomic Energy Commission, 449 F.2d 1109, 1114 (D.C. Cir. 1971). Further, NEPA section 102(2)(E) requires that the federal lead agency study, develop, and describe appropriate alternatives to recommended course of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources.... 42 U.S.C. 4332(2)(E). The duty to consider alternatives under NEPA 102(2)(E) is at least as broad as the duty under NEPA section 102(2)(C)(iii). The purpose is to insist that no major federal project should be undertaken without intense consideration of other more ecologically sound courses of action, including shelving the entire project or of accomplishing the same result by entirely different means. Environmental Defense Fund v. U.S. Army Corps of Engineers, 492 F.2d 1123 (5th Cir. 1974); see Mandelker, supra 9:22, p. 9-53. 39 Muckleshoot Indian Tribe, supra, 177 F.3d at 814 (quoting Citizens for a Better Henderson v. Hodel, 768 F.2d 1051, 1057 (9th Cir. 1985)). April 13, 2020 Page 20 and Conservation Council (NPCC) into account at each relevant stage of decision-making processes to the fullest extent practicable. 40 The program currently seeks to achieve smolt-to-adult return rates in the 2-6 percent range (minimum 2 percent; average 4 percent) for listed Snake River and upper Columbia salmon and steelhead.41 Additionally, it seeks an increase in total adult salmon and steelhead runs to an average of 5 million annually by 2025 to, among other things, support tribal and nontribal harvest.42 Despite the limitations of the models, the DEIS is clear that removing the lower Snake River dams is the best option for Snake River salmon and steelhead. Both the LCM and CSS model find that MO3 offers Snake River salmon and steelhead the best chance for recovery by improving smolt-to-adult returns (SARs) by the highest percentages of all the studied alternatives. But, as noted above, the benefits to fish populations from this alternative are likely vastly underestimated given modeling limitations. Yet, the Action Agencies selected a different set of actions without LSRD as the preferred alternative. The preferred alternative is expected to yield improvements to SARs that are far less than MO3. In fact, depending on how the assumptions play out, it is possible that the preferred alternative will not even meet the ESAs survival requirement for Snake River salmon and steelhead let alone not appreciably reduce the likelihood of recovery. Depending on the model and Evolutionarily Significant Unit (ESU)/Distinct Population Segment (DPS), the effects to anadromous fish in Regions C and D have the potential to range from a moderate adverse impact to a major beneficial effect. The ranges in potential effects are due to uncertainty and spread between modeled estimates for the Juvenile Fish Passage Spill measure because of the unknown magnitude of latent mortality and an unknown level of reduction in transportation for some species. DEIS, p. 7-88. 40 The Northwest Power Act requires the Northwest Power and Conservation Council (NPCC) to adopt and renew at least once every five years a Fish and Wildlife Program to protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, on the Columbia River and its tributaries. 16 U.S.C. 839b (h)(1). 41 Columbia River Basin Fish and Wildlife Program, Northwest Planning and Conservation Council, 2014 Program and Part II of 2020 Addendum available at https://www.nwcouncil.org/reports/2014-columbia-river-basin-fish-and-wildlife-program. 42 Id. April 13, 2020 Page 21 If a moderate adverse impact situation materializes, the LCM model predicts SARs for Snake River spring/summer Chinook could decrease 7.5 percent under the preferred alternative, with a lower end of the predicted SAR range of less than 1%. This means the preferred alternative is predicted to provide SARs below even the threshold necessary to avoid continued population declines, well below the 2% minimum required for population maintenance, and significantly below the regions 4% average SAR goal (range of 2%-6%) for rebuilding Snake River stocks of salmon and steelhead. The DEIS does not explain how its ESA and Northwest Power Act obligations can be met when this scenario is a real possibility. Moreover, the preferred alternative does not appear to do anything to ameliorate important limiting factors for listed salmon and steelhead, including many factors that will worsen with climate change. For instance, as noted in section II(a)(iv) supra, the preferred alternative does not improve temperature conditions as compared to the no-action alternative. Accordingly, the preferred alternative does not meet the requirements of the ESA or the Northwest Power Act.	Chapter 8 of the EIS demonstrates the co-lead agencies compliance with various laws, including the ESA and Northwest Power Act. As demonstrated in Sections 3.5 and 7.7.4, different models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. As described in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. As for the Northwest Power Act mandates and compliance, some context is necessary to understand where the co-lead agencies stand with regard to the goals and objectives of the Northwest Power and Conservation Council (Council). For additional analysis, please also see response to Comment 31775-119. The Act anticipates a Columbia River Basin Fish and Wildlife Program (Program) based primarily on hydrosystem actions and identifies two mitigation priorities for anadromous fish, both of which the region has largely achieved. The Program must provide for improved survival of such fish at hydroelectric facilities and provide flows of sufficient quality and quantity between such facilities to improve production, migration, and survival of such fish. 1/ These goals and objectives apply to all hydroelectric projects in the Northwest. Appendix B to the Councils 2014 Program, which remains in effect, indicates the hydrosystem affecting anadromous fish in the basin includes 136 dams, some built even before Bonneville Dam. 2/ Congress required four agencies the Corps, Reclamation, and Bonneville along with the Federal Energy Regulatory Commission, which has regulatory authority over more than 100 dams in the basin to implement the substantive mitigation provisions of the Act. 3/ Four agencies and over 100 dams are thus needed to implement the Councils Program, because Congress mandated that Northwest Power Act mitigation be planned and implemented on a system-wide basis. 4/ Moreover, neither the Act nor the Councils Program has goals and objectives specific to the CRS (or the FCRPS). Suggesting that the co-lead agencies failed to meet Northwest Power Act mandates by falling short of the Councils Program goals conflates system-wide goals applicable to over 100 dams to the 14 hydroelectric projects comprising the CRS. In addition to applying to more than just the CRS projects, the Councils five million salmon goal can be influenced or even thwarted by factors other than the dams that have had adverse impacts on salmon, including population growth, habitat degradation, harvest, irrigation, and natural conditions including ocean conditions and climate. The Councils SARs goals suffer a similar shortcoming. Research shows that SARs are heavily influenced by factors other than in-river flows and spill conditions, particularly ocean conditions that are beyond the control of CRS operations. For example, one study found a threefold difference in SARs for sockeye salmon that migrated downstream as juveniles in 2008 and 2010 despite nearly identical survival through the CRS from McNary to Bonneville dams. 5/ The researchers found the difference in sockeye SARs most closely correlated with ocean and climate indicators and concluded the large difference in SARs were the result of varying ocean conditions. The Councils SARs and adult fish goals do not reasonably apprise co-lead agency compliance with the Northwest Power Act because those goals are not tailored to the CRS specifically and do not meaningfully inform compliance with the Acts mitigation mandates. 1/ 16 U.S.C. 839b(h)(2)(A), (6)(E). 2/ See Council, 2014 Program, Appendix B, Compilation of Information on Salmon and Steelhead Losses in the Columbia River Basin, page 136 (Mar. 1986). 3/ 16 U.S.C. 839b(h)(11)(A). 4/ 16 U.S.C. 839b(h)(1)(A). 5/ Williams, J.G., Smith, S.G., Fryer, J.K., Scheuerell, M.D., Muir, W.D., Flagg, T.A., Zabel, R.W., Ferguson, J.W., and Casillas, E., INFLUENCE OF OCEAN AND FRESHWATER CONDITIONS ON COLUMBIA RIVER SOCKEYE SALMON ONCHORHYNCHUS NERKA ADULT RETURN RATES in Fisheries Oceanography (2014).
6929	9	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	viii. MO3 is the Only Alternative with Potential to Rebuild Snake River Stocks to an Abundance Needed to Meet ESA Obligations, Northwest Power Act Goals and Treaty Obligations At a minimum, the preferred alternative must provide reasonable assurance that ESA obligations will be met. However, to achieve cultural and economic stability provided by healthy salmon and steelhead stocks, and to honor federal treaties with Native American tribes, restoring abundant, healthy, and harvestable/fishable populations of naturally produced salmon and steelhead is needed. That is the goal clearly articulated by the Columbia Basin Partnership. MO3, which includes LSRD is the only alternative that has the potential to achieve abundant, healthy, and harvestable/fishable populations of naturally produced Snake River stocks. Accordingly, MO3 is the only legally defensible option for a preferred alternative because it alone has potential to rebuild Snake River stocks to the level of abundance required to comply with the Northwest Power Act, the Endangered Species Act and honor treaty obligations with Columbia Basin tribes. It also is the only alternative that could meet the recovery goals established by the Columbia Basin Partnership. April 13, 2020 Page 22 Actions contained in MO3 are best considered with other complementary actions, such as increased spill, predator management and habitat improvements, that will benefit both Snake River stocks and other ESUs and DPSs in the Columbia Basin. For instance, an analysis by the Fish Passage Center found that combining lower Snake River dam removal with spill to the 125%	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. However, the preferred alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				tailrace TDG levels (MO34) resulted in the greatest expected improvements across all biological response metrics for Snake River stocks as compared to the DEIS alternatives including on average exceeding the 4% average SAR regional goal.43 Increased spill operations would also benefit other Columbia stocks. For example, the DEIS notes that under MO3 (spill to the 120% tailrace TDG levels) there is a predicted increase in Columbia spring Chinook salmon in-river survival due to increased spill levels in the lower Columbia River. DEIS, p. 7-9. All included actions should be accompanied by a robust adaptive management program to monitor the effectiveness of the actions toward meeting clearly articulated habitat and biological goals and objectives and to adjust implementation as warranted. These actions can be undertaken in a manner that meets the needs of all stakeholders in the region, including water users, power producers and local communities. a. Lower Snake dam removal is necessary to meet ESA requirements and recovery goals MO3 is the alternative that gives Snake River fish the best chance for persistence and recovery by improving smolt- to- adult returns to the Snake River, with anticipated improvements of 14 percent to 170 percent considering estimates from both models. Snake River salmon and steelhead population numbers have been declining for decades and now stand far from their historic levels. In 2020, Idaho (the final spawning destination for most) saw some of the worst returns on record for both salmon and steelhead. In the 1800s, an estimated 4 million salmon and steelhead made it to the Snake River Basin, gaining 6,000 feet in elevation over 800 miles as they swam from the ocean to spawn. In the 1920s, large-scale dam building began on the Columbia River, the gateway to the Snake River, and populations began to drop. 43 See Life Cycle Evaluations of Fish Passage Operations Alternatives From the Columbia River Systems Operations, Environmental Impact Statement, Fish Passage Center available at https://www.wildsalmon.org/images/factsheets-and-reports/2020.FPC.Report.DEIS.Alternatives.pdf. April 13, 2020 Page 23 By the mid-60s as the Snake River dams were nearing completion only 100,000 adults returned. In 2018, barely 18,000 wild Chinook salmon and steelhead returned to Idaho. 44 While there are multiple causes for the decline of Snake River salmon and steelhead, the best available science is clear on two points. First, if the current conditions experienced by Snake River salmon and steelhead populations do not reverse, these iconic populations will face extinction. Second, removal of the four lower Snake River dams would vastly improve the chances for survival of the Snake River stocks and presents the best chance at recovering those stocks to abundant, healthy, and harvestable/fishable and levels. The reason this action is expected to be so effective is multi-fold. While ocean conditions do have a big impact on salmon and steelhead populations and always have, salmon and steelhead have, over their evolutionary history, developed resiliency in the face of changing ocean conditions through diverse life histories that are spread spatially and temporally across their freshwater and ocean habitats. This diversity ensures overall stability for the different major stocks and allows them to readily take advantage of good years with suitable ocean conditions. Salmon and steelhead fare on average far better over time in watersheds with fewer dams to cross than they do in the Lower Snake River, where they must pass eight dams to get to their spawning grounds this is in spite of being impacted by the same ocean conditions. Additionally, physical contact with each dam kills a certain number of fish, and yet this is only one of many causes of dam-related mortality. Other dam-related mortality factors include: 1) large reservoirs behind the dams provide prime habitat for predators that prey on salmon and steelhead; 2) slow moving water which requires more energy to pass through to get to the ocean and increases the average time for smolts to reach the sea by 10 times; 3) high water temperatures that do not cool at night as they have historically and increase stress on migrating salmon and steelhead; 4) loss of important complex lotic habitat, including spawning reaches for Fall Chinook, due to 140 miles of impounded water; and 5) cumulative stress from the experience of navigating the hydro-system, which subsequently kills a substantial number of successful migrants after they reach the estuary or ocean so that these fish do not return to 44 TU analysis of Fish Passage Center data. April 13, 2020 Page 24 spawn. Dam removal would alleviate these dam-related mortality factors and open the untapped potential of the Snake River to salmon and steelhead. And the benefits of reopening the Snake River would persist, and become ever more critical, with climate change. Representing twenty percent of the total accessible stream habitat within the native distribution of salmon and steelhead on the West Coast and sixty-five percent of the future available cold water, a re-accessible Snake River would be a major climate change refuge for salmon and steelhead populations. Consequently, it has the greatest potential for recovery of any basin on the Columbia River. The DEIS acknowledges that MO3 presents the best opportunity for improving fish SARs and water quality. As described in Chapter 3, model estimates for MO3 showed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead amongst the alternatives. The two models used to evaluate effects to certain salmon and steelhead (see section 3.5 for 340 specific species) predict a wide range of improved SARs for this alternative, indicating higher uncertainty pertaining to the level of benefits compared to the other alternatives. For example, MO3 is predicted to result in improvements to SARs for Snake River Spring/Summer Chinook that range from 14 percent (LCM) to 140 percent (CSS) relative to the No Action Alternative. Additionally, under MO3 there is a slight increase predicted in upper Columbia spring Chinook salmon in-river survival due to increased spill levels in the lower Columbia River. The quantitative model results vary in the magnitude of their predictions due to how they factor in latent mortality and density dependence. DEIS, p. 7-9 Overall, long-term water quality would improve in the lower Snake River under MO3, with improved water temperatures during the fall and increased nighttime cooling in the summer. In addition, riverine processes would be restored, eliminating some of the pH, and harmful algal bloom problems that currently exist. Elevated TDG would also be eliminated. Additionally, there would be major increases in Snake River fall Chinook spawning habitat and associated potential beneficial effects for recreational, tribal, and commercial fishing. DEIS, p. 7-12. Yet, despite ESA obligations and the overwhelming scientific evidence supporting dam removal, the Action Agencies declined to select MO3 as the preferred alternative because of the April 13, 2020 Page 25 impacts to the power system and the fact that additional authorities/legislation would be required to implement certain components. As described below, neither justification should have precluded consideration of MO3 as the preferred alternative.	absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6929	10	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	b. The DEIS should include a comprehensive and objective analysis regarding costs and benefits of Lower Snake River dam removal. Under NEPA, social and economic effects must be considered if they are related to the proposed projects natural or physical effects. 40 CFR 1508.8. Inaccurate or incomplete economic information may defeat the purpose of an EIS by impairing the agencys consideration of the adverse environmental effects and by skewing the publics evaluation of the proposed agency action.45 The DEIS notes that MO3 does not meet the purpose and need because removal of the lower four Snake River dams would eliminate hydropower generation and river barge navigation on the lower Snake. This alternative would eliminate hydropower generation and navigation on the lower Snake River which affects the ability of this alternative to meet the Purpose and Need. DEIS, p. 7-9. In recommending that the Action Agencies more thoroughly consider removal of the four lower Snake dams as part of their preferred alternative, TU is mindful of the large economic benefits provided by some, but not all, of the federal dams that constitute the FCRPS. Several produce a large amount of hydroelectric power, the loss of which would have serious negative impacts on the Pacific Northwest. Such impacts are appropriately considered in determining the reasonableness of this action. However, the DEIS discounts information demonstrating that the public benefits currently provided by the Lower Snake River dams can be adequately provided in alternative ways. Additionally, as noted in Section II(a)(ii)(b) supra and Section II(a)(vi)(d) infra, the DEIS fails to adequately capture the immense biological, ecological and economic benefits expected from removing the Lower Snake River dams. These omissions heighten the risk that the Action Agencies consideration of the adverse environmental effects will be impaired and that the publics evaluation of the DEIS will be skewed. 45 Hughes River Watershed Conservancy v. Glickman 81 F. 3d 437, 446 (4th Cir. 1996). April 13, 2020 Page 26 For instance, a report by ECONorthwest, found that public benefits of removing the dams actually outweigh the costs.46 The economic feasibility study demonstrated that transportation of agriculture products could be accomplished just as efficiently and cost-effectively on existing rail lines, and that effects on irrigation would be minimal because most farming in the region is not irrigated. The giant economic value of the regions salmon and steelhead fisheries exceed the value of removal, the report claims. Its authors estimate only a $1 to $2 per month power bill increase for consumers across the region and a slight increase in greenhouse gas emissions. Additionally, in response to DEIS claims that significant cost increases would be needed to replace the energy and capacity of the Lower Snake River dams if they are removed, Rocky Mountain Econometrics produced a follow-up analysis to test the need for the LSRD [Lower Snake River Dams] and what it would cost to cover that need in a pragmatic, economic fashion. The report found that: [a]veraged over the past 11 years the cost of replacing enough power to keep BPAs interchange power levels above 2,000 aMW, to the full capability of the LSRD, by purchasing the equivalent amount of LSRD energy at NP15 prices, is only about $11 million per year, $38 million per year cheaper than the current LSRD M&O cost[.] Rocky Mountain Econometrics, Replacing Needed Lower Snake River Dam Energy Cheaper Than Operating the Dams, February 2020. It is clear that differing estimates exist pertaining to what it will cost to replace the benefits provided by the lower Snake River dams because these estimates are entirely dependent on underlying assumptions. Additionally, there are differing estimates regarding the economic benefits that will materialize from dam removal although the DEIS does not consider this point with any robustness. When a NEPA document includes a cost-benefit analysis, it cannot be misleading.47 Factors that should have been explored in more depth in the DEIS include but are not limited to: the costs of maintaining the aging infrastructure of the dams if they are not removed, changes to reservoir recreation and its associated industry, economic benefits associated with a restored commercial and recreational fishery and the tourism that accompanies 46 See Economic Study on Lower Snake River Dams: Economic Tradeoffs of Removal, ECONorthwest, July 29, 2019 available at	As indicated in the comment, the EIS evaluated tradeoffs associated with the management of the system. However, a benefit cost ratio was not calculated for the CRSO EIS because it is not a requirement of NEPA or the basis of alternative selection under NEPA (see 40 C.F.R. 1502.23). Instead the EIS analyzed, the direct and indirect effects to the natural and human environment, with some effects evaluated quantitatively and monetized, and others evaluated qualitatively. The comment noting the economic benefits and adverse effects of losing hydropower are consistent with the findings of the EIS. Regarding the ECONorthwest study on the costs and benefits of breaching the four lower Snake River dams, the EIS considered this study among others that used various approaches to valuing benefits. This discussion can be found in the draft EIS in Section 3.15.2.2, Benefit Transfer Studies. The EIS analyzes the direct, indirect and cumulative effects to resources affected by CRS operations, maintenance and configuration. Chapters 3, 4, 6 and 7 detail this effects analysis, and denote adverse and beneficial impacts, where appropriate. Moreover, Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. Contrary to the comment, the loss of the hydropower under MO3 (which includes breaching the four lower Snake River dams) would have substantial adverse effects to the regional power system requiring replacement resources to maintain reliability. See draft EIS, Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1. The costs mentioned in the comment are inconsistent with the findings of the EIS. Section 3.7.3.5 Potential Replacement Resources describes the reliability and replacement resources identified under Multiple Objective Alternative 3. The comment references a study that relies on spot market prices in California. As discussed in the EIS, power purchases from the spot market prices are not comparable to the sale of firm, reliable service under long-term contracts. Spot prices reflect the price of power at that time and do not guarantee supply for any duration beyond the time offered. Spot sales are typically for short term duration and are usually for a fixed supply. Thus, relying on power purchases on the wholesale market does not ensure reliability. Further, the spot market does not always have sufficient liquidity (i.e., assured quantity) to supply power whenever needed. See Section 3.7.2.5, pages 3-801-02 of the draft EIS. Contrary to the comment, the EIS considered the avoided operations and maintenance (O&M) (expense) and capital costs associated with breaching the four lower Snake River dams in the cost analysis and included these cost savings in the power rates analysis. See Section 3.7.3.5, Bonneville's Fish and Wildlife Program and Lower Snake River Compensation Plan Costs, at page 3-913 in the draft EIS. As described in the draft EIS in Section 3.7.3.5, Table 3-166, the cost savings associated with the loss of the four lower Snake River dams would be offset by higher resource replacement costs, integration costs, and other cost pressures. Section 3.19 discusses System and Implementation Costs of each of the MOs, including MO3. The cost analysis estimates the capital and O&M costs savings that would occur under MO3 (see Tables 4-1 and 5-1 in Appendix Q in the draft EIS). The capital costs include additional construction and capital requirements that would be needed in the future to maintain the four lower Snake River dams. Therefore, the costs of maintaining the infrastructure of the dams under the No Action Alternative are included in the cost analysis. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective Alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.

				https://static1.squarespace.com/static/597fb96acd39c34098e8d423/t/5d41bbf522405f0001c67068/1564589261882/LSRD_Economic_Tradeoffs_Report.pdf. 47 High Country Conservation Advocates v. U.S. Forest Service, 52 F. Supp. 3d 1174, 1182. April 13, 2020 Page 27 it, the economic benefits associated with increased recreation on a free-flowing Snake River such as increased boating, camping, hiking and hunting opportunities, potential for waterfront redevelopment in Lewiston/Clarkston, and projected costs of flood risk mitigation projects that will be needed if the dams remain (such as raising levees in Lewiston). Without this information, it is impossible for decision-makers and the public to meaningfully weigh the costs and benefits of the alternatives. Importantly, even without dam removal, the Bonneville Power Administration faces the addition of wind, solar, storage, customer-side resources, and grid modernization technologies that are fundamentally changing the Northwest power system and impacting BPAs business model. BPA is experiencing increasing costs and it cannot command the price for wholesale energy that it once could.48 Its aging infrastructure requires significant new investment. Meanwhile, BPAs required fish and wildlife restoration costs - $17 billion over 20 years now account for about 25 percent of BPAs direct power costs yet have failed to restore abundant salmon populations to the Snake River and its tributaries.49 Status quo is not an option for BPA, a fact that is not adequately acknowledged in the DEIS. It is, however, acknowledged in BPAs Strategic Plan. The continuation of some financial policies and practices particularly those around cost management, debt management and reserves would put BPAs long-term financial health at risk.50 BPA must strategically modernize its operations in ways that will benefit consumers, the regional economy and salmon and steelhead. Discounting all information that suggests a change in the status quo is warranted is not productive and will not alter the current unsustainable path. The status quo is not an option for salmon and steelhead either. Actions to protect and recover salmon can be undertaken in a manner that meets the needs of all stakeholders in the region, including BPA, power purveyors, water users and local communities. However, it will take leadership from the Action Agencies to reflect on all available information and enable a fair dialogue with the regions 48 See BPAs 2018-2023 Strategic Plan, page 37 noting that BPA is now selling more surplus power at wholesale prices that are lower than its Priority Firm power rates. This has reduced total revenues and put continued upward pressure on power rates. 49 Bonneville Power Administration, 2018-2023 Strategic Plan, page 41. 50 Bonneville Power Administration, 2018-2023 Strategic Plan, page 12. April 13, 2020 Page 28 stakeholders regarding what is necessary restore salmon and secure a climate friendly energy future that benefits people and the economy.	The comment is correct in that the energy industry is changing rapidly. The EIS acknowledges that more wind and solar would be built in the region, increasing demand for balancing reserves. Likewise, the market is evolving. The EIS discusses Bonneville competitiveness in Section 3.7.2.5, Competitive Pressure on Bonneville's Power Rates in the draft EIS. In recent rate cases, Bonneville has implemented substantial cost reductions which have mitigated cost increases while balancing the need to protect fish and wildlife affected by Federal Columbia River Power System (FCRPS) operations and development. Lower market prices on the wholesale power market have increased cost pressures by decreasing the value of net secondary revenues which serve as an offset to revenue requirement costs collected in rates charged to long term power customers. The need for Bonneville to remain competitive is addressed in Bonneville's Strategic Plan, and Bonneville is on its way to executing that plan. While competitive pressures on the wholesale market are expected to continue, the Preferred Alternative is predicted to benefit salmon and steelhead and also meet the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. Bonneville's revenues have not declined over time, but less of Bonneville's revenue requirement is covered by net secondary sales of surplus power due to an industry-wide decline in market prices for wholesale power, which has required rates to firm requirements customers under long-term contracts to increase. In light of these competitive pressures, Bonneville developed both strategic and financial plans to ensure Bonneville's rates continue to be competitive. See draft EIS, Section 3.7.2.5, at pages 3-801-802 and Section 3.7.3.1, at pages 3-842-843. Bonneville has instilled a renewed focus on cost management discipline, resulting in a cost reduction of $66 million per year for the current rate periods operating costs compared to the last rate periods operating costs. This resulted in an average 0% base rate increase for Power customers at a time when the general economy was facing material inflationary pressure. Bonneville's cost management discipline, and revenue enhancing activities continue to maintain Bonneville's competitiveness relative to other load serving power producers. However, actions such as removing the four lower Snake River dams would result in substantial upward rate pressure for Bonneville customers, moving Bonneville's competitive power products to be less competitive in the marketplace. See Section 3.7.3.5, Table 3-166 of the draft EIS. Moreover, the comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish). The spring spill operation for juvenile fish passage included in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis described in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and NMFS COMPASS models predict that powerhouse encounters would be cut in half relative to the No-Action Alternative for Snake River spring/summer Chinook salmon. The real uncertainty lies in the hypothesis that reduced powerhouse encounters would result in increased adult returns. To address this uncertainty, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas-related mortality of juvenile migrants. The co-lead agencies looked at the totality of effects to craft the Preferred Alternative, provided in Chapter 7. As the analysis demonstrates, this alternative is not a continuation of the status quo and includes operational, structural and mitigation measures that will provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery.
6929	11	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	c. The Action Agencies must adequately evaluate alternatives that are beyond the agencies current authority to implement. The DEIS contends that MO3 cannot be selected as the preferred alternative because it would not meet current congressionally authorized purposes for the four lower Snake River dams. Alternative MO3 would not meet the congressionally authorized purposes of operating and maintaining the four lower Snake River dams for navigation, hydropower, envisioned recreational benefits, and providing irrigation. New congressional authority through the passage of new laws and associated funding would be required to implement the dam breaching measures in MO3. However, the dam breaching measures in MO3 were carried forward in the analysis to align with the District Court's Opinion and Order, and in response to comments received during public scoping that requested this alternative be evaluated. DEIS, p.7-4 NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in this chapter is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Records of Decision (ROD). Their inclusion in this chapter serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. DEIS, p. 5-2 However, the Action Agencies are not precluded from thoroughly considering MO3 as the preferred alternative even if new Congressional authorities or funding are needed to implement certain actions. NEPA requires the full consideration of all reasonable alternatives even if outside the lead agencys jurisdiction. This requires the Action Agencies to [r]igorously explore and objectively evaluate all reasonable alternatives . . . [and] [i]nclude reasonable alternatives not within the jurisdiction of the lead agency. 40 C.F.R. 1502.14. This includes April 13, 2020 Page 29 reasonable alternatives that are outside the scope of what Congress has approved or funded. 51 NEPA guidance also makes clear that an EIS may serve as the basis for modifying the Congressional approval or funding in light of NEPA's goals and policies.52 Therefore, even if the Action Agencies need congressional authorization or funding for some aspect of MO3, they can thoroughly consider it and then use the DEIS to recommended to Congress new authorities and investments necessary to implement it. Additionally, the Action Agencies can commit in the DEIS to take concrete steps to comprehensively consider elements of MO3, such as seeking a reconnaissance study. The authority to review completed Corps projects was granted in the Flood Control Act of 1970, P.L. 91611, Section 216, which reads: The Secretary of the Army, acting through the Chief of Engineers, is authorized to review the operation of projects the construction of which has been completed and which were constructed by the Corp of Engineers in the interest of navigation, flood control, water supply, and related purposes, when found advisable due (to) the significantly changed physical or economic conditions, and to report thereon to Congress with recommendations on the advisability of modifying the structures or their operation, and for improving the quality of the environment in the overall public interest. Clearly the physical and economic environment has shifted significantly since the Lower Snake River Dams went into operation. Accordingly, this provision is applicable and is a step that the Corps could commit to taking now.	Breaching the earthen embankment of the lower Snake River dams is a major Federal action that conflicts with the authority granted by Congress under which these projects were constructed and are operated. Therefore, de-authorization of the projects by Congress would be required prior to this action occurring. This action also would require expenditures from the Federal government to implement the action which have not been appropriated. The co-lead agencies do not have the authority to override Federal decisions of Congress, remove congressionally approved purposes, or appropriate Federal monies outside of the decisions outlined in annual Congressional Federal appropriation bills. De-authorization and appropriation for the breaching of the earthen embankments are a requirement to implement MO3, which includes breaching the four lower Snake River dams. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
6929	12	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	d. The DEIS understates biological, ecological and economic benefits of wild fish recovery that MO3 would deliver As described more fully in Section II(a)(ii)(b) supra, the DEIS does not fully capture the range of biological and ecological benefits likely to materialize from breaching the lower Snake River dams. The DEIS also fails to fully capture the economic benefits from breaching. One of 51 See Envtl. Def. Fund, Inc. v. Army Corps of Engineers, 492 F.2d 1123, 1135 (5th Cir. 1974) ([u]nder NEPA, an agency must consider [reasonable] alternatives which may be outside its jurisdiction or control, and not limit its attention to just those it can provide. Central to NEPAs goal of ensuring that agencies do not undertake a project without intense consideration of other more ecologically sound courses of action is a thorough consideration of all appropriate methods of accomplishing the aim of the action, including those without the area of the agencys expertise and regulatory control.) 52 See NEPAs Forty Most Asked Questions, Question 2b.(A) https://www.fws.gov/r9esnepa/NEPA_Handbook/40_Asked_Questions.pdf. April 13, 2020 Page 30 the glaring weaknesses is the failure to assign an economic value to wild fish recovery and increased angling activity that dam breaching and wild fish recovery would bring. Instead, the DEIS uses a qualitative analysis to suggest that new opportunities for angling and recreation may offset other changes. Fishing Activities, as well as other recreation types, would be considerably reduced in the short term during and immediately following breach, but could rebound in the long-term as anadromous fish populations improve. The largest increases in the number of Snake River salmon and steelhead are projected under MO3. Therefore, fishing for these anadromous species could increase in the long term relative to the No Action Alternative. The value of trips could also increase due to the increased abundance and diversity of wild fish. DEIS, p. 3-1214 [N]ew opportunities for land and water-based river recreation and possibly anadromous recreational fishing may offset visitation lossesand recreational opportunities may even increase in the long-term relative to the No-Action Alternative. DEIS, pp. 3-1222, 1223 Despite acknowledging that breaching presents increased long-term fishing opportunity, the DEIS entirely excludes the monetary value of post-breach salmon and steelhead fishing. The DEIS claims that fishing value is limited by uncertainties related to ESA restrictions and similar estimates were excluded from 2002 Corps analysis that was used as the primary basis of this economic impact estimate for the breach option. DEIS, p. 3-1219. In effect, this leaves MO3 without an assigned economic benefit in the DEIS. This improperly skews the finely tuned balancing analysis between environmental and economic considerations that the DEIS must undertake.53 NEPA does not permit analytical gaps. The Action Agencies must find ways to quantify values or properly weigh unquantified environmental amenities and values.54 To remedy this deficiency, the Action Agencies should utilize available, relevant information 53 See Calvert Cliffs Coordinating Comm. v. U.S. Atomic Energy Commn, 449 F.2d 1109, 1113 (D.C. Cir. 1971) (NEPA mandates a rather finely tuned and systematic balancing analysis of environmental costs against economic and technical benefits). 54 NEPA section 102(2)(b); 42 U.S.C. section 4331(a). April 13, 2020 Page 31 including values from the EcoNorthwest Economics Tradeoff Study and provide better assurance that these values are being fully captured in the alternatives selection process. 55	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS describes the effects of the alternatives, including dam breach under MO3, on fish (Section 3.5), wildlife (Section 3.6), air quality and greenhouse gases (Section 3.8), recreation (3.11), and commercial fisheries and passive use (Section 3.15). While the effects on fish and passive uses are not monetized, they are described qualitatively. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.. Consistent with this comment, the EIS describes that the results of the study are designed to reflect the value people hold for restoring salmon populations and therefore have limited applicability to the benefits of the CRSO alternatives.
6929	13	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	ix. The Cumulative Effects Analysis Lacks Sufficient Detail to Permit a Meaningful Understanding of How Interconnected Actions Will Affect Aquatic Resources NEPA regulations specify that an EIS should consider cumulative impacts of agency action in an EIS. 40 C.F.R. 1508.25(c). Cumulative impact is defined as the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency... undertakes such other actions. Id. 1508.7. NEPA regulations also require analysis of indirect effects of an agency action. The indirect effects of an action are those caused by the action and are later in time or farther removed in distance but are still reasonably foreseeable. 40 C.F.R. 1508.8(b). More than a cataloguing of related past, present, and future actions is needed; the DEIS must provide	The co-lead agencies recognize both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Chapters 6 and 7 incorporate the past and present effects described in Section 3.5 into the cumulative effects analysis for fish as described below. The cumulative action analysis methods are based on the policy guidance and methodology originally developed by CEQ (1997a). This method includes identifying affected resources and associated direct/indirect effects; establishing the geographic and temporal boundaries of the analysis; identifying the cumulative action scenario; and analyzing the cumulative effects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				detailed analysis.56 [V]ery broad and general statements devoid of specific, reasoned conclusions, will not suffice.57 Regrettably, especially as it relates to impacts to anadromous and resident fish populations, the DEIS mostly catalogues applicable cumulative actions, emphasizes uncertainty and engages in no real analysis of how the actions interplay. For example, the DEIS highlights 17 actions, in addition to the preferred alternative, that will cumulatively affect anadromous fish but contains little specific analysis about these actions relying instead on general conclusions and deferral to uncertainty. Depending on which model is used (LCM or CSS), the effects to anadromous fish in Regions C and D would likely have the potential to range from a major adverse effect to 55 See Economic Study on Lower Snake River Dams: Economic Tradeoffs of Removal, ECONorthwest, July 29, 2019 available at https://static1.squarespace.com/static/597fb96acd39c34098e8d423/t/5d41bbf522405f0001c67068/1564589261882/LSRD_Economic_Tradeoffs_Report.pdf 56 Muckleshoot Indian Tribe v. U.S. Forest Service, 177 F.3d 800, 810 (1999). [The EIS] must analyze the combined effects of the actions in sufficient detail to be useful to the decision maker in deciding whether, or how, to alter the program to lessen cumulative impacts [quoting City of Carmel-By-The Sea v. U.S. Dept. of Transp., 123 F.3d 1142, 1160 (9th Cir. 1997)]. Detail is therefore required in describing the cumulative effects of a proposed action with other proposed actions. Neighbors of Cuddy Mountain, 137 F.3d at 1379; see also Blue Mountains Biodiversity Action v. Blackwood, 161 F.3d 1208, 1214-15 (9th Cir. 1998). 57 Id. at 811. April 13, 2020 Page 32 a major beneficial effect. These results also vary by ESU and DPS. Consistent with Chapter 6, the co-lead agencies determined RFFAs 1, 2, 3, 5, 6, 7, 8, 12, 13, 14, 15, 17, 19, 20, 22, 23 and 26 would likely impact anadromous fish. RFFAs that have the potential to increase TDG, water temperatures, variability of flow, and reduce water levels in the future, such as population growth and development, changes in land use, water withdrawals, new storage projects in the mid-Columbia basin, habitat degradation, and climate change, which could adversely impact anadromous fish, but it is uncertain to what degree. DEIS, p. 7-209. The consideration of cumulative impacts must contain some quantified or detailed information and general statements about possible effects and some risk do not constitute a hard look absent a justification regarding why more definitive information could not be provided.58 This omission lessens the value of the DEIS as the level of improvements that fish populations will see over the life of the project is, in part, dependent on how these other categories of activities are implemented. The fact that the DEIS is constructed to minimize the scope of the Action Agencies obligations to fish species makes it even more critical that these interdependent actions be fully analyzed and considered together in the cumulative effects section. For example, the DEIS fails to give more than a cursory analysis to certain past, present and reasonably foreseeable future impacts to fish populations, such as hatchery and harvest impacts. In the case of hatchery impacts, as noted in Section II(a)(ii)(d) supra, those that are supported by the LSRCP should have been analyzed in the DEIS as direct effects. However, in addition to the LSRCP hatcheries, the DEIS notes that there are more than 100 other hatchery programs in the Columbia River basin. DEIS, p. 6-10. The past, present and reasonably foreseeable future effects of these other hatcheries are appropriately part of the cumulative effects analysis and require more than a perfunctory non-quantitative nod. The science is clear that the productivity and resiliency of wild populations decreases when hatchery fish spawn in the wild and that density-dependent effects are due, in part, to supplementation programs. ISAB at 141. The DEIS generally notes that there are adverse effects that would continue to occur from interactions between hatchery and naturally reproduced 58 Great Basin Mine Watch v. Hankins, 456 F. 3d 955, 971 (9th Cir. 2006). April 13, 2020 Page 33 fish but proceeds to devote the majority of the cumulative effects analysis on this topic to the adverse effect of MO3 concerning reduction of hatchery fish leading to decreased juvenile production. DEIS, pp. 6-44, 6-48. This is a very narrow lens with which to view such a complex issue and constitutes little more than a general statement about possible effects. The cumulative effects analysis should analyze how past and present hatchery activities affect wild salmon and steelhead populations and how reasonably foreseeable actions could alleviate density-driven limits and genetic effects on wild salmon and steelhead. Whether and how these impacts are alleviated will affect the productivity of wild salmon and steelhead which in turn will help determine how effectively the alternatives will meet ESA and recovery goals. This is just one example. As a practical matter, the piece-meal approach to different actions taken in the past, and continued in this DEIS, frustrates rather than enables informed decision-making. The fact is that the major actions being implemented in the Columbia basin are interdependent. Their respective impact on salmon and steelhead (positive and negative) depends on what happens in the other major action areas. Together, they have cumulative impacts on salmon and steelhead. The cumulative effects analysis is the only opportunity in the DEIS, as currently constructed, to consider the potential gains/impacts from various actions in a comprehensive, holistic manner. The DEIS is legally insufficient without it.	The Environmental Consequences sections of Chapter 3 present the direct and indirect effects of the Columbia River System Operations (CRSO) Environmental Impact Statement (EIS) Multiple Objective Alternatives (MOs) on each resources affected environment as presented in the Affected Environment sections of Chapter 3. The resource conditions described in those sections account for the effects to resources related to past and present actions. Chapter 6, Cumulative Effects, further considers the cumulative effects of each alternative combined with reasonably foreseeable future actions and conditions for all resources. RFFAs are considered in the cumulative effects analysis for each resource in chapter six. RFFAs are proposed activities that could cause similar effects in the same space and time as the MOs, but that are proposed by an outside entity. RFFAs are not yet implemented. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. The evaluations are clear, transparent, and repeatable based on the best available information. See Sections 6.3.1.4 and 7.9.7 for the cumulative effects analysis to Anadromous Fish.
6929	14	Chandra Ferrari; chandra.ferrari@tu.org	Trout Unlimited	x. The DEIS Climate Change Analysis is Legally Insufficient and Does Not Comport with the Courts Directives NEPA requires agencies to consider the environmental impact of a project and courts have made clear that obligation extends to climate-related environmental impacts.59 Additionally, the Action Agencies note that the purpose of the DEIS is, in part, to respond[] to the Opinion and Order issued by the U.S. District Court for the District of Oregon. DEIS, Executive Summary, p. 16. A key purpose of the DEIS is to [c]onsider and plan for climate change impacts on resources and on the management of the System. Id. Despite these guiding directives, the 59 Center for Biological Diversity v. NHTSA, 508 F.3d 508, 556, 37 ELR 20281 (9th Cir. 2007); Western Organization of Resource Councils et al v. U.S. Bureau of Land Management et al, No. 4:2016cv00021 - Document 34 (D. Mont. 2017); High Country Conservation Advocates v. United States Forest Service, Civil Action No. 13-cv-01723-RBJ (D. Colo. June 27, 2014). April 13, 2020 Page 34 Action Agencies have failed to produce a climate change analysis that is legally sufficient under NEPA or comports with the Courts directive. In its ruling ordering this EIS and a companion biological opinion, the U.S. District Court found that climate change will have a significant negative effect on salmon and steelhead populations and conveyed its expectation that the EIS and the companion biological opinion thoroughly consider climate change effects on ESA-listed salmon and steelhead. The Court described the many ways climate change will impact Columbia River salmon and steelhead: The best available information indicates that climate change will have significant negative effect on the listed populations of endangered or threatened species. Climate change implications that are likely to have harmful effects on certain of the listed species include: warmer stream temperatures; warmer ocean temperatures; contracting ocean habitat; contracting inland habitat; degradation of estuary habitat; reduced spring and summer stream flows with increased peak river flows; large-scale ecological changes, such as increasing insect infestations and fires affecting forested lands; increased rain with decreased snow; diminishing snow-packs; increased flood flows; and increased susceptibility to fish pathogens and parasitic organisms that are generally not injurious to their host until the fish becomes thermally stressed. Even a single year with detrimental climate conditions can have a devastating effect on the listed salmonids. 184 F.Supp.3d at 874. After finding that the best available information indicates that climate change will have a significant negative effect on endangered and threatened salmon and steelhead in the Columbia and Snake Rivers, the Court described what the climate change analysis must contain. Importantly, the Court indicated that the analysis should be based on the best available science, assess climatic changes as additive to the harm already inflicted by dams and other human activities and assess if and how climatic change will affect actions already being taken to restore endangered salmon. Id. That latter point is key as it recognizes that certain measures will be less effective going forward or over a longer-term because of the additive effects of climate change. Further, the Court noted that if climate change impacts on fish populations are large, measures to prevent or moderate them must be large enough to ameliorate the impacts. The Columbia-Snake Basin is a critical geography for salmon and steelhead populations and actions taken pursuant to this EIS will dictate how resilient these populations will be to climate April 13, 2020 Page 35 change effects. Actions that are not guaranteed to meaningfully improve SARs or address limiting factors under current conditions will leave salmon and steelhead populations even more vulnerable to the extreme conditions expected with climate change bringing their extinction closer. The DEIS acknowledges that anadromous fish will be negatively affected by climate change and that the preferred alternatives benefits are likely to be offset by these effects. Because temperature is such a critical factor to anadromous fish habitat, increases in stream temperature due to increased air temperature and changes in hydrology, including declining snowpack, could further impact fish in all regions. Increased water temperatures could also increase suitable habitat for invasive species (e.g., shad and small mouth bass) that could have adverse impacts to native anadromous fish. Positive effects for anadromous species in this Preferred Alternative could be offset by adverse effects from changes in flow and increased stream temperature due to climate change. DEIS, p. 7-201. Yet, contrary to the Courts direction, there is no analysis of the degree to which climate change will cause added harm to listed species and reduce the effectiveness of mitigation measures, and whether the purported benefits from the preferred alternative are sufficient in light of additional harm and decreased effectiveness. The preferred alternative is not guaranteed to even meet replacement level smolt-to-adult return rates for certain species under current conditions. Climate change effects will make it even more difficult for the preferred alternative to meet those target rates and the benefits that it does offer will likely erode with time. Without the implementation of actions that have larger, more durable benefits, anadromous fish populations will continue to decline. Neither does the DEIS adequately explain how it can find that the preferred alternative meets its purpose and need to plan for climate change impacts on resources. Articulating an inadequate solution that will be less effective with time is not a plan to deal with climate change. To better plan for climate change, the DEIS should have identified how climate change will affect specific regions in the Columbia Basin more than others such that certain actions should be prioritized as providing more benefit to salmon and steelhead populations in climate change conditions. It should have then used that information to identify actions sufficient in magnitude and number to	The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with USACE climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in USACE Engineer Technical Letter 1100-2-3, "Guidance for Detection of Nonstationarities in Annual Maximum Discharges." The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the Tribes. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. The same is true for projecting changes to TDG. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				address the scale of the climate change threat. For example, the DEIS should have acknowledged the significant level of high-quality cold-water fish habitat in the April 13, 2020 Page 36 Snake River Basin that is expected to remain in the face of climate change and the role that dam removal would play in connecting imperiled fish to that habitat. 60	
6931	1	theconservationangler@gmail.com	N/A	Our comments on the Columbia River DEIS focus primarily on the failures of the Action Agencies Preferred Alternative, which, unless there is a huge turn of events that occurs during your review, will not result in choosing an alternative that leads to a fundamental, thoughtful or comprehensive solution to the regions salmon, energy and environmental issues. The Columbia River DEIS maintains a poor status quo for the wild fish and the communities. It will also fail to protect endangered Columbia-Snake River wild salmon and steelhead, perpetuates failing and subsidized infrastructure and river operations and ignores solutions that are as plain as day for all communities. The Columbia River DEIS considers multiple management alternatives, including one that restores the lower Snake River by removing its four federal dams. However, this option is rejected in favor of implementing an already operational measure relying on a spill management plan already previously rejected it does not protect salmon. The Columbia River DEIS fails to fully and fairly consider exercising broad authority to consider comprehensive solutions that exceed existing legal authorities. As a result, the DEIS only focuses on extinction preventing rather than wild salmon and steelhead restoration. Yet even independent scientific analysis demonstrates that current spill levels will not reverse the current decline of wild salmon and steelhead populations and in fact, only serve to make the river safer for hatchery fish which are even less able to survive their journeys to the 80 or more artificial production facilities that merely add to the travails for wild steelhead and salmon. The Columbia River DEIS fails to articulate a decision-making path forward that provides solutions to specific problems that exist as a result of 90 years worth of mistakes. The Preferred Alternative does nothing to avoid ensuring that salmon recovery must compete with clean energy presenting poor and false choice between affordable energy bills and restoring healthy salmon and steelhead because it exaggerates the cost of replacement power with clean energy sources. The Preferred Alternative ignores wild salmon science throughout the Columbia and Snake River Basins because it does nothing to address the regions subsidy for hatchery production. Without a focus on wild salmon and steelhead, the Federal Partners are simply trying to make the river safe for hatchery salmon and steelhead. The DEIS dismisses an overwhelming body of scientific research that makes it clear that wild salmon and steelhead are best adapted to navigate a healthy the lower Snake River and effectively use the vast amount of highly functional spawning and rearing habitat that is their best chance to recover. The Preferred Alternative ignores the benefits of increasing wild salmon and steelhead runs for struggling fishing communities and Tribal Nations, as well as fails to elaborate on the costs of maintaining the current infrastructure which is already failing, requires huge subsidies to operate and has generally failed to deliver the community and ecological benefits promised at the time of original construction. The Columbia River DEIS fails to protect wild steelhead and salmon or to acknowledge that recommendations for flexible spill at the federal dams will not change the survival benefits for endangered wild salmon and steelhead, and ignores that potential spill benefits will be eroded by climate impacts something a free flowing river can help mitigate. The Columbia River DEIS ignores the benefits and opportunities that come with wild steelhead and salmon recovery for communities up and down the Columbia and Snake Rivers. Instead the DEIS focuses on the financial costs of salmon and steelhead recovery (largely a hugely wasteful expense focused on hatchery salmon and steelhead) and ignores the sacrifices already made by all river communities in terms of lost fishing opportunity, reduced employment and incomes, impacts on Tribal cultures, diets, and feelings of well-being that come from a healthy watershed. Many economic and community benefits will be created by wild steelhead and salmon recovery investments and the associated employment that a healthy watershed generates . The Columbia River DEIS also lightly treats the positive elements of a dam removal alternative in failing to proactively address the issue of avoided costs. By helping the region step away from aging and failing infrastructure as well as the endless addiction to mitigation resources like ill-adapted hatchery salmon and steelhead, abundant flatwater recreation opportunities found elsewhere, The Action Agencies ignore the anticipated savings of more than $1 billion by eliminating the rising capital, operations and maintenance costs for the four Snake River dams. The Preferred Alternative does not contain a thoughtful, regional and agency cross-cutting investment package that absolutely should have been considered, including funding for dam removal, a re-commitment to wild salmon and steelhead recovery, clean energy initiatives and transportation projects can help solve problems and move us all forward together.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Finally, the commenter's comments on cost savings are incorrect (See Section 3.19 and Appendix Q). For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.

6932	1	ireland@kootenai.org	Kootenai Tribe of Idaho	The Kootenai Tribe has submitted comments on the Columbia River System Operation Draft Environmental Impact Statement (DEIS) through letters from the Upper Basin Sovereigns and the Upper Columbia United Tribes. In addition, the Kootenai Tribe emphasizes the importance of continued Government to Government consultation with the Co-Lead Agencies on the DEIS and Appendix V - Columbia River System Biological Assessment.	The co-leads appreciate your comments and participation in the development of the Draft EIS. The co-lead agencies will continue to consult with the Kootenai Tribe of Idaho throughout this process.
6935	1	sharongrace@centurylink.net	N/A	Fatal Flaws Abound in the CRSO DEIS The Federal Agencies Failed to Comply with the National Environmental Policy Acts Central Purpose, which Is to Inform The National Environmental Policy Act (NEPA) requires an EIS for a proposed action that will significantly affect the quality of the environment. NEPA and its implementing regulations clearly set forth the purpose of an EIS. It shall provide full and fair discussion of significant environmental impacts and shall inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment. 50 CFR 1502.1. To do this [t]he EIS should present the environmental impacts of the proposal and the alternatives in comparative form, thus sharply defining the issues and providing a clear basis for choice among options by the decisionmaker and the public. 50 CFR 1502.14. The DEIS fails to sharply define the issues or provide a clear basis for choice among the alternatives. For example, it is difficult even to find a cohesive, concise definition of the proposed action for which the CRSO EIS is required. The definition below is borrowed from the Endangered Species Act (ESA) Section 7(a)(2) Biological Opinion and Magnuson-Stevens Fishery Conservation and Management Act Essential Fish Habitat Response, Continued Operation and Maintenance of the Columbia River System, p. 29: This ESA section 7(a)(2) consultation evaluates the effects of an ongoing federal action: the operation, maintenance, and management of the 14 federal dam and reservoir projects in the Columbia River System that are managed as a coordinated system for multiple congressionally authorized public purposes by the Action Agencies (BPA et al. 2018a). The proposed action includes operational measures (e.g., flood risk management, navigation, fish passage, and hydropower generation) and non-operational measures (e.g., support for conservation hatchery programs, predation management, habitat improvement actions, and RM&E programs). The proposed action, including both operational and nonoperational measures, is largely consistent with RPA measures stemming from the 2008 biological opinion, as supplemented in 2010 and 2014. Presumably this is also the CRSO DEIS No Action Alternative from September 2016, that this member of the general public could not find in the DEIS. Compare this to the confusing Purpose and Need Statement set forth in the CRSO DEIS Executive Summary, p. 16. Since the federal agencies use the No Action Alternative as the baseline, the failure to provide a clear definition of the No Action Alternative is a fundamental failure. The CRSO DEIS is not user friendly. For example, eleven downloads are necessary to obtain a complete copy of the DEIS. Each section does not have its own table of contents. Only the first download contains the table of contents, the table of figures, the table of tables, and the definitions for abbreviations. Therefore, the reader must go back and forth between the first part and any other part to find particular sections or subjects of interest. Perhaps more significant is the fact that for key word searches, one must search through eleven separate downloads in an attempt to find information on a particular subject. This might be reasonable if the comment period were six months. But it is not reasonable for a 45 day comment period. The DEIS is difficult to understand. It uses industry and scientific jargon and goes into great detail on many issues only experts could understand, while providing little or no detail on foundational elements for the public. As an informational document, the CRSO DEIS should be written in lay language that clearly and concisely sets forth each alternative and its associated effects on the environment. This it fails to do.	Chapter 8 of the EIS demonstrates the co-lead agencies' compliance with various laws, including NEPA and the ESA. The No Action Alternative is described in detail in Chapter 2 and its effects are discussed in throughout Chapter 3 in the respective affected resource sections. The proposed action (i.e. preferred alternative) is described and analyzed in detail in Chapter 7. The Table of Contents will be expanded in the Final EIS to aid readers in finding materials. The index is also a good reference. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The public had several ways to submit comments such as the online comment form and through the mail. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined the 45-day public comment period was adequate consistent with NEPA regulations
6935	2	sharongrace@centurylink.net	N/A	Another fundamental failure is that the DEIS is biased heavily in favor of operations and maintenance of the hydrosystem and its economic effects, while paying almost no attention to commercial, sport or recreational fishing and its economics. It is also biased heavily in favor of the economics of the status quo, rather than the economics abundance fish runs would provide to the Snake/Columbia Basin economy, or the economic benefit that would accompany dams breaching.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River). As described in Section 3.15.3.5, under MO3 commercial and ceremonial and subsistence fisheries targeting anadromous fish species across all regions may see major beneficial effects in the long term. Ceremonial and subsistence fisheries targeting residential species in Region C may see long term benefits, while those in Regions A may experience some moderate adverse effects. As described in Section 3.15.3.5, under MO3 commercial and ceremonial and subsistence fisheries targeting anadromous fish species across all regions may see major beneficial effects in the long term. Ceremonial and subsistence fisheries targeting residential species in Region C may see long term benefits, while those in Regions A may experience some moderate adverse effects.
6935	3	sharongrace@centurylink.net	N/A	An additional foundational flaw in the DEIS is that the federal agencies failed to consider readily available public documents when they drafted the document. Examples are reports drafted by Rocky Mountain Econometrics on hydropower, transport, and navigation; NOAAs studies and recovery plans for Snake/Columbia Basin salmonids; NOAAs studies and documents that discuss the importance of Columbia River Chinook to Southern Resident Killer Whales; University of Washington studies documenting the importance of Columbia summer/spring Chinook to Southern Resident Killer Whales; Earth Economics reports on Snake or Columbia Basin recreation, natural capital, and the economic benefits of breaching the dams; independent studies on Pacific Northwest energy resources, and public studies of reservoir greenhouse gas emissions, to point out a few.	In the Draft EIS, the co-lead agencies used current high quality information and best science, including models, reports and studies published in peer review science journals, in the analysis of these issues. Chapter 11 in the Draft EIS includes references of the many relevant local and published documents considered by the co-lead agencies in the Draft EIS. In the case of documents on killer whales the list of current high quality information reviewed included: NMFS. 2013. Southern Resident Killer Whales: 10 years of Research and Conservation Report Summary; FR. 4264. Endangered and Threatened Species Initiation of 5-Year Review for Southern Resident Killer Whales; NOAA. Ford, Michael J. 2013. Status Review update of Southern Resident Killer Whales; Ford, Michael J., Jennifer Hempelmann, M. Bradley Hanson, Katherine L. Ayres, Robin W. Baird, Candice K. Emmons, Jessica I. Lundin, Gregory S. Schorr, Samuel K. Wasser. 2016. Estimation of a Killer Whale (Orcinus orca) Population's Diet Using Sequencing Analysis of DNA from Feces. PLOS One 11(1): e0144956. Doi: 10.1371/journal.pone.0144956; NMFS. 2016. Southern Resident Killer Whales and Snake River Dams Fact sheet; NOAA. 2016. 6935	4	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed since the Federal Agencies Suppressed Relevant Information from the Public while Drafting the DEIS The federal agencies are required to make every effort to disclose and discuss at appropriate points in the draft statement all major points of view on the environmental impacts of the alternatives including the proposed action. Emphasis added; 50 C.F.R. 1502.9. The federal agencies failed to comply with this regulatory mandate. In fact, rather than share major points of view while drafting the EIS, the federal agencies actively suppressed information. At the same time the federal agencies were sending updates to the public, (see the Columbia River Systems Operations Update that the federal agencies emailed, mailed and made available on the CRSO website),1 they were hiding important fish survival information analyses developed by other agencies. To withhold this information from the public, the federal agencies required the Fish Passage Center (FPC) to sign a nondisclosure agreement that required the FPC to withhold information from decision makers and the public, until the federal agencies had published the CRSO DEIS. See Attachment 1 to these Comments, FPC Document, DeHart Memo to File re Alleged Noncompliance, dated 10/4/19. As a result, the public was able to review only that information the federal agencies published. The FPC was prohibited from posting its relevant information for the public to review until February 28, 2020, the date the federal agencies published the CRSO DEIS. On that date the FPC posted Chapter 2 of the Comparative Survival Study, the analysis of the CRSO EIS alternatives, in which the FPC determined that lower Snake River dam breaching was the best biologic alternative for salmon and steelhead. See http://www.fpc.org/documents/CSS.html, CRSO tab, Attachment 2 to these Comments. The federal agencies non-disclosure agreement regarding the FPC analyses of the DEIS alternatives forces decision makers and the public to read the FPC material, as well as the 8000 page DEIS in the short 45 comment period. The obvious purpose of the federal agencies forced nondisclosure agreement was to hinder publication of information relevant to the DEIS options. Otherwise it had no purpose. The nondisclosure agreement is particularly repugnant, in light of the fact that taxpayers and ratepayers fund the federal agencies. The public has a right to see that information as it is developed.	Bonneville contracted with several entities to help prepare certain sections of the Draft EIS. As part this process, Bonneville asked its EIS contractors with existing Bonneville contracts, including the National Marine Fisheries Service and Fish Passage Center (FPC), to sign nondisclosure agreements that would expire when the Draft EIS was released. This allowed all contractor information to be reviewed by the co-lead and cooperating agencies and integrated into the overall EIS analysis before release to the public. Specifically, Bonneville contracted with FPC and NMFS to analyze effects to fish from the No Action and Multiple Objective Alternatives. This information is displayed in Sections 3.5 and 7.4 and Appendix E. Consistent with NEPA, this information was used to inform other chapters, including Climate Change (Chapter 4), Mitigation (Chapter 5) and Cumulative Effects (Chapter 6) as well as Chapters 3 (Direct and Indirect Effects Analysis) and Chapter 7 (Preferred Alternative). Prematurely releasing information may have chilled the agencies deliberations, and without proper context it could have served to confuse the public about the actual impacts to affected resources. Thus, waiting until the Draft EIS was released allowed all relevant information to be published at the same time, providing context for the information and reducing unnecessary confusion. It also allowed the public to consider the direct, indirect and cumulative effects to resources affected by the CRS comprehensively instead of reviewing partial information. Finally, NEPA does not require release of preliminary information to the general public prior to release of the Draft EIS, but it does provide for sharing of this type of information with cooperating agencies. The co-lead agencies provided preliminary fish results including the FPCs results to all members of the EIS Fish Technical Team, which included states and Tribes. The cooperating agencies were then offered the opportunity to provide comments on this analysis prior to release of the Draft EIS. Thus, FPCs results were available to the cooperating agencies to the same extent as other analysis prepared by the agencies themselves. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed or reviewed by the co-lead and cooperating agencies as part of this EIS. The co-lead agencies also note that any additional modeling conducted by FPC outside the EIS process does not have comparative NMFS Lifecycle Model results.
6935	5	sharongrace@centurylink.net	N/A	The Federal Agencies Failed to Comply with the Page Limits Prescribed in the Federal Regulations The text of final environmental impact statements (e.g., paragraphs (d) through (g) of 1502.10) shall normally be less than 150 pages and for proposals of unusual scope or complexity shall normally be less than 300 pages. Emphasis added; 50 C.F.R. 1502.7. Paragraphs (d) through (g) refer to the body of the EIS. The body includes the purpose and need for the action, the alternatives, the affected environment and the environmental consequences. This is the heart of an EIS. Nat'l Wildlife Fedn v. Nat'l Marine Fisheries Serv., 184 F. Supp. 3d at 878. To sharply define the issues and provide a clear basis for choice among the alternatives to protect ESA-listed fish did not require more than 300 pages. Nevertheless, the Army Corps of Engineers (Corps), Bureau of Reclamation (BOR) and Bonneville Power Authority (BPA) (collectively the federal agencies) ignored the page limit. Rather than draft an EIS the public and decision makers could understand, the federal agencies chose, instead, to write the body of the statement using 5000 pages in a complicated, difficult to read, difficult to analyze DEIS that does not sharply define issues or provide a clear basis for choice among the alternatives.2 To expect the public to be able to read, digest, analyze and make intelligent comments about this four-year-in-the-making DEIS in the 45 day comment period is unreasonable. Thus, the DEIS fails as an informational document.	The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agencies' specific NEPA regulations. The Draft EIS includes all required elements such as purpose and need for the action, alternatives, affected environment, and environmental consequences necessary for an EIS as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1502.10. The Draft EIS has a large geographic scope of four states, and discusses complex and detailed information. In order to present enough information for the decisionmakers to make an informed decision and for the public to be informed, the EIS exceeded the recommended number of pages. The Executive Summary provides the reader a condensed summary of the Draft EIS. The public had several ways to submit comments such as the online comment form and through the mail. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined the 45-day public comment period was adequate consistent with NEPA regulations
6935	6	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed because It Uses an Inappropriate Baseline The DEIS uses the No Action Alternative as a baseline against which to compare all other alternatives. While this is standard practice in ordinary EISs, this is not an ordinary EIS. There is a history of 25 years of unlawful biological opinions behind this DEIS. The Oregon district court has ruled that the No Action Alternative in the 2008 BiOp has been unlawful from the time it was first drafted, because the 73 RPAs in it fail to adequately protect ESA listed species.3 Finding negligible or minor adverse impacts to ESA listed species, when compared to an unlawful baseline, is akin to declaring, as the Bush administration did in 2004, that the dams have existed so long that they are part of the natural landscape and, consequently, dont have to be considered. The court rejected this contention.	The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change. For this EIS, the No Action Alternative describes the operation, maintenance, and configuration of the CRS, from September 30, 2016, the date the Notice of Intent to complete the CRSO EIS was published in the Federal Register. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 Code of Federal Regulations [CFR] 1502.14). The co-lead agencies assume that, to the extent possible, all ongoing, scheduled, and routine maintenance activities for the Federal infrastructure and all structural features, including those recently constructed or reasonably foreseeable, are included in the No Action Alternative. The No Action Alternative provides a baseline condition for comparing environmental effects of the action alternatives, or MOs and the Preferred Alternative. The No Action Alternative assumes the CRS will continue to be operated for all congressionally authorized purposes, requiring a balancing of operations across the 14 projects within the CRS. Current operations include actions agreed to in previous ESA consultations among the co-lead agencies, National Marine Fisheries Service (NMFS), and U.S. Fish and Wildlife Service (USFWS). Additionally, NEPA and the ESA are different laws with different baseline definitions; the co-lead agencies applied the appropriate baseline to the No Action Alternative for the CRSO EIS.
6935	7	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed because It Fails to Accurately Set Forth Important Facts Another fatal flaw to the CRSO DEIS is that it fails the honesty test. Spin is abundant. For example, the federal agencies state that the Preferred Alternative better meets the Purpose and Need and objectives of the hydrosystem, while avoiding, reducing, or minimizing adverse effects to environmental, economic, and social resources. CRSO DEIS, p. 7-15. Yet the federal agencies again announce, as they did in 2002, that breaching the four lower Snake River dams and restoring the lower Snake River to a near free flowing river would give migratory fish the best chance of recovering. See, e.g., Executive Summary, p. 25. The agencies also admit that dam breaching is the most cost effective, and is supported by the tribes. Indeed, the tribes have been strong proponents of dam breaching, asserting that breaching the dams will result in large improvements to certain salmonid populations, and this in turn would have beneficial impacts to the overall function of the Northwest ecosystem and for tribal ways of life. Id. at 7-9. As the tribes and federal agencies are well aware, the Ninth Circuit en banc in United States v. Washington, 853 F.3d 946 (9th Cir. 2017), held that both Washington State and the United States governments are liable to signatory tribes for blocking or impeding salmon migration in violation of the 1855 Stevens Treaties. This exposes the United States and potentially 2 Compare this 5000 page DEIS to the 103 page report the Pentagon drafted in 2017 for the security of the United States to warn the nation of the likelihood of a pandemic brought on by a novel coronavirus, predicting with startling accuracy shortages of masks, hospital beds and ventilators that could occur in an outbreak. See, https://www.thenation.com/article/politics/covid-military-shortagepandemic/. 3 The DEIS states that the No Action Alternative includes all operations, maintenance, fish and wildlife programs, and mitigation efforts in effect when the EIS was initiated in September 2016. Executive Summary, p. 19. This is, in essence, the 73 RPAs the court considered and struck down in May 2016. Washington State to huge damages liability to the tribes, if the dams continue to be maintained. Breaching the dams this year can cut off this liability. Another example of the federal agencies shading the truth is that for several years Snake River steelhead runs have been so low that they have hit the trigger prescribed in the federal agencies 2009 FCRPS Adaptive Management Implementation Plan.4 The trigger requires the agencies to engage in immediate action to save the species. Nevertheless, the federal agencies have ignored the trigger. Rather than acknowledge that the trigger has been hit and that the federal agencies are ignoring it, the DEIS merely states: On February 4, 2020, the co-lead agencies viewed a presentation prepared by NMFS regarding returns for the 2019 fish passage season and the Adaptive Management Implementation Plan. Although not all returns occurred prior to the presentation, NMFS utilized current return numbers to project return numbers if current return rates continued in 2020 and 2021. These projections signaled that returns are low, especially for Snake River steelhead. The co-lead agencies are currently evaluating the information provided by NMFS and will have a more detailed discussion of this information in the final EIS, including any updates that NMFS may provide once all returns have occurred, if appropriate. Id., at 3-301. Thus, the DEIS fails its central purpose, to inform the public and decision makers that immediate action is needed to save Snake River steelhead. This would seem to be a critical fact for the public and decision makers to know. In other parts of the CRSO DEIS, the federal agencies are flat out inaccurate with the truth. This is particularly true regarding hydropower and its effects and costs. The federal agencies state as fact that new congressional authority and associated funding would be required to implement lower Snake River dam breaching measures evaluated in the EIS. DEIS Executive Summary, p. 12. But the federal agencies do not inform the public or decision makers that neither new funding nor new congressional authority would be needed to make the dams nonoperational, which is different than the measures the federal agencies evaluated in the EIS. Without additional appropriations or congressional authority, the earthen berms could be breached, allowing fish to pass around the concrete structures. Existing fish credits and mitigation money could cover most, if not all, of the breaching costs.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. Moreover, those contending that Bonneville has authority to fund the breach of dams typically suggest two statutory alternatives. The first is Bonneville's discretionary direct funding authority found at 16 U.S.C. 839d-l. Congress granted this authority as a means for Bonneville, the Corps, and Reclamation to proceed with funding additions, improvements, or replacements to the multiple purpose projects of the CRS without having to first wait for appropriations for the entire activity. Instead, Bonneville provides the power share directly so that the Corps and Reclamation need only seek appropriations to cover the non-power share; that is, the share attributed to the non-power purposes of the dam. Stated another way, Bonneville can provide direct funding to cover only hydropower costs, whereas costs attributable to or shared by other purposes of the dams would be joint projects and would require congressional appropriations to cover the non-hydropower share of the cost. The breach of a dam is not an addition, improvement, or replacement of a dams power features, so the direct funding authority does not apply to the breach of a dam. Moreover, even if for arguments sake it did, Bonneville could provide no more than the power share of the cost of breaching. Congress would still have to provide appropriations to the Corps for the non-power share. The use of Bonneville's discretionary direct funding authority therefore cannot provide a means of funding the breach of dams absent an act of Congress. The second statutory authority suggested for Bonneville to fund the breach of dams is the Northwest Power Act section 4(h)(10)(A) found at 16 U.S.C. 839(b)(h)(10)(A). The Bonneville Administrator must use the Bonneville Fund to protect, mitigate, and enhance fish and wildlife affected by the operation and development of the FCRPS in a manner consistent with the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program, the Councils Power Plan, and the purposes of the Act. Currently, dam breaching is not part of the current Council Fish and Wildlife Program, the Seventh Power Plan, or evident within the purposes of Act. For example, dam breaching is inconsistent with the statutory purpose of Section 2(6) of the Act, which says in relevant part that anadromous fish are dependent on environmental conditions substantially obtainable from operations and management of the Columbia River System and other hydropower facilities in the basin. Additionally, as Section 3.7 (Power Generation and Transmission) demonstrates, dam breaching is also inconsistent with another purpose of the Northwest Power Act, Section 2(2), which provides for assuring the Pacific Northwest an adequate, efficient, economical, and reliable power supply. Section 4(h)(10)(A) therefore does not mandate or confer authority on the Administrator to fund the breach of a dam.

					Finally, the language related to the Adaptive Management Implementation Plan has been updated in the final EIS.
6935	8	sharongrace@centurylink.net	N/A	The federal agencies state as fact that the lower Snake River projects provide more than 2,000 MW of sustained peaking capabilities during the winter, and a quarter of the federal power systems current reserves holding capability. Executive Summary, p. 25. The agencies fail to inform the public or decision makers, that if the lower Snake River dams were to be used for sustained peaking power, the drawdown behind the dams needed to sustain the peaking power would damage the banks, roads, rail tracks and other infrastructure. It would also take days to refill the reservoirs, during which no power would 4 See https://www.salmonrecovery.gov/Files/BiologicalOpinions/AMIP_09 10 09.pdf. be generated. The agencies contend that the dams play an important role in maintaining reliability, and their flexibility and dispatchability are valuable components of the CRS. Executive Summary, p. 25. The agencies fail to inform the public and decision makers that the Snake River dams generate the most energy when it is least needed in the springtime, when demands for heating and air conditioning are at their lowest. Energy from the Snake River dams is constrained during the low river flows the rest of the year in cold winter months and hot summer months, when the energy is most needed. Thus, the Snake River dams capacity for reliability and flexibility is much less than described by the federal agencies.	Contrary to the statement in the comment and as explained in Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs, MO3, which includes breaching the four lower Snake River dams, would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. Breaching the four lower Snake River dams would reduce energy to meet regional load requirements, and reduce generating capacity (peaking capacity) to meet variability in loads (see Section 3.7.3.2, Effects on Power System Reliability). The lower Snake River projects operate within a 3- to 5-foot elevation range in the fall and winter, and within a 1- or 1.5-foot elevation range during the fish passage season. Bonneville does use this small operating range to peak, i.e. to increase generation for brief periods of high demand when conditions permit. This is within the normal operating range and does not cause the projects to draw down so deeply as to cause additional effects to affected resources. Regarding seasonality, while the four lower Snake River dams are run-of-river projects, upstream storage projects (Dworshak and Brownlee), regulate some of the water flowing into the lower Snake River, which flows year-round. While the statement in the comment that the most generation occurs in the springtime is accurate, the four lower Snake River projects also produce a substantial amount of power in the winter, which is currently the region's highest demand period. The dams provide up to 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. See Section 3.7.3.5, Changes in Power Generation, Table 3-159; and Appendix J, Chapter 3, for additional detail on hydropower generation results and analysis in the Draft EIS.
6935	9	sharongrace@centurylink.net	N/A	The federal agencies argue that lower Snake River dam breaching would more than double the regions risk of power shortages compared to the No Action Alternativefrom 6.6 percent risk of a year having power shortages in the No Action Alternative (roughly one year in 15) to 13.9 percent in MO3 (or nearly one year in 7). Id., p. 25. The federal agencies also contend that significant quantities of replacement resources would have to be built to maintain regional power reliability at the No Action Alternative levels. They state that without such a resource build-out, the region would face the likelihood of a loss of load event, e.g. a power blackout, nearly one in every seven years in MO3 for the base case including the current fleet of regional coal plants. Id., p. 25. These contentions are not correct. According to Rocky Mountain Econometrics, energy from the lower Snake River dams was needed for only two hours in the last 10 years, and that energy could have been purchased on the open market. In addition, BPA has had surplus energy every year for the last 80 years, except in 1937, a low water year.	Contrary to the statements in the comment, the EIS finds that MO3, which includes breaching of the four lower Snake River dams, would require substantial quantities of replacement resources to maintain regional power reliability at No Action Alternative levels. As explained in Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). These dams provide over 1,000 MW of carbon-free energy and up to sustained 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. Regarding the claim that power from the four lower Snake River dams was only needed for two hours in the last 10 years, this is inaccurate. The reference in the Rocky Mountain Econometrics report to Bonneville's Balancing Authority data is specific to the Balancing Authority area for Bonneville's Transmission. This data set represents loads and resources in Bonneville's Balancing Authority (BA) including some that are not Bonneville's resources. It does not include Bonneville's loads served by transfer, scheduled out of region, or scheduled to customers with their own Balancing Authorities such as Seattle and Tacoma. In other words, it does not encompass all of Bonneville's load and includes generation that is not serving Bonneville's preference customers. The seasonality of the power supply is important. The region often has surplus power in the spring when the weather is mild and flows are high. Conversely, there are times of the year, more often in the winter and late summer, when Bonneville may not have enough power to serve its load and relies not only on all of the power from the four lower Snake River dams but is also purchasing power. The Loss of Load Probability analysis of MO3 showed that the region would have an annual risk of power shortages of around 14 percent stemming from shortages in the winter and summer. Please see Appendix J, Hydropower, Section 4.1.2.4 in the Draft EIS. Given upcoming coal retirements, the EIS findings indicate that the region would likely experience a significant regional deficit of power, which will require adding power resources to maintain power system reliability at the No Action Alternative levels. See EIS Sections 3.7.3.3 through 3.7.3.6 and Section 3.7.3.5, Potential Replacement Resources and Associated Costs. Regarding comments about surplus energy, Bonneville's firm power obligations are determined by the load placed on Bonneville throughout the year. These loads tend to be winter peaking, meaning the extra surplus produced in spring does not assist in meeting these firm obligations.
6935	10	sharongrace@centurylink.net	N/A	Regarding costs, the federal agencies contend that for Bonnevilles wholesale power rate, MO3s (the dam breaching alternatives) conventional least-cost natural gas turbine resource portfolio, would cost about $200 million per year. The agencies state that this along with related structural and fish and wildlife spending adjustments, places upward rate pressure of between 8.2 percent and 9.6 percent over the No Action Alternative, depending upon the source of funding for those resources. Id., pp. 25-26.	The costs and upward rate pressures cited by the comment are consistent with the findings of the EIS. See Section 3.7.3.5 Electricity Rate Pressures, pages 3-918-924; and Table 3-166 in the Draft EIS.
6935	11	sharongrace@centurylink.net	N/A	If the Snake River dams energy production were to be replaced by green energy, the federal agencies falsely project a $419 million annual cost for a zero carbon portfolio. Id., p. 26. They then state that, [t]he costs of an expanded zero-carbon resource portfolio designed to replace the full capability of the lower Snake River dams would be significant: up to $527 million a year above the resource costs assumed in the base case analysis. Id. They continue, If Bonneville had to replace the lower Snake River projects full capability with zero-carbon resources, the rate pressure could be up to 50 percent on wholesale power rates. Id., p. 27. All of this cost information is false, since replacement power is not needed. The federal agencies recognize this in the maps set forth in Appendix H where they show that MO3 actually exerts negative pressure on rates in most areas. See DEIS Figure 5-4 and 5-6, Residential Rate Pressure Mapping, below. But if the public or decision makers were to read only the CRSO DEIS Executive Summary, they would not have the true information that dam breaching exerts negative to no pressure on rates. This is the best ratepayer result of all the alternatives.	The figure that the commenter cites, Appendix H, Figure 5-4, displays the data for Multiple Objective (MO) Alternative 2, but was inadvertently mislabeled in the draft EIS. Figure 3-186 in Section 3.7 of the draft EIS, shows the correct figure for MO3. The Tables in Appendix H, Chapter 5, correctly show rate increases for MO3. The error in the graphs in Appendix H is corrected in the final EIS. The other cost numbers cited by the comment are consistent with the findings of the EIS.
6935	12	sharongrace@centurylink.net	N/A	Further, the federal agencies fail to inform the public or decision makers that the No Action Alternative has high costs. BPA customers have experienced a 36% increase in wholesale electricity rates over the last 10 years with the No Action Alternative. According to BPA, 12% of its revenue comes from what BPA calls surplus sales or secondary revenue.5 BPA admits that when BPA produces more power than its wholesale customers need, then BPA goes to the spot market (like a stock trading market) and sells it power at a rate oftentimes lower than BPAs wholesale rate. Id. BPA sometimes pays to get rid of surplus power to avoid too much power on the transmission grid. By statute, BPA is required to set its wholesale rate at its cost of energy production. BPA actually sets it rate at its cost of production of energy, reduced by projected income from BPAs surplus sales. If BPA sells energy for anything less, BPA loses money on the sale. Yet BPA admits that it often sells surplus power for less than the cost of production. That means that BPA ratepayers must pay a higher wholesale rate than surplus buyers pay, but also that ratepayers subsidize surplus buyers. These are most frequently California customers. The federal agencies continue the disinformation throughout the DEIS. In Chapter 7, Table 7.1, page 7-18, the agencies compare the alternatives. In the category whether MO3, the dam breaching alternative, will Provide an Adequate, Efficient, Economical, And Reliable Power Supply That Supports the Integrated Columbia River Power System, the agencies answer No. Due to loss of hydropower generation on Lower Snake Projects, which adversely affects the adequacy, economics and reliability of the system, and leads to significant upward pressure on power rates relative to the No Action Alternative. Compare the two maps below for MO3, dam breaching and the Preferred Alternative for the four states of Washington, Idaho, Montana and Oregon. They show that the pressure put on rates from MO3, the dam breaching alternative, for most areas is -2.5% to 0%, while the preferred alternative exerts rate pressure of 0% to 1%. The rate pressure for the other alternatives rises above 10% in some areas. The information contained in these maps is buried in the CRSO DEIS, at Appendix H, at pp. H-5-39 through H-5-44. The residential rate pressure maps for MO3, the breach alternative, and the Preferred Alternative are displayed below. 5 See https://www.lagrandeobserver.com/news/regional/bpa-seeks-to-clearmisconceptions/ article_fb12c546-7534-11ea-a1bc-affe6d07f750.html. [Text contains figures that do not transfer to database.]	The comment makes numerous statements about Bonneville ratemaking procedures and surplus power. Several of these are accurate and consistent with the methodology, specifically that Bonneville sells power into the spot market and these costs offset wholesale power costs for preference customers. However, other comments are not consistent with the EIS or Bonneville ratemaking procedures. Specifically, it is Bonneville policy not to bid on negative market prices (i.e., to pay a party to take delivery of power). In addition, surplus sales help to reduce the power rates sold to preference customers, not increase them as implied by the comment. The commenter is incorrect to suggest that Bonneville loses money on the sale when it sells power at spot market prices that are below its costs. Bonneville sets its firm wholesale power rates to recover its total costs. Surplus and secondary sales are included in the calculation of these rates as a rate credit. This rate credit is set based on market prices. If the market price is below Bonneville's fully allocated rate, Bonneville provides less rate credit to its firm customers, but this lesser rate credit does not indicate Bonneville has lost money on the sale. Bonneville rates were set to recover its costs. The foundation for Bonneville's power sales and rate-setting is the firm power produced by the Federal Columbia River Power System, namely the power that Bonneville can rely on, even in an adverse water year. Additional power generated in a better water year leads to surplus power which is sold in shorter-term blocks, (hourly, daily, monthly, and sometimes longer periods). Contrary to commenter's statements, the EIS finds that Multiple Objective 3 (MO3) does not meet the objective to provide an adequate, efficient, economical and reliable power supply. Contrary to the statement on power rates in the comment, the EIS finds that power costs increase under MO3. The figure that the commenter cites, Appendix H, Figure 5-4 (on page H-5-41 of the Draft EIS) displays the data for Multiple Objective 2 but was inadvertently mislabeled in the Draft EIS. The error in the graphs in Appendix H have been corrected in the Final EIS. Figure 3-186 in Section 3.7 of the Draft EIS, shows the correct figure for MO3. The tables in Appendix H, Chapter 5 correctly show rate increases for MO3.
6935	13	sharongrace@centurylink.net	N/A	The Federal Agencies Buried the Fact that Dam Breaching Is the Most Cost Effective Alternative for Ratepayers What should be headline information for ratepayers that dam breaching is the most cost effective alternative in terms of operating and maintaining the hydrosystem, the federal agencies have buried in a chart on the very last page of Chapter 3. There the federal agencies finally acknowledge that breaching the four lower Snake dams is the most cost effective alternative. This is despite the many pages the agencies spend discussing the highly inflated costs they have assigned to dam breaching, and after they falsely state that dam breaching could raise rates by as much as 50%. Without the inflated costs, the savings from dam breaching are far greater. [Text contains tables that do not transfer to database.] CRSO DEIS, p. 3-1481.	Section 3.19 and Appendix Q of the EIS describe the implementation and system costs under Multiple Objective 1, 2, 3, and 4, as well as the No Action Alternative. These costs include capital and operations and maintenance costs to maintain the system, construction costs of the structural measures under the action alternatives, and the mitigation measure costs. The costs of dam breaching under MO3 are included in the cost analysis as part of the construction costs of the structural measures. As the commenter indicates, it is true that the implementation and system costs are lower under MO3 than under the other alternatives. However, these cost changes do not include power replacement costs, or reductions in navigation, recreation, and water supply benefits that occur under MO3. These evaluations are described in Section 3.7, Power and Transmission; Section 3.11, Recreation; Section 3.10, Navigation; and Section 3.12, Water Supply. Regarding the dam breaching costs, the method proposed for breaching the four lower Snake River Dams is based on extensive analysis completed for the 2002 Feasibility Study, which also considered dam breaching. The methodology developed is intended to minimize impacts to ESA-listed fish, other aquatic organisms, the built environment, and provides maximum protection to human health and safety. The Draft EIS, inflates the 2002 cost estimates to 2019 price levels. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6935	14	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed because It Contains Disinformation on the Crux of the Issues It Is Supposed to IlluminateEndangered and Threatened Salmon and Steelhead Survival Contrary to the federal agencies attempt to spin the truth that juvenile survival from passage through the dams is in the mid to high ninety percentages, real survival rates may be as low as 14%, when latent mortality is included. As stated previously, the district court in Oregon has found that salmon and steelhead must pass a number of damseight for the Snake River runsand suffer a very high mortality rate in doing so, sometimes as high as 92%. Id. at 788-789. The court made this finding after carefully considering the evidence presented in prior court hearings and documents. Nevertheless, in this DEIS the federal agencies ignore the courts previous finding and relitigate the issue. In doing so they present the same tired disinformation that they have spread throughout the Pacific Northwest for years, and have introduced in court previously to make their specious argument that juvenile salmonid survival through the hydrosystem is excellent. These estimates [ ] show progress towards meeting the individual dam survival goals developed during the 2008 Biological Opinion of 96 percent survival past each dam for yearling Chinook and steelhead, and 93 percent for Snake River sub-yearling fall Chinook. CRSO DEIS, p. 3-301. The DEIS sets forth a map to illustrate the spurious survival rates, terming them recent estimates of dam survival. [Text contains figures that do not transfer to database.] Figure 3-112. Recent Estimates of Dam Survival at Columbia River System Projects 7279 Note: These dam-specific survival estimates do not include systemwide or latent effects. 7280 7281 Figure 3-113. 20152019 Snake River Spring/Summer Chinook Salmon Upstream Survival 7282 Rates 7283 Figure is based on data from NMFS (2017). 0% 20% 40% 60% 80% 100% SR Fall Chinook SR Spr/Sum Chinook SR Sockeye SR steelhead Average Upstream Survival (conversion) Rates adult Snake River salmon and steelhead 2012-2016 BON to LGR (Corrected - harvest and straying removed) BON to LGR (Uncorrected - Includes all sources of loss including harvest and straying) Id. at p. 3-302. The federal agencies include this same map at DEIS Executive Summary, p. 19, Figure ES-4. The map disingenuously depicts juvenile salmon survival through the dams. It purports to show a 92% to 98% dam passage survival rate, rather than a rate as high as 92% mortality. Maps and facts such as these and the accompanying text, couched as fact, render the CRSO DEIS useless as an informational document.6 Moreover, the disinformation-filled graph also shows that the federal agencies believe that the federal court is powerless to curb the federal agencies long-running lawless activity. 6 Nuggets of information are buried deep in the DEIS. If the public or decision makers have the time to read and re-read the 8000 page document, they may be able to find valid information to counter the more readily available disinformation that is highlighted in the DEIS. For example, deep in Chapter 3, the federal agencies admit that COMPASS and CSS modeling estimates of juvenile Snake River spring/summer-run Chinook salmon survival range from 50.4 to 57.6 percent, respectively. CRSO DEIS at p. 3-382.	The data in the Draft EIS are accurate and fully described. Estimates of survival through the dams are put in context in the Draft EIS on page 301: "To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CRS. Figure 3-112, shows recent estimates of survival at the eight lower CRS projects with fish passage. The dam survival estimates do not include systemwide or latent effects (see Section 3.5.3.1). These estimates were developed show progress towards meeting the individual dam survival goals developed during the 2008 Biological Opinion of 96 percent survival past each dam for yearling Chinook and steelhead, and 93 percent for Snake River sub-yearling fall Chinook." Later in this Section (referenced in the quotations above), the Chapter 3 analysis discusses system survival rates, as well as latent mortality. The analysis of alternatives presented in-river system survival, which reflects the commenters "cumulative losses," and SARs (for those populations which could be modeled), among other metrics. The analysis of alternatives presents estimates of survival rates from LowerGranite to Bonneville dam (eight dams) for Snake River spring/summer Chinook and Snake River steelhead from two different models, with the estimates ranging from 40-60%. The mechanism and magnitude of latent mortality are not well understood, as presented in the discussion of Independent Scientific Review on Page 381.
6935	15	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed because It Fails to Elucidate an Approach that Will Move the ESA-listed Species Out of Peril The court ordered the federal defendants to prepare the EIS in the expectation that it would elucidate an approach that would finally move the ESA-listed species out of peril. See Nat'l Wildlife Fedn v. Nat'l Marine Fisheries Serv., 184 F.Supp.3d at 948. The DEIS does not elucidate such an approach. For example, fall Chinook, a primary focus of the EIS, were not modeled. Executive Summary, p. 12. Had the federal agencies analyzed the data correctly, it is likely that lower Snake River dam breaching would have been included in the Preferred Alternative, particularly since the agencies admit that the current Preferred Alternative has only minor benefit to in-river fish survival.7 DEIS, Table 7.1, p. 7-17.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. The commenter is correct that fall Chinook were not modeled because no reliable model for this ESU currently exists. Effects to fall Chinook were evaluated qualitatively. Specific to other species of salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In relation to the comment that fish passing few dams have higher SARs and survival, the co-lead agencies follow the guidance from the Independent Science Advisory Board, and to not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons.
6935	16	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed because It Ignores the Best Available Science regarding Salmon and Steelhead Productivity in the Snake/Columbia Basin The best available science demonstrates that with lower Snake River dam breaching, large increases in salmon productivity would result. The Fish Passage Center (FPC), in its review of DEIS alternatives, found that for all fish survival metrics, the Preferred Alternative resulted in only slightly better performance than the No Action Alternative and MO1, and had lower performance than both MO3, the dam breaching alternative, and MO4, the high/flexible spill alternative. In addition, the results for the Preferred Alternative are likely overestimates of fish survival, according to the FPC, because the modeled datasets provided by the federal agencies used daily averages. In fact, the FPC reported in 2017 in its Comparative Survival Study (CSS) that breaching the four lower Snake River dams and increasing spill on the four mainstem Columbia Dams to 125% Total Dissolved Gas could increase the salmon runs up to four fold. The FPC did not consider the increase to fall Chinook runs that the recovery of 140 miles of mainstem spawning habitat would bring, although the federal agencies did acknowledge this. DEIS Executive Summary, p. 25. This could increase the salmon runs up to seven fold, according to fisheries biologists. Further, the FPCs report does not include consideration of increased production from more salmon and steelhead migrating through a free-flowing lower Snake River that would result in greater utilization of the high-altitude spawning habitat in Idaho that is the refuge most capable of withstanding the predicted effects of climate change and global warming. Hence, dam breaching best mitigates even the effects of climate change. In addition, emissions of the potent greenhouse gas methanethat the federal agencies did not analyze in the DEIS, except to say that dam breaching would increase greenhouse gas emissions, without critical analysis would be reduced both by near natural flows and the elimination of the warm slack water reservoirs. A near free flowing river would also restore habitat and would return the lower Snake River to a more natural temperature regime under which the salmon evolved and flourished. 7 Moreover, the federal agencies admit that climate change likely will negate any increase in benefits to migratory salmonids that the Preferred Alternative may confer. The FPCs analysis of substantially increased salmon abundance that dam breaching would bring agrees with decades of federal agency reports, as shown by the chronology below, which also exposes the federal agencies unfounded position that the lower Snake River dams need not be breached to recover wild salmon and steelhead. In 1999 the National Marine Fisheries Services (NMFS), aka NOAA Fisheries, determined that to recover Snake River spring/summer Chinook, the most risk averse action would include dam breaching, a harvest moratorium, and vigorous improvements in habitat and hatcheries. (Emphasis in original.)8 For Snake River fall Chinook and steelhead, dam breaching by itself would likely lead to recovery.9 In 2001 the Plan for Analyzing and Testing Hypotheses (PATH) analyses, commissioned by the federal agencies, suggested that breaching was more likely than any other change in the hydropower system to meet survival and recovery criteria for the listed species across the widest range of assumptions and scenarios.10 The Corps 2002 Lower Snake River EIS revealed that breaching the dams had the highest probability of meeting the governments salmon survival and recovery criteria. In comparison, implementing the other so-called reasonable alternatives in the EIS would be slightly worse than doing nothing.11 Further improvements in spill and bypass systems or in transportation were deemed unlikely to be adequate to rebuild the threatened and endangered Snake River salmonid populations.12 In its 2002 Record of Decision the Corps relied on the NMFS 2000 Biological Opinion that concluded, despite the science showing that dam breaching through channel bypass was the best option for salmon recovery, breaching was not necessary at that time. NMFS reserved breaching as a contingency management alternative depending upon the findings in the 2005 and 2008 check-in.13 Check-ins that did occur were cursory at best, or they would have found that fish recovery goals were not being met, and that dam breaching would have to be instituted. In making the decision not to breach in 2002, the Corps announced to the taxpaying public that the dams would not have to be breached, if $350 million were spent (at least $1 billion has been spent to date) on massive system improvement projects (Alternative 3 in the 2002 EIS) on the four Snake River dams to permit less hazardous 8 Budy, P., Analytical Approaches to Assessing Recovery Options for Snake River Chinook Salmon (2001), p. 4, UTCFWRU 2001(1): 5-6, http://www.fws.gov/columbiariver/publications/recopt.pdf. 9 Id., p. 6. 10 USACE, Record of Decision, Lower Snake River Juvenile Salmon Migration Feasibility Study (2002), p. 15, accessed in 2015 athttp://www.nww.usace.army.mil/Portals/28/docs/environmental/lsrstudy/lsr_rod.pdf. 11 USACE, Summary, Improving Salmon Passage, Lower Snake River Juvenile Salmon Migration Feasibility Report (2002), p. 25, accessed in 2015 at http://www.nww.usace.army.mil/Portals/28/docs/environmental/lsrstudy/Summary.pdf. 12 Id. Nonetheless, the federal agencies propose these changes once again. 13 USACE, Record of Decision, supra, p. 21. Recovery goals have not been met for any of the ESAlisted runs, yet the Corps has not implemented breaching as a contingency management alternative. juvenile fish passage. This would give the region time to determine if salmon survival and recovery could be effected through the non-breaching alternatives.14 If these efforts did not succeed, the nine involved federal agencies, including NOAA, agreed that EIS Alternative 4, dam breaching, must be considered.15 Ten years was the outside time period allowed for results.16 It is 18 years later. None of the ESA-listed runs have recovered. NOAA admits in its 2017 recovery plan for spring/summer Chinook and steelhead that Snake River salmon and steelhead are not likely to recover in the next 50 years without dam breaching:17 NMFS estimates that recovery of the Snake River spring/summer Chinook salmon ESU and steelhead DPS, like recovery for most of the ESA-listed Pacific Northwest salmon and steelhead, could take 50 to 100 years. This recovery plan contains an extensive list of actions to move the ESU and DPS towards viable status; however, the actions will not get us to recovery. 18 Emphasis added. The move towards viable status, a much lower standard than the trending toward recovery standard the district court in Oregon has rejected, likely will continue unless the dams are breached immediately, particularly since Snake River salmon runs have declined drastically over the last three years.	In our analysis of effects, the co-lead agencies used current high quality data and the best available science, including models and studies published in peer review science journals. This does not include the PATH analysis, which is over twenty years old and does not include analysis of current operations. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% as a result of the Preferred Alternative. In their 2017 report CSS study FPC, analyzed increased spill over BiOp spill and found that without dam breach, a 2.0- to 2.5-fold increased in abundance for Snake River salmon could be achieved with spill to the 120% and 125% gas cap. Regarding dam breach: the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. Any modeling not presented in the CRSO EIS was not developed by the co-lead and cooperating agencies. Regarding water temperatures: under dam breach scenarios our analysis of MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures as well as fall water temperatures would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. Regarding the comments on recovery: the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The commenters statement "In addition, emissions of the potent greenhouse gas methane that the Federal agencies did not analyze in the Draft EIS, except to say that dam breaching would increase greenhouse gas emissions, without critical analysis would be reduced both by near natural flows and the elimination of the warm slack water reservoirs" is not accurate. Appendix G contains a detailed methane evaluation of the Columbia Basin reservoirs. This information is also summarized in Chapter 3.8.2.2. Reservoir drawdown can influence rates of methane ebullition due to a reduction in the hydrostatic pressure on littoral sediments. The magnitude of effects of fluctuating reservoir levels on methane emissions from the littoral zone and riverine areas depends on specific localized site characteristics (Falter 2017). For more discussion on this topic, please refer to Appendix G.

6935	17	sharongrace@centurylink.net	N/A	The DEIS Is Fatally Flawed because It Fails to Consider the Vital Effects of the Decimation of Snake/Columbia Basin Chinook Salmon on the Critically Endangered Southern Resident Killer Whales These facts are clear regarding the Snake/Columbia Basin, salmon and the salmondependent Southern Resident Killer Whales (SRKWs). The Columbia River historically was one of the largest, if not the largest, salmon producing river in the world. 14 Federal Caucus, Conservation of Columbia Basin Fish, Final Basinwide Salmon Recovery Strategy, Vol. 3, (2000), p. 20, http://permanent.access.gpo.gov/lps57088/d3/Final_Strategy_Vol_3.pdf. 15 Id. 16 Lower Snake River Juvenile Salmon Migration Feasibility Report (2002), Appendix A, Anadromous Fish Modeling, p. A ES-8, It will require anywhere from 2 to 10 years for these studies to provide information about the feasibility of achieving demographic improvements through different management actions. http://www.nww.usace.army.mil/portals/28/docs/environmental/lsrstudy/Appendix_A.pdf. 17 Dam breaching is not one of the measures included in the recovery plan. 18 ESA Recovery Plan for Snake River Spring/Summer Chinook & Snake River Basin Steelhead 2017, p. 241, https://www.fisheries.noaa.gov/resource/document/recovery-plan-snake-river-springsummer- chinook-salmon-and-snake-river-basin. The Snake River, as the largest tributary to the Columbia River, produced about half of the salmon migrating out to the ocean. Based on their historical production, the Snake and Columbia rivers have the most potential for again producing millions of additional salmon. The dams in the Columbia and Snake Rivers kill juvenile salmon in their downriver migration. The federal agencies admit this. See Nat'l Wildlife Fed'n v. Nat'l Marine Fisheries Serv., 839 F. Supp. 2d 1117, 1131 (D. Or. 2011) [T]here is ample evidence in the record that indicates that the operation of the FCRPS causes substantial harm to listed salmonids. . . . NOAA Fisheries acknowledges that the existence and operation of the dams accounts for most of the mortality of juveniles migrating through the FCRPS. Emphasis added. The mortality rate of juveniles passing through the eight dams of the Snake River and Columbia River is as high as 92%. National Wildlife Federation, et al. v. National Marine Fisheries Service (NMFS), et al., 184 F. Supp. 3d 861, 788-789. The high juvenile mortality rate decimates adult returns. The Southern Resident orcas foraging patterns show that the whales likely evolved preying on the huge runs of Chinook produced in the Snake/Columbia Basin. Despite these facts, the federal agencies failed to find the Preferred Alternative that maintains the dams would adversely affect the critically endangered Southern Resident orcas. They were able to do this by ignoring both readily available public documents and the best available science. The federal agencies also failed to consider the fact that from 2016 to the present, which was the operative time for drafting the DEIS, the Southern Resident orcas have significantly increased their time foraging in coastal waters, while significantly reducing the time they spend in the inland Salish Sea. See Bain, David, et al., Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review of the Available Scientific Evidence (February 2020), Attachment 3 to these Comments. The Review compiles much of the more recent scientific research and findings that establish the vital connection between Southern Resident orcas and Snake/Columbia Basin salmon. Ignoring the best available science, and without analysis or scientific basis, the federal agencies state that an increase in food availability would have a negligible effect on killer whales, given that the Snake River and Columbia Chinook populations constitute a small portion of their overall diet. CRSO DEIS, at p. 7-151. There would be a negligible effect on SRKWs prey availability since [t]he Snake River spring/summer Chinook salmon is a negligible portion of their overall diet. CRSO DEIS, at p. 3-779. This is disinformation. It flies in the face of the best available science developed by NOAA and other scientists. Recently in June 2018 NOAA and the Washington Department of Fish and Wildlife (WDFW) developed a prioritized list of West Coast Chinook salmon stocks that are important to the recovery of Southern Resident Killer Whales. See Southern Resident Killer Whale Priority Chinook Stocks, 2018. The Snake and Columbia Rivers produce seven of the top 15 priority stocks identified in the report. Id. at pp. 7-8. A priority stock is defined as a stock that is important to increase critical prey to SRKWs. Id. at p. 2. The Snake/Columbia priority stocks are the Lower Columbia fall Chinook stock, the Upper Columbia and Snake fall stock, the Lower Columbia spring stock, the Middle Columbia fall stock, the Snake River spring/summer stock, the Middle and Upper Columbia spring stock, and the Middle and Upper Columbia summer stock. Id. Significantly, it is likely that the importance of Snake/Columbia Chinook to SRKWs is understated in NOAAs priority prey stock report. The majority of NOAAs sampling was done in inland waters in the Salish Sea during the summer months. Relatively little sampling was done in coastal waters in the fall, winter or spring months. The report itself states, there is currently no spatial correction factor for sample collection. Id. p. 2. NOAA also fails to correct for the timing of the sampling. In addition, the report does not consider the historical contribution of the Snake/Columbia runs to SRKWs, or the dams decimation of the runs over the last 50 years, in determining the current priority stocks. Yet, despite these shortcomings, NOAA determined that the Snake/Columbia Basin produces nearly half the critical prey stocks for the critically endangered Southern Resident orcas. To reach the negligible effect finding for SRKWs in the DEIS, the federal agencies also ignored the coast-wide presence of Snake/Columbia Basin Chinook. The Wild Fish Conservancy compiled data from the Salmon Technical Committees Chinook catch composition for the Pacific Salmon Treaty Managed ocean fishery for the years 1999 to 2010, and for the year 2016. The yellow slice of the pie represents Chinook from the Snake/ Columbia Basin. [Text contains figure that does not transfer to database.] The data shows that Chinook from the Snake/Columbia Basin are by far the largest source of catch from Southeast Alaska to the southern Oregon coast. The charts also demonstrate that since 2010 the Snake/Columbia Basin runs have become a larger part of each depicted Chinook fishery, while Puget Sound stocks have become a smaller part, except in the Georgia Strait fishery. This makes the recovery of the Snake/Columbia runs that much more important and urgent for all predators, including the Southern Resident orcas. The importance of Snake/ Columbia Basin Chinook is not something that NOAA has just stumbled upon. In June 2008 NOAA stated that "[p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon from the Columbia River basin. . . . Returns during the 1990s averaged only 1.1 million salmon, representing a decline of 90 percent or more from historical levels. NOAA, SRKW Recovery Plan Recovery Plan for Southern Resident Killer Whales, (Orcinus orca), National Marine Fisheries Service, Northwest Region, Seattle, Washington, January, 2008, p. II-82. The evidence that NOAA fisheries scientists have collected since 2008 on coastal foraging only strengthens this statement. In 2013 NOAA reported that the Southern Residents could be found in the coastal waters more than half the year.19 More than half of this time is spent between the mouth of the Columbia River and Westport. In fact, NOAAs monitoring data indicates the Southern Resident orcas have been present off the mouth of the Columbia River thirty-five times more 19 See 134 J. Acoust. Soc. Am. 5, Hanson et al., Assessing the Coastal Occurrence of Endangered Killer Whales Using Autonomous Passive Acoustic Recorders (November 2013), 3486, http://oceanwidescience.org/cms/wp-content/uploads/2014/12/Hanson-et-al-2013.pdf (on average the Southern Residents occur in inland waters less than half of the days each year.) often than would be expected by chance.20 21 The Southern Residents visits to the coastal waters off Westport, Washington and the mouth of the Columbia River have coincided with high concentrations of nutrient rich, fatty spring Chinook salmon. University of Washington research shows that the whales appear to be especially reliant on the Snake Rivers nutrient rich, high fat content early spring-run Chinook.22 NOAA reports that the coastal Washington area and northern Oregon inshore area is a Southern Resident killer whale high-use area, particularly for foraging, with documented consumption of essential prey sources. NMFS, Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales, Draft Biological Report, September 2019, p. 36. While these areas have salmon originating in many rivers from Canada to California, the largest contributions are from the Columbia Basin (seasonally >50%). Id., pp. 37, 41. NOAAs research indicates the importance of Snake/Columbia salmon to the Southern Resident orcas: Satellite tag data indicated K and L pods utilized the entire Washington outer coast from January-May, an area that represents only 16.2% of the total area they used, but where the whales spent 53.1% of their time. The area between Grays Harbor and the Columbia River is the area of highest concentrated use (Hanson et al. 2017). Tagged whales traveled more slowly off the northern and southern portions of the Washington coast (mean of the median speed of all tagged whales 6.0 and 6.1 km/hr [3.7 and 3.8 mi/hr], respectively) compared to when they were off Oregon and California (7.2 km/hr [4.5 mi/hr]) 20 Hanson, M.B., E.J. Ward, C.K. Emmons, and M.M. Holt. 2018. Modeling the occurrence of endangered killer whales near a U.S. Navy Training Range in Washington State using satellite tag locations to improve acoustic detection data. Prepared for: U.S. Navy, U.S. Pacific Fleet, Pearl Harbor, HI. Prepared by: National Oceanic and Atmospheric Administration, Northwest Fisheries Science Center under MIPR N0007017MP4C419. 8 January 2018. 33 p., Appendix A hereto (Figure from NOAA NWFSC showing concentration of orca presence off Columbia River mouth). 21 Satellite tagging for 2013 through 2016. https://www.nwfsc.noaa.gov/research/divisions/cb/ecosystem/marinemammal/satellite_tagging/blog .cfm (2013); https://www.nwfsc.noaa.gov/research/divisions/cb/ecosystem/marinemammal/satellite_tagging/blog 2014.cfm (2014); https://www.nwfsc.noaa.gov/research/divisions/cb/ecosystem/marinemammal/satellite_tagging/blog 2015.cfm (2015); https://www.nwfsc.noaa.gov/research/divisions/cb/ecosystem/marinemammal/satellite_tagging/blog 2016.cfm (2016) 22 Ayres KL, et al., Distinguishing the Impacts of Inadequate Prey and Vessel Traffic on an Endangered Killer Whale (Orcinus orca) Population (2012) PLoS One 7: e36842, http://journals.plos.org/plosone/article?id=10.1371/journal.pone.0036842; Wasser, S.K., J.I. Lundin, K. Ayres, E. Seely, D. Giles, K. Balcomb, J. Hempelmann, K. Parsons and R. Booth. 2017. Population growth limited by nutritional impacts on pregnancy success in endangered Southern Resident killer whales (Orcinus orca). PLoS One 12: e0179824. (Hanson et al. 2017). Slower travel speeds may be associated with foraging activities. Id., p. 39. The concentration of SRKW visits to the mouth of the Columbia River, illustrated by this NOAA map, demonstrates the importance of Snake/Columbia River Chinook to SRKWs. [Text contains figures that do not transfer to database.] Id., p. 22. Yet, despite all of this evidence, including the fact that Chinook runs	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				from the Snake/Columbia Basin constitute nearly half of the SRKWs priority prey, in the CRSO DEIS the federal agencies speciously state as a main finding that Snake and Columbia Chinook are a negligible portion of the SRKWs overall diet. Maybe the best evidence of the Snake Rivers importance to the Southern Resident Killer Whales is the so-called baby boom. The live births of eight orca calves between December 2014 and January 2016 coincided with larger Snake River hatchery salmon runs that occurred in 2013 through 2015. The larger runs occurred in association with a hatchery transport research project that greatly inflated the Snake River Chinook runs. The research project has ended, with the last large runs taking place in 2015. Nevertheless, it provides good evidence that when there are plentiful Snake River Chinook, the endangered orcas can conceive, reproduce, survive and recover. Notable also is that since the transport research project adult Chinook salmon last returned to the Snake River in large amounts in 2015, the Chinook runs have been miserable. Also notable is that at least three of the calves from the 2015 baby boom era have died, along with one of their mothers. Each of the surviving calves (now juveniles) is small in relation to other killer whales their age. Only one baby boom survivor is female. This portends poorly for the future survival of the Southern Residents, as NOAA has reported.	
6936	1	N/A	N/A	The DEIS Preferred Alternative is nothing more, or less, than a program of managed extinction. For 40 years, since the 1980 passage of the Northwest Power Act, states, tribes, Congress, and eventually the Court has granted deference to agency expertise in producing a plan to restore Columbia and Snake River salmon. Since 1995, federal agencies have failed to produce, much less implement a legal salmon recovery plan. Certainly, the expertise is available within each respective federal agency to produce, at minimum, a legal salmon plan. Scientists, policy experts and engineers employed at these agencies, all with advanced degrees in their respective fields, undoubtedly understand what the law requires and what management steps must be taken to meet these requirements. And yet for 40 years, the agencies have failed.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery..
6936	2	N/A	N/A	Federal agencies have not merely missed minimum standards for a legal recovery plan. As previous court decisions have pointed out, theyve cynically ignored these standards. In this DEIS, theyve taken the further step of subverting these minimum standards to serve interests outside the ecological health of the river system. For example, drafting up to 1.2 million acre feet from upper Columbia reservoirs in the FCRPS in winter, as called for by the DEIS, facilitates more irrigation and increased power production - but does nothing for fish. It also reduces spring time flows, which negatively affects juvenile salmon survival rates.	The co-lead agencies are not responsible for developing recovery plans. That responsibility lies with the National Marine Fisheries Service and the U.S. Fish and Wildlife Service. The analysis considers the effects of alternatives on ESA-listed species, including compliance with the co-lead agencies' obligations under Section 7(a)(2) of the Endangered Species Act. As described in Section 7.6.3.6, Lake Roosevelt Additional Water Supply was updated for the Preferred Alternative to pump up to 45,000 acre-feet of water above the No Action due to the uncertainty over the timing and extent of the development of new water supply projects for the full volume. Finally, under the Preferred Alternative, spring flows decrease by less than 3% on average on the lower Snake River, and are essentially unchanged from the No Action Alternative in May and June. On the lower Columbia River flows decrease by less than 2% in March, and less than 1% the rest of spring. There would be negligible effects to juvenile salmon survival rates based on flow changes. See Sections 7.7.1 and 7.7.4.
6936	3	N/A	N/A	Today, with abundant, affordable distributed energy options, the question should be inverted - how does the Federal Columbia River Power System (FCRPS) fit our vision of shared abundance in the region? Otherwise, we are dancing around the fundamental conflict of interest underlying this DEIS: it is coordinated by an unappropriated federal agency dependent for its existence on sales of electricity from a portfolio of aging hydropower dams and from which it derives considerable economic, social, and political influence. This DEIS has much to do with BPAs challenged competitive position, and its struggle to remain what Administrator Elliot Mainzer has called the power provider of choice, and less to do with confusion about what salmon need.	Bonneville is a public agency, providing an adequate, efficient, economical, and reliable power to the region as directed by Congress and the Northwest Power Act. In addition, it provides other social benefits such as energy efficiency, residential exchange (sharing the benefits with customers of investor-owned utilities), low density discounts, and irrigation rate discounts in addition to funding fish and wildlife mitigation programs. See draft EIS, Power Revenue Requirement at pages 3-804 to 3-807. If the region chose to reduce Bonneville's size (and Congress agreed in the case of breaching of the four lower Snake River dams), then Bonneville would act accordingly. However, should Bonneville provide less power to the region, other entities in the region would need to acquire new resources to maintain reliability, which would have a similar impact on electricity rates paid by retail customers compared to Bonneville acquiring replacement resources. These two scenario are included for the EIS alternatives as the Bonneville Finances and the Region Finances scenarios described in Chapter 3, Section 3.7.3.1, and Appendix H. Regarding the comment about abundant and affordable distributed generation, the EIS analysis incorporated the regional generation and load as forecasted by the Northwest Power and Conservation Council (Council) for 2022 in its power analysis. This includes wind and solar power. Despite the large increase in wind and solar generation in recent years, the EIS analysis finds that the regional loss-of-load probability (risk of a year with blackouts) for the No Action Alternative is at 6.6% , which is above the Councils target of 5%. Wind and solar power are variable generation resources and are not always available when demand for power is high such as during a winter cold snap when the wind may be calm and the sun not shining as intensely as in the summer. With the announced retirement of most coal-fired generating plants in the region, the risk of power shortages is expected to increase rapidly unless the region builds more new generation. See draft EIS, Section 3.7.3.2.
6936	4	N/A	N/A	In fact, for over 25 years, fisheries biologists have told us how: remove the four lower Snake River dams (LSRD) in eastern Washington that impair migration to and from the best habitat remaining in the lower 48 the high elevation, cold water streams of central Idahos vast wilderness. And, more recently, the 2019 Comparative Survival Study (CSS) added another definitive result. A product of the Independent Scientific Advisory Board (ISAB) for the Northwest Power and Conservation Council, the CSS determined that, despite more than $16B spent on the Columbia basin Fish & Wildlife program in the last 20 years, smolt-to-adult survival (SARs) for Snake River salmon remain well below thresholds for even maintaining populations, much less recovery. The agency responsible for collecting and processing relevant data, the Fish Passage Center, addressed the futility of alternatives to restoring the rivers flow: it is clear that there are only two options left for the region, increase spill to the 125% gas cap and/ or remove the four lower Snake River dams. Conversely, the CSS quantifies expected benefits of actual restoration modeling a 4x increase in abundance by removing the LSRD and allowing water to flow through the remaining Columbia River dams during the juvenile outmigration: This analysis predicts that higher SARs and long-term abundances can be achieved by reducing powerhouse passage and water transit time, both of which are reduced by increasing spill, and reduced further when the lower four Snake River dams are breached, This finding is consistent with the opinion of the Western Division of the American Fisheries Society, which recently renewed a resolution stating that, based on the best scientific information available, if society-at-large wishes to restore Snake River salmon, steelhead, Pacific lamprey, and white sturgeon to sustainable, fishable levels, then a significant portion of the lower Snake River must be returned to a free-flowing condition.	The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the draft CRSO EIS. Any modeling not presented in the EIS was not developed by the co-lead and cooperating agencies. We are unsure what information CSS used in the analysis referenced in this comment and it was also not modeled under the NOAA Life Cycle model. All models used in the analysis for this EIS must undergo independent external peer review. Recent reviews by the ISAB and independent contractors hired by the co-lead agencies for the Independent External Peer Review Process are still ongoing. This information will be provided in the FEIS. The co-lead agencies acknowledge in the Draft EIS that implementation of MO3 would have benefits to salmon and steelhead. However, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6939	1	Emmett Palmer	N/A	Currently in the Northwest, we have 2.5 times more energy in clean energy, wind and solar, than that produced by the four dams on the lower Snake River. We can adjust to live without the electricity from these dams; they produce only two to four percent of electricity used in the Pacific Northwest. Only six percent of the power they generate goes to Idaho. In 2016, the Pacific Northwest had a surplus of 16 percent in energy. California used to be a large purchaser of power from BPA, but because the state has invested substantially in solar energy, California no longer needs or buys as much as energy from BPA. Also, we have to acknowledge that these dams are part of a hydro system designed for a climate that no longer exists. Snow is melting earlier, meaning peak water in the dams no longer corresponds with peak electrical load. In other words, the value of summer electricity produced by these dams is not as high as it once was.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. For example, the four lower Snake River dams produce around 1,000 aMW of power, which is approximately 12 percent of the average power produced by the CRS. See Section 3.7.3.5, Changes in Power Generation, Table 3-159. This amount of lost power from breaching the four lower Snake River dams is equivalent to the amount of power used to serve 730,000 homes in the Pacific Northwest. See draft EIS, Section 3.7.3.5, Summary of Effect at page 9-935. Moreover, these projects produce during the peak times of usage. Using average water conditions, and 80-year water data, the four lower Snake River dams produce between 460 aMW to upwards of 1400 aMW of power during the winter months of December through February, which are typically the most energy intensive months for Bonneville. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159, noting that generation from the four lower Snake River dams is approximately 90 percent of the power loss in Multiple Objective Alternative 3. As described in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907. Regarding the percentage of power delivered to Idaho, Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, a portion of the power generated from the four lower Snake River dams is not exclusively sold to Idaho. Further, the seasonality of the power supply is important. The region often has surplus power in the spring when the weather is mild and flows are high. The Loss of Load Probability analysis for MO3 showed that the region would have an annual risk of power shortages of around 14 percent stemming from shortages in the winter and summer. See draft EIS, Appendix J, Hydropower, Section 4.1.2.4; Section 3.7.3.5 at pages 3-918-924; and Table 3-166. The statement that Bonneville's revenues include the sale of surplus energy is accurate; however, Bonneville's surplus power is still in demand, and is sold regionally and exported beyond the region when available. If the output of the four lower Snake River dams is removed, then Bonneville would have less firm power (used to serve regional utilities) and less surplus power to sell. The rate pressure impacts of this outcome are described in the draft EIS in Section 3.7.3.5, Table 3-166. Regarding potential climate change effects on hydropower generation, the EIS analyzed multiple scenarios and the potential effects of climate change on hydropower generation are described in Section 4.2.5, Power Generation and Transmission, for the No Action Alternative, MO1, MO2, MO3, MO4 and in Chapter 7 for the Preferred Alternative.
6940	1	Valerie Yates	N/A	So with regard to my comment, I share that with you because I'd like to get right to a recommendation. And like prior commenters, I'd like to share that I'm recommending a two-tiered approach to save our endangered Snake River salmon, Southern Resident orca, and our ratepayers lots of money. The first tier being an emergency response action for the immediate drawdown and breach of the Lower Granite and Little Goose Dam, followed by the remaining two dams in subsequent years. Tier 2 is addressing system operations and further mitigation activities in the rest of the Columbia River basin using the new EIS, assuming that the four lower Snake River dams have been breached.	The Draft EIS evaluated under Multiple Objective 3 (MO3) removal of the earthen embankment of the four lower Snake River dams (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the CRS and mitigation for effects to resources from implementing this alternative. If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The ESA does not require the co-lead agencies to take affirmative actions to support recovery of ESA-listed species. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run,

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The EIS analysis in Section 3.6 (Vegetation, Wetlands, Wildlife and Floodplains) The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.7 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative.
6940	2	Valerie Yates	N/A	As we've heard on this call and I'm sure all the written comments, there are many reasons to breach the lower Snake River dams. Here, there are biological and economic reasons that I think are really important. The first is, endangered Snake River salmon and steelhead have not recovered since the 2002 EIS was implemented, and actually have gotten much worse over the last four years.	Based on the Preferred Alternative analysis, it will make a substantial contribution to recovery, but broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6940	3	Valerie Yates	N/A	Secondly, the economic benefits of the dams to the region have declined and operational costs have risen.	The EIS estimates the costs to operate the Columbia River System dams, and presents current and historical benefits information (e.g., hydropower production, tons of inland shipping) in both quantitative and qualitative ways. For capital and expense costs of the dams, see EIS Section 3.19, and for potential effects of dam breaching both beneficial and adverse, see Table 3-1 of the Draft EIS for the summary of effects by resource For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four lower Snake River dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four lower Snake River dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four lower Snake River dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6940	4	Valerie Yates	N/A	Third, the Army Corps of Engineers already spent seven years and $33 million of ratepayer and taxpayer money on the 2002 EIS, with a breach recommendation	Thank you for your comment.
6940	5	Valerie Yates	N/A	The Army Corps of Engineer has the fiduciary responsibility to cease operations and place a project into non-operational status when projects are losing money economically or causing nresolvable biological harm. Thus, the Corps of Engineers does not need specific authorization from Congress or anyone else to secure the project and breach the four lower Snake River dams. The federal agencies have a responsibility to comply to the Endangered Species Act and to take the necessary action.	Breaching the earthen embankment of the lower Snake River dams is a major Federal action that conflicts with the authority granted by Congress under which these projects were constructed and are operated. Therefore, de-authorization of the projects by Congress would be required prior to this action occurring. This action also would require expenditures from the Federal government to implement the action which have not been appropriated. The co-lead agencies do not have the authority to override Federal decisions of Congress, remove congressionally approved purposes, or appropriate Federal monies outside of the decisions outlined in annual congressional Federal appropriation bills. De-authorization and appropriation for the breaching of the earthen embankments are a requirement to implement MO3, which includes breaching the four lower Snake River dams. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
6941	1	Zorah Hesch	N/A	The agencies' preferred alternative perpetuates an approach that has pushed salmon, orca, and other wildlife population to the edge of extinction. No species should go extinct under our watch. There are option that allow us to co-exist. Policymakers, tribes, stakeholders, and communities need to work together on these complex problems to craft creative and sustainable solution that support the entire ecosystem. To come up with such an inclusive plan, the comment period must be extended. Here are some of the reasons why: All stakeholders need to have the opportunity to review the facts and scientist data available as well as consider best practices across the nation and the world. It is impossible to read the full draft EIS and validate its content n the given time period. The CRSO website offers to view the draft EIS electronically in various formats, including public libraries. Many public libraries are closed for weeks and will remain closed. Many people currently have either no or limited access to computers to read the draft EIS or to conduct research of its validity.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA species is the purview of NMFS and the U.S. Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives for resident fish, hydropower, water management, water supply and emissions, while minimizing adverse impacts to communities and the economy. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

6941	2	Zorah Hesch	N/A	There's a disconnect why native wildlife like the double-crested cormorant is still used as a scapegoat. Scientific data needs to be considered and the persecution of native predator species must be eliminated from this plan	The co-lead agencies utilized current high quality information and best available scientific data in its analysis in the CRSO EIS. The co-leads appreciate your concern for native predator species. However, the co-lead agencies are required to ensure operation of the CRS complies with the law. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. There are many factors that contribute to salmon and steelhead populations including changes to ocean conditions, predation, harvest, etc. The analysis in this study focus on the migratory impacts to salmon and steelhead from the operations, maintenance, and configuration of the Columbia River System projects. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm
6942	1	Elizabeth Dunne	N/A	I have worked as an attorney for 20 years. I've worked for large law firms. I've worked as a clerk for federal judges. And now I have my own practice. And I want to speak to the congressional authority issue. As an earlier commenter noted, the congressional authority is a red herring. The Army Corps clearly has congressional authority -- clearly has authority without Congress to breach these dams by putting them in non-operational status. I've reviewed the applicable statues and regulations, and I have no doubt that that is the case. So that needs to stop. The perpetuation of that falsehood is destructive and continues to basically make the corps look like an agency that we can't have faith in, and we can't believe anything that the corps is saying. So that's my first point on the congressional authority. I also want to speak to the -- I guess I will add, too, that I'm actually surprised that the corps would even want to say that it doesn't have authority to take such an action, given that the corps obviously wants the flexibility as an executive agency that it would actually cede power to the congressional -- to Congress to act in such a manner. And I think that in this day and age what we're seeing happening here with executive authority, it's really absurd to even continue to perpetuate that falsehood. Secondly, as to the appropriations, no new appropriations are required. The current (indiscernible) mitigation money that's being used can be reallocated to breaching the dams, which is a much more cost-effective solution. Also, as an alternative, the corps can use the emergency provisions under NEPA because of the emergency that we're in with the extinction of the salmon and the orcas. And there are regulations that recognize that in emergency situations, a loss of a public resource, the dams can be breached, and an environmental assessment document can be prepared for NEPA coverage.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. Those contending that Bonneville has authority to fund the breach of dams typically suggest two statutory alternatives. The first is Bonneville's discretionary direct funding authority found at 16 U.S.C. 839d-l. Congress granted this authority as a means for Bonneville, the Corps, and Reclamation to proceed with funding additions, improvements, or replacements to the multiple purpose projects of the CRS without having to first wait for appropriations for the entire activity. Instead, Bonneville provides the power share directly so that the Corps and Reclamation need only seek appropriations to cover the non-power share; that is, the share attributed to the non-power purposes of the dam. Stated another way, Bonneville can provide direct funding to cover only hydropower costs, whereas costs attributable to or shared by other purposes of the dams would be joint projects and would require congressional appropriations to cover the non-hydropower share of the cost. The breach of a dam is not an addition, improvement, or replacement of a dams power features, so the direct funding authority does not apply to the breach of a dam. Moreover, even if for arguments sake it did, Bonneville could provide no more than the power share of the cost of breaching. Congress would still have to provide appropriations to the Corps for the non-power share. The use of Bonneville's discretionary direct funding authority therefore cannot provide a means of funding the breach of dams absent an act of Congress. The second statutory authority suggested for Bonneville to fund the breach of dams is the Northwest Power Act section 4(h)(10)(A) found at 16 U.S.C. 839(b)(h)(10)(A). The Bonneville Administrator must use the Bonneville Fund to protect, mitigate, and enhance fish and wildlife affected by the operation and development of the FCRPS in a manner consistent with the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program, the Councils Power Plan, and the purposes of the Act. Currently, dam breaching is not part of the current Council Fish and Wildlife Program, the Seventh Power Plan, or evident within the purposes of Act. For example, dam breaching is inconsistent with the statutory purpose of Section 2(6) of the Act, which says in relevant part that anadromous fish are dependent on environmental conditions substantially obtainable from operations and management of the Columbia River System and other hydropower facilities in the basin. Additionally, as Section 3.7 (Power Generation and Transmission) demonstrates, dam breaching is also inconsistent with another purpose of the Northwest Power Act, Section 2(2), which provides for assuring the Pacific Northwest an adequate, efficient, economical, and reliable power supply. Section 4(h)(10)(A) therefore does not mandate or confer authority on the Administrator to fund the breach of a dam.
6944	1	Jonah Coffman	N/A	Since the listing of sockeye salmon as endangered in 1991 under the Endangered Species Act, we, the taxpayers and utility payers, have spent 16 to 17 billion dollars on fish ladders, dam modifications, hatcheries, barging smolts out to see, researching and monitoring, captive rearing of sockeye, and using irrigation water from the upper Snake River to flush smolt out to sea. Hatchery fish are not the solution. They were created for people to catch and for mitigation for destruction of habitats. But hatchery fish cannot do what wild salmon do and have not replaced wild fish. Low and worsening salmon and steelhead returns hurt commercial and tribal fishermen and fishing guides and the hurt communities throughout Idaho and the region. The current draft EIS only gives us more of the same failed solutions, which are not real solutions at all.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Finally, management of commercial fisheries is outside the jurisdiction of the three co-lead agencies. Specific discussion pertaining to commercial fishing is discussed in Section 3.15, Fisheries and Passive Use. Actions taken by other agencies are described in Chapter 6, Cumulative Effects, and Section 7.9, Cumulative Effects of the Preferred Alternative. Alternatives to include changes to harvest are not within the scope of this EIS. A recent EIS addressing harvest was conducted by NMFS. We cited this study in Chapter 3.15 as we used it's results to determine abundance considerations. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors.
6947	1	Keith Kutchins	N/A	This draft EIS fails because it doesn't develop alternatives that meet the needs of threatened and endangered fish protected by the Endangered Species Act, but, instead, only at best, it might improve fish, but no discernible level. The draft fails because the preferred alternative makes the needs of water supply, navigation, and electricity production the priority. Those needs are guaranteed to be met first and foremost. Then, and only then, does the preferred alternative work to, no, not meet, but, instead, only, at best, simply improve fish. Remember, the EIS -- the ESA is this EIS' mandate, and it's the floor we cannot go below, not a ceiling we can't exceed as this faulty draft is written.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6947	2	Keith Kutchins	N/A	This EIS needs to finally adopt a preferred alternative that, first and foremost, meets the needs of threatened and endangered fish. And then, tries to meet the needs of water supply, navigation, electricity production.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
7542	1	Diane Foulds	N/A	I'm writing to beg you to prevent the orca whale from extinction. They are part of the delicate food chain that nature has created over thousands of years. We don't understand all of its intricacies, but we do know that every time a piece of that food chain breaks, the repercussions are extensive and irretrievable. Our own existence depends on its delicate balance, and right now, it's in severe danger. Orcas depend on salmon, but the salmon population is crashing in the Pacific Northwest. This decline started when the four lower Snake River dams were put into service, and it is those salmon -- the ones that these dams have cut off -- that orcas depend on for survival. At last count, only 72 are still alive. Starving females are losing their unborn calves, as was visible in a heartbreaking video that went public a few months ago showing a mourning orca mother refusing to abandon her dead newborn. Do something about this. You are in a unique position to do so. The U.S. Army Corps of Engineers can restore salmon populations by removing the earthen portions of the Snake River's four lower dams and replacing them with wind or solar. If you get busy on this quickly enough, we'll keep the food chain from collapsing, and our own future will look a great deal brighter. Once the orcas are gone, there will be no getting them back. Please act now! Respectfully,	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s,

					before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
7605	1	Amy Dessert	Natural Resources Defense Council	There are not enough salmon in the Columbia and Snake rivers to feed the Southern Resident orcas. The dams on the rivers have eliminated the ability of the salmon to spawn.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible.
7615	1	Amy Hansen	Natural Resources Defense Council	Please, U.S. Army Corps of Engineers,We are so worried about the irreplaceable critically endangered orca whales. Please revise the Columbia River Systems Operations draft environmental impact statement (EIS) so that salmon are strongly protected, and the orcas that depend on them will survive. Our friends, the Native peoples', must be helped and their rights must be protected. It is so terrible that salmon populations in the Columbia Basin have so declined since the four lower Snake River dams were built. [Form And the at one time-abundant species such as chinook salmon, which make up 80 percent of an orca's diet, are only returning at a small fraction of historic levels.: 87.1%] Please take action before it is too late! There is something you can do, to help the people, the salmon and the whales - it is time to redraft the EIS so that you address the impact that dwindling salmon populations in the Columbia and Snake rivers have on Southern Resident orca survival. This is heartbreaking, and we ask you to act now to save the beauty of the world in this area!	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible.
9031	1	Beth Jones, informed & thus outraged expat	N/A	Once-abundant species like the chinook salmon (which make up 80 percent of an orca's diet!) are only returning at a small fraction of historic levels. Your draft EIS unwisely fails to adequately account for the impact that dwindling salmon populations in the Columbia and Snake rivers have on Southern Resident orca survival.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies disagree that the EIS does not adequately account for impacts on SRKW. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible.
12038	1	david holland	Natural Resources Defense Council	The Snake River dams were originally constructed to facilitate the shipment of grain and other bulk products to the coast through the Columbia River. The anticipated barge traffic did not materialize and the dams provide little economic benefit. Rather,they are a loss to the taxpayer. Accordingly, the best long term economic action is to remove the dams in a well considered fashion.	Access to barge transportation is the most cost effective means of accessing export markets for the many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but that decline is mostly attributed to investments in shuttle rail terminals. While the Snake River freight volume is certainly smaller than the volume of the other river systems, it is nonetheless an important transportation option for a large volume of freight, particularly for farm products, with the Columbia-Snake River system serving as one of the largest exporters of farm products in the U.S., and the largest exporter of wheat. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5.

29657	1	Susan Donaldson	Natural Resources Defense Council	Is it possible to construct adjacent water "corridors" (my word) that salmon could pass through, on the order of underpasses beneath highways for land animals? Please seriously consider that or something similar.	A wide array of measures were considered and during the creation of alternatives for these analyses. Canal or pipe systems were discussed for fish transport but were determined as technically infeasible. Other passage technology was suggested such as fish cannons or similar devices, which has demonstrated some success on smaller scales, and their use will continue to be evaluated for future applications. The four lower Snake River and four lower Columbia River dams have fish ladders that safely and effectively pass millions of adult salmon upstream. Adult upstream passage success through these dams is relatively high, generally around 90% from Bonneville to Lower Granite dam. In addition to passing up to 60,000 salmon per day, some of these dams may pass upwards of 250,000 shad in a single day.
31744	1	Shelley Silbert	Great Old Broads for Wilderness	The public participation process for the CRSO DEIS is flawed, and has become almost insurmountable in this time of pandemic. We have spent significant time, effort and money in order to ensure our substantive comments have been filed. This has been accomplished by our team of lawyers, scientists, retired government employees, and other professionals. Others attempting to comment may not have the resources and time that we do. It is important to remember that the Draft Environmental Impact Statement is 315 mb and 7,620 pages long, including 22 Appendices. Yet you provided only 45 days to submit comments on these numerous voluminous documents. We first attempted to submit our comments on line at comments.crso.info. That website limits comments to 100 kb. Attachments are limited to five attachments of 2 mb each, so that our entire comments were essentially limited to a maximum of 10 mb. These limits are incredibly small, given that the DEIS is 315 mb. We believe that these limits are unprecedented in federal commenting procedures and inconsistent with the National Environmental Policy Act (NEPA). Your procedures limited public input in scope, size, content and filing procedures, had a very short and arbitrary deadline for such a large, complex document, and thus weakened both public and scientific review. Our comments were 6.3 mb including figures, graphs and data to support our remarks and explanations. Because of limitations imposed by your agency we had to break our comments into five separate parts to submit them, a process which should not have been necessary! Because of the limitations of the online process, we decided to take other measures to file the documents including mailing and hand	The co-lead agencies are sorry for any technical difficulty experienced. It is accurate that the website had file size limitations that were listed for a single entry. That was not to limit you in your comments, but to alert you to submit in multiple entries either contact the CRSO info helpline, or mail your materials to the P.O. Box listed on the CRSO website and on other news and informational releases. Hand delivery was not a provided option for public comments. It was fortunate you were able to access the building and hand deliver regardless. Unfortunately with the COVID-19 pandemic response, the co-lead agencies office buildings were closed and personnel were directed to work from home. As indicated in the NOA, all comments mailed with the post-marked dates prior and up to April 13, 2020, or delivered by a delivery service with access to the mail room by 5:00 pm on April 13, 2020, were accepted. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				delivery. This involved making color copies of the 82-page document which was expensive, and of course involved exposure to other persons and possibly to the Corona virus. There is only one place listed where comments to the CRSO DEIS can be hand delivered which is the USACOE office at 1201 NE Lloyd Blvd in Portland Oregon. The entire building was locked. There is no sign that indicates that the USACOE is located at that building and no instructions on hand delivery options. We attempted to find the USACOE on the callbox and did not see them listed. We called up the only name that was recognizable, the National Oceanic and Atmospheric Administration office. Someone answered and had no idea what to do in this situation. Apparently that person called security and a guard came up to let us in to the building. The security guard took us to the floor of the building where the USACOE is located, and both doors were locked with no one in sight. We waited outside the locked doors and a second security guard showed up who had access to the Corps office, but could not accept the envelope containing the comments. He opened the door, checked my identification and had me sign in. He then started calling a number of people but seemed to get no response. The guard then walked me around through the offices to a third reception area where there was someone dressed in Corps attire. He accepted my package which I told him contained our comments on the DEIS but no receipt was provided. We also mailed a copy at the post office, another expense and exposure to danger. As can be seen below, the public hearings were cancelled on March 13, and telephone hearings were provided. The last one was thirteen days before the end of the 45 day comment period. Participants at the telephone hearings were limited to a three minute comment. This process does not allow an ordinary person to make anything other than the briefest and most summary comments. If they try, they are met with frustrations, expense and exposure to the virus. These are not ordinary times, but even in ordinary times the process created by the Corps does not meet the most basic elements of due process and public participation, and violates both the spirit and the letter of the law.	
31750	1	Abagayle Shane	N/A	The Task Force failed to recommend the bold action, immediate breaching of the 4 Lower Snake River Dams (4LSRDs) necessary to save these endangered whales while disregarding public input. In its Summary of Public Comments on 9/24 Report, the Task Force notes that the most prevalent comment received, of the 994 total comments relating to hydropower, called for dam removal. Indeed, 36.7 percent- or 365 comments-said "breach the lower Snake River dams," while an additional 10.4 percent-or 103 comments-said to "prioritize and remove dams in general." I am gravely disappointed with some of the recommendations you released on November 16th, especially your support of Task Force Recommendation 9, for stakeholder process to further discuss the potential breaching or removal of the 4LSRDs. This only delays action that should be taken immediately. The government efforts to save the Chinook Salmon and Endangered Southern Resident Orcas are failing and costing billions in taxpayer dollars.There is no need to fund the CRSO/EIS process which would take too long. Army Corps of Engineers can supplement the 2002 Environmental Impact Statement promptly and use Alternative 4 to breach the lower 4 Snake River Dams starting in winter 2018/19. Waddell, Twa and others have demonstrated that the 2002 EIS can be used to breach these dams and they have created Appendix D that would reduce the cost of breaching by $600Million. No new authorities are needed to place these dams in "non-operational" status; the. Corps can do so immediately if they are asked. Please ask the Army Corps to begin breaching as follows: Army Corps of Engineers can supplement the 2002 Environmental Impact Statement promptly and use Alternative 4 to breach the lower 4 Snake River Dams by Fall 2019. 1. Prepare Supplemental EIS materials & Record of Decision. 2. Prepare/Solicit/Award Cost-Type Contract for Excavation 3. Lower Granite draw-down begins. 4. Controlled hydraulic breach of Lower Granite Little Goose drawdown begins. 5. Lower Granite & Little Goose breached. 70 miles of Free Snake River.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using high quality information, the co-lead agencies developed the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Increasing flows as a potential measure was evaluated in the EIS. If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. The EIS acknowledges previous analyses of breaching the four lower Snake River dams. However, the EIS relies on current information to evaluate the tradeoffs associated with dam breach under MO3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago. Further, please see Section 3.7.3.5, Social And Economic Effects Of Changes In Power And Transmission, for a discussion of the regional retail rate effects of dam breaching. As described in that section, the general impacts of breaching the four lower Snake River dams is to increase the rates of most consumers of energy in the region, which has the potential to have the highest impact on rural areas. Higher retail rates means less spending on production, which reduces job growth. See Table 3-175 for the regional economic effects from changes in household spending on electricity. The commenters suggestion that billions in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
31754	1	Erika Lorrain	N/A	Please sir - breach the lower Monumental Dam and Little Goose Dam as soon as possible, this will save the salmon and our endangered Orcas from extinction. Each dam kills 2 million salmon every year and then just recently there was an oil spill, which harmed the Salmon and Snake river ecosystem. If only 2 of the 4 snake river dams were breached we would save 4 million salmon this year.	Without a specific reference, it was difficult for the co-lead agencies to assess the 2 million per dam loss claim made in this comment. The co-lead agencies used current high quality information and the best scientific information available in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted a Biological Assessment to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31761	1	timsalmonstate@gmail.com	N/A	Please accept the following comment letter from SalmonState regarding the Columbia River System Operations Draft Environmental Impact Statement (EIS). The Draft EIS falls far short of what is needed to protect and recover endangered salmon and steelhead populations in the Columbia Basin. The Draft EIS not only ignores well-documented science showing that dam removal on the Snake River is essential to restoring local fish populations, but it also fails to acknowledge that salmon know no boundaries and the economic health of Southeast Alaskas fisheries and coastal communities depends on the health of the Columbia River. A new approach is urgently needed with state and federal policymakers from both the Northwest and Alaska working closely with stakeholders, sovereigns and citizens to craft a lawful, science-based plan. SalmonState is an Alaska-based nonprofit initiative with the mission to ensure that Alaska remains a place where wild salmon and the people who depend on them thrive. It is not coincidence that Alaska is home to our countrys last great wild salmon fisheries. In Alaska, we still have healthy wild salmon populations because we still have intact free-flowing rivers and streams. While it may seem like Alaska is a world apart, it is closely linked in many ways to the health and abundance of Columbia-Snake Chinook. Salmon spend most of their lives in the ocean in mixed stock schools that range thousands of miles from their natal streams. In fact, for decades now, Southeast Alaska fishermen have been on the hook for much of what happens in the Columbia system. The fact is, just like Southern resident Orca, thousands of commercial, sport and subsistence fishermen in the region are inextricably linked to the health of the salmon runs on the Columbia and Snake Rivers.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, theoperation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6% for these same fish under MO3 (with no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase, Smolt-to-Adult return rates (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2%). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8%, which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. Under the Preferred Alternative, the CSS model predicts that average SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region), increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas-related mortality of juvenile migrants. See Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information. The Preferred Alternative will make a substantial contribution towards recovery.
31761	2	timsalmonstate@gmail.com	N/A	How to restore the Columbia Basins salmon populations is not a new discussion, which makes the Draft EIS worrisome and frustrating. Rather than embracing calls dating back to the 1990s for a major overhaul of hydrosystem operations to protect threatened and endangered salmon 1 and steelhead, this new report recommends only minor adjustments to a status quo plan that will perpetuate many serious mistakes from the past. The draft report does not offer a new approach; rather it recommends minor tweaks to a 25-year federal approach that has cost billions of dollars, brought salmon and steelhead today to some of their lowest levels on record, helped push orcas to the edge of extinction, increased uncertainty for communities across the region, and has been invalidated five times consecutively in federal court. Flexible spill is the centerpiece of the governments Preferred Alternative. While the science shows that increased levels of spill can buy some additional time to put in place more effective actions for imperiled fish populations, it is not, by itself, a long-term survival strategy, let alone a recovery strategy. Indeed the parties to the current, short-term Flexible Spill Agreement made this explicit and respected regional scientists have confirmed that the flexible spill included in the Preferred Alternative will not deliver salmon the survival benefits through the hydrosystem they need.	The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waiver standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative.
31761	3	timsalmonstate@gmail.com	N/A	The changing climate will further erode any benefits of flexible spill as a long-term approach and only underscores the urgency for meaningful action. The draft plan includes little to address these intensifying impacts on the Columbia Rivers salmon populations.	Through on-going regional climate change studies and related work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for use in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. The same is true for projecting changes to TDG.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
31761	4	timsalmonstate@gmail.com	N/A	Based on the approach recommended by this Draft EIS, recovery will not be an option and extinction becomes nearly certain for remaining endangered Snake River stocks: sockeye, spring/summer chinook, fall chinook and steelhead. SalmonState supports restoring a freely flowing lower Snake River as an essential cornerstone for any effective strategy to protect and recover its endangered wild salmon and steelhead. The scientific support for restoring the lower Snake River and native fishes that use this basin through dam removal is well established. For over two decades, Tribal, federal, state and independent research has repeatedly corroborated this determination. The just-released 2020 Draft EIS also acknowledges that restoring this river will deliver greater benefits to endangered Snake River fish populations than any other option considered or analyzed. Restoring the lower Snake River through dam removal should be included as a foundational element of the Preferred Alternative. A dramatically new approach is urgently needed in the Columbia Basin. The Draft EIS falls far short of what is needed to protect and recover endangered salmon populations, putting thousands of American fishing families and businesses at risk with them.	Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but broad sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation, maintenance, and configuration of the 14 CRS projects. The co-lead agencies used the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31762	1	wanda@portofclarkston.com	Port of Clarkston	The Port believes the public input process was appropriate and responsive to the circumstances in which we found ourselves (protecting people from COVID-19). 1. People did not have to travel to provide comments, making the opportunity available to a broader range of constituents (including those less affluent). 2. Some people would have been limited to attending a single meeting, had there been in-person public comment sessions. However, the Port of Clarkston was able to attend more than one, to gain a better understanding of the perspectives of others, and based on comments we heard, it was clear that others did as well. 3. At a time when large numbers of people were required to stay home, but were making connections through technologythereby increasing their physical (computer) connections as well as their personal technical skills--the crso.info website was clear, informative, accessible and user-friendly. For these reasons, the Port believes that the telephonic forum offered advantages over other in-person forums of outreach; we support the agencies determination that opportunities for comment were adequate. In addition, the action agencies public outreach during scoping was very favorable to informing people so they could make concrete, meaningful comments during that phase of the process. Inclusion of transcribers to help obtain comments during scoping resulted in a record amount of feedback during federal scoping processes. The Port understands that there has been push-back by special interest groups because individuals could not grandstand with an audience that offers applause whether it is discouraged or not. Such forums keep those with quiet opinions quiet and makes it appear that there is less of a balance of perspectives than actually existed. We offer our congratulations on successful approaches in both scoping and collecting comments on the draft document.	Thank you for your comment.
31762	2	wanda@portofclarkston.com	Port of Clarkston	2. The Port believes Judge Michael Simon ruled in error to mandate examination of Lower Snake River dam removal as one of the alternatives. a. This has actually led to a schizophrenic approach within the DEIS which must be corrected before it can be finalized. Please see Attachment 1 to this letter for detailed comments on contradictions identified by the Port especially the shift FROM the 2002 EIS that there will be no take of endangered and threatened species of fish for recreational fishing TO this DEIS in which increased recreational fishing is being touted to balance lost reservoir recreation under MO3. Both conclude that hatcheries and habitat improvements will disappear when mitigation requirements for the four LSRD is no longer required. But this DEIS leaves within fish models hatchery counts as if hatchery fish will continue to be produced.	The analysis of breaching the lower Snake River dams is evaluated as MO3 in the Draft EIS and compared to both the No Action Alternative as well as other multi-objective alternatives. The co-lead agencies used current high quality information regarding assumptions of recreational fishing in the region in response to predicted increases in anadromous and resident fish under MO3. This information is updated from that used in the 2002 EIS. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. The Draft EIS (page 3-550) objectively presents these factors and discusses the tradeoffs, including: 1) the predators that remain after dam breach would by mostly native fish adapted to riverine systems and there would be lower predation by non-native reservoir fish; 2) decreased travel time through the corridor would reduce avian and piscine predation; 3) the reduced predation risk may be offset by a reduction in hatchery fish and lower predator swamping effect. A summary of this qualitative discussion is provided for the reader for each Snake River species.
31762	3	wanda@portofclarkston.com	Port of Clarkston	b. Further, the Port concurs with PNWA that the finalized EIS should not simply discuss results (that are less than accurate because they presume continued release of hatchery smolts) from the two models which predict increases in smolt to adult returns. The final EIS should discuss the science behind the two models and choose one on which to rely in order to make a proper determination. In addition, if continued production of hatchery smolts will cease, this must be reflected in all analysis.	Given the inherent characteristics of the fish models, it would be challenging or infeasible to rerun scenarios of MO3 using NMFS COMPASS and CSS with Snake River hatchery production not included. NMFS COMPASS model relies on the record of hydrosystem survival data estimated with both hatchery and wild tagged Chinook and steelhead. The NMFS Lifecycle Model already reports only wild spawner abundance. Likewise, the CSS Chinook lifecycle model in the Grande Ronde/Imnaha also only included wild spawners. For both models, density related effects in downstream locations such as the mainstem, the Columbia River estuary and ocean could only be estimated with hatchery fish present. For this EIS process, the co-lead agencies have decided to report results from NMFS and from the CSS models. The science behind those models is discussed in Chapter 3.5 as well as in the modeling appendix.
31762	4	wanda@portofclarkston.com	Port of Clarkston	The Port of Clarkston incorporates the following comments, by reference, into its positions stated herein: 1. Letter by City of Asotin, WA, all parts, but in particular the discussion on its personal experience with land conveyance and the lack of ease in making that happen. Nearly six years has passed since authority under WRRDA was granted for the City to assume ownership of U.S. Army Corps of Engineers (hereinafter Corps) property and no measurable progress can be reported to date. Further, the City of Kennewick has been undergoing property ownership transfer for over two decades. Discussion within the DEIS of ownership transfers fails to take into account how that has not worked well for decades and how expensive it has been,	Real estate costs were included in the costs analysis under MO3 and described in Appendix Q Section 3.1.2.2. Under the dam breaching measures of MO3, it could be necessary to negotiate agreements with affected parties and property owners and enter into relocation contracts for the alteration or replacement of affected structures. Real estate administrative costs were developed for renegotiating contracts, leases, agreements, rights-of entry, etc. Given the uncertainty in the design and specifics of MO3 at this point, the real estate evaluation used the approach from the Lower Snake River Juvenile Salmon Migration Final Feasibility Report and Environmental Impact Statement (2002) and updated the data and costs as needed (Corps Walla Walla District Real Estate Division, 2019). If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments.
31762	5	wanda@portofclarkston.com	Port of Clarkston	2. The Port of Lewiston comments, specifically with regard to rail capacities and the loss of opportunity to reach Canada and middle parts of the U.S. States with dam removal. (The cargo did not simply stop or start with the navigation system; there are interconnections with roadways that are of importance.)	Comment seems incomplete. However, the EIS discusses many of the potential concerns raised in Navigation and Transportation, Section 3.11, including increased shuttle rail capacity.
31762	6	wanda@portofclarkston.com	Port of Clarkston	We also question the calculation in Chapter 3, p 1099 regarding 124,000 cy of dredge material per year. There was a gap of 9 years between dredging events; the volume of material removed needs to be divided by 9, for 41,400 cy per year or 1/3 the stated amount.	It is true that in recent years the average annual dredged volume of material has been much lower than the 124,000 CY/yr cited. This is because the number cited is an average from 1975 to 2015. Typically longer averaging periods are more representative. However, there has been a change in dredging patterns that should be acknowledged. The PSMP has a provision for dredging outside of the navigation channel for the sole purpose of increasing flow conveyance to maintain flood risk at Lewiston. This provision is in harmony with the Lower Granite Water Control Manual, which states that maintaining levee freeboard at Lewiston is a project function. The current requirements for conveyance dredging, which are outlined in the PSMP, are more stringent (i.e. several criteria need to be met before performing conveyance dredging) than conveyance requirements during the early years of the project. As such, conveyance dredging has not been performed in recent years. Since conveyance dredging has not been performed since the new requirements were put into place, data to determine annual conveyance dredging volumes, does not exist. While 124,000 CY/yr might be a high estimate, in the absence of data it was judged to be the most representative number, given that 41,000 CY/yr is a low estimate that does not include any conveyance dredging.
31762	7	wanda@portofclarkston.com	Port of Clarkston	3. The attached CRSO-EIS Hatchery & Transport comments which offers biological review and comments for increasing SARs for transport of fish and improved transport in river (TIR) ratios by better management of total dissolved gas levels in the Fish Collection and Transport Systems during high spill/high TDG events. We believe that transport will outperform spill even at higher TDG levels if critical degassing equipment is installed. Variable spill/TDG has been markedly increased, yet fish return numbers are decreasing.	Gas Bubble Trauma (GBT) disease is a combination of exposure level and duration during both the current condition as well as past exposure. Severity is also a function of overall health as well as availability of depth compensation. In general, for fish without the ability for depth compensation, TDG levels greater than 110% can lead to higher mortality and shorter response time at higher TDG levels. Past studies regarding TDG effects on survival have been of short duration thus high TDG exposure effects on Smolt-to-Adult survival remain unknown. In general, GBT disease tends to reduce overall fitness and thus can lead to reduced survivability. Over the past two years, the Corps has examined TDG exposure levels in the fish transport barge holds and collection raceways. Findings indicated transport barge aeration systems were successful at reducing TDG levels to less than 110% when the intake river water was 120% TDG. The results also indicated the raceway water supply at Little Goose Dam may need modifications to provide degassing when the water supply TDG is greater than 120%. Current adult returns are likely related to poor ocean conditions rather than passage conditions in the CRS, which have been improved in recent years. Adult return rates over the next few years will be considered through adaptive management to inform any necessary alterations of operations in order to better benefit to Snake River salmon and steelhead.
31762	8	wanda@portofclarkston.com	Port of Clarkston	6. Visit Lewis-Clark Valleys comments on a range of topics, but particularly including a change to the language in Chapter 3, page 1102 regarding the possibility of cruise ship ridership may increase. Documented ridership has shown an annual increase of 6.5% per year since 2014, and two additional cruise boats, owned by a single line, were planned for 2021 and 2022. Cruise boat business was exploding on the Columbia/Snake, exceeding that on the Mississippi.	Cruise ship visitation is described in Section 3.10, and is characterized as growing over time, and providing important regional economic effects. Section 3.10.3.5 describes the contribution of cruise ships as providing demand for approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales).
31762	9	wanda@portofclarkston.com	Port of Clarkston	The preferred alternative appropriately reflects the purpose of the DEIS, which is to make sure that continued operation of CRSO does not reduce appreciably the likelihood of both the survival and recovery of a listed species. The DEIS cannot be a fish recovery plan, because so many elements relating to survival and a return to abundance are global; they are far outside the area of influence in the agencies management of 14 of 60 dams on a single river system. The factors are not within the purview of the government of the United States.	The co-lead agencies agree that both human-caused and natural actions that are outside the responsibility and control of the co-lead agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion.
31762	10	wanda@portofclarkston.com	Port of Clarkston	MO3 will have a very significant and damaging impact to people of the Pacific Northwest, but has a higher concentration of negative impacts on the residents of four counties in southeast Washington, and five counties in north central Idaho than elsewhere.	Based on public comments, the co-lead agencies revised the Environmental Justice analysis (Section 3.18) to provide additional discussion of the potential effects to low-income and minority populations. The Environmental Justice analysis of water supply effects on irrigated farmland in Region C (which includes counties along the lower Snake River in north central Idaho and southeast Washington) acknowledges the potential for moderate disproportionate and adverse effects on low-income and minority populations living in this area under MO3 due to expected changes in water supply and irrigated farmland.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31762	11	wanda@portofclarkston.com	Port of Clarkston	MO3 cannot be entered into lightly. Science must be used properly to prove beyond a doubt that promised benefits for fish recovery exists before MO3 can be a considered a serious option. At present time, there is so much uncertainty, it should not even be on the table. Two significant areas are lacking in the analysis. Salmon survival benefits are uncertain, speculative, and subject to scientific dispute because models used for prediction have entirely different assumptions and put different weights on complicated combinations of environmental variables. The modeling is further flawed because both include a presumption of continued hatchery fish productionput in place as a mitigation measure when the four lower Snake River dams were built--when that it not the case. TWO MODELS OR EVEN ANOTHER MODEL FOR CONCLUSIVE, RELIABLE SCIENCE: Work needs to be done to determine which of the two models (COMPASS/Life Cycle Model or CSS) should be used to project fish returns, or whether a third model (yet to be identified) might provide greater scientific certainty with regard to the benefits associated with MO3. Assumptions and combinations of environmental variables feeding into these models result in very different predictions on smolt to adult (SAR) increases. The DEIS correctly notes that "currently, hatchery fish account for 80-90 percent of all juvenile Snake River fish passing CRS projects. COMPASS and CRS models do not account for this potential major reduction in juvenile fish production." (3-548, lines 16557-16558). This means that neither a 14% increase to SARs under the COMPASS/LCM nor the 170% increase under the CSS model predictions are of any value (see discussion immediately below).	The NMFS COMPASS/Life Cycle models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under MO and Preferred Alternative scenarios of operations of the CRS projects with respect to flow and spill. The Fish Technical teams for the EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Appendix E contains results from all modeling efforts, including both CSS models. Section 3.5 will be updated based on IEPR and ISAB reviews and will address the elements of the two CSS models described in this comment. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
31762	12	wanda@portofclarkston.com	Port of Clarkston	MITIGATION OR NO MITIGATION IF FOUR LOWER DAMS ARE REMOVED: Page 29 of the Executive Summary states the following, under the MO3 model involving breaching of the four lower Snake River dams: . . . there would likely be major long-term beneficial effects to river-based recreation, and improved recreational and tribal fishing. This is an empty promise. As stated above, Chapter 3, p. 548, lines 16557 through 16558 state: Currently, hatchery fish account for 80-90 percent of all juvenile Snake River fish passing CRS projects. COMPASS and CSS models do not account for this potential major reduction in juvenile fish production. Nez Perce Tribal Fisheries expert David Johnson stated at the Washington Governors Stakeholders meeting in Clarkston, WA, on January 7, 2020 that without hatchery fish, there would be no fishing. Recreational fishing does not allow take of wild, endangered species of fish. At the same meeting Birgit Koehler, Policy Lead for Power on the Columbia River System Operations Environmental Impact Statement at the Bonneville Power Administration (BPA) stated that BPA, stated that with dams removed, there would be no line item in BPAs future budgets for hatcheries and habitat improvement. Essentially, mitigation funding goes away when the dams are removed. No additional sources of funding for continued hatchery production or habitat improvements are identified in the DEIS. Even if they were, such identification would be speculative. If that is the plan, --to find outside funding--MO3 needs a broader than the present description such it that would not only address breaching of the dams but involve a constant infusion of additional, confirmed resources, in order to meet stated objectives (increased Tribal and recreational fishing).	The lower Snake River projects currently support 2.6 million visitors and $24.5 million in social welfare value annually. Breaching the four lower Snake River dams would have both beneficial and adverse effects on recreation. Dam breach would preclude reservoir recreation during and shortly after the breach, eliminating reservoir recreation; over time, and as recreation areas and access are redeveloped by others, long-term beneficial effects to river recreation, including angling, are anticipated. Section 3.11 of the EIS describes that the visitation in the long-term in the lower Snake River would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. No Federal mitigation is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, Federal agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4 and the Preferred Alternative, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Long-term effects to regionally implemented hatchery programs are outside the scope of this EIS. Similarly, habitat restoration programs would continue under every alternative and levels of funding and numbers of projects would be determined during implementation.
31762	13	wanda@portofclarkston.com	Port of Clarkston	The no-investments-for-hatcheries concept is pretty consistent in the document. Chapter 3, p. 559 lines 16895 through 16902 state: . . . reductions in hatchery fish could reduce the numbers of juvenile Snake River Chinook by as much as 85%. This reduction in the number of hatchery fish would likely result in a reduction of these predicted survival rates of wild Chinook because of increased predation rates. "Closure of the hatcheries funded by BPA will result in a loss of 19 million salmon, steelhead and resident rainbow trout." (2-36, lines 1151-1164; 3-897, line 24727). Further, the "COMPASS and CSS modeling results indicate that survival rates would increase by as much as 25% and travel times would decrease by as much as 30% relative to the No Action Alternative. However, as reductions in hatchery fish could reduce the numbers of juvenile Snake River chinook by as much as 85%, this reduction in the number of hatchery fish would likely result in a reduction of these predicted survival rates of wild Chinook because of increased predation rates." (3-559, lines 16895-16902). (Emphasis added)	The Draft EIS acknowledges that with breaching of the Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, other mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer be possible. The effects to populations as they transition from primarily hatchery production to an increased wild production, as well as the abundance considering the cessation of transportation, is discussed in Section 3.5.3.6. Under all other alternatives, including the Preferred Alternative, hatchery support from the co-lead agencies would continue similar to the No Action Alternative (levels supported in September 2016, when the Notice of Intent to Prepare an EIS was filed).
31762	14	wanda@portofclarkston.com	Port of Clarkston	The 2002 EIS rightly recognized that increased fishing in the area could not be assured post-breaching: "recreational fishing visitation was not included in the 2002 study due to the uncertainty around it being an allowable activity, given the current measures to regulate, protect and support ESA-listed fish populations and habitat in the region."(3-1219, lines 1821-1824). Yet in the current DEIS, improved recreational fishing after dam breaching is touted, with no explanation for this reversal in logic. The DEIS needs to explain why the 2002 position was set aside in favor of allowing recreational fishing after dam removal, and what support there is for the conclusion that it will increase.	The 2002 EIS evaluates the potential for recreational fishing in Appendix I, Economics. The recreational fishing analysis presents two approaches: one based on projected higher salmon and steelhead catch rates leading to proportional increases in angler visitation; and the second based on higher salmon and steelhead catch rates leading to a higher value per day but no increase in angler trips. Page I3-73 summarizes and states "The IEAB recognized that the more accurate was likely a combination of the two [approaches], so it was decided to use the mid-point of these two approaches in this analysis." This EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. In addition, as described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels. Although Bonneville's funding of the Lower Snake River Compensation Plan hatcheries would no longer be authorized, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries.
31762	15	wanda@portofclarkston.com	Port of Clarkston	1 Attachment 2 Port of Clarkstons Comments on the CRSO DEIS TOURISM Chapter 3, p. 1463, Lines 9459 9466 describes the loss of visitors as costing the region $103 million, a decrease in 1,230 jobs and $39 million in labor income. We take exception to these numbers. That impact could be felt alone in the Lewis-Clark valley. The Idaho State Parks and Recreation commissioned a report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho. The report was released in 2016 and reflects 2015 data for just Nez Perce County, Idaho. Power Boating generated 18,274 boating trips in Nez Perce County, generating $14,279,660 in direct spending for boats and moorage and an economic value of $22,810,512 annually (pages 10, 12 and 17). Cruise boat traffic was on an excellent growth trajectory and losses over the next decades will be greater than the DEIS calculation of losses. Visitation to golf courses and hotels are dependent upon the golf courses being green. The loss calculation does not factor in potential future lack of access to surface water for watering the Lewiston and Clarkston Golf and Country Clubs. Numbers touted above do not include stays for region track meets, fun runs and more. We request a re-examination of these numbers. Prior to revegation of the newly revealed shorelines, the communities of Lewiston, Clarkston, and Asotin will lose 100% of their visitors, due to terrible air quality and fugitive dust.	Section 3.11.2.2 describes gaps in the recreational visitation data. Data were not available for all sites, including along the Snake River below Hells Canyon Dam and above Lower Granite Lake. The 2016 report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho was considered for the EIS, but not relied upon directly due to the limited types of visitation data in the report, so it does not appear in the references. In addition, this region was not anticipated to be affected by changes in water surface elevations. Estimates of power boating use from that study are broadly consistent with visitation data from Federal and state agencies used in the EIS where data are available. The expenditure data collected for that study cover power boating in Idaho, while the recreational expenditure data applied in the EIS cover the CRSO basin and the broader range of activities reflected in the Federal and state visitation data. Section 3.11.3.5 describes the decrease in visitation in the short-term as the four lower Snake River dams are breached. Cruise ship visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). Regarding the air quality and dust impacts, Section 5.4.3.4 describes the proposed Federal mitigation for vegetation, wildlife, wetlands, and floodplains, including proposed mitigation to replant approximately 13,000 acres of arid, upland native vegetation on newly exposed soils and approximately 1,500 acres of emergent and forested, scrub-shrub wetland habitat adjacent to the new surface elevations of the lower Snake River. These actions would reduce erosion and dust from the drawdown, improving air and water quality. This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis accordingly concludes that pumps are unable to deliver water to an estimated 48,000 acres.
31762	16	wanda@portofclarkston.com	Port of Clarkston	RECREATION Page 29 of the Executive Summary states the following, under the MO3 model involving breaching of the four lower Snake River dams: . . . there would likely be major long-term beneficial effects to river-based recreation. The Port of Clarkston respectfully disagrees. River-based recreation will require significant investment in access, something that is not in place presently, in terms of roadways or boat ramps for much of the lower Snake River. Resources for these investments are neither included in mitigation numbers nor identified by any other source of funding likely to be available. River-based recreation will be degraded by noxious weeds and invasive species as MO3 fails to adequately address resources needed for habitat and recreational management. (Chapter 3, p. 749, Lines 23057 through 23061). With the U.S. Army Corps of Engineers gone because the project is, 26 existing recreational amenities will be orphaned. Visitation counts at formal entry points for these recreational amenities were calculated at over 1.7 million visits in Fiscal Year 2018 by the U.S. Army Corps of Engineers (see POC cover letter for website where this document can be found). River-based recreation will be degraded by fugitive dust, as there is an inadequate plan for revegetation. Per the 1992 OA/EIS (Appendix 4-59), there are air quality concerns relating to drawdown of reservoirs, . . . fugitive dust generated by strong windows blowing across exposed sediments during dry conditions [which can] result in high dust loadings and nuisance conditions for nearby residents and recreational users 2 The promise of improved recreational and tribal fishing is exceedingly unlikely as discussed in Attachment 1. The DEIS touts the benefits of land-based recreation as if it was an alternative for reservoir-based recreation. This fails to account for the summertime temperatures, when temperatures exceed 100 degrees for days on end. (Theres no mystery as to why Hells Canyon refers to hell; it has to do with heat levels.) Survival for people who live in the region is water-based. Land-based recreation is not attractive many months of the year due to high temperatures. On the other hand, pleasure boating occurs regularly between March and December. Stand-up paddle-boarding, kayaking, jet skiing and swimming are from May to October. And youre lucky to find room to play on the	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. Mitigation by the co-lead agencies is not anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, it is anticipated that the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to assess the requirements of the project and to potentially compensate for the changes in river conditions. Section 5.4.3.4 describes the proposed mitigation for vegetation, wildlife, wetlands, and floodplains, including proposed mitigation to replant approximately 13,000 acres of arid, upland native vegetation on newly exposed soils and approximately 1,500 acres of emergent and forested, scrub-shrub wetland habitat adjacent to the new surface elevations of the lower Snake River. These actions would reduce erosion and dust from the drawdown, improving air and water quality. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No

				reservoir on Labor Day weekend. The DEIS fails to adequately account for the number of cruise boat passengers and fails to mention Clarkston, WA as an important location in the debarkation of one set of passengers and embarkation of another. Cruising the Columbia and Snake Rivers is so popular that beginning 2018, cruise boat passenger numbers exceeded numbers of cruise boat passengers on the Mississippi River. The Columbia/Snake counts continue to be higher since then. The cruise boat industry goes away with MO3 (dam breaching alternative) in the draft EIS. All existing cruise lines with a week-long or longer itinerary call at the Port of Clarkston. The American Queen Steamboat Company spends 9 hours at its turnaround in Vancouver, WA (not Portland as stated in the DEIS), and spends 55 hours at its turnaround in Clarkston, WA. Thats why refueling in Clarkston is preferred; in addition, a fuel-laden boat can travel downriver more efficiently than upriver.1 Inadequate discussion exists with regard to nationally-designated recreation sites: 1. The Clearwater & Snake River National Recreation Trail was recognized in 1988. At that time, it was 19-miles of wheelchair accessible trail along the Clearwater and Snake Rivers. The connection to the river is the biggest contributor to the recreation experience. Today, it has expanded to well over 26 miles. Along with normal uses (walking, running, walking dogs, fun runs), the Trail serves as an important part of regional middle school, high school and college track meets, bringing thousands to our region to participate in or watch competitions in mild spring weather. (As stated above, this one just one of the amenities contributing 1.7 million visits in fiscal year 2018.) 2. The Hells Canyon National Recreation Area is accessible only by boat. Increases in visits, as recorded by the U.S. Forest Services, over the past 10 years directly correspond with increases in numbers of cruise boat passengers. There is no other easier way to experience N. Americas deepest gorge than via the tours arranged through cruise lines. Passenger surveys consistently identify this element as the highlight of their week-long cruise. Land-based recreation cannot take the place of reservoir recreation especially in hot summer months. In 2016, the Idaho Department of Parks and Recreation completed a study titled Economic Impact and Importance of Power Boating in Idaho (website location in POC cover letter). In this report, economists found spending in 2015 on power boating related products and services in Nez Perce County was over $14 million (p. 12). An additional $8.55 million was expended on other goods and services. This is a total impact of over $22.55 million in Nez Perce county in just 2015! The Lewis-Clark Valley is widely recognized as the Jet Boat Capital of the World. Produced here are more boat-building jobs than almost anywhere else in the United States. Not just jet boats are 1 Per the American Queen Steamboat Company, it purchased $900,000 in fuel in the Lewis-Clark Valley in 2017. It takes 8 hours and three tanker semis of fuel to fill the American Empress. 3 produced. Propeller boats produced here are designed for the reservoir that exist, not riverine conditions which means that many residents will have boats that sit idle or have to be trailered to other locations. The DEISs description of items of flat-water recreation limits the motor boating to only that in fiberglass boats. It fails to consider any propellered boat having problems. Smooth water kayaking preferred by older generations will be gone, as will stand-up paddleboarding and jet-skiing. These need to be included in the description.	Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The potential for visitation under MO3 in the lower Snake River in the long-term is predicated on that access would be developed for the resource. As described in Section 3.11.3.5, access to the river and its recreational opportunities will be paramount for the reestablishment of river visitation to the lower Snake River. For example, parking lots, boat launches, new trailheads, access roads, etc., would need to be developed to facilitate the drawing of visitors to the region. In addition, examples of the costs that would be incurred are provided. As described previously, further studies and NEPA would be conducted if MO3 were chosen for implementation. Regarding hatchery impacts associated with MO3, as described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels. Although Bonneville's funding of the Lower Snake River Compensation Plan hatcheries would no longer be authorized under MO3, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries. Cruise ship visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). Clarkston, Washington, and its role as a primary point of debarkation, is described in Section 3.10.3.2. Impacts on the industry, including Clarkston, are described in Section 3.10.3.5. Section 3.11.2.2 describes gaps in the recreational visitation data. Data are not available for all sites, including Hells Canyon National Recreation Area. The note under Table 3-256 in Section 3.11.2.2 states that visitation to National Forests and other USFS-managed lands is estimated for the entire unit, not specifically for recreation sites along rivers. The 2016 report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho was considered for the EIS, but not relied upon directly due to the limited types of visitation data in the report. In addition, this region was not anticipated to be affected by changes in water surface elevations. Estimates of power boating use from that study are broadly consistent with visitation data from Federal and state agencies used in the EIS where data is available. The expenditure data collected for that study cover power boating in Idaho, while the recreational expenditure data applied in the EIS cover the CRS basin and the broader range of activities reflected in the Federal and state visitation data.
31764	1	JOHN.OGAN@JWOGANLAW.COM	Confederated Tribes of Warm Springs	Comment letter attached	The co-lead agencies confirmed the Warm Springs Tribe's comments were submitted by the Columbia River Inter-Tribal Fish Commission coded as Letter 31775. Please see responses to comments under Letter 31775.
31766	1	portdave@portoflewiston.com	Port of Lewiston	We believe a modified M02 provides the greatest opportunity to achieve abundant salmon and steelhead runs while reducing spill and greenhouse gases. The Port is 'concerned that Total Dissolved Gas (TDG) levels as described in the Preferred Altemative (PA) maybe harmful to smolts migrating downstream. TDG levels exceeding 125% have not been adequately studied and may cause gas bubble disease thereby contributing to delayed mortality. In-river TDG's exceeding 125% should only be implemented after it is . successfully proven that TDG at these levels do not cause Latent . Mortality.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams such as the Technical Management Team.
31766	2	portdave@portoflewiston.com	Port of Lewiston	Page 3-1064, Line 31831: The Port of Lewiston has shipped numerous pieces of oversized equipment to Canada. Dam breaching would eliminate utilization of the Columbia/Snake River and U.S. Highways 12 and 95 as shipping routes to Canada and the interior of the U.S. Utilizing the Columbia Snake River and U.S. Highway 12 provides a unique transportation route because there are no height restrictions. U.S. Highway 12 has no overpasses and similarly, there are routes in Montana that have no height restrictions. There are no alternative west coast rail or highway routes that offer transport of cargo without height restrictions into the interior of U.S. When Highway 12 was initially constructed, U.S. defense considerations were a large factor in authorizing the construction of this highway. This is an exceptional transportation route that will no longer be available if dams are breached. The EIS should address the loss of this transportation option.	Section 3.10.3.5 includes a Section that discusses oversized load transit through the Port of Lewiston.
31766	3	portdave@portoflewiston.com	Port of Lewiston	Page 3-1087, Line 32284, Survey responses could be bias due to a 4-month extended lock closure during 2016. This bias may would be reflected in the modeling assumptions.	Although there was a planned shutdown of the Snake River at the end of 2016 for a few weeks, the freight tonnage on river was not significantly affected. Freight tonnage in 2016 was 4 percent lower than the 10-year average. This would not substantially affect the SCENT model results, and would not affect the modeling conducted for MO3 (dam breach). For additional information, please refer to L.2.2 in Appendix L.
31766	4	portdave@portoflewiston.com	Port of Lewiston	Page 3-1093, Line 32490: If 2016 is the base year for the analysis, does the 4-month extended lock closure impact the analysis?	Although there was a planned shutdown of the Snake River at the end of 2016 for a few weeks, the freight tonnage on river was not significantly affected. Freight tonnage in 2016 was four percent lower than the 10-year average. This would not substantially affect the SCENT model results, and would not affect the modeling conducted for MO3 (which includes the dam breach measure). For additional information, please refer to L.2.2 in Appendix L.
31766	5	portdave@portoflewiston.com	Port of Lewiston	Page 3-1095, Line 32518: Question the assumption that grain shipped down the river system will remain constant over time. For example, when the cost per barrel of oil increases to 2012 levels, Class A rail companies will dedicate equipment to oil shipments causing rail car shortages for other commodities. Furthermore, rail companies will institute rail car surcharge rates costing thousands of additional dollars to secure a rail car. The agriculture industry is unable to compete with the oil industry when high rail surcharge rates are instituted. We have seen this before and this scenario will undoubtedly occur again in the future. The river system will be needed to ship grain due to rail car shortage and pricing, however if dams are breached, river transportation will not be available.	The demand for waterway transportation is influenced by many factors, both related to the river operations and competing modes of transportation. In many cases, that demand is affected by private sector choices (investments by Class I railroads, construction of shuttle rail elevators by grain companies) that are largely difficult to predict into the future. The approach taken in the EIS is to utilize historical volumes as a barometer of what generally has been demanded and to provide impacts relative to that. In order to better characterize the level of uncertainty in which impacts should be considered, additional information has been added to the Navigation Appendix that puts the findings into context using recent historical highs and lows as a guide. How rail rates would change without lower Snake River shallow draft barging can not bet known with certainty. Therefore, in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road maintenance costs may occur. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. Ultimately, rail infrastructure investments would be at the discretion of the railroads.
31766	6	portdave@portoflewiston.com	Port of Lewiston	Page 3-1099, Line 32567: Question 124,000 cy of dredge material per year. The confluence of the Clearwater and Snake River was dredged in 2006. The next dredging project was undertaken in 2015 - a period of 9-years between dredging projects. In the 2015-2016 dredging project 372,603 cy of sediment was removed. If we divide 372,603 by 9 years = 41,400 cy average per year sedimentation rate. The 124,000 cy of dredge material per year is a high estimate. Additional information on page 3-1081, Line 32108.	It is true that in recent years the average annual dredged volume of material has been much lower than the 124,000 CY/yr cited. This is because the number cited is an average from 1975 to 2015. Typically longer averaging periods are more representative. However, there has been a change in dredging patterns that should be acknowledged. The PSMP has a provision for dredging outside of the navigation channel for the sole purpose of increasing flow conveyance to maintain flood risk at Lewiston. This provision is in harmony with the Lower Granite Water Control Manual, which states that maintaining levee freeboard at Lewiston is a project function. The current requirements for conveyance dredging, which are outlined in the PSMP, are more stringent (i.e. several criteria need to be met before performing conveyance dredging) than conveyance requirements during the early years of the project. As such, conveyance dredging has not been performed in recent years. Since conveyance dredging has not been performed since the new requirements were put into place, data to determine annual conveyance dredging volumes, does not exist. While 124,000 CY/yr might be a high estimate, in the absence of data it was judged to be the most representative number, given that 41,000 CY/yr is a low estimate that does not include any conveyance dredging. This has been clarified in the FEIS in Section 3.10.3.2.
31766	7	portdave@portoflewiston.com	Port of Lewiston	Page 3-1102, Line 32697: Question the use of may - that cruise ship ridership may increase over time. On page 3-1099, line 32574 the EIS states that the Columbia River outsold the Mississippi River in 2018 for cruise ship passenger. Replace "may" with "will".	The language cited by the commenter relates to the No Action Alternative, which states that cruise ship ridership may increase. This language is consistent with other wording used in the EIS regarding future actions and has not been changed.
31766	8	portdave@portoflewiston.com	Port of Lewiston	Page 3-1118, Line 33058: The EIS states that "others" agree that a 50% increase is likely to be a reasonable upper limit. Who are "others"? Idaho Cooperating Agencies and meetings with agricultural representatives have stated that a 100% increase is reasonable to expect in a monopolistic transportation market. The EIS does not demonstrate that a 50% increase in rail rates would entice shipping volume back to barge movements at the Tri-Cities. Stating that a 50% increase is a reasonable upper limit is without foundation. The EIS does not provide empirical data to support this constraint. The cost of trucking is the only constraint to rail pricing. Current trucking rates are $3.81per mile. Realistically, rail companies would find the "sweet spot" for pricing at a rate that would be optimal for rail revenues, but not enough to support a truck/barge move to the Tri-Cities. Additional analysis is required to arrive at a valid upper end increase in rail rates.	How rail rates would change without lower Snake River shallow draft barging can not be known with certainty. Therefore, in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. The FEIS includes an additional discussion of sensitivity to some parameters in Appendix L.
31766	9	portdave@portoflewiston.com	Port of Lewiston	Page 3-119, Line 33086: Question "with some limited expansion". Please see explanation for line 33092 below. Constructing facilities to handle an additional 39 M bushels of capacity is not "limited expansion".	The EIS states in Section 3.10.3.5 that in order for these shuttle rail facilities to accommodate that increased volume, in excess of the 3 million existing capacity, expansions and improvements would be necessary. Since the word "limited" is a judgment, this word has been removed from the referenced sentence in the FEIS.
31766	10	portdave@portoflewiston.com	Port of Lewiston	Page 3-1119, Line 33089: The EIS states that "shippers have reported that shuttle rail facilities can accommodate up to 25 million bushels per year with some storage adjustments ... " The shuttle storage facilities themselves MAY be able to handle the volume of grain, however the rail infrastructure serving the shuttle rail facilities is not adequate to handle the increased rail volume. Significant rail improvements would be necessary at Four Lakes and McCoy unit train facilities. Additionally, the unit train facility at Endicott (Lacrosse) is not capable of handling 25 million bushels per year. Rail construction	It is true that wheat shippers periodically are impacted by rail freight demand from other products or shipping demand that impacts rail service levels. The EIS provides the historical volumes moving down the river system and the economic rationale for why that volume produced would continue to be produced and marketed. The EIS states in Section 3.10.3.5 that in order for these shuttle rail facilities to accommodate that increased volume, in excess of the 3 million existing capacity, expansions and improvements would be necessary.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				costs are approximately $1 million per mile. The cost to improve rail in order to reach a volume of 25 million bushels at the shuttle facilities is significant. The EIS must further define these costs.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. There would need to be investments in infrastructure if dams are breached, both public and private sector investment in the absence of river navigation. These infrastructure improvements are discussed in section 3.10 of the EIS.
31766	11	portdave@portoflewiston.com	Port of Lewiston	Page 3-1119, Lane 33092: This sentence seems to imply that the 3M ton (99 M bushel) capacity of the four-unit train facilities is adequate to transport 138 M bushels of grain (71 M bushels (rail)+ 67 M bushels (barge). It appears that the capacity of the four-unit train facilities are 39 M bushels short. The first assumption under Scenario 1 would not be true without constructing 39 M bushels or 39.4% of additional handling capacity	The EIS states in Section 3.10.3.5 that in order for these shuttle rail facilities to accommodate that increased volume, in excess of the 3 million existing capacity, expansions and improvements would be necessary.
31766	12	portdave@portoflewiston.com	Port of Lewiston	Page 3-1119, Line 33110: Typo - Should be "Ritzville".	This is correct and will be changed in the Final EIS to state "Ritzville". It currently says "Ritzfield".
31766	13	portdave@portoflewiston.com	Port of Lewiston	Page 3-1119, Line 33108: There appears to be a disconnect between line 33108 and line 33121. In the first sentence, the EIS states that the four shuttle rail facilities can absorb the increased grain shipments. In Line 33121, the EIS states that "Due to this required increased in capacity, it would seem that this increase would be unlikely to occur without an associated increase in rail rates". Line 33108 is inaccurate.	There is not a disconnect in the text. The paragraph in Section 3.10.3.5 accurately explains that the ability for those shuttle rail facilities to accommodate that volume would be a stretch, given existing handling capabilities. Significant investments would be necessary for that to occur.
31766	14	portdave@portoflewiston.com	Port of Lewiston	Page 3-1120, Line 33157: As previously noted, should the number of unit trains increase by 94%, the rail infrastructure is unable to handle the increase. As stated in Page 3-1102, Line 32669: the cost to upgrade the entire PCC rail network to the 286,000-pound standard, WDOT would have to invest $150 million.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. There would need to be investments in infrastructure if dams are breached, both public and private sector investment in the absence of river navigation. The existing WSDOT estimate to upgrade the rail system is described in Section 3.10.3.2. It is not certain that the entirety of the system would require upgrade solely as a result of MO3 (which includes the dam breach measure).
31766	15	portdave@portoflewiston.com	Port of Lewiston	Page 3-1123, Line 33193: The EIS notes that Pasco, WA would experience a large volume increase, mostly from shipments arriving via truck traveling longer distances to access river ports. What substantiates this statement? Current trucking rates are approx. $3. 81 per mile ($3.29 per mile+ fuel costs of $0.52/mi.). Pasco is 130 miles from Lewiston. The McCoy unit train facility is 72 miles from Lewiston. Hauling to Pasco adds approx. $0.44 per bushel in transportation costs. It is questionable whether Idaho grain would be transported to Pasco even if rail rates increased by 25%. Costs associated with Scenario 2 should be further researched. The NAA cents/ bushel appears low.	The estimate of transportation costs under the No Action Alternative are based on survey responses as well as published rates, where available.
31766	16	portdave@portoflewiston.com	Port of Lewiston	Page 3-1125 Line 33226 - 33233: Question the accuracy of 50% representing a reasonable high estimate. The EIS states that rail rates increased by 40% during periods of lock closure. Lock closures are temporary and grain transport is planned for months in advance. Grain is prepositioned at Lower Columbia River elevators ahead of lock closure. Overseas buyers are aware of lock closures and plan for scheduling grain purchases. Breaching dams is permanent. If rail companies increase rates by 40% under a temporary lock closure, then increasing rates by only 50% under a monopolistic transportation scenario is not reasonable. Rail companies will price their services just under trucking rates.	How rail rates would change without lower Snake River shallow draft barging can not be known with certainty. Therefore in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. The FEIS includes an additional discussion of sensitivity to some parameters in Appendix L.
31766	17	portdave@portoflewiston.com	Port of Lewiston	Page 3-1126, Line 33242: Noted that Idaho farmers will experience rate increases double or triple a 24 cent per bushel increase in transportation costs.	This comment is consistent with the EIS. The EIS estimates under this scenario in Section 3.10.3.5 that average transportation costs would represent a 24 cent per bushel increase from the No Action Alternative (an increase of 33 percent when compared with the No Action Alternative). It also states that this increase would represent an increase of 33 percent on average, but that some individual shippers may experience increases that are more than double this amount, depending on their location.
31766	18	portdave@portoflewiston.com	Port of Lewiston	Page 3-1127, Table 3-246: The total change from NNA of 24 cents per bushel is low when considering the cost of trucking is $3.81 per mile. Additionally, it should be noted that 24 cents per bushel does not reflect how farmers will be impacted by the increased cost to improve rail lines (short line and class 1), unit train facilities, storage facilities, highways and additional handling costs.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS explains in Section 3.10.3.5 that additional costs for investments in infrastructure would be required separate from the increases in transportation costs to farmers. There would need to be investments in infrastructure if dams are breached, both public and private sector investment in the absence of river navigation.
31766	19	portdave@portoflewiston.com	Port of Lewiston	Page 3-1132, Line 33414: For the cost comparison of a Colfax farmer versus a Grangeville farmer, the trucking cost component should reflect $3.81 per mile throughout the comparison.	The commenter seems to be confusing the discussion of the increases in costs with the total transportation costs that are presented in Section 3.10.3.5. The $0.07 and $0.24 metrics are measuring the changes in transportation costs that would be anticipated to occur.
31766	20	portdave@portoflewiston.com	Port of Lewiston	Page 3-1137, Line 33587: Typo - Scenario "3". Not Scenario 1. Page 3-1137, Line 33593: Clarification - Construction cost should be $25 million. Not $25 million per year.	Thank you for your comment. This has been corrected in the FEIS.
31766	21	portdave@portoflewiston.com	Port of Lewiston	Page 3-1140, Line 33605: Quoting the 2002 EIS, states ... " if rail carriers face effective competition in rail-served markets". The point being that there would not be serious competition to rail service other than trucking.	The commenters assertion is correct and is the reason that the scenarios include rail rate increases from 25 percent to 50 percent.
31766	22	portdave@portoflewiston.com	Port of Lewiston	Page 3-1140, Line 33613: Reference Page 3-1102, Line 32667. WSDOT estimated the cost just to upgrade the PCC network to handle 286,000-pound cars at $150 million.	The existing WSDOT estimate to upgrade the rail system is described in Section 3.10.3.2. It is not certain that the entirety of the system would require upgrade solely as a result of MO3 (which includes the dam breach measure).
31766	23	portdave@portoflewiston.com	Port of Lewiston	Page 3-1140, Line 33620 - 33626: Referencing the 2002 EIS concerning mainline rail capacity is not appropriate. The 2020 EIS should not rely on statements by a BNSF representative from 18 years ago. Additional research should be undertaken concerning mainline rail capacity issues.	Estimates were developed for these costs based on input from local stakeholders during this study period, as well as using published reports as information sources, including the 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report. To the extent possible, the CRSO EIS navigation and transportation model structure reflects the best available current information based upon input from both shortline and mainline rail representatives. As described in Section 3.10.3.5, increases in infrastructure demands could vary widely following dam breach, depending on factors such as the changes in rail rates, which influence the mix of alternative transportation modes that are utilized. In EIS scenarios, the largest demands on rail would occur under Scenario 1, when rail rates are assumed not to increase and rail transit would be relatively more attractive. In contrast, increased highway use would be highest under Scenario 3, when rail rates are assumed to increase by 50 percent. The EIS also notes that the high rail demand scenario and the high highway demand scenario would not both occur. In addition, infrastructure investments are transitional costs, and would primarily be borne by private entities, including rail lines and grain shippers. Over time, prices should adjust to cover these costs. Some highway costs would be transferred to the trucking industry through fees, though most costs would likely be borne by public entities. The EIS states in Section 3.10.3.5 that, due to the high level of uncertainty surrounding these costs, interpretation should be done with caution.
31766	24	portdave@portoflewiston.com	Port of Lewiston	Page 3-1142, Line 33697 - 33702: A study by FCS Group found that the average regional net farm cash income was only $42,825. Given the devastating increase in agricultural transportation costs, over 1, 100 farms may be at risk on bankruptcy.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are much higher, depending on their specific location and other conditions. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Note, more specific cost scenarios for farmers are presented in the Regional Economic Effects Section. The Section acknowledges that this would reduce the profitability of farming in Region C due to increased transportation costs.
31766	25	portdave@portoflewiston.com	Port of Lewiston	Page 3-1142, Line 33707 - 33715: This paragraph brings to mind several questions which the EIS should analyze: Will the U.S Government subsidize the increase in transportation costs to the agricultural industry, farmers, timber interests and other businesses negatively impacted by dam breaching? Adequate rail capacity could take decades to construct, if ever. Rail companies will have monopolistic pricing opportunities. What is the economic impact to rural Idaho communities due to the impact of higher transportation costs? For example, how many rural Idaho farmers are expected to go out of business? When the first barge departed from Lewiston in 1975, rail rates fell throughout Idaho and eastern Washington as railroads now had to compete with barge transportation. If dams are breached, rail rates will increase due to monopolistic pricing opportunities throughout Idaho and eastern Washington. The EIS should provide analysis on not just local increases in rail rates, but increases throughout the region.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest will be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports.
31766	26	portdave@portoflewiston.com	Port of Lewiston	Page 1145, Line 33795: Question the increased transportation cost range of $0.07 to $0.24 per bushel. This analysis should be revised to reflect actual truck rates of $3. 81 per mile. Additionally, it should be noted in this section that the full impact of increased transportation costs is not captured within the $0.07 to $0,24 per bushel range. Costs associated with improvements to unit train loading facilities, storage capacity, rail lines (short line and class 1), highways and additional handling costs are not captured within the stated cost increase. These additional costs will be substantial and ultimately paid by the farmer.	The commenter seems to be confusing the discussion of the increases in costs with the total transportation costs that are presented in Section 3.10.3.5. The $0.07 and $0.24 metrics are measuring the changes in transportation costs that would be anticipated to occur under MO3.
31766	27	portdave@portoflewiston.com	Port of Lewiston	Appendix L Navigation and Transportation Content of Appendix L and Chapter 3 of the EIS shows that the content concerning navigation and transportation in the two document is very similar. Concerns express above for Chapter 3 of the EIS are similarly expressed for Appendix L.	Thank you for your comment. Please see the comment responses to your concerns about navigation and transportation for Chapter 3 of the EIS.
31766	28	portdave@portoflewiston.com	Port of Lewiston	A series of discussions from a broader Basin-wide focus resulted in the following concerns and opportunities to be included in Port's comments on the currently proposed Draft EIS: The lack of any degassing infrastructure in the Transport fish collection and holding raceways below the Lower Snake Dams to remove excess TDG' s. Hatchery and Wild fish spend up to 48 hours in this shallow environment where TDG's exceeded 115% in 2019 and may have approached 120% in years where Spill resulted in TDG levels exceeding 125%. The lack of any degassing infrastructure on the 2000-series barges to reduce TDG levels to those considered acceptable in a hatchery environment. Fish transported on the 2000- series barges spend up to 48 additional hours in transport on the barges. The lack of sufficient degassing infrastrncture on-board the 4000 & 8000-series Transport barges to reduce TDG levels to those considered acceptable in a hatchery environment. New evidence from the 2019 Fish Transport TDG Monitoring Report suggests Transport fish TDG exposure increases above levels considered safe in a hatchery environment even at Fore bay TDG levels of 110%. Prior to the 2019 Fish Transport TDG Monitoring Report the Transport System was viewed much like a Control Group where variables were considered minimized in Comparative Survival Studies (CSS) evaluating the survival of Transport fish (T) with respect to In River fish (IR). (The survival ratio of Transport vs In River fish is expressed as TIR. When TIR > 1 then Transport survival exceeded In River survival). The likelihood that Latent Mortality on Transport fish was higher than that of In River fish when TDG's increased above levels considered unacceptable in a hatchery environment due to the cumulative stress effects of: o Fish collection at high TDG levels o Fish enumeration at high TDG levels o Holding in raceways in a new environment for up to 48 hours at very high TDG levels o Fish loading stress from raceways to Barges at elevated TDG levels o Barge transport in a new environment for up to 48 hours at high TDG levels o Fish dumped below Bonneville Dam into a high-predation/high TDG level environment after 96+ hours of multiple stressor events at TDG levels That	Gas Bubble Trauma (GBT) disease is a combination of exposure level and duration during both the current condition as well as past exposure. Severity is also a function of overall health as well as availability of depth compensation. In general, for fish without the ability for depth compensation, TDG levels greater than 110% can lead to higher mortality and shorter response time at higher TDG levels. Past studies regarding TDG effects on survival have been of short duration, thus high TDG exposure effects on Smolt-to-Adult survival remain unknown. In general, GBT disease tends to reduce overall fitness and thus can lead to reduced survivability. Over the past two years, the Corps has examined TDG exposure levels in the fish transport barge holds and collection raceways. Findings indicated transport barge aeration systems were successful at reducing TDG levels: the 8000 series, with its packed columns, to less than 102%, and the 2000 series, with its spray bars, to less than 105% TDG when the intake river water was 120% TDG. However, the results also indicated the raceway water supply at Little Goose Dam may need modifications to provide degassing when the water supply TDG is greater than 120%. Therefore, direct loading into the barges is being maximized. TDG exposure at these levels, if the fish are deeper than a meter, is no risk of GBT. Every meter of depth compensates for 10% increased saturation. Two meters of depth has the same effect as 100% at the surface. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				existing data supports this potential connection of Latent Mortality in Transport fish due to high Transport system TDG's. The lack of any Latent Mortality studies for either Transport (barge) or In River (Spill) fish at the current gas cap of 110%. The lack of any Latent Mortality studies at the 120% and higher TDG's levels proposed under the Alternatives in the Draft EIS. Future TIR comparative survival studies should be performed with the improvements implemented to the Transport collection, holding, and barging systems to obtain TDG levels deemed safe in a hatchery environment prior to commencement.	
31766	29	portdave@portoflewiston.com	Port of Lewiston	The Draft EIS does not include any mention of improving the abundance of fish through optimization and standardization efforts of the existing BP A Direct and Indirect funded hatcheries. The hatcheries are considered by many to be one of the most important tools for meeting fish mitigation goals, yet they vary widely in their operations, infrastructure, efficiency, and in their effectiveness.	Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
31766	30	portdave@portoflewiston.com	Port of Lewiston	The proposed decrease in hydroelectric production represents a certain path towards substantially increasing Greenhouse Gas emissions (GHG)	Section 3.8.3 of the EIS does demonstrate that a reduction in hydropower generation from the CRS projects would likely increase greenhouse gas (GHG) emissions. The Preferred Alternative is estimated to increase GHG emissions by 1.5%, or 0.54 million metric tons, compared to the No Action Alternative.
31766	31	portdave@portoflewiston.com	Port of Lewiston	The data for energy costs used in the Draft EIS is likely very outdated due to rapidly lowering energy storage costs and renewable energy pricing. The exclusion of more affordable energy storage opportunities in coordination with current hydroelectric production levels could increase the availability of clean, renewable energy on the Grid while reducing drafting and Cultural Concerns cited in the Draft EIS.	The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The use of storage technologies is considered a long-term resource of the Council's 7th Power Plan, not a primary resource; it has become more commercially available since the release of the 7th Power Plan and was examined in the EIS. Storage will likely be considered a primary resource in the Councils 8th Power Plan. To address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the Final EIS. The Final EIS also includes the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan. The EIS describes the effects on hydropower generation, drafting and cultural resources (see Section 3.16). The magnitude that hydropower operations shift generation and draw down due to new power generation from replacement resources is unlikely to substantially change the effects on cultural resources from drafting. Contrary to the implication in the comment, the inclusion of storage resources is similarly unlikely to substantially affect the drafting at CRS projects under each alternative evaluated (see draft EIS Section 3.8.3.1, Methodology, and Appendix J for additional details on the hydropower modeling). New renewable resources like wind and solar require dispatchable generation like hydropower to increase and decrease generation to balance the variability of wind and solar. This may exacerbate the concern raised in the comment, but is too speculative to analyze in the EIS at this time. See draft EIS, Section 3.7.3.2, Potential Replacement Resources and Associated Costs at page 3-849 and Section 3.7.3.1, Integration Services at page 3-832.
31766	32	portdave@portoflewiston.com	Port of Lewiston	It is the Port's position that a holistic Columbia River System Operators EIS cannot be considered complete unless included within the Multiple Objectives and Preferred Alternative is a sincere evaluation of the results for optimizing the performance of the hatchery and fish passage programs that BPA funds across the Columbia Basin. There is tremendous opportunity to improve the performance of the direct and indirect hatchery and fish passage facilities beyond the scope of anything discussed within the CRSO Draft EIS. These improvements provide a path for utilizing capital dollars for the improvement of our resources (fish, energy, water) and increase the number of adults returning to the Basin while ultimately lowering the long-term Fish and Wildlife program O&M costs. It will also lower the carbon footprint of these programs while decreasing the need for additional spill thereby lowering greenhouse gas (GHG) emissions. It is imperative that any strategic approach for improving the performance of the Columbia River System (CRS) for all Stakeholders ensures that the existing system is operating as efficiently and as effectively as possible. Data used to evaluate the performance of the existing system must be as accurate and as relevant as possible. Such a strategic approach would thus further minimize capital dollars necessary to make such improvements. It would also minimize any potentially negative effects from subsequent alterations to the existing operations and infrastructure. From this perspective, the Draft EIS failed to incorporate a number of opportunities to make improvements to the performance of the existing hatchery programs. The Draft EIS fails to identify critical infrastructure that is necessary to reduce excessively high total dissolved gas (TOG) levels in the Fish Collection and Transport Systems during high spill/high TOG events. The implementation of which would very likely result in increased SAR's for transport fish and improved transport in river (TIR) ratios under these conditions. As a result of this critical infrastructure exclusion, we strongly disagree with the EIS statement that "M02 is less effective than the other MO's at meeting the 'Improve Juvenile Salmon', 'Improve Adult Salmon', and 'Improve Resident Fish Objectives'". Past data has convincedly shown, that under reasonable TOG levels, in-river fish transport system has routinely outperformed spill year after year. We believe that transport will continue to outperform spill even at higher river TOG levels if critical degassing equipment is implemented. This information was previously been shared with LSRCP, USCOE, and BPA managers in the Spring of 2018.	The scope of the CRSO EIS is to evaluate alternatives to CRS operations, maintenance and configuration and not evaluate alternatives to Bonneville's Fish and Wildlife Program. Bonneville's Fish and Wildlife Program is appropriately described in Chapters 2, 3, 5 and 7. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during discussions of mitigation actions for each alternative, but were only proposed for MO3 due to the substantial short-term impacts to ESA-listed species during drawdown and breach of the four lower Snake River dams. Hatcheries are managed to meet individual hatchery objectives. Specific hatchery operations are separate actions from operation of the CRS and are outside the scope of this EIS. Under the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region), increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information. Additionally, the Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. and habitat measures that are described in Section 7.6.4.1 with examples listed in Table 7-5 in the Draft EIS. Finally, Sections 3.5 and 7.74 provide additional information on transport fish and improved transport in river for the alternatives.
31766	33	portdave@portoflewiston.com	Port of Lewiston	In recent years, evidence is mounting that additional spill which further elevated TDG levels negatively impacted Steelhead and Chinook returns to Idaho. TDG's measured below the John Day pool have increased annually since 2015, approaching 130% in both 2017 and 2018. The more recent returns for both Spring Chinook and Steelhead to the Clearwater River have been some of the worst on record. This is despite the fact that LSRCP chi nook production targets have increased by approximately 35% on the Clearwater System over the last two decades. Dworshak Hatchery alone increased Spring Chinook smolt production numbers from approximately 600,000 smolts in 2001 to around 1.6 Million smolts in 2019. If return numbers are decreasing despite increasing hatchery production numbers into a system where the variable of Spill/TDG has been markedly increased, shouldn't we be looking for what the CSS model may have overlooked? It is already well accepted that high TDG impacts Delayed Mortality in hatchery systems. The BPA F&W program, the USCOE, and the USFWS have all spent significant time, money, and effort to address TDG impacts on Delayed Mortality. We believe that Columbia River System operations resulting in 120% - 130% TDG levels in the river due to increased Spill is not reflective of what the TDG levels would be in an open flowing river system. Thus, how can we expect to use test results from a river flowing at-or-above 120% TDG levels to predict the outcome of breaching the dams if any part of the spill test might increase Latent Mortality effects? Especially when any Transport vs. In-River comparison at elevated TDG's is inaccurate due to the lack of adequate TDG degassing infrastructure in the Transport facilities? We have decades of evidence that TDG's at these levels contributes to Delayed Mortality in hatchery infrastructure similar to the fish collection system raceways. Fish returns to the Snake and Clearwater River Systems continue to decline despite large increases in hatchery production and with releases into higher Spill/higher TDG's. In the April 3rd, 2020 Lewiston Tribune Fish Forecast titled "Steelhead, chinook seasons look grim," IDF&G Fish Biologist Alan Byrne told the Tribune "if the (Steelhead) forecast is accurate it would be similar to the 2018 run and register as the seventh lowest on record. Last year was the second lowest recorded, and 2018 was the sixth lowest." Washington Department of Fish and Wildlife Fish Program Manager Chris Donley stated that "Last year's return of hatchery Brun steel head was so dismal that fishing was closed on the Clearwater and lower Snake rivers during the fall." These are returning runs of fish that were released as juveniles into already higher Spill/higher TDG conditions. The May 24th, 2019 issue of the Spokesman-Review article titled 'Chinook return "changing for the worse every day"' (a quote taken directly from the interview with IDF&G Regional Fisheries Manager Joe DuPont) stated "The gloomy run performance also includes some bad news for the 2020 run. Fisheries managers had hoped they would see a healthy return of jack chi nook because of improving ocean conditions. Jack chi nook spend just one year in the ocean before returning to spawn and often give managers a hint about future returns. But the latest projections indicate this year's jack return to Clearwater River hatcheries and Rapid River Hatchery will be the second lowest in the past 10 years." It must be noted that this 'second lowest return of jack chinook in the past 10 years' was released from the hatcheries in 2018 when Lower Snake River and Columbia River Spill levels were extremely high and the TDG levels in the system were recorded to have approached 130%. We do not know with any certainty that these high Spill/high TDG levels had a positive effect on this cohort of fish, however we could - and perhaps should infer from this very poor performance that the abnormally high Spill/TDG levels may have had a negative impact on this hatchery release group. And these were Spill/TDG levels reflective of those proposed in the Draft EIS 'Preferred Alternative'. The Port feels strongly that it cannot support a position that promotes increasing Spill/TDG's and subsequently increasing GHG's until further studies of the effect of TDG's on Delayed Mortality are performed and the necessary degassing equipment has been installed for the transport collection and barging systems. This is imperative because the transport SAR data can no longer be considered the 'control group' when high Spill/high TDG conditions exist in the river and in the shallow fish holding raceways. The result of any additional Latent Mortality in the transport population of fish from this exposure would result in an unfair comparison of TIR when the assumed high TDG controls are removed. Given the existing lack of any effective degassing infrastructure in the fish collection systems and the dismal returns of both Steelhead and Spring Chinook released into higher In River and Transport TDG levels, we believe there is a high probability that the TIR is not a fair analysis at elevated TDG levels.	Return rates of salmon can vary by two or more orders of magnitude among years. Most of this variability is to due the differing conditions in the ocean where they spend most of their life. Recent years, have resulted in very poor returns. However, returns in 2014 and 2015 were record highs. With the exception of 2015's very hot weather, conditions did not vary to such a degree. However, a number of indicators of ocean temperatures, food sources, and salmon predators do correlate well with the differing returns. With so many factors, it is very difficult to identify cause and effect relationships to salmon populations. Regarding TDG levels in the juvenile transportation system, Over the past 2- years the Corps has examined TDG exposure levels in the fish transport barge holds and collection raceways. Findings indicated transport barge aeration systems were successful at reducing TDG levels: the 8000 series, with its packed columns, to less than 102%, and the 2000 series, with its spray bars, to less than 105% TDG when the intake river water was 120% TDG. However, the results also indicated the raceway water supply at Little Goose Dam may need modifications to provide degassing when the water supply TDG is greater than 120%. Therefore, direct loading into the barges is being maximized. TDG exposure at these levels, if the fish are deeper than a meter there is no risk of GBT. Every meter of depth compensates for 10% increased saturation. Two meters of depth in 120% TDG has the same effect as 100% at the surface. This monitoring will continue with the increasing spill. Indeed, the Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty in how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
31766	34	portdave@portoflewiston.com	Port of Lewiston	There have not yet been any successful studies focused on determining Latent Mortality effects on Transport (T) or In River (IR) at the current gas cap of 110% - even prior to a proposed jump to 120% or more. Nor have there been any Latent Mortality studies of the effects of holding the transport fish for up to 48 hours in shallow raceways without any degassing equipment under high Spill/high TDG conditions. This is despite the fact that hatcheries across the basin and across the country have gone to great lengths to avoid exposing their fish for even the briefest periods of time under such conditions. Furthermore, there have not yet been any studies evaluating Latent Mortality on the transported population of juvenile fish that looks closely at the effects of transport among the different 2000, 4000, and 8000 series barges once TDG levels become elevated above acceptable hatchery conditions.	Gas Bubble Trauma (GBT) disease is a combination of exposure level and duration during both the current condition as well as past exposure. Severity is also a function of overall health as well as availability of depth compensation. In general, for fish without the ability for depth compensation, TDG levels greater than 110% can lead to higher mortality and shorter response time at higher TDG levels. Past studies regarding TDG effects on survival have been of short duration thus high TDG exposure effects on Smolt-to-Adult survival remain unknown. In general, GBT disease tends to reduce overall fitness and thus can lead to reduced survivability. The duration of exposures between a hatchery fish (many months) and a transported fish (versus a maximum of 2 days in holding raceway or a maximum of 3 days in the barge if direct loaded) are enormous. These different exposure time frames and different gas levels are very different.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				The 4000 and 8000 utilize degassing equipment that has been proven ineffective for elevated TDG conditions under high spill conditions from the Dworshak Dam resulting in only 115% TDG levels by the Dworshak Hatchery Operators, and the older 2000 series barges do not even have degassing equipment onboard to reduce TDG's. To summarize, transport fish populations spend up to 48 hours after fish are collected in a shallow raceway environment that would be deemed unacceptable at a hatchery facility under similar conditions because of the likelihood of Gas Bubble Disease Trauma and potential Delayed Mortality effects. Those fish are loaded into barges with degassing equipment that is also deemed unacceptable at a hatchery facility under similar conditions to spend the next 48+ hours in Transport down the Snake River and Columbia River. Despite all of these concerns of exposure to elevated TDG's, Transport Fish populations continue to see higher survival rates than the In-River fish in most years. To emphasize this point, BPA and the USCOE have spent millions of dollars across the Columbia Basin hatcheries to design and implement TDG removal systems on water supply systems to fish-holding infrastructure very similar to the Fish Collection and Holding Raceways below the dams at hatcheries. Perhaps most relevant is the massive vacuum degassing-style TDG removal systems that were designed and implemented by Dworshak Hatchery operators and the USCOE. This project was developed to address the concerns of TDG levels spiking above 104+% posttreatment with a goal of reducing gas levels at-or-below 102% for fish held in a similar environment. The previously used Packed Column system (similar to the systems currently in place on the 4000 and 8000 series barges) had been determined to be ineffective at preventing Gas Bubble Disease and Delayed Mortality TDG conditions from the Dworshak Dam with a gas cap of only 110%. Despite the significant upgrades to the degassing systems, managers of these projects became extremely concerned when Dworshak Dam was spilling water into the Dworshak Hatchery water intake structure with TDG levels of 115% as the result of turbine maintenance efforts. The USACE and Dworshak Hatchery operators monitored the TDG levels from the Degassing System very closely during this time. They were greatly concerned about increased Delayed Mortality in Spring Chinook and Steelhead populations within the hatchery. The improved degassing abilities of the new Vacuum Degassing Systems installed at the Dworshak Hatchery allowed the operators to successfully navigate the 115% TDG window during Dworshak Dam turbine maintenance. The staff were so relieved and so impressed, that they prepared a presentation which was given multiple times across the Columbia Basin. They shared their story to help other facilities reduce the likelihood of Delayed Mortality due to Gas Bubble Trauma experienced at TDG levels above approximately 102.5%. The slide below from Dworshak Hatchery 2018 LSRCP Power Point presentation identifies the successful performance of the vacuum degassing system at 115% TDG levels in the influent water supply, as well as the unsuccessful performance of the original packed column system to perform adequately at those same levels. The 4000 and 8000 series transport barges use packed column degassing systems similar to the ones that failed to perform adequately at 115% TDG levels, and the 2000 series barges and the fish collection system holding raceways do not have any degassing infrastructure for water treatment. [graph included in document: Dworshak NFH comparison of packed columns vs. vacuum degassers] In 2001 when hydro production was maximized to meet the challenges of the Enron crisis, River TDG levels were the lowest in the past 25 years, at approximately 110% during juvenile fish passage. In that year Transport SARs were almost 9-times higher than In River SAR's. Low flow conditions in 2015 once again resulted in relatively low TDG levels (closer to 115%) and Transport outperformed spill 4:1. Data from Table 4 of the 2019 Fish Transport TDG Monitoring Report suggests TDG exposure in the fish Transport holding raceways at Lower Monumental Dam and Little Goose Dam would have been at-or-below 104% and 107.9% TDG levels respectively in 2011. That same report also suggests that TDG levels throughout the rest of the Transport system would have been at-or-below TDG levels considered a concern at the Dworshak Hatchery and other Columbia Basin hatcheries for even short-term TDG exposure to salmon ids. Furthermore, when Spill levels were increased and TDG levels in the Transport fish system rose far above levels considered safe in a hatchery environment the exact opposite was the result. In 1997 and again in 2011 high flows/high Spill resulted in TDG levels exceeding 120% and approaching 130%. In these years Transport survival fell far below In River survival -to 0. 74 and 0.68 TIR respectively. In these years the data in Table 4 of the 2019 Fish Transport TDG Monitoring Report suggests that fish held up to 48 hours in the Lower Monumental Dam Raceways experienced TDG levels of approximately 110%, and the fish collected at Little Goose Dam were held for up to 48 hours in raceways that approached 120% TDG levels without any ability to compensate at depth because those raceways are only 3 feet deep. It is important to note that when the fish at Dworshak Hatchery held in raceways similar to the Transport raceways experienced TDG levels of only 105% in March, 2017, the Dworshak Managers reported fish showing signs of gas bubble trauma. When these fish were examined under a microscope the fish had bubbles in the gills, lateral lines, and eyes. Furthermore, the fish even stopped eating. These are conditions that increase Latent Mortality in a hatchery environment. The Port of Lewiston believes that there is clearly a significant opportunity to even further improve survival of the transport population of juvenile salmon and steel head. And improve TIR under elevated TDG conditions if the conditions and infrastructure in the holding raceways and on the barges were improved with the same focus that BPA, USCOE, and LSRCP has given to the hatchery facilities.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
31766	35	portdave@portoflewiston.com	Port of Lewiston	Our concerns also include that the EIS Draft document has been developed using energy costs and GHG data that is now outdated as the result of rapidly lowering energy storage costs. These greatly reduced costs for commercial-scale energy storage solutions could further eliminate reliance on the natural gas peaker plants cited in the MO2 option. Energy storage solutions used in combination with the full suite of renewables available in the Columbia Basin (hydro, wind, and solar) could dramatically reduce reservoir drafting requirements and subsequent cultural concerns while even further reducing O&M costs on the grid. BPA has to look no further than to its colleagues at PG&E who are already underway with this approach on a very large scale to know that this is a feasible solution that would significantly reduce GHG levels beyond those stated in the Draft EIS.	The EIS evaluates two potential replacement portfolios for each MO to return the regional reliability (as measured by Loss of Load Probability [LOLP]) back to the No Action Alternative level. One is a conventional least cost portfolio that uses natural gas-fired resources and the other is a least cost carbon-free portfolio. See draft EIS, Section 3.7.3.5 at pages 3-904-910. For Multiple Objective (MO) Alternative 3, the carbon-free portfolio includes 1,275 MW of batteries in the draft EIS. In response to public comments, the final EIS uses a revised battery figure to account for what is needed to return MO3's LOLP to that of the No Action Alternative. The final EIS includes consideration of declining costs of storage and renewable resources. The EIS includes the de-escalating cost curves prepared by the National Renewable Energy Laboratory, which will likely be considered by the Northwest Power and Conservation Councils in their 8th Power Plan. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission at Section 2.2. The use of storage technologies was considered a long-term resource of the 7th Power Plan, but not a primary resource. It has become more commercially available since the release of the 7th Power Plan and was examined in the EIS. Storage will likely be considered a primary resource in the Councils 8th Power Plan. Contrary to the statement in the comment, the EIS finds that MO2 would not require replacement resources to maintain the same level of power system reliability as the No Action Alternative and does not require gas peakers as the comment suggests (see Section 3.7.3.4, Impacts to Power Reliability in the draft EIS). New renewable resources like wind and solar require dispatchable generation like hydropower to increase and decrease generation to balance the variability of wind and solar. This may exacerbate the concern raised in the comment. See draft EIS, Section 3.7.3.2, Potential Replacement Resources and Associated Costs at page 3-849.
31766	36	portdave@portoflewiston.com	Port of Lewiston	The Port is strongly in favor of expanding the juvenile fish transport season - particularly in the face of a changing climate, and believes the Columbia Snake System could benefit from starting and stopping on a fish trigger count, as suggested as a management tool approach in MOI Expanding the juvenile fish transport season with fish count triggers would create the opportunity to increase the number of transport trips performed by barge instead of by truck. The barge trips are more efficient with lower GHG emissions per smolt delivered below Bonneville while providing the opportunity to circulate imprinting water within the fish holds along the route. Barge transport may also improve SAR's over trucking as a result.	The juvenile salmon transportation program is managed by expected fish benefits as well as cost efficiency. SAR estimate for each week of the outmigrations, combined with other environmental and biological data, drive the decisions. Prior to these data being available, transportation began at the beginning of April; however, we learned that fish transported in early April performed very poorly. Transporting too early is not effective and does not justify the expense. Similarly, transport by truck beginning when the collection is small enough that they can be transported safely in a truck can be done at a much lower cost. A minitanker in a pickup is used when collections are very small.
31766	37	portdave@portoflewiston.com	Port of Lewiston	It is recommended that BPA explore opportunities to electrify the towboat fleet - similar to the electrification conversion efforts recently approved for the Washington State Ferry System in the Puget Sound. This would even further reduce GHG emissions from the transport effort.	Electrifying the towboat fleet is outside the scope of this EIS, which focuses on the operations, maintenance and configuration of the Columbia River System dam and reservoir projects.
31766	38	portdave@portoflewiston.com	Port of Lewiston	Install degassing equipment to remove excess TDG levels from the water entering the fish collection systems and fish holding raceways below the Lower Snake Dams. These systems must be able to remove excess TDG from levels as high as 120% to levels at-orbelow 102% TDG, as is targeted for hatchery degassing system designs for fish-rearing raceway systems which are very similar to those used in the fish collection & holding systems. This is imperative because fish collected in these systems are held for up to 48 hours in very shallow hatchery-style raceways, during this time they are exposed to unnecessarily high TDG levels. We believe that exposure to even 110% TDG for up to 2 full days in these shallow holding raceways would increase Latent Mortality in the Transport fish population. The USCOE could incorporate much of their existing degassing designs from the recent degassing projects at Dworshak Hatchery with a similar degree of success. Install adequate degassing systems on the 2000, 4000, and 8000 series transport barges. These systems must be able to remove TDG from levels as high as 120% to levels at-orbelow 102% TDG under ALL conditions. This should reduce Latent Mortality of Transport fish during any future high TDG/high Spill events. Install constant-monitoring TDG meters in the fish holding raceways below the Lower Snake River Dams. Install constant-monitoring TDG meters in the sea chest and in all fish holding chambers on all of the transport barges. This is necessary to provide both pre-and-post degassing data so that degassing efficiencies and system limits can be determined. Following the installation and successful testing of adequate transport fish system degassing and monitoring equipment, BPA should perform a comparative Latent Mortality study between In-River fish and Transport fish with real-time data that includes In-River and Transport TDG exposure levels (Transport data must include TDG levels in both the collection holding raceways and within the barge fish holds). Including this data, in combination with ensuring that transport fish are not exposed to harmful/lethal TDG levels when being held up to 48 hours in shallow raceways before Transport, would significantly improve the ability of the CSS to more accurately predict the effect of increased Spill/TDG on SAR's.	In response to discovering elevated TDG levels at the Little Goose raceways, currently direct loading onto the fish transport barges is being maximized rather than holding fish in the raceway. Nevertheless, degassing alternatives are being developed. As Gas Bubble Trauma (GBT) is a combination of exposure level and duration during both the current condition as well as past exposure. Severity is also a function of overall health as well as availability of depth compensation. In general, for fish without the ability for depth compensation, TDG levels greater than 110% can lead to higher mortality and shorter response time at higher TDG levels. However, a fish at 1 meter depth would be affected the same as though there were 100% TDG, saturation. Hatchery exposures can be over many months, while fish are held in the raceways for a maximum of 48 hours. The analysis of on barge TDG monitoring recommended has been ongoing over the past two years. The Corps has examined TDG exposure levels in the fish transport barge holds and collection raceways. Findings indicated transport barge aeration systems were successful at reducing TDG levels The 8000 series, with its packed columns, has reduced TDG levels to less than 102%, and the 2000 series, with its spray bars, has reduced TDG levels to less than 105% TDG when the intake river water was 120% TDG. Regarding the recommendation to conduct a latent mortality study, latent mortality cannot be directly measured due to a number of confounding variables. However, the Seasonal Effects study comparing SARs of in-river, bypassed, and transported fish, as well as the CSS study, will continue.
31766	39	portdave@portoflewiston.com	Port of Lewiston	Perform a high-level analysis of BPA's Direct and Indirect Funded Hatchery programs and infrastructure. It is typically not BPA's position to opine on Direct or Indirect Funded hatcheries, but to instead leave those decisions to the State, Federal, and Tribal Sponsors, their A/E teams and contracted	Thank you for your in depth suggestions. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. Analysis under NEPA for each individual hatchery and of how well hatcheries are run and any maintenance/operational issues is accomplished in other documents and beyond the scope of this EIS. This EIS compares the effects of the range of alternatives for operation, maintenance, and configuration of the CRS projects to one another and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				support teams to determine "how to build and operate it" (hatcheries). As a result, there is much room for improving the performance of these facilities while reducing O&M and GHG's through standardization and modernization efforts based on adopting the highest performing designs and methods across the larger program. This will also free up monies in existing budgets to help fund improvement projects to implement newer technologies. To accomplish this, analysis should focus on: o Identify the highest performing hatchery programs and infrastructure from the perspective of SAR's and implement those successes at lower-performing hatchery facilities where practical to improve SAR's across the Columbia Basin o Identifying rearing infrastructure and size at release goals that minimize travel time of released smolts. o Implementing methods and policies that minimize unnecessary Capital and O&M costs. o Reducing Overhead costs between Funding Agencies and Sponsor Programs. o Minimizing the amount of energy used per adult salmon returned. o Minimizing the number of broodstock necessary to meet release and return goals at each hatchery. o Identifying and developing methods to reduce the Carbon Footprint of the Hatchery Programs (any hatchery facility that can reduce its biomass and/or its energy consumption and achieve a similar or higher SAR, is operating at a higher Carbon Footprint than necessary). o Implementing monthly reporting for energy consumption and fuel use from all hatchery facilities. o Standardizing the annual hatchery budget request forms and processes for all Direct and Indirect Hatcheries, so that improved opportunities for programmatic efficiencies can be identified. o Perform an analysis of basin-wide hatchery release size goals. The size of the smolts released was increased to compensate for the effects of the dams 25-30 years ago. This was done prior to the improvements made to turbines, barging, and fish bypass systems. Getting past dams gotten easier for smolts, but the size-at-release goals were never revisited for the more efficient system. There is thus significant potential to return hatchery fish released at closer to wild fish sizes, a concept that is receiving growing support for increasing fish survival. o Where hatchery programs can successfully reduce size at release goals without the need to increase hatchery production numbers, the overall reduction in hatchery biomass at those facilities will improve hatchery/wild density dependence interactions. And additionally reduce hatchery O&M, reduce the Carbon Footprint and GHG's of those facilities, and in some instances, may improve SAR's as supported by studies performed by Don Larson and Brian Beckman of NOAA and others. o SAR's for both the Steelhead and Spring Chinook programs at Dworshak and Clearwater Hatcheries are very similar. According to IDF&G, there is an opportunity to increase production numbers of these programs at the Clearwater Hatchery by as much as 33% without any additional infrastructure. This can be achieved with minimal additional O&M simply by reducing the size at release goals of the Clearwater Hatchery programs to match the smaller-sized goals of the Dworshak Hatchery program. o It has already been successfully proven that there is tremendous opportunity for additional flexibility and capacity between the two Hatchery programs. Following the catastrophic failure of the Dworshak Dam main pipeline that delivers water to the Clearwater Hatchery in 2012, most of the entire Clearwater Hatchery Spring Chinook program was moved into available rearing space and successfully raised at the Dworshak Hatchery (while all Dworshak programs were still on site). The Clearwater Hatchery Spring Chinook program successfully reached their size and release goals, and the Dworshak Hatchery was awarded the LSRCP Hatchery of the Year award for those efforts. This forced a closer look at what could really be achieved from a production perspective if both hatcheries would be willing to adopt similar management metrics to reach similar SAR's. o If the most efficient and effective hatchery rearing metrics were adopted between Dworshak and Clearwater Hatcheries, they could produce almost 500,000 additional Steelhead smolt collectively without any additional infrastructure modifications or any additional water to either hatchery (see table at end of comments). This literally represents the capacity of an entire new hatchery facility without any additional costs to electrical rate payers. o Finally, it is recommended that BPA revisit the EIS analysis to upgrade the energy storage costs to expand opportunities to further reduce GHG's by reducing dependency on natural gas peaker plants beyond the initial scope of MO2 through hydro, wind, and solar renewable sources while reducing reservoir drafting and cultural concerns.	to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed.
31768	1	humairaf@pacificpud.org	Pacific County Public Utility District No. 2	The Co-lead Agencies should be wary of any national interest group advancing specific outcomes that are single issue focused. MO3 and MO4 alternativesbreaching of the four Lower Snake River Dams (LSRD) or sustained high spill levels would hit our struggling communities the hardest. BPAs power costs rates would increase by 50% . The District purchases nearly 96% of wholesale power supply from Bonneville Power Administration (BPA). Anytime BPA increases its rates, we pass those costs onto our ratepayers. Wholesale power supply costs represent roughly half of total retail bills, that would equate to a 25% increase in monthly electric bills for our residential and business customers.	The statement in the comment regarding potential wholesale rate increases is consistent with the findings of the EIS. See EIS, Section 3.7.3.5, at 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. The EIS also discusses that Bonneville customers, such as the utility district mentioned in the comment, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. Section 3.7.3.5, Residential Effects, at 3-929 in the Draft EIS, and Chapter 5 of Appendix H, Power and Transmission in the Draft EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-juvenile and adult anadromous salmonids (two of the objectives) as well as the other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The co-lead agencies did not identify Multiple Objective alternative 3 or Multiple Objective alternative 4 as the Preferred Alternative because of the adverse effects to affected resources, including the effects mentioned by the commenter.
31768	2	humairaf@pacificpud.org	Pacific County Public Utility District No. 2	Blackouts are an existential threat: Northwest Power Pool and Northwest Power and Conservation Council have sounded the alarm that the region does not have enough resource adequacy by 2021 due to a number of coal plants retiring. The Loss of Load Probability (LOLP) for 2021 is 7.5% but by 2024 the LOLP increases to 12.8%, by 2026 the LOLP increases to 26% . The potential shortfall events are likely to occur in winter and are expected to last longer. Most importantly, these scenarios include the presence of LSRD as part of the regions resource mix. The LSRD provide more than 2,000 MW of sustained peaking capabilities in the winter and 25% of the federal power systems current reserves holding capability. LSRD play a significant role in maintaining grid reliability, and their flexibility and dispatchability are valuable to the operation of the Columbia River System. MO3 would more than double the regions risk of power shortages . To contemplate removing LSRD would be reckless and irresponsible. The Covid-19 pandemic demonstrates the importance of our reliance on electricity. It is a matter of national health and security to keep the lights on 24/7.	The statement that without resource replacement, regional power reliability would decline under MO3 is consistent with the findings of the EIS. In the Draft EIS, please see Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; see also Appendix H, Table 2-1. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability at the No Action Alternative level. Please see in the Draft EIS, Section 3.7.3.5, at pages 3-904-910. Under these replacement portfolios, regional power rate pressure increases. See in the Draft EIS, Section 3.7.3.5, Table 3-166. The statement about the peaking capability of the four lower Snake River dams is also consistent with the findings of the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS. While the EIS did not analyze the specific years and loss of load probability (LOLP) cited by the comment, the EIS also finds that increasing retirement of coal power plants would adversely affect regional power reliability. See Section 2.3 of Appendix H, Sensitivity of LOLP to Assumptions about Coal Capacity in the Draft EIS. The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative (PA) on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative.
31768	3	humairaf@pacificpud.org	Pacific County Public Utility District No. 2	Furthermore, the DEIS quantified the cost of replacing LSRD with carbon free resources. The analysis found that the closest replacement portfolio for the energy, sustained ramping, and balancing capability of the projects would be 3,306 MW of solar, 1,144 MW of wind, and 2,515 MW of battery storage. The annual cost of this portfolio to replace the full output of the LSRD with carbon free resources is nearly $1 billion a year.	The renewable resource capacities and costs cited by the comment are consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at 3-904-909; see also Table 3-162.
31768	4	humairaf@pacificpud.org	Pacific County Public Utility District No. 2	Extinction is not an option: Improving juvenile and adult salmon migration and survival rates is a key objective of the DEIS and it is also an important objective to the District. For purposes of context only, Pacific County is home to over four fish hatcheries including one that is the oldest in Washington StateSea Resources established in 1893. Columbia Land Trust owns over 1,165 acres of pristine habitat in Pacific County. Willapa Bay is the second largest estuary on the Pacific coast where five salmon species pass through the bay en route to natal rivers on the east side of the bay. Our local communities are stewards of the environment. Our commitment to the environment is evident in the fact that our rate payers are directly responsible for funding BPAs Fish and Wildlife programs. This includes: 1) funding fish and wildlife projects in the Columbia Basin, including habitat restoration, hatcheries, land acquisitions, predator control and research and evaluation; 2) funding Corps and Reclamation for the portion of the costs to operate and maintain the fish passage improvements at the dams and for O&M costs for certain hatcheries operated by the Corps, Reclamation and the U.S. Fish and Wildlife Service; 3) paying for fixed capital expenses related to fish and wildlife costs at federally owned hatcheries and fish passage improvements at the dams; 4) paying for power purchases associated with fish operations such as spill; and finally 5) forgoing revenues due to operations. Nearly 25% of our power rates help fund these efforts. We are committed to mitigations efforts for the impacts of the FCRPS. Concurrently, any mitigation must be science based and cost-effective. Should the preferred alternative result in additional cost to BPAs rate payers, the economic burden should be equitably shared with the public at large.	Based on the EIS analysis, the Preferred Alternative would make a substantial contribution to improving Snake River anadromous fish runs. Broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it would provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. The statement that roughly a quarter of costs from Bonneville's power rates are due to fish and wildlife spending is consistent with information provided in the EIS. The EIS recognizes the concern voiced in the comment regarding increasing power rates. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1 at page 3-187. As described in Section 3.19 and Appendix Q of the EIS, funding to operate the system comes through multiple mechanisms, including federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the Federal Columbia River Power System and the long-standing accounting procedures used to implement them. As described in Chapter 7 of the EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made as part of the CRSO EIS process. Future budget adjustments would be made in coordination with the regional entities that help Bonneville implement its Fish and Wildlife Program.
31768	5	humairaf@pacificpud.org	Pacific County Public Utility District No. 2	We are committed to science-based solutions that help hydropower and salmon coexist and thrive. CRS is clean power: The Columbia River System (CRS) is the source of economical, reliable, and clean power generation. It provides the region with some of the least greenhouse gas (GHG) intensive electricity in the United States. On average, the CRS produces 8,500 average megawatts of carbon-free power reducing the need to use other carbon-emitting resources, like gas and coal plants. The flexibility of the CRS also helps integrate variable renewable resources like wind and solar by stabilizing the system when these resources are unavailable. Hydropower is the most unique among generating fleets. It can provide nearly all the attributes necessary for a reliable and resilient electric grid from dependable capacity to black start capability and is GHG-free. As the grid integrates more variable energy resources such as wind and solar, hydropowers ability to provide firm capacity, frequency response, voltage support, load following, and long-term storage become increasingly critical.	The various characteristics of hydropower described in the comment are consistent with the findings and discussions in the EIS. The amount of carbon-free hydropower generation from the Columbia River System projects is also consistent with information presented in the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 in the draft EIS.
31769	1	Aaron Lieberman	Idaho Outfitters & Guides Association	THE DEIS DISREGARDS THE ECONOMIC CONTRIBUTIONS AND IMPACT OF SALMON AND STEELHEAD FISHING, AND GUIDING, IN IDAHO AND THE NORTHWEST. 1 9450 W FAIRVIEW AVE., STE. 110 | BOISE, ID 83704 | 208.342.1438 | OFFICE@IOGA.ORG CONTACT Our goal has been to develop an approach to river management that balances these multiple perspectives and can serve as a springboard to continued progress in the region on recovery and mitigation for fish and wildlife, reliable and affordable clean electricity, and economic vitality for the many communities that depend on	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the CRS for their livelihoods.2 Whereas the CRSO DEIS process acknowledges The Opinion and Order from US District Court for the District of Oregon, which states the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species, the CRSO process, within the framework of the National Environmental Policy Act, also ostensibly identifies broad-based environmental and socio-economic impacts associated with the proposed alternatives. However, in its analysis of the [socio]economic impacts of the respective Multiple Objective Alternatives, the CRSO DEIS fails entirely to consider the Sportfishing economyits contributions and the anticipated impacts of the respective alternatives to it. Despite the dEISs utter and complete ommitance, the importance of these fish and the outfitting & guiding industry to these rural Idaho communities cannot be overstated. Ours is an industry that has long been negatively impacted by the decline in sportfishing opportunities for salmon and steelhead, in our businesses as well as their respective communities economically, culturally and socially. According to the Idaho Outfitters and Guides Licensing Board (IOGLB), there are currently between 1500 and 2000 guides in Idaho Licensed for, and reliant on, Salmon and Steelhead fishing. Approximately 80% of these resident Idaho Outfitters live in and contribute to the economies of communities with an average population of ~500. Idaho riverside towns, where these Salmon and Steelhead outfitters and guides reside and operate, are overwhelmingly rural and heavily dependent on natural resource and recreational based economies. According to the Idaho Department of Labor, the annual average earnings of steelhead guides is ~$23,000. Using the Income Multiplier generated for our industry by the Idaho Department of Labor, that represents and economic contribution of between $58,650,000 and $78,200,000 associated with Salmon and Steelhead guides alone. This figure, staggering in and of itself, does not include the broader impact and generated spending of the outfitters3 that employ those guides, not least the induced spending of those businesses and professionals nor that of their clients in their respective communities and Idaho as a whole. 4 The importance of salmon and steelhead fishing in rural Idaho communities and their economies is thrown into still sharper relief when framed in terms of the States Sportfishing economy on the whole (beyond outfitting and guiding specifically). On the whole, the sportfishing economy contributes an estimated $757 million dollars per year in Idaho alone.5 Based on estimates from the Idaho Department of Fish and Game regarding the proportionate angling effort for Salmon and Steelhead, that would extrapolate to a base contribution of between $151-189 million/year to the State for Salmon and Steelhead fishing. Table 1: Summary of Regional and Other Social Effects. [Text contains table that does not transfer to database.] The agencies analysis of regional and other social effects is shown in Table 1 above. Whereas the Action Agencies plan details the impacts on other industries/sectors, including agriculture, subsidized barging, and power generation, the dEIS relies solely on qualitative, rather than quantitative analyses to evaluate impacts of/on sportfishing (not to mention Idahos outfitters, guides, and rural fishing communities)despite the existence of several current studies on the economic contributions of outdoor recreation and sportfishing in states with anadromous fish runs. This contrasts with the analysis of water supply, irrigation, navigation, and hydropower generation, all of which were evaluated quantitatively. For all management alternatives and their Preferred Alternative, the economies of recreation and fishing (from guiding, outfitting, hotels, restaurants, gas stations, boat shops, license fees, etc.) were not even accounted for despite existing, publicly available data. At the March 5, 2020, Idaho Governors Salmon Recovery Workgroup meeting, an Army Corps of Engineers economist stated economic impacts of sportfishing were outside the scope of the EIS, despite all other resources evaluated in the analysis included quantified effects. In 2001, during the height of our modern day anadromous fish returns to Idaho, anglers fished 475,000 days for steelhead and 448,000 for salmon.6 The 2-4-month salmon seasons generated $46 million to 15 river communities and $43 million to the rest of the state.7 That year, the spring Chinook season brought $10 million to Riggins alone (estimated population 417), where the total spending that year was $44 million. That same year Lewiston saw $8.8 million and Orofino $8 million from the same salmon season. In 2003, the Idaho Department of Fish and Game calculated that sportfishing generated $438 million in direct spending, including $32 million on outfitters and guides. (Adjusted for inflation, that would amount to $598,197,213 statewide and $51,898,388 on outfitters and guides, again, without factoring in additional, standard multipliers.)8 Just as robust salmon and steelhead returns can provide an economic boom to these riverside towns, feeble returns can devastate them. During the four-month steelhead fishing closure on the Clearwater River in 2019, the Clearwater Region missed out on $8.6 million a month ($34.4 million total), with the majority of the loss in Clearwater County.9 The Idaho Fish and Game Commission then re-opened the fishing season in 2020 for only catch and release opportunity for hatcheryorigin steelhead. These losses can and will be felt for years following the 2019 steelhead fishing season closure for businesses directly and indirectly tied to steelhead fishing. A survey in 2001 concluded that if salmon fishing were not available in Idaho that 73% of Idaho salmon fishermen would go elsewhere.10 Fishing outfitters, guides, and their rural communities continue to helplessly watch the downward arc of Idahos anadromous fish. Their hardship is not hypothetical; it is real and immediate and longendured. That the dEIS neither quantified the economic potential of abundant fish returns nor the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and throughout the Pacific Northwest is unacceptable. The economic and cultural impacts of salmon and steelhead in Idaho must be given full consideration by the federal agencies that control this system. Previous EISs included such information, but this newest iteration does not.	middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam break under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
31769	2	Aaron Lieberman	Idaho Outfitters & Guides Association	THE DEIS IS INADEQUATE TO RESTORE SALMON & STEELHEAD The dEIS Executive Summary acknowledges its impetus as being in response to the need to review and update management of the CRS, including evaluating impacts to resources in the context of new information and changed conditions in the Columbia River basin, and further, that the operation and maintenance of the Columbia River System affects threatened and endangered fish populations within the region, and the co-lead agencies are committed to mitigating these effects. Despite the Congressionally authorized and mandated objectives of the Columbia River Systems Operations, not least the calls from stakeholders across the region for actions that will lead to recovery of listed and endangered Snake River stocks of Salmon and Steelhead, the Preferred Alternative identified in this dEIS fails to put forward operational and structural measures/changes to improve smolt to adult rates (SARs) to levels identified and accepted by scientists as necessary for harvest or recovery. This failure has largely to do with the fact that the dEIS uses the legally discounted No Action Alternative (NAA) as its baseline for relative improvements vis-a-vis Smolt-to-Adult Return (SAR) metrics. To put it very simply, the approach is not dissimilar from a student receiving a failing grade of 50% on a test, then claiming to have rectified the shortfall by an improvement to 55% the next time around. Rather, the dEIS selects strategies already in use and makes small tweaks to reservoir releases in the higher tributaries. Both central approaches in the PA are already in use, and while each has utility in particular cases and in degrees, neither have yielded results approximating Federal obligations to conserve endangered fish populationeven just above extinction-trend levels. The Northwest Power and Conservation Council (NPCC) has identified SAR ranges from 2-6% as necessary for true recovery for anadromous stocks (this range provides a gauge of whether life cycle survival rates can both avoid extinction and make progress toward broad-scale salmon restoration). The NPCC 2%6% SAR objectives are consistent with analyses conducted by PATH, in support of the 2000 Biological Opinion of the Federal Columbia River Power System (FCRPS) found that median SARs of 4% were necessary to meet the National Marine Fisheries Service (NMFS) interim 48-year recovery standard for Snake River spring/summer Chinook; meeting the interim 100-year survival standard required a median SAR of at least 2%. Current SARs for Snake River sp/su chinook sit just under 1%, which is less than half of the minimum SAR range the Northwest Power and Conservation Council has affirmed for multiple years as necessary for maintenance of existing populations. The Comparative Survival Study (CSS) also notes in its 2017 annual report that 1% SAR is associated with population decline. This is a far reach from the mid-to-upper goals of 4-6% SAR identified as population abundance and recovery. 11 It is important to consider survival in all life stages and in certain areas of the Columbia River system when assessing SARs. Snake River sp/su chinook and steelhead consistently display some of the lowest SARs in the Columbia River Basin, despite enduring the same pinniped predation, ocean conditions, and downstream fishing pressure. Studies have displayed that survival rates of sp/su chinook is lower than similar downriver populations that experience fewer dams.12 Despite the dEIS claiming that juvenile survival is high through the lower Snake River, the 2019 CSS report estimates 48% juvenile survival from Lower Granite dam to Bonneville Dam for Snake River steelhead from 1994-2019. Snake River chinook survival is estimated only slightly better at 54% on average. The CSS Report noted that the risk of mortality increase by about 12% of each powerhouse encounter a juvenile salmon experiences.13 This CSS report does not even account for mortality in reservoirs. Additionally, there is evidence that Snake River chinook suffer substantial delayed mortality as a result of their outmigration experience in the smolt stage.14 Management actions taken in the Preferred Alternative estimate high-end SARs for Snake River sp/ su chinook to reach 2.7%. The anticipated SAR for Snake River Steelhead under the Preferred Alternative is worse still at 2.4%. The Life Cycle Model predicts a potential extinction trajectory under the PA with a SAR below 1%, with Snake River sp/su chinook SARs predicted at a troubling 0.81%. Beginning in 2013 the Comparative Survival Study (CSS) workgroup began developing life cycle models for the purpose of examining survival at specific life stages, which is a critical component of NOAAs Biological Opinion on the operation of the Federal Columbia River Hydrosystem. This modeling provides integrated assessments of tributary smolt production, main-stem passage survival, ocean survival, and smolt to adult return rates. At the request of the Federal Action Agencies, the CSS used the Grande Ronde Life Cycle Model and the cohort-specific model to analyze six federal operational alternatives for the Columbia River Systems Operations (CRSO) Environmental Impact Statement (EIS), using the 80-year water record. The Fish Passage Center conducted the analyses of the alternatives in this dEIS through the Comparative Survival Study (CSS). The analyses concluded that the Preferred Alternative results	It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				in a SAR that is less than one percent 36-39% of the time for yearling chinook and steelhead, while MO3 results in a SAR less than one percent only 12-19% of the time. The MO3 yields SARs greater than two percent up to 68% of the time compared to the PA of 37% of the time. CONCLUSION This dEIS demonstrates an immensely expensive exercise in marginal revisionism. It follows in the wake of five previous plans, all of which were invalidated by courts as inadequate for meeting fish & wildlife conservation objectives and hence illegal. in the most recent 2016 ruling, US District Judge Michael Simons writes Despite billions of dollars spent on these efforts, the listed species continue to be in a perilous state... The [Federal Columbia River Power System] remains a system that cries out for a new approach. Similarly, The Northwest Power and Conservation Council states that despite $16.3 billion spent on fish and wildlife restoration, all Snake River anadromous fish remain at high risk of extinction.15 Nevertheless, the dEIS stops short of making anything more than marginal changes to existent practices/operations/structures in its Preferred Alternative, in so doing ensuring at best marginal improvements, which will once again fall short of mandated obligations and the will of the people, not least Idahos Outfitters and Guides.	
31771	1	wwpinneys@gmail.com	N/A	The first 2 LSRds need immediate breaching this winter under Emergency policies of the Corps et al, whereas the supplemental EIS to 2002 FR/FEIS for the Snake River can be concurrently drafting for the supplementation, as policy allows under Emergencies. Then the Draft E CRSO can be much readily modified for the more significantly effective Columbia River dam salmon lifestage passage survivals over the pathetic COMPASS and CRS estimates in the 4- Tables of Appendix E, and most of past years' NOAA NWFSC PIT-tag detection modeling reach survival estimation.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
31771	2	wwpinneys@gmail.com	N/A	Increasing spill is only increasing un-testable, hence un-document-able circulatory pollution of the salmon and steelhead lifestage proportions exposed, as well as eroding critical dam supporting infrastructure for which the Corps or BPA cannot and all-probable will not have capability to fund and repair in time to not substantially wipe out blocks of salmon runs.	There are potential issues related to water quality as a result of increasing spill, specifically the increase of total dissolved gas concentrations to 125% of saturation. The proposed operations and resulting TDG levels will be monitored, along with effects to juvenile and adult salmon. If unintended consequences occur, operations will be adaptively managed as proposed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. The co-lead agencies will also monitor dam structures for erosion, and make any necessary adjustments in operations and repairs as needed.
31771	3	wwpinneys@gmail.com	N/A	Additional discussion v2 for Fatal Flaws of the CRSO DEIS: NAA is 2016 configuration and operation condition of the Federal Columbia River Power system. NAA is Jeopardy to the listed salmon stocks. Previous hydro management has extirpated those other native stock populations that were not listable, principally because they were already extinct, then some were attempted to be replaced through ineffective hatchery mitigation. NAA is grossly negative modified baseline (changing baseline ploy) that was designed in 2008 through 2014 BiOps to relieve salmon and steelhead populations from Jeopardy status. Failure once again through litigation. So, 2018 BiOp, not required by the judgement is just another attempt in following BPA-NOAA strategy model to not have Jeopardy. It is not even NAA, but 2016 with higher spill, which is a negative of at least 10% upon salmon production from NAA. This basically became the Preferred Alternative with more hydropower flex and irrigation contract satisfaction (BoR), all to further detriment of the salmon and steelhead for which it is mandated to protect under ESA. Following BPA-NOAA breaking process model, they will now use the 2018 BiOp they previously devised to apply to satisfy the pre-selected Preferred Alternative, for which that BiOp was really originally devised for. NAA is not the true basecase for Biology/Ecology evaluation to satisfy ESA, only another incremental step that fails ESA. Wild fish are just a mere secondary consideration whereas wild fish are the only basis for ESA compliance. The Action Agencies (I see they no longer prefer this long-held title) need to use the previous court-accepted baseline for comparing the environmental evaluations leading to the Final Preferred and Environmental Alternative decision. Using the legal baseline or basecase Environmental condition, only MO3 with Breaching is acceptable. BPA (who really does own this EIS in their usual bullying, and this one is not really a monies throw-out case because BPA admitted they did not have the monies or the experienced people to throw at this, so they and the Corps and BoR threw those staff that needed something to do and needed funding to continue their working (or at least showing up)), Corps (directed out of Division), BoR (after more irrigation contracts they were not allowed to grant to date, but was in their hopper for decades), AND NOAA (funded under BPA open contracting with usual Univ of WA data-streamers) continue to place themselves and their agencies in quite a quandary because they keep their changing baseline phenom hoaxing so often in flux from not stating or acceptably using the true baseline/basecase and alternative that would get salmon and SRKW out of Jeopardy. Judge ruled that 2016/NAA was/is Jeopardy and BiOp remanded. So, even though 2016 can be the NAA for this CRSO EIS, it cannot be the baseline for comparison toward a Preferred Alternative decision. All those required RPA actions (Reasonable and Prudent Actions) in the previous 2008-2014 base BiOps HAVE NOT been implemented and evaluated, especially the 2010 and post caveat under adaptive management programming that clearly states that if all else added into that BiOp does not perform to increased salmon and steelhead production, escapement numbers, etc to ease out of Jeopardy, then breaching dams starting with LSRds (the final and over delayed experiment in the Adaptive (defined as Experimental to determine what actually works) Management Implementation Plan of 2010 litigation outcome). All EISs and BiOps say this based on the biological data and models. MO4 is increase in spill to 125% Total Dissolved Gas systemwide. It does not state the new Injunction negotiation for flex spill, which was morphed into the Preferred Alternative pre-selection (since the AAs now feel they have some buy-in from litigants, and states and tribes that remain greatly limited in voice by their Accords funding requirements). MO4, just like all MOS and NAA and true baseline, needs to be compared to each other as well as to the spurious NAA. On a side track, the public and the judge should also require an all-H BiOp from an independent NOAA (outside of Pacific Northwest hands) and ISAB expert collaboration since the significance of this issue has grown even so more intensely dramatic. Maybe even Congress and Governors should demand for a long-overdue all-H BiOp simultaneously with calling the LSR an Emergency handled by breaching the 4 LSRds.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The PA also meets the other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Under the PA, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region), increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the PA includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information. The Preferred Alternative will provide a substantial contribution to recovery targets. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams, including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
31771	4	wwpinneys@gmail.com	N/A	I would also like them to entertain the Max Fish with Breach alternative that I submitted to the CRSO teams, and for which the Policy Team (at that time, all members retired or reassigned soon after my submission) said to Fish Leads they were scared of it, so immediately waste basket filed without any presentation to the Cooperating Agencies. That alt also included non-native piscine predator control through long-proven and established drawdowns over spawning beds and temperature cooling/ habitat restoration drawdowns to spillway crest of John Day and McNary reservoirs, only seasonal during hot climatic periods and spawning timeframes. This has always been a negotiating point of despair in the region. Vast research and evaluation, even accomplished by BPA funded PNNL-Battelle Labs (Department of Energy) and USGS-Cook (a couple PhD dissertations) and Univ of WA open-contractors, all with my collaboration, has scientifically proven up the significant benefits to salmon production, especially that which would feed SRKW and more recently expressed NRKW away from imminent extinction.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The PA includes a measure that allows the Corps to manipulate the John Day reservoir elevation to decrease avian predation on ESA-listed juvenile salmon and steelhead in the lower Columbia River. Improving juvenile and adult anadromous salmonids were two of the eight objectives of the CRSO EIS. The co-lead agencies assume that the Max Fish with Breach Alternative you describe is a combination of measures in MO3 with measures in Multiple Objective alternative 4 (MO4). The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% Total Dissolved Gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, MO3 and MO4 individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in every seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. For perspective, 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023, per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built soon enough to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
31771	5	wwpinneys@gmail.com	N/A	NAA, MO1, MO2, MO4, and Preferred Alternative are all Jeopardy to SRKW. Only an adequate and true baseline using prior-capture conditions and productivity metrics for the LSR and Columbia River, and Salish Sea and Coastal chinook stocks would define the Jeopardy line/standard. ONLY MO3 would be substantially and significantly adequate enough to avoid Jeopardy. The need is management of wild or re-wild populations that produce 30, 40, 50, 60+ lb spawners up to their expanded carrying capacities due to vast miles of restored spawning and rearing habitats that result from Breaching dams and reservoirs. HAVE to get rid of those aging sewers we call reservoirs. Orca scientists/biologists have estimated/calculated how much chinook biomass is required for an individual orca per day, then calculated up to an existing population level and what a recovered population level should be. This metric is the chinook standard for all EISs and BiOps. This is based on the total footprint of chinook productive streams/rivers, including SR, CR, Salish Sea and coastal. Timeframes for overlapping encounter rates define the feeding regimes, as well. Considering all the biological and ecological facts this evaluation must be the baseline in which to compare Preferred alt selection capability for orca non-extinction (survival) and recovery, both required by the ESA. The Snake River chinook population productivity is clearly standing as the most probable and exacting boost to keep SRKW (and other orca populations) out of Jeopardy and significantly through reduced timeframes trending toward recovery. Even though the AAs contriving this CRSO EIS failed to address orca needs (somewhat based in their twisted justifications that the judge did not put his thumb done on their couple of paragraphs on SRKW, the region knows a significantly increased degree of orca data and population/individual starving and death spiraling since the last orca and salmon/steelhead BiOp (no AA EIS exists that addresses SRKW or any orca)). Mitigative (quite a loose term) and minimized hatcheries and their failures and studies cannot be scapegoated for a dreamed response. A full up-to-date truly scientific/biological, not technological, evaluation discussion has to be demanded for sufficient action toward rescue-ing SRKW demographics from extinction in the not-so-forseeable and near immediate future. Weitkamp LA. 2010. Marine Distributions of Chinook Salmon from the West Coast of North America Determined by Coded Wire Tag Recoveries. Transactions of	Regarding dam breach: the EIS analysis found only a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the SRKW depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the American Fisheries Society 139:147170. Weitkamp L and D Teel. 2015. Hatchery production and marking rates of juvenile salmon stocks along the West Coast of North America. Presentation at the Salmon Ocean Ecology Meeting, March 24-26, 2015, Victoria, British Columbia. Weitkamp LA, DJ Teel, M Liermann, SA Hinton, DM Van Doornik, and PJ Bentley. 2015. Stock Specific Size and Timing at Ocean Entry of Columbia River Juvenile Salmon and Steelhead: Implications for Early Ocean Growth. Marine and Coastal Fisheries 7:370392. The proposed preferred alternative, as weakly presented, does not even address benefits toward non-Jeopardy for SRKW. Just the usual pooh-pooh jargon of NOAAs now-getting-ridiculously-old and ineffective not enough by itself (which is not a requirement to satisfy ESA), not necessary at this time (although it actually was necessary and required 20+ years ago for both orca and chinook salmon), and/or inconsequential or marginal language spouting. Such a thorough and honest evaluation, as critically reviewed by independent scientists, is legally required in not only the Cumulative Effects section but also its own decision-influencing section/chapter. No more treatment as a second-thought only because people ask in an attempt to satisfy at some minimal level NEPA requirements, as well as continue pressure for us AAs to actually perform our job with truth and honesty. The intent to address and satisfy NEPA and ESA, CWA, MMA, MBA, et al requirements remains at issue here, not the AAs interpretation of being privy to allowance to weaken the required documentation of inconveniences to them. NAA (2016 plan) does not meet/exceed the SR chinook biomass standard/criteria for non-Jeopardy. MO4 fails as well due to the increased spill regimes additive negative effects on SR chinook productivity. MO1 fails, small tweaks to status quo is disgraceful. MO2 fails most as the greatest money-wasting and fish-wasting scam. MO3 is the only passing alternative for enough chinook biomass produced across the foraging spectrum/footprint principally due to the vast extension of required hydraulics and spawning (84 miles of the 140 miles) and rearing habitat (140 miles bankwidth of the 140 miles) that results in only 2-5 years with breaching the 4 LSRds. Breaching needs (necessity) to be NOW, IMMEDIATE, this winter. The Proposed Preferred Alternative is the same old sham and shame full arrogant spit-in-the-face-of-the-judge attempt that has been tried 5 times already. Although the PPA does not even evaluate its implementation effects on SRKW, or even for chinook salmon effects and trends, the PPA will fail the SR chinook biomass standard for orca re-designation toward non-Jeopardy. The PPA is actually a step backward, throwing the usual more study for NOAA staff pet-peeve suggestions they have whined about for years, but not accepted by AAs due to ineffectiveness and minor inconsequential benefits and unrealistic/highly uncertain means of such operation even having the hydraulics and salmon cues to have any benefit. Until now, grasping at short straws. Sound familiar. PPA actually modifies MO4 spill to 125% TDG to flex spill and includes it. This manipulation is actually a reduction in the former bandaid placed on the same festering cancer. The litigation outcome should not only breach LSRDs, but also require what was imposed on the tobacco industry to break their 1970s-1990 strategy model paying for education of the truth across vast mediums, including a blatant and discriminating advertisement program of TV ads and billboards et al where they apologize for their mafia-ism, tell the truth graphically, and put a very large Warning to Health statement on all remaining dams and other electric power generating infrastructure. Admit that hydro is truly not clean or renewable energy source, but destroys ecosystem health, species health and existence, and public health. 20 years ago as a Corps Walla Walla District senior fishery biologist and population lifecycle modeler I wrote the scientifically robust justification for the selection of Alt 4 Breaching Lower Snake River dams in 2002 Feasibility Study/EIS. The Draft FS/EIS and the Draft Biological Opinion from NMFS selected to start the breaching process ASAP since enough wild salmon and steelhead remained to give a hint of hope for recovery. The vast acreage of restored spawning and rearing habitat function, hydraulic function, and productivity released from under those long-past aged reservoirs would ensure the only sustainable boosting required for recovery. After a rather emotional strong-arming of NMFS agency heads to switch to kicking-the-can-down the dead-end road by Corps officers (and BPA even though BPA was actually only a Cooperating Agency, soon to morph beyond their marketing mandate into the other 'sister' agency's puppetmaster). Three more lawsuit loses later addressing the same laws, acts, and regulations only evolved into worthless and costly (to taxpayer and ratepayer) mitigation of increasing spill bandages, structural passage bandages needing expensive repairs routinely, and the sneaking in of factory hatchery as 'naturals' to supplant wild production which serves as illegal practices to satisfy ESA; all leading to salmon and steelhead escapement (of which wild spawning component is near non-existent following this 20+ years of non-leadership for actually caring for both the salmon and fisher groups and the Federal and State environmental laws and acts for which NEPA requires. The CRSO EIS brings more of the same, but an even weaker and saddening farce. Breaching alt4 was moved to a weakened MO3 where lower Columbia River actions to benefit to salmon have been eliminated or reduced in their hopes of Poison Pilling the significant long-term recovery potential for salmon and steelhead for which the judge just simply "required" in the BPA and Corps interpretation. These agencies no longer fear the press and egging-of-their-red-faces from litigation for doing the wrong strategy because after nearly 6 marginalizations attempted at not losing in court they know they will just have to 'do it over again' with additional funding and years of time until they get their extinct salmon and steelhead for which they planned for. FIX MO3 NOW, implement MO3 this fall. Legally analyze >2 paragraphs for SRKW.	
31771	8	wwpinneys@gmail.com	N/A	Also, include statements that this cold snap peaking farce operations of breaking their own regulations for rapid peaking cannot physically be done for hot day periods in summer irregardless of fish passage requirements and the same low flows that limit such peaking (or any higher power gen) during the cold snap. In late summer, Reservoir Control negotiates emergency cut-offs for spill when inflows [greater than or] approaching 11 kcfs and need to go to station power single turbine. At/near this point the water is too hot (over 68 deg F and up to/exceeding 80 degrees F recorded recently) and water velocity too slow in forebays and reservoirs (instead of the ~1 fps in higher average flows, velocities can be only to of 1 fps = stagnant except in that single operating turbine of maybe 1-2 fps at most) for any fish exposure times leading to lethargy and mortality.	The co-lead agencies will only interrupt fish protection measures to avoid a power system emergency based on established protocols that have been developed and coordinated with regional fish experts through the Technical Management Team (TMT). Any additional available flexibility within fish protection measures is available for use as needed, but must often be coordinated through the TMT unless expressly provided for the annual Fish Passage Plan (FPP), including the annual Fish Operations Plan (FOP). Prior to any interruption of fish protection measures Bonneville will have taken all available options (see TMT Emergency Protocols, Appendix 1 of the annual Water Management Plan). Even with these restrictions in place, the CRS, including the lower Snake River projects, is generally available to respond in the event of a power system reliability event. Cold snap operations are typically outside of the fish passage season where sufficient flexibility exists to meet the power system needs and avoid interruption of fish protection measures. The co-lead agencies do not agree with the characterization that Reservoir Control negotiates emergency cut-offs for spill. The Corps follows the guidelines in the FOP and FPP for low flow operations. It should also be noted that water temperature below Lower Granite Dam did not exceed 72 degrees F in 2015, which was the lowest flow and highest water temperature year in recent years. Even with low flow and increased water temperatures that can occur in late summer, the reservoirs support sub-yearling fall Chinook that reside in the reservoirs in the summer and resume migration in the spring as yearlings.
31771	9	wwpinneys@gmail.com	N/A	In support of Fish Passage Centers write-up on the new turbine design at Ice harbor unit 2 only being worst not better than the original (and existing other 5 turbine units)Wrong and unscientific when survival testing is based on 1) sensor fish of PNNL-Battelle (Daniel Deng lab) due to known/proven/well established to have problems once they are in a turbulent environments, especially where there is drop and following the first hit/strike of hardness, resulting in self-induced tumbling, spinning, end-over-end flipping, etc giving spurious garbage data (proven in the raised spillbay weir tests and actually suspended after fight for throwing that data out of the first attempted test (maybe tags only good for pressure changes); 2) ERDC physical turbine models based on released beads strike numbers/proportions and where along blades and gaps that the beads strike; 3) balloon tag tests (and extrapolations from other tests of traditional designs, etc) for which these tags only give trauma and physical damage (ripped operculum, etc, broken spines, etc) as recollected immediately at turbine exit opening4) differential in pressure (atm) spiking distribution, magnitude, etc between old 5 blade and new 6 blade turbine; and 5) or which no one ever addresses except Martin Amman and me, is that each sample must enter and pass through the same wicket gate adjustments and draft tubes whether its a new or old turbine design. This concentrated and highly turbulent unstable velocity forced-circling determines location and speed each fish intersects the blades and hub and has been found to be likely the most influential parameter for fish conditioning. FPC is correct that even the Corps best guess on survival due new bladed unit would not be any better and highly probable worst than old units, and the next move would be pulling diversion screens so the high proportion of fish would remain through the turbine instead of the bypass, and multiplying higher proportion against a same or lesser survival term would equal less survival. AND this is why Division and BPA strongly fought against District doing a direct fish survival study Drawdown Comparative Analysis: 1) At MOP there is 52 feet of water vertically to the spillway crest elevation of 681 ft. 1992 DD Test lowest fsml was 697 ft, about 16 feet of water above the spillway crest ogee resulting in free-flow through the bays. This would actually not be that bad for smolt passage, free-flow nap and immediate tailwater was pretty laminar green water, not air filled white water (LGR was constructed with flip-lips). Your Scenario (Sc) 1 is only 3 feet above spillway crest ogee and Sc2 after 5 days of peaking operation the forebay elev is 10 ft above spillway crest ogee elev (msl). Conclusion: peaking operation is even quite a bit more dramatic than the 1992 DD Test operation and peaking would be yo-yo-ing daily to a eroding degree where 1992 DD was held for about a week then refilled, resulting in a one-time excursion. Damage due to evacuating groundwater to roads, turbidity, etc is greater during a yo-yo-ing operation, thus requiring more expensive and beefier repairs/avoidance means. This is precisely one of the engineering reasons why the Corps design team always moved toward permanent breaching to natural river channel and ecological/hydraulic function. You may want/need to adjust for Full Pool operating point of reference, as in your modeling?	Sensor fish successfully identified and played a significant role in solving spillway passage injuries at both The Dalles and Ice Harbor dams. Although certainly not a perfect analogue for a fish, their motions are controlled by the hydraulics of the water and structure impact and therefore do provide a measure of the physical environment fish are passing through. Less violent sheer and turbulence is obviously a benefit for fish. Balloon tags best represent the potential for trauma to passing fish and not total mortality. Certainly, fewer traumatic injuries would lead to a lower mortality rate. The commenter incorrectly states the wicket gate assembly and draft tubes are the same as the old turbines. The stay vanes have been modified to decrease the probability of fish strike and for fish to pass through the gap between the stay vanes and wicket gates. The draft tube was modified to decrease turbulence, and eliminate recirculation within the draft tube that could bring fish back to the turbine blades after passing most of the turbine. Again, these modifications will be positive for passing fish. The magnitude of the survival rate increase for naturally passing fish is unknown. Relying on the best available science, the co-lead agencies assumed mortality would be halved. The opinion that mortality would be increased relies on an assumption that more fish would pass the turbine because of the increased hydraulic capacity. It should be noted that only the turbines planned for McNary dam have increased hydraulic capacity. In any event, the amount of water passing through the powerhouse is actually controlled by operation decisions on spill levels, and is not solely dependent on the hydraulic capacity of the turbines. Turbine intake screens would not be removed unless a telemetry based survival study demonstrates survival would not be decreased.
31771	10	wwpinneys@gmail.com	N/A	The CRSO EIS Draft Proposed Alternative is proposing some winter spill in lost ability hopes for overshooting adult pre-spawning steelhead and fall chinook that need winter return vector back to their downriver natal tributaries, all the way to John Day. 3) If Corps operated at drawing down with spilling at near spillway crest, it would result in a substantial benefit to salmon and steelhead production towards recovery over what has occurred as wasteful practices in operational adjustments tweaking the old status quo for a near same new status quo. It would also eliminate the ridiculous smolt transport welfare-to-nmfs program that for over 40 years in development has not proven any sustained benefit to Snake River salmonid production (SARs are or + <1% in a small moving range highly dependent on how bad the river conditions are, or higher spill TDG supersaturation/reservoir passage temperatures near lethality maybe can pull out an inconsequential gain in transport SAR. All has resulted in meaningless arguments to avoid spill and breaching. My point here is that the 1992 DD test was purposely performed in March when the least number of juvenile salmonids would be present, and actually migrating smolts were not present. Dworshak was entraining/emitting/passing from its reservoir winter held kokanee that got counted as	While drawdown to MOP was considered as part of MO4, drawdown to spillway crest was not. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in relevant literature. These alternatives represent a reasonable range of alternatives for the maintenance, configuration, and operation of the CRS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				mortalities stranded on exposed shorelines downstream, as well as some emerging fall chinook and rearing spring chinook parr out of the subbasins. The cold snaps contrived peaking periods in the CRSO EIS for which this (max peak ability not realistic little ramp up ability) scam has been developed are now occurring in early- to mid-March (2017, 2019)So, same overlap in time, so, similar effects reasonably expected on anadromous fish between peak and 1992 DD scenarios, EXCEPT the rate and duration and magnitude of reservoir evacuation as alluded to earlier, AND the CRSO peaking operation would have NO spill to move fish out of the turbines for those low number of early migrators (most likely still in some rearing form and if moved by forced hydraulics they would end up in a worse rearing environment in the next manipulated reservoir downriver. For fish and ecology--Once you draw down to spillway crest elevation drawdown it is best to just operate there and not raise the pools, avoid surging/pulsing as the flex spill would also do. Remember 1992 DD Test was a very short-term effect (with little to no anad fish present) for a significant long-term benefit to anad fish production if it became seasonal or permanent. Yo-yo-ing to an ultimate spillway crest water surface elevation would only result in a higher degree of false cues and conditions for which pre-smolts would have to over-stress to until they are eaten. In such conditions many studies have documented pre-smolts and smolts trying to swim upriver within the reservoirs in order to locate that positive rheotaxis hydraulic condition cue for which they evolved to discover.	
31771	11	wwpinneys@gmail.com	N/A	Review of peaking power capability analysis: Average rate of drawdown for each 10 day peaking sequence would in 9.4 ft/day for Sc1 and 6.6 ft/day for Sc2. For 10 hour long draws at a rate of <1 ft/hr to ~.7 ft/hr, both less than the established 2 ft/day of the 1992 DD Test that was estimated as most comfortable to result in the least degree of erosion and bank/water table dependent damage and failure. So, your model used the .7-1 ft/hr draws on the reservoir? With 5 hrs of refill to some less-than-target pool elevation. Even with the realization that the BPA contrived a worst case scenario operation utilizing an unrealistic and feasible peaking scenario just to generate some politician ignorant swaying in their economics of chicken-little-ing, would the expected erosion/damage be comparable to the relatively minor (and easily fixable) damage due to the 1992 DD Test at/throughout Lower Granite dam and pool, where 1992 scenario was a more steadily paced draw that was both binned and continuous for a period of hours each day at less than 1/2 the rate, then held a little higher in elevation for about 2 weeks? BPA just needs a little come-to-Jesus confession that they are contriving to get to that enormous economic modifying figure, and they have never and would never do this peaking because it would never be needed using the Snake River dams alone, and would be easily sucked up in the existing power gridding. Why else have a grid? Forced to face the facts of increments (possibly?) of what the 2017 and 2019 operations truly were. This is the same old bluff similarly used for their longstanding foregone power revenue loss due the spill for fish negotiated operations, for which they include in their dreamed-up over-inflated mitigation costs even though they never actually needed or intended to generate that lost power, but used as leverage in their economic analysis.	The commenter may be conflating two different issues. Drawdown for dam breaching in MO3 would occur at a rate of 2 feet/day to minimize erosion (see Section 2.4.5.1 in the Draft EIS). This drawdown rate is not determined for power generation. In fact, power generation would cease at these projects within in the first day or two of drawdown when the water levels would no longer be high enough to operate the turbines. For the MO3 (based on the 2002 EIS), draw down would start in August with subsequent breach occurring in October (see Section 2.4.5.1.). The typical rate of reservoir draw down averaged 2 feet per day down to a minimum flow passage elevation with a total draw down range of 80 to 110 feet at each of the four lower Snake River dam sites over a period of ten weeks. The pool would hold at this elevation for a period of days to allow for removal of the earthen portion of the dam and construction of the bypass channels before a final dam breaching action would occur. In other alternatives, the lower Snake River projects operate within a 3- to 5-foot elevation range in the fall and winter, and within a 1-or 1.5-foot elevation range during the fish passage season. Bonneville does use this small operating range to peak, i.e. to increase generation for brief periods of high demand when conditions permit.
31775	1	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	CRITFC was created by and provides technical and policy coordination services to the Confederated Tribes of the Warm Springs Reservation of Oregon, the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes and Bands of the Yakama Nation, and the Nez Perce Tribe. These four tribes possess rights they reserved by treaties with the federal government to take a fair share of those fish destined to pass their usual and accustomed fishing places in the Interior Columbia River Basin. Inherent in the right to take fish is the conservation and protection of the fishery resource. Under their Treaties of June 1855, the tribes reserved for themselves and their members the right to take fish at all usual and accustomed areas. Tribal members have fished on the Columbia River for subsistence, ceremonial and commercial purposes since time immemorial. The Supreme Court of the United States has repeatedly recognized the significance of the treaty reserved right to fish at off-reservation usual and accustomed places, holding that the right is not much less necessary to the existence of the Indians than the atmosphere they breathed. Washington v. Washington State Comml Pass. Fishing Vessel, 443 U.S. 658, 680, 99 S. Ct. 3055, 3071-3072 (1978), quoting United States v. Winans, 198 U.S. 371, 380 (1905). This treaty right to fish is a property right, protected by the Fifth Amendment to the Constitution of the United States. See Muckleshoot Indian Tribe v. United Sates Corps of Engineers, 698 F.Supp. 1504, 1510 (W.D. Wash. 1988), citing Menominee Tribe of Indians v. United States, 391 U.S 404, 411-412, 88 S.Ct. 1705, 1710-1711 (1968). The treaties also create a federal trust responsibility under which the federal government maintains an affirmative obligation to safeguard the subject matter of federal treaties. Thus, federal agencies must use their authorities in a manner that will protect and enhance-- not degrade – the fish species that underlie treaty fishing rights. Further, [i]n carrying out its fiduciary duty, it is the government's, and subsequently the Corps', responsibility to ensure that Indian treaty rights are given full effect. NW Seafarms v. US Army Corps, 931 F.Supp. 1515, CRITFC DEIS Comments April 13, 2020 Page 2 of 59 1520 (W.D.Wash. 1996), citing, Seminole Nation v. United States, 316 U.S. 286, 296-97, 62 S. Ct. 1049, 1054-55, 86 L. Ed. 1480, 86 L. Ed. 1777 (1942) (finding that the United States owes the highest fiduciary duty to protect Indian contract rights as embodied by treaties). This duty does not cease once a fish run becomes viable. Tribal members must be allowed to achieve their "moderate living," even if this living standard may only be achieved by allowing the tribes to enjoy the "same level of exclusive use and exploitation" they had at the time the treaty was signed. United States v. Adair, 723 F.2d 1394 (9th Cir. 1984) cert. denied, 467 U.S. 1252 (1984). In short, the Tribe has an absolute right to a fair share of the fish destined to pass tribal fishing places. U.S. v. Oregon (Sohappy v. Smith), 302 F. Supp. 899 911 (D.Or. 1969). These fish include those artificially propagated for rebuilding, mitigation and enhancement purposes. United States v. Washington, 759 F.2d 1353 (9th Cir. 1985)(en banc) (holding that hatchery-reared fish are fish within meaning of treaty fishing clause and subject to allocation thereunder). CRITFC worked with and supported the CTUIRs participation as a Cooperating Agency in the CRSO EIS study. As a Cooperating Agency the CTUIR submitted comments to the co-lead agencies on draft products as they were produced, including but not limited to draft EIS chapters, the December 2019 Administrative Draft EIS, and the January 2020 draft Preferred Alternative. All of the CRITFC and CTUIR comments submitted on those products, and throughout the CRSO EIS study process, are incorporated as if restated in these comments on the DEIS.	The co-lead agencies acknowledge that the four Native American Tribes identified in the comment have protected treaty rights, including the right to fish at usual and accustomed (U&A) fishing sites, and the federal government has certain trust responsibilities concerning those treaty rights/resources. The co-lead agencies do not believe the Preferred Alternative identified in the CRSO Draft EIS would impair reserved tribal treaty rights, including the right to fish at U&A sites. Additionally, the co-lead agencies are using their authorities and available resources in a manner intended to conserve and enhance fish species.
31775	2	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	II. Executive Summary The DEIS is a product of a failed process. It suffers from structural flaws. These structural flaws include, but are not limited to, overly narrow purpose and goal statement, overly narrow Affected Environment, inconsistent and improper modeling analyses, and the absence of fishery impacts analyses. The DEIS is also in inadequate due to incomplete and improper cultural resources analyses, poor analyses of mitigation and questionable assumptions.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies disagree that the Purpose and Need Statement is too narrow given the wide breadth of resource and legal and institutional purposes it encompasses. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) as well as the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies relied on current, high quality information in the evaluation of effects to resources affected by CRS operations, maintenance and configuration. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. The EIS does analyze, however, impacts to fisheries are analyzed in Section 3.15 and 7.7.17. In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources" as this is consistent with Federal laws and regulations, which focus on specific bounded properties. The co-lead agencies also view the cultural resources study area as adequate to conduct a comparative impact analysis on cultural resources across the No Action Alternatives and the Multiple Objective alternatives (MOs). Tribal interests and holistic perspectives on the integration of Native American culture with the environment were addressed throughout the EIS and by inclusion of statements from the Tribes. The co-lead agencies note that many of the traditional cultural properties (TCPs) analyzed in the Draft EIS incorporate elements of the natural environment. Please see Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas, Section 3.17.2 for Tribal Perspectives Summaries, and Section 3.17.3 for Tribal Interests. Additionally, the EIS evaluates social and economic effects as well as effects to the natural and physical environment consistent with 40 C.F.R. 1508.14 and 1508.8. For additional information on mitigation, see Chapters 5 and 7.
31775	3	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The DEIS also does not appropriately incorporate tribal sovereign perspectives.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the development of the Draft EIS analyses and in the formulation of the Preferred Alternative. Please see the Tribal discussion in the Executive Summary, the Tribal Perspectives Section of 3.17 and submittals from Tribes in full in Appendix P. Effects to resources are discussed in Section 3.17.2, Tribal Perspectives Summaries.
31775	4	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The DEIS also fails to adequately address Indian Trust Assets.	The co-lead agencies have analyzed Indian Trust Assets consistent with applicable statutes, regulations, and guidance.
31775	5	golc@critfc.org	Columbia River Inter-	The DEIS further suffers from a bias in favor of power generation and flood control throughout. In sum, the DEIS fails to disclose and analyze significant considerations that are part of the fabric of laws and policies that address the protection mitigation and enhancement of fish affected by the development and continued operation of the CRSO A.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
			Tribal Fish Commission		benefit framework for decision-making (see 40 C.F.R. 1502.23). Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) as well as meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
31775	6	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Failed Cooperation and Collaboration Limited the Disclosure and Analyses of Significant Issues The process for assembling and analyzing the alternatives failed to distinguish truly significant issues from non-significant issues. There was also a failure of cooperative consultation, which should be emphasized in a NEPA process. 40 CFR 1501.1(b). Tribal Cooperating Agencies were expected to raise questions about the environmental reviews and information gaps. 40 CRITFC DEIS Comments April 13, 2020 Page 3 of 59 CFR 1503.3 (c). Questions tribal cooperating agencies raised throughout the process, and comments submitted, were often disregarded or ignored by the staff of the co-lead agencies (US Army Corps of Engineers, Bureau of reclamation and Bonneville Power Administration) leading the EIS process. In the end, the co-leads provided virtually no feedback to cooperating agencies whether our comments and suggestions were incorporated in the analysis or not, and why or why not.1 The timeline for the CRSO EIS also precluded transparent and meaningful analysis, review, dialogue and collaboration. The Trump administrations October 2018 Executive Memorandum on Promoting the Reliable Supply and Delivery of Water in the West, arbitrarily imposed an inadequate timeline on the development of the CRSO EIS, shortening the timeline established by the United States District Court for the District of Oregon. The current comment deadline fell during spring First Foods ceremonies, the day after Easter, and during Passover. Moreover, the tribes and other sovereigns in Pacific Northwest are prioritizing the health and safety of the people in responding to the COVID-19 emergency. Since February 28, more than 20,000 people within the United States have died as a result of COVID-19 infections. https://www.cdc.gov/coronavirus/2019-ncov/cases-updates/cases-in-us.html (last visited April 12, 2020). Adherence to the CRSO timeline and associated comment deadlines during the COVID-19 pandemic further compounded the flaws of the DEIS. As a result of the COVID-19 pandemic, elected officials have little time for policy consideration of the DEIS. Mandated social distancing measures prevent meaningful government-to-government consultation on the DEIS. The broad disruption caused by the COVID-19 emergency frustrated the ability of the tribes and the public to provide input on the DEIS. Despite these complications, the federal government refused to suspend the CRSO EIS process or extend the public comment deadline, despite repeated requests by multiple sovereigns.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The Draft EIS was subject to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
31775	7	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	B. Structural Flaws Obscured Meaningful Review of Alternatives, Impacts and Benefits Many of the structural flaws in the DEIS are broad and are programmatic or policy in nature. These flaws typically affect more than one chapter of the DEIS. These flaws include a narrow purpose and need statement, a failure to study all reasonable or viable alternatives, and a lack of rational explanations for alternatives not studied. Further, much of the DEIS suffers from a preference for technical detail over analysis of the programmatic issues, including but not limited to the Columbia River Fish Mitigation (CRFM) program, lamprey restoration program, and the analysis for Upper Columbia salmon and steelhead stocks. Another structural flaw is that the co-lead agencies incomplete or inaccurate understanding of 1 A draft matrix responding to tribal comments on the administrative draft EIS was provided to the tribes on Friday afternoon, April 10, less than one business day before tribal comments were due on the DEIS.	Chapter 2 describes the process of developing measures and alternatives for the EIS, based on input from public on the EIS scoping process, co-lead agencies' and cooperating agencies' expertise. Each alternative was based on the framework of meeting eight objectives and the EIS Purpose and Need Statement. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives is detailed in Chapters 3, 4, 5, 6, and 7. The EIS was drafted to address specific operations, configurations, and maintenance of 14 projects in the CRS and make a recommendation for future operations to be implemented in the Record of Decision. It is not a programmatic EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives) as well as the objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 in the Draft EIS provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. To achieve a broad range of alternatives, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, the eight single objective alternatives (SOs), and then four Multiple Objective alternatives (MOs). After completing the effort to develop the SOs and MOs, the co-lead agencies evaluated all 12 alternatives against screening criteria of completeness and efficiency. Completeness was used to evaluate the extent to which a given alternative provides and accounts for all actions to meet most or all objectives, and thereby satisfying the Purpose and Need Statement. Efficiency was considered as how well (without duplication of effort) an alternative would meet objectives. Usually, cost effectiveness is part of this consideration, but costs were not available at the early screening of alternatives. In this case, efficiency was based on efficiency of analysis of measures and the elimination of duplication of effort. A detailed descriptions of the single objective alternatives and their measures are located in Appendix A, Alternatives Development. A description of the alternatives removed from further consideration is in Section 2.4. The co-lead agencies recognize the importance of Pacific lamprey and will continue to work with CRITFC, CRITFC member tribes, and regional entities through existing frameworks such as the Corps-Tribal Lamprey Work Group, the Pacific Lamprey Conservation Initiative and the Corps Regional Forum workgroups (e.g., FFDRWG) to implement ongoing programs, as well as the lamprey measures described in the Preferred Alternative. The analyses completed and described in this Draft EIS were for the purposes of comparing the effects of the multiple objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs related to lamprey, such as habitat restoration, reintroduction and translocation, and other efforts. Measures identified in the Draft EIS do not include all lamprey passage improvements that could be potentially implemented at the lower Columbia and lower Snake River dams, but the Corps believes that potential actions contemplated in preliminary lamprey program planning discussions with CRITFC staff and others related to the 2018 Accords Extensions are consistent with the measures and analyses included in the Draft EIS. CRITFC is correct that actions beyond the scope of the measures included in the Draft EIS or ongoing activities would potentially require further NEPA analysis. Lamprey measures identified in the Draft EIS (and similar operational or structural measures) do not include research, monitoring or evaluation actions that may be needed to refine passage designs, inform operations, or address critical uncertainties. This includes the juvenile lamprey and adult lamprey migration behavior and fate studies identified in the 2018 Accords Extensions and in subsequent program planning and coordination discussions with CRITFC and others. For the purposes of the Draft EIS, measures must address known operational and structural issues, but this does not preclude development and implementation of future juvenile and adult lamprey studies. For Columbia River System dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is a result of significant investments in construction of components of the dams for the benefit of improved salmon passage. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps will continue to express capability in the annual budgeting process. Implementation of all measures including lamprey measures is dependent on funding availability. In 2020, the Corps did receive $20M in funding to implement actions contemplated in the 2018 Accords Extensions. As noted by CRITFC, and in similar comments from CTUIR, the Corps is currently refining cost estimates and developing a preliminary implementation plan for this $20M program. The Corps will continue to coordinate closely with CRITFC and other Accords tribes on prioritization of actions within this program and will continue to ensure consistency with measures identified and analyzed in the Draft EIS. Additional information on CRFM is included in Chapters 2, 5 and 7 of the EIS.
31775	8	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	CRITFC DEIS Comments April 13, 2020 Page 4 of 59 the CSS, COMPASS and HEC-WAT analytical models resulted in a confusing, albeit detailed, assemblage of model results without clear analysis of their implications, limitations and relevance to the objectives of each alternative.	The co-lead agencies followed standard NEPA practices when laying out the various components of their analysis. Fish modeling results are presented in chapter 3.5, which HEC-WAT results are presented under the water quality sections. Effects of the No Action Alternative, the MOs, as well as the Preferred Alternative are summarized in Chapter 7.
31775	9	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Additionally, the DEIS fails to analyze impacts to fishery management or harvest opportunity. The tribal harvest should be included in the baseline. The lack of harvest opportunity analysis runs counter to the Tribal Perspectives of the Columbia River Treaty Tribes, as well as the goals for non-Indian fisheries (and the corresponding economic effects of the non-Indian fisheries).	The EIS recognizes the value of commercial as well as recreational fishing to the region. Section 3.15 describes the values associated with fisheries in the Pacific Northwest. Section 3.11 characterizes recreational fishing activities in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively.
31775	10	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The discussions in the Affected Environment sections do not meaningfully depict the nature and extent of the impacts that the Basins hydro system has had on the Columbia Basins anadromous fish. Meaningfully depicting these impacts cannot be avoided. Under NEPA, regardless of the selection of the baseline, all cumulative effects must be revealed.	Consistent with the Council on Environmental Quality's (CEQ) June 24, 2005 guidance and interpretation of CEQ Regulations for Implementing the Procedural Provisions of NEPA, 40 C.F.R parts 1500-1508, "Agencies are not required to list or analyze the effects of individual past actions unless such information is necessary to describe the cumulative effect of all past actions combined. Generally agencies can conduct an adequate cumulative effects analysis by focusing on the current aggregate effects of past actions without delving into the historical details of individual past actions." The cumulative effects analysis in the EIS adequately considers the ongoing effects of the existence of the system to anadromous fish and other resources affected by the CRS.
31775	11	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	C. Poor Analysis of Mitigation The CEQ regulations concerning mitigation describe several types of mitigation actions at 40 CFR 1508.20. As pointed out in the DEIS, these include rectifying the affected environment and compensating for the impacts to resources of concern. The omission of ongoing mitigation from the DEIS and the limited scope of proposed mitigation are major issues that need to be rectified. Further, there is no alignment of identified impacts with proposed mitigation. Specific impacts are identified in Affected Environment, but there is no reference to those impacts in Mitigation chapter. The mitigation chapter does not reflect the significant input requested of, and provided by, the Cooperating Agencies. Finally, the DEIS uses the No Action Alternative (NAA) as a baseline for mitigation obligations. This NAA was already deemed inadequate by the District of Oregon. The DEIS fails to present any alternative with adequate mitigation measures.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. Moreover, ongoing mitigation actions, such as the Bonneville's Fish and Wildlife Program, are included in Chapters 2, 5 and 7, and all additional mitigation proposed in Chapters 5 and 7 relates to the effects analysis in Chapters 3, 4, 6, and 7. NEPA does not require identification of mitigation for the continuation of the No Action Alternative. The co-lead agencies, in coordination with technical teams, including the cooperating agencies, compiled lists of all potential suites of mitigation measures. Then, in comparison of the effects of each alternative to the No Action Alternative, highlighted where there were minor, moderate, and major adverse effects. If adverse effects were negligible or minor but otherwise not measurable, and the resource did not otherwise have institutional or legal significance (i.e. wetlands), then mitigation was not proposed. If, when compared to the No Action Alternative, there were moderate or adverse effects, the teams proposed mitigation measures of appropriate scale and effect. The suite of potential mitigation measures the team used were in the mitigation tool box (Appendix R, Part 3), which also presents rationales for not carrying forward mitigation measures.
31775	12	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	D. Bias in Language and Model Results Improperly Influenced Results As noted above, the DEIS fails to adequately explain the differences between COMPASS and the CSS data and complexity, and what those differences mean for the model results. Further, the description of model effects is biased and inconsistent, in favor of uses and objectives other than fish and wildlife. This is also apparent in the level of detail given to various impacts. For example, the Executive Summary goes into great detail on impacts to power rates from the measures, but only gives a general discussion for other affected purposes.	The Comparative Survival Study model was run by the Fish Passage Center; and the COMPASS and Life Cycle models were run by the National Marine Fisheries Service's Northwest Fisheries Science Center for the co-lead agencies. Regarding the SARS model, the hatchery fish are one of many components that are aggregated into the forecasts from historically-observed SARS. The models do not have inputs for the hatchery or harvest rates. Different models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other.

					The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5.
31775	13	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	E. Other Flaws Other flaws noted in the body of these comments include, but are not limited to inadequate definitions and analyses of cultural resources, sacred sites and Indian Trust Assets; inadequate and illogical water temperature model results that are inconsistent with other federal agency models; inconsistent comparisons of effects to objectives, and inconsistent time and geographic scope analyses between objectives.	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources" as this is consistent with Federal laws and regulations, which focus on specific bounded properties. The co-lead agencies also view the cultural resources study area as adequate to conduct a comparative impact analysis on cultural resources across the No Action Alternatives and the Multiple Objective alternatives (MOs). Tribal interests and holistic perspectives on the integration of Native American culture with the environment were addressed throughout the EIS and by inclusion of statements from the Tribes. The co-lead agencies note that many of the traditional cultural properties (TCPs) analyzed in the Draft EIS incorporate elements of the natural environment. Please see Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas, Section 3.17.2 for Tribal Perspectives Summaries, and Section 3.17.3 for Tribal Interests. Additionally, the EIS evaluates social and economic effects as well as effects to the natural and physical environment consistent with 40 C.F.R. 1508.14 and 1508.8. Indian Trust Assets are analyzed in Section 3.17.1. Given the importance to the Tribes of these resources, which do not meet the Department of Interior's definition of an Indian Trust Asset, effects to those resources are discussed in Section 3.17.2, Tribal Perspectives Summaries. The co-lead agencies disagree with your statement that the water temperature analysis is inadequate or illogical, but the co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the highest quality information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The EIS analysis indicates that the operations of the CRS do effect water temperature, but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally, high air and water temperatures result in water quality standard exceedances that are beyond the ability of the CRS to cool. Temperature in the Snake River upstream of the confluence with the Clearwater River often exceeds state water quality standards. Drier and warmer years such as 2015, as summarized in National Marine Fisheries Services 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. The EPA is the lead agency on developing the temperature TMDL, and in doing so will evaluate the impact of all anthropogenic and natural sources of heat in the Columbia and Snake rivers. In contrast, the Draft EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. Thus the Draft EIS did realistically and clearly analyze, to the extent practicable, whether operation of the CRS is contributing to compliance with the water quality standards as compared to historic river temperatures. In addition to investigating the operational impacts on water temperature, the co-lead agencies have taken other actions to address water temperature impacts on fish passage. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the Draft EIS. In addition, the co-lead agencies are actively working on implementing the recommendations identified in NMFS' 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision-making and reduce, to the extent practicable, the adverse impacts of high summer temperatures on migrating salmon, including adult sockeye salmon. Finally, the temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives (with the exception of the socioeconomic-related resource analysis - 50 years). The accuracy and reliability of climate change information was also a consideration for determining the temporal scope. The co-lead agencies would continue to re-asses the operations and maintenance of the CRS at regular intervals to ensure that accurate and high quality information is considered in managing the CRS.
31775	14	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	In addition, the DEIS omits analysis of compliance with other environmental statutes, such as the Endangered Species Act and Northwest Power Act. CRITFC DEIS Comments April 13, 2020 Page 5 of 59	Chapter 8 describes how the project is complying with all appliable laws including the Endangered Species Act and Northwest Power Act.
31775	15	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The Preferred Alternative (PA) and Biological Assessment (BA) do little for fish survival as compared to the No Action Alternative (NAA). Model runs from NOAA models do not demonstrate a benefit from the NAA and the Proposed Action. When compared against the flex spill that is currently in place, the Preferred Alternative appears to be a step backward for fish survival. These shortcomings, and others are discussed below. CRITFC DEIS Comments April 13, 2020 Page 6 of 59	The Preferred Alternative is analyzed in comparison to the No Action Alternative, not to the 2019 /2020 flex spill operation, but nevertheless, the co-lead agencies do not agree that the Preferred Alternative is a step backward in terms of survival. Based on our analysis of the Preferred Alternative, it will make a substantial contribution to improving Snake River anadromous fish runs, but broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation, maintenance, and configuration of the 14 CRS projects. The co-lead agencies used current high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality.
31775	16	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	III. Failed Cooperation and Collaboration with Cooperating Agencies NEPA implementation should emphasize cooperative consultation among agencies. 40 CFR 1501.1(b). At a minimum, consultation is a dialogue where information is shared. As cooperating agencies, we were expected to raise questions about needing additional information to fulfill our environmental reviews. 40 CFR 1503.3 (c). Our cooperative agency experience was far from what these NEPA regulations envision. Exploration of issues during scoping, regardless of significance, were typically allocated five minutes for discussion on a conference call convened with more than 40 participants. There was little opportunity for collaborative dialogue among subject matter experts from the cooperating agencies and co-lead federal agencies.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation, maintenance and configuration of the dams in the CRS system. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
