31775	17	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The process for assembling and analyzing the alternatives seems to have failed to discern truly significant issues from non-significant issues. This was due to the nature by which information was collected by the co-lead federal agencies, which seemed to have be based on accumulating detail for minor actions, rather than collaboratively developing a shared understanding of the programmatically integrated suite of measures that have already been implemented and using these as a departure point for future plans. Multi-Objective Alternatives were developed and reworked when Single Objective Alternatives were unilaterally dropped by the co-lead agencies with no input from the cooperating agencies.	The EIS was developed to allow the co-lead agencies to operate the CRS to meet congressionally-authorized purposes for the next 25 years. The co-lead agencies conducted a robust scoping effort, and included regional agencies and Tribes in the development and analysis of alternatives. There were numerous opportunities for stakeholders to identify issues that they believe to be significant, and the co-lead agencies considered all comments submitted during scoping. Fundamentally, the EIS was developed to analyze options for future operation of the system to meet authorized purposes, and the Purpose and Need Statement and the range of alternatives reflect that requirement.
31775	18	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Questions throughout the process could not be asked in technical workgroups, but needed to be directed to the NEPA policy team. We eventually came to understand that this team was comprised of the designated NEPA leads for the co-lead federal agencies. When the cooperating agencies convened their own meetings for collaborative scientific discussion, the co-lead agencies issued a written admonishment directing that no cooperating agency should provide information, or collect, assemble, or analyze data related to the CSRO EIS unless specifically requested by the co-lead agencies. The co-lead agencies opined instead that, if we needed assistance identifying and developing specific applicable information, collecting or assembling relevant data, and analyzing data related to these areas, we knew which cooperating agency to contact.2 Technical input from individual cooperating agencies was directed to continue to be formatted into cells in an Excel spreadsheet, which aided input-tracking but did not create any dialogue with the cooperating agencies. 2 Undated letter from Frances E. Coffey, Director of Programs USACE to Cooperating Agency distributed by email on July 11, 2019. CRITFC DEIS Comments April 13, 2020 Page 7 of 59	The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The CRSO EIS technical teams included experts from across over 30 cooperating agencies. Ultimately, the co-lead agencies are responsible for selecting and implementing an alternative. The rationale for doing so is presented throughout Chapter 7, which identifies a Preferred Alternative based on weighing the benefits in achieving the Purpose and Need Statement and EIS objectives while considering the potential adverse effects to the human and natural environment. With such large co-lead agency and cooperating agency teams, the co-lead agencies used spreadsheets to ensure the cooperating agency comments were captured accurately, so the co-lead agencies could respond, appropriately. As for analysis conducted outside of the CRSO EIS process, any use of predecisional information developed as part of the CRSO EIS process is inappropriate and a violation of the MOU signed by cooperating agencies, as discussed in the letter sent to the cooperating agencies at the time.
31775	19	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	IV. Scope and Foundation of the EIS A. The Purpose and Need Statement and Objectives are Improperly Narrow The co-lead agencies constructed improperly narrow Purpose and Need Statement and Objectives for the DEIS. As written, these essentially prescribe a status quo outcome. In doing so, the co-lead agencies effectively ignored the May 4, 2016, District of Oregon Order where Judge Simon specifically charged the action agencies with preparing an EIS to take a hard look at the programmatic plan to offset the adverse effects of the FCRPS on native fish species and affirmed that the CRS cries out for a major overhaul in terms of fish survival rates. Instead, the Objectives of the DEIS, or the statements of the desired outcome of the EIS, merely strive for actions considered in the EIS to improve listed salmonids within the CRS: Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival within the CRS through actions including but not limited to project configuration, flow management, spill operations, and water quality management. (Improve Juvenile Salmon) Improve ESA-listed anadromous salmonid adult fish migration within the CRS through actions including but not limited to project configuration, flow management, spill operations, and water quality management. (Improve Adult Salmon) These objectives, by their explicit terms, do not include ESA, NWPA or treaty rights compliance. As a result of these narrow objectives, probabilities of survival and recovery of listed salmonids (ESA compliance) were not analyzed in the DEIS. Its noteworthy that they are not analyzed in the draft BA either. Similarly, alternative "offsite mitigation" measures (a term of art under the Northwest Power Act in 16 USC 839b(h)(8)(A)) were not analyzed in the DEIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Regarding the Preferred Alternative, this alternative is not simply a minor change to operations and maintenance of the CRS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The comment suggests that alternative offsite mitigation measures were not analyzed in the Draft EIS. Many of the mitigation programs funded by the co-lead agencies consist of offsite mitigation. Bonneville's Fish and Wildlife Program is primarily an off-site mitigation or enhancement program. See 16 U.S.C. 839b(h)(8)(A). In other words, Bonneville funds off-site enhancement, not mitigation at the dams. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and the Northwest Power Act.
31775	20	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	B. The Current Conditions and Programs under the NAA are not Adequately Described or Analyzed The DEIS fails to disclose that AMIP Safe-Guards Under the current Biological Opinion had been triggered. Late in 2019, NOAA notified the region that Adaptive Management Implementation Plan (AMIP) safe-guards (low adult returns had been meet for Snake River steelhead and were likely to be met for Upper Columbia River Steelhead. Yet, the DEIS fails to meaningfully disclose and analyze this underlying biological condition. Moreover, the PA and BA should ensure that additional measures and safe-guards to improve and protect adult returns be implemented, but they do not. The tribes are working with NOAA to identify further AMIP actions, such as more kelt collection and reconditioning, and avian hazing at Miller Rocks. We have also asked the co-lead agencies to accelerate actions for which they have authority to do CRITFC DEIS Comments April 13, 2020 Page 8 of 59 (now) to reduce avian predation on listed Upper Columbia and Snake River stock, e.g., implementing the John Day reservoir operation this year, 2020. Again, the co-lead agencies have failed to move-out on any of these actions, nor have they included new actions in the DEIS Proposed Action. Notably, the DEIS PA identifies only two actions (the flex spill operation, and the John Day reservoir operations to reduce nesting at the Blalock Island) to improve the survival of all ESA listed species, including those that have already triggered the AMIP safe-guards	The co-lead agencies discussed current status of AMIP triggers on lines 7236-7243 in the Draft EIS. The co-lead agencies reviewed the Rapid Response Actions identified in the AMIP and note that several actions were implemented in recent years that are likely to increase abundance and productivity. In particular, the co-lead agencies implemented spring juvenile fish passage spill operations that exceeded the performance standard spill operations developed in coordination with NMFS. These operations are part of the 2019-2021 Spill Operation Agreement with the states of Oregon and Washington and the Nez Perce Tribe to increase spill levels with the intention to benefit juvenile salmonids, while offsetting impacts to power generation and operational feasibility. Increased levels of spill were also implemented in 2020. The co-lead agencies have also started transport in 2018 and 2019 earlier than in the past, with the intended benefit of increasing the rates of Snake River steelhead transportation. Moreover, the co-lead agencies are also taking many steps to curtail predation of ESA-listed salmonids by a variety of predators, including pinnipeds, avian predators, and Northern pikeminnow. The co-lead agencies worked with regional stakeholders and enabled additional collection of Snake River steelhead kelts for subsequent reconditioning at Little Goose Dam. That operation was subsequently affected by access restrictions due to COVID-19 response but is expected to resume. The co-lead agencies did not implement modifications to John Day pool operations as those are the focus of this Draft EIS review and are proposed for inclusion in the Preferred Alternative. If warranted, additional kelt collection may continue to be implemented after current ESA consultation and NEPA consultation have completed. Adaptive management to address these types of issues will continue to be a point of emphasis for the co-lead agencies. Finally, the agencies are continuing their efforts in funding hatchery programs to preserve and rebuild the genetic resources of ESA-listed salmon and steelhead in the Columbia and Snake River basins. The BA includes similar safe-guards that were identified under the amended 2008 NMFS BiOp Adaptive Management Implementation Plan (AMIP; refer to Section 2.6.4, Adaptive Management and Contingency Actions). Actions such as spill, bypass, and transport operations at mainstem Snake and Columbia River projects will continue to be adaptively managed based on results of biological studies and monitoring information. These results will be discussed, and operations modified in collaboration with Federal, state, and Tribal sovereigns through the Regional Forum, to ensure expected benefits to salmon and steelhead are being met based on the best available scientific information. One example of this commitment is to continue kelt reconditioning in years of low steelhead returns. Additionally, the Preferred Alternative does call for actions that are different from those that have been implemented in the past: Flexible spill. One major change that the Preferred Alternative represents is a new spill operation (flexible spill), which would test an innovative approach to balancing fish benefits and energy goals by spilling more water in the spring for juvenile fish passage. The intent of flexible spill is to increase spill when the projected value of power is relatively low, pass higher proportions of fish through the spillway, and spill less water for limited durations when the projected value of power is relatively higher (e.g., during peak power demand). The flexible spill operation creates an opportunity for a major potential benefit to salmon and steelhead through increased spill, as indicated by the CSS model, while avoiding many of the adverse effects to power generation and reliability associated with juvenile spill operations analyzed in MO4. The flexible spill operation in the Preferred Alternative would be implemented through an adaptive framework that allows the co-lead agencies to adjust operations as new information emerges as detailed in Appendix R. While the flexible spill operation was originally initiated under the 2019-2021 Spill Operation Agreement, this type of operation is a major change from the No Action Alternative and how the co-lead agencies have operated the system historically. Increased spill. As part of the flexible spill operation, we would increase planned spill up to 125% total dissolved gas levels at some projects, which is the new state water quality standard for the maximum allowable total dissolved gas limit. Previous state water quality standards limited juvenile fish passage spill to lower amounts of spill. The goal of higher spill is to increase the number of juvenile fish passing through the spillways, in lieu of the powerhouse bypass systems and turbines, which is predicted to result in increased adult fish returns. Extensive regional collaboration. The flexible spill operation included as part of the Preferred Alternative is a result of extensive regional collaboration. Negotiations for the 2019-2021 Spill Operation Agreement began in the summer of 2018. The parties to the original agreement included the co-lead agencies, the states of Oregon and Washington, and the Nez Perce Tribe. The Preferred Alternative intended to build off of the collaboration fostered through the agreement and apply that to the existing regional coordination processes (Regional Forum). Other changes. The Preferred Alternative also contains measures to benefit resident fish, as well as lamprey, while providing reliable flood risk management, water supply for irrigation, and flexibility in hydropower generation that would be valuable for integrating wind and solar energy. Specific details of the Federal obligation: The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives of the CRSO EIS for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
31775	21	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	C. The Alternative Selection Process was Flawed and Omitted Important Measures and Considerations from Disclosure and Analysis Section 2.3 of the DEIS suggests that cooperating agencies were collaborated with during the alternative selection process. This was not the case. While cooperating agencies were invited to suggest discrete measures that could be included in alternatives, strategic decisions about the content of the single and multiple-objective alternatives (MOs) were made by processes completely internal to the co-lead agencies; in no way was the process collaborative. Likewise, the decision to remove single-objective alternatives (SOs) and revamp the multi-objective alternatives was completed solely within the co-lead agencies own internal processes. The slight exception was MO4, which was presented for consideration by the Nez Perce Tribe. However, here the co-lead agencies significantly amended MO4 from what the Nez Perce submitted without coordination with the tribe. The co-lead agencies built their alternatives out of various narrow measures upon the theory that the alternatives would then provide (1) bookends of impacts i.e., the extremes; and (2) modularity the ability to decipher which measures were driving various impacts. This approach assumed that ultimately, a preferred alternative could be built out of the various measures with known impacts. However, this effort failed for multiple reasons: The focus on specific actions, or measures, failed to consider important programmatic efforts relevant to the CRSO (discussed more below). Due to the condensed schedule for completing the EIS, the Single Objective alternatives (SOs) were eventually dropped from the analyses. These SOs would have presented a better bookend review. Multi-Objective (MO) combinations obfuscated useful conclusions. All the MOs were formulated in a way that produced similar results from the biological modeling. For instance, MO3 negates the benefits of breach by reducing spill in the lower river; MO4 takes away from the fish benefits of 125% TDG by reducing spring and summer flows through changed reservoir operation. This obfuscation runs counter to the public disclosure requirements of NEPA. The effects analysis of the MOs did not evaluate the component measures within each of the MOs, making it difficult to identify which components of an MO provide benefits for fish versus which are a detriment. Additionally, some measures within MOs, especially MO4, were written with biases that preclude a thorough comparison of the alternatives. CRITFC DEIS Comments April 13, 2020 Page 9 of 59 MO4 uses a hard constraint for flow augmentation as measured at McNary Dam versus the target constraint used in NAA and MO1 and analyzed in previous biological opinions. Inclusion of the hard constraint exaggerated the power impacts of the alternative, masking the power effects of max spill. This makes MO4 look unreasonable due to significant cost, extensive reservoir drainage and increased impacts to resident fish. The description of the McNary flow target measure in MO4 is insufficient to disclose the significant impact of the hard flow constraint on the alternative as a whole. MO4 also failed to limit spill at Bonneville to 150Kcfs. Such is a structural limitation of the facility and it is unrealistic to assume that the Corps would exceed this spill level, and capricious then to include such in hydro and fish modeling. The tail-race erosion concerns at Bonneville Dam are well-known and limit spill to below 150 Kcfs. 3 Without this limit, the alternatives appear to spill more than is realistic, this makes the results for both the power cost analyses and smolt to adult returns (SAR) effects artificially high. In this way, the alternatives are not reasonable, and the results biased. Moreover, the EISs reliance on bookends and modularity precluded evaluation of several reasonable alternatives: A true breach or natural river alternative was not analyzed. MO3 the breaching alternative negates the fish benefits of breaching of the Snake River Dams by, among other actions, decreasing spill in the lower river, thus precluding a true analysis of the potential benefits of breaching on Snake River stocks. A true breach/ natural river alternative would include lower river spill supportive of juvenile fish passage, adequate spring flows, and optimize Dworshak flow release schedules to regulate water temperature as was included in MO1. The DEIS does not explain why these measures were omitted from MO3, particularly in light of the District Courts order. Realistically implementable operations were not analyzed. As formulated, none of the four MOs provide a balanced, standalone operation or were ever intended to be considered as the final action as written. An optimized spill operation was not considered in the DEIS. Such operation was requested during scoping and would have looked dam-by-dam at optimal and balanced spill operations that provide the best passage for fish while considering power needs. The current Flex Spill operation. While the proposed alternative eventually incorporated the 2020 Flex Spill operation (with significant unilateral changes), a reasonable analysis 3 The 150 kcfs spill limitation has been implemented to safe-guard the spillway to reduce erosion and reduce the risk of	Section 2.2 of the Executive Summary of the EIS specifically states that the cooperating agencies contributed to the EIS by providing information, participating on technical teams, and reviewing draft documents. It does not state that the cooperating agencies collaborated in the alternative selection process. However, they did participate in the review and prioritization of measures within them. The MOU signed by cooperators specifically states that the co-lead agencies maintain responsibility for decisions. Regarding alternatives, the preliminary analysis of the Single-Objective (SO) alternatives informed the development of the Multiple-Objective (MO) alternatives. However, the SO alternatives were not developed as viable, complete solutions, as they were focused on only one resource and would not provide the comprehensive management strategy needed for the multi-purpose CRS or would the SOs meet the Purpose and Need Statement. The SOs did provide bookends, as you noted, for example regarding effects of various spill regimes, and the team used them in that way. Ultimately, the range of alternatives needed to provide realistic options for meeting competing project purposes and congressional authorities. See Appendix A for more information. Finally, the co-lead agencies adequately evaluated breaching the four lower Snake River dams with 120% fish passage spill at the lower Columbia River Projects. The measure to adjust Dworshak releases under MO1 was ineffective as discussed in Section 3.4, and that was why it was not carried forward into the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				dam failure, yet the DEIS disregards this limitation and models spill in excess of 150 kcfs. In a response to comments we received from the co-lead agencies DEIS team (late Friday, April 10, less than 3 days until our comments are due) the comments acknowledged that this was not a mistake and that the DEIS wanted this damaging level of spill as bookend. This is counter to the co-lead agencies own Fish Passage Plan which limits volunteer spill to 150 kcfs to safe guard the spillway. So, it is illogical and a waste valuable time modeling an operation that is that could severely damage power operations at Bonneville, The Dalles and John Day dams. Worst yet, this misleading operation baises the results and makes each alternative where the 150 Kcfs limitation disappears worst from an economic standpoint. It seems that the co-lead agencies were gaming the process to manipulate the outcome. CRITFC DEIS Comments April 13, 2020 Page 10 of 59 of alternatives would have included the flex spill operation as an MO so the results were available for consideration in developing a preferred alternative. The EIS analysis was a chance to take a hard look at a new approach to CRS management and the opportunity to evaluate a practical suite of measures or reasonable alternatives for achieving the DEIS objectives. The DEIS does not provide a rational explanation for its failure to do so.	
31775	22	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	D. The DEIS Fails to Disclose and Analyze Important Operational and Structural Modifications to the Hydrosystem Proposed During Scoping. In the tribes initial scoping comments, we indicated that the EIS should consider a range of system operations and improvements with the goal of improving fish passage and whole system survival, including: An optimized spill program under existing water quality waivers based on individual project characteristics and designed to maximize juvenile survival. Permanent drawdown or seasonal drawdown at specific projects. Altered flood control operations in low and mid-range water years to better support spring flow for migrating juveniles. Replacing the drum gates at Grand Coulee Dam or change the way the work is done on them to eliminate or reduce the need for maintenance and associated reservoir draw down. Additional turbines at certain reservoir projects to increase system and flood management flexibility and ensure delivery of flow augmentation when needed for migrating juvenile fish. Additional predation control measures, such as additional bird wires and pinniped control measures. Additional analysis to determine what additional options, either structural or operational, could be implemented to reduce thermal issues now and in the future. Additional lamprey measures. See lamprey discussion below. None of these measures were analyzed in the DEIS.	Alternatives for the Columbia River System Operations EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies (including Washington), and expert opinion from within the co-lead agencies and in the literature. Section 2.2.1 of the EIS outlines eight objectives. Objective 8 is, "Improve conditions for lamprey within the CRSO project area through actions potentially including but not limited to project configurations, flow management, spill operations, and water quality management." The Preferred Alternative includes the following measures for the benefit of lamprey: Lower Granite Trap Modification (Section 7.6.2.5); Bonneville Ladder Serpentine Weir Modifications (Section 7.6.2.17); Closeable Floating Orifice Gates (Section 7.6.2.18); Bypass Screen Modifications for Lamprey (Section 7.6.2.19); Lamprey Passage Ladder Modifications (Section 7.6.2.20); Turbine Strainer Lamprey Exclusion (Section 7.6.2.21). The Columbia River Fish Mitigation Program and the Columbia Tributary Habitat Program are ongoing programs that provide benefits to lamprey. The Preferred Alternative meets the lamprey objective. 7.6.3.15 describes the Predator Disruption Operations measure which has been incorporated into the preferred alternative.
31775	23	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	E. Significant Programmatic Issues Are Obscured from Review by Measure-Based Alternatives The focus on specific actions, called measures, in the DEIS has overshadowed important programmatic issues of significance to the tribes. NEPA documents must concentrate on the issues that are truly significant to the action in question and the DEIS fails to do so. CRITFC DEIS Comments April 13, 2020 Page 11 of 59 The following examples highlight that the DEIS appears to be a harbinger of the elimination of certain ongoing Corps programmatic efforts. Since the DEIS is intended to have a 25-year duration, the focus on specific measures to the exclusion of programmatic needs is troubling. - The DEIS does not meaningfully disclose and analyze the reductions in the CRFM program The Corps Columbia River Fish Mitigation program (CRFM) has been a decades long endeavor supported by the tribes, Pacific Northwest states and congressional delegation. The history, accomplishments and lessons learned from the CRFM are not described in the DEIS. Presumably one would expect to find a discussion of the CRFM in section 1.7 of the DEIS. Over $2 billion dollars has been appropriated by Congress to support this program and institutions such as the System Configuration Team (SCT) have developed around this program.4 While the NAA and MOs assume some continuing level of structural improvements at the CRS dams, the pace of CRFM activity is only revealed by Table 6.1 in Appendix Q (Costs), which identifies that CRFM funding will be reduced to $2 million per year. At its peak, CRFM funding was two orders of magnitude greater, sustained at between $80 million and $100 million per year. There are two broad consequences related to the scope change of CRFM that the DEIS fails to disclose. First the CRFM program is more than just a collection of construction projects at the Corps dams. It represents the Corps ongoing programmatic support, including personnel, for Columbia River anadromous fish passage. The loss of staff capability represented by this budget contraction will impact ongoing working relationships between the Corps and CRITFCs member tribes. While providing repetitive detail about a limited list of structural measures in the NAA and MOs, the DEIS fails to address the programmatic consequences of the loss of the CRFM and the Corps ability to participate in regional decision making concerning its CRS dams. The DEIS should describe the effects of eliminating or drastically modifying the CRFM program. Second, the breadth of configuration measures for the CRS dams is limited and non-representative of ongoing and planning actions. If the DEIS is intended to represent future structural measures for a 25-year period, the measures are far too narrow and too specific to portray a realistic range of activities currently envisioned by co-managers. For example, collection and reconditioning of steelhead kelts has shown significant benefits in the Yakima and Snake river systems. The discussion of steelhead kelts in the DEIS does not reveal either the scope of efforts now ongoing or planned actions such as expanded kelt trapping operations at CRS dams.5 The only kelt measures in the DEISs MOs are spill passage related. The DEIS fails 4 System Configuration Team (SCT). The SCT reviews the physical make-up of the hydroelectric system in the Basindams, fish screens and ladders, spill deflectors (flip lips), and other structuresto determine what the optimal system would look like that incorporates all the needs of the system. It meets regularly to prioritize capital expenditures on system configuration facilities for improving fish passage. https://www.bpa.gov/p/Generation/Hydro/hydro/columbia_river_inside_story.pdf 5 See NPTH Hatchery Operations and Snake River Steelhead Kelt Reconditioning Environmental Assessment at pages 11-14 discussing trapping kelts at Little Goose Dam, in addition to current trapping operations at Lower Granite Dam. CRITFC DEIS Comments April 13, 2020 Page 12 of 59 to address current knowledge concerning kelts and current and planned trapping at Corps dams and reconditioning actions be undertaken by the tribes.6 Similarly, other measures in the full suite of potential salmon and steelhead measures should be examined. Even in the near term, questions about the SCT project priority lists for 2018 and 2019 have been repeatedly addressed to the co-lead federal agencies by the Tribes. We have asked that the DEISs range of alternatives at least examine the full range of measures in the SCT project prioritization lists so as not to preclude their future management consideration and implementation. These actions are at least reasonably foreseeable, yet many of them are not disclosed or analyzed at all in the DEIS. The measures in the NAA and MOs fail to fully include the SCT actions under active consideration by state, federal and tribal experts who participate in SCT.7	For Columbia River System dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is a result of significant investments in construction of components of the dams for the benefit of improved salmon passage. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding, including funding to operate and maintain the many improvements that were constructed under CRFM. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps would continue to express capability in the annual budgeting process and continue to coordinate these actions in the Regional Forum (e.g. SCT, FPOM, TMT, SRWG, and FFDRWG). The CRSO EIS includes a description of the CRFM program in Chapters 2, 5, and 7; kelts are also addressed in the EIS (see Section 3.5).
31775	24	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Lamprey measures are incomplete in the alternatives Following the 2008 Accords Agreement, the Corps developed a detailed programmatic approach to address the needs of Pacific Lamprey at CRS dams.8 Attached is the Corps Lamprey Program Prioritization Matrix (spreadsheet) identifying priority fixes for adult and juvenile lamprey at mainstem dams. See Attachment B. The spreadsheet identifies relative costs and Corps and CRITFC Lamprey Tribal Task Force (comprised of representatives from CRITFC member treaty tribes) priorities as of March 2020. The priority actions matrix developed by the Corps is not a comprehensive list of ALL the needed fixes for adult and juvenile lamprey at mainstem dams. It should be regarded as a starting point of known and immediate needs to be addressed in the near-term. From this list, the Lamprey Tribal Task Force identified a subset of high priority actions at recent meetings. Those included (1) a. Improving juvenile downstream passage and survival through Columbia and Snake river dams; b. Monitoring and evaluation of juvenile survival and passage success through mainstem Columbia and Snake river dams using juvenile lamprey acoustic tags, (2) Structural modifications to fishways at Columbia and Snake River dams to improve upstream adult passage efficiency and success, (3) Enhancement of the tribal translocation program through improvements to adult trapping systems, and improvements to existing and development of new adult holding facilities at Bonneville, The Dalles and John Day dams, and (4) Assessing the fate of adult lamprey in the lower Columbia River between Bonneville and John Day dams through acoustic telemetry. The Corps is currently working on developing revised cost estimates and timelines for the projects identified in the spreadsheet, which could alter priority rankings. https://www.bpa.gov/efw/Analysis/NEPADocuments/nepa/Nez_Perce_Hatchery/NPTH_Final%20EA_01_30_2019.pdf 6 https://www.critfc.org/wp-content/uploads/2019/01/19-01.pdf. This report contains and excellent summation of lessons learned and extensive references. 7 Email from Ian Chane, USACE CENWP to multiple recipients concerning SCT July Meeting including prioritization spreadsheets, dated July 17, 2018. See Attachment A. 8http://pweb.crohms.org/tmt/documents/FPOM/2010/Task%20Groups/Task%20Group%20Lamprey/10%20Year%20Lamprey%20Plan%20update%20final%202015.pdf CRITFC DEIS Comments April 13, 2020 Page 13 of 59 These lamprey actions have been funded through the CRFM. If the CRFM is dismantled as indicated by the cost assumptions in Appendix Q and discussed above, the DEIS fails to disclose how the Corps participation in the lamprey passage program be accomplished. The Corps recently allocated $20 Million of workplan funding towards lamprey, which is great news, but that money in only available and will only fund lamprey efforts through about 2022. With a proposed 25-year term for the EIS, and the CRFM budget dwindling, the continuation of and support for needed lamprey effort is highly uncertain and is not disclosed or analyzed in the DEIS Each of the MOs contains the same partial list of lamprey measures, which only address a portion of the lamprey priority list identified above. The EIS should include the whole priority list as possible actions for the 25-year term of the EIS. The lamprey measures seem to be focused at dams within the Portland District and not the Walla Walla Districts projects (McNary Dam upstream to Lower Granite Dam). For instance, with regard to adult passage modifications, the action list for McNary Dam and the Snake River dams upstream is limited to rounding 90-degree corners at fish ladders. Rounding ladder features is an inexpensive and short-term process, yet the scope of the DEIS, without further NEPA analysis, could preclude other adult passage measures at the Walla	The co-lead agencies recognize the importance of Pacific lamprey and will continue to work with CRITFC, CRITFC member tribes, and regional entities through existing frameworks such as the Corps-Tribal Lamprey Work Group, the Pacific Lamprey Conservation Initiative and the Corps Regional Forum workgroups (e.g., FFDRWG) to implement ongoing programs, as well as the lamprey measures described in the Preferred Alternative. The analyses completed and described in this Draft EIS were for the purposes of comparing the effects of the multiple objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs related to lamprey, such as habitat restoration, reintroduction and translocation, and other efforts. Measures identified in the Draft EIS do not include all lamprey passage improvements that could be potentially implemented at the lower Columbia and lower Snake River dams, but the Corps believes that potential actions contemplated in preliminary lamprey program planning discussions with CRITFC staff and others related to the 2018 Accords Extensions are consistent with the measures and analyses included in the Draft EIS. CRITFC is correct that actions beyond the scope of the measures included in the Draft EIS or ongoing activities would potentially require further NEPA analysis. Lamprey measures identified in the Draft EIS (and similar operational or structural measures) do not include research, monitoring or evaluation actions that may be needed to refine passage designs, inform operations, or address critical uncertainties. This includes the juvenile lamprey and adult lamprey migration behavior and fate studies identified in the 2018 Accords Extensions and in subsequent program planning and coordination discussions with CRITFC and others. For the purposes of the Draft EIS, measures must address known operational and structural issues, but this does not preclude development and implementation of future juvenile and adult lamprey studies. For Columbia River System dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is a result of significant investments in construction of components of the dams for the benefit of improved salmon passage. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps will continue to express capability in the annual budgeting process. Implementation of all measures including lamprey measures is dependent on funding availability. In 2020, the Corps did receive $20M in funding to implement actions contemplated in the 2018 Accords Extensions. As noted by CRITFC, and in similar comments from CTUIR, the Corps is currently refining cost estimates and developing a preliminary implementation plan for this $20M program. The Corps will continue to coordinate closely with CRITFC and other Accords tribes on prioritization of actions within this program and will continue to ensure consistency with measures identified and analyzed in the Draft EIS.

				Walla District projects during the following 20-year period. Failure to return Pacific Lamprey to the Snake River Basin is unacceptable. The DEIS fails to disclose and analyze the effects of its alternatives on Snake River lamprey populations.	
31775	25	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- The DEIS Fails to disclose and analyze the need for a comprehensive predator control program Both the Northwest Power and Conservation Council and Columbia River Treaty Tribes visions for predator management recognize the value of a coordinated and systematic approach to predator management which are described below: Wy-Kan-Ush-Mi Wa-Kish-Wit Since the publication of the tribes Spirit of the Salmon Plan in 1995 (Wy-Kan-Ush-Mi Wa-Kish-Wit) an alarming increase in predation of salmon, lamprey, and juvenile sturgeon by birds, marine mammals, and other fish has occurred (Rieman et al. 1991; Collis et al. 2002; Evans et al. 2012; Stansell et al . 2010). In the basin, newly created habitat from navigation dredge spoils increased predacious bird populations; a lack of historical primary food sources brought more hungry sea lions upriver who congregated at Bonneville Dam to feed on Spring Chinook; and changes in the CRS flow regime and the explosion of exotic species in CRS reservoirs gradually expanded predacious fish populations. These negative changes in avian, mammalian, and fish species population dynamics have tipped the predator/prey balance to the point that active management is required to rebalance predator populations and reduce salmon, lamprey, and sturgeon losses.	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from fish, pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of a comprehensive predator control program throughout the Columbia River basin. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes and to comply with all pertinent laws. Under the ESA, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Ultimately, recovery is a broader regional goal that is the role of NMFS and the USFWS and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Based on our analysis in the fish resources section of Chapter 7, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation, would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy."
31775	26	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Active management will keep predators at a level that is more in balance with the environment and reduce losses of Columbia River salmon and other native fish populations. Responding to these observations the tribes recommended the following actions in 2014: CRITFC DEIS Comments April 13, 2020 Page 14 of 59 Develop a common metric for fish, bird, and marine mammal predation (i.e ., adult equivalents) so that comparisons and impacts can be properly assessed . Investigate, monitor, evaluate, and propose solutions to habitat changes at Columbia River tributary confluences where hydro- logic modifications have resulted in increased sediment deposition and potentially attracted predator responses. Investigate indirect food web effects of predation. Apply active, adaptive management practices to predation sources. Pursue legislative solutions to barriers preventing active management. Persuade co-managers to prioritize salmon management in anadromous waters and remove barriers to harvest non-native fish species. Focus public outreach on benefits of native fish communities and balanced ecosystems. Develop greater cross-agency cooperation and investigation opportunities.	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation and adaptive management of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing common metrics, identifying measures, and implementation of measures that will aid in the reduction of predation impacts and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies, many of the items listed are outside the co-lead agencies' authorities. The Preferred Alternative includes a large suite of predation mitigation measures. Some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary.
31775	27	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	https://plan.critfc.org/assets/wy-kan-update.pdf A recent presentation by CRITFC to the NW Council is attached to these comments. See Attachment C. The DEIS fails to disclose and analyze the tribes proposals for comprehensive predator management.	The co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from fish, pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value in a comprehensive predator control program throughout the Columbia River basin. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes and complies with all pertinent laws. Under the ESA, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Ultimately, recovery is a broader regional goal that is the role of NMFS and the USFWS and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Based on our analysis in the fish resources section of Chapter 7, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation, would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
31775	28	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	NPCC Fish and Wildlife Program In its most recent Fish and Wildlife Program, the Northwest Power and Conservation Council also recognized the growing impacts of predators on the anadromous fish of the Columbia River Basin. Predator management is requiring more program resources and efforts year by year. Everyone involved in the program, including the Council, Bonneville, the Corps of Engineers, the fish and wildlife agencies and tribes, and others, must work together to continue developing a more effective systemwide, ecosystem-based approach for assessing and addressing the impacts of fish, avian, and pinniped predation on salmon and steelhead and other fish species important to the program. It is imperative to scientifically advance the understanding of predation impacts. It is important to understand which predator management actions have the greatest effect on adult returns and SARs and retarget efforts on those actions for cost-effective predation management. https://www.nwcouncil.org/sites/default/files/2020-1.pdf. The Program contains systemwide measures for predator control that are directed to Bonneville, the Corps, Bureau of Reclamation and others for their implementation. For example, the Program provides: Predation by double-crested cormorants, Caspian terns, and several other bird species continues to have a significant impact on ESA-listed juvenile salmon and steelhead in the Columbia and Snake rivers. A recent trend has been reduced support for this effort. The action agencies (Bonneville, Corps of Engineers, Bureau of Reclamation) working with state and tribal partners, should continue to provide adequate funding to implement activities, both in the estuary and inland, to reduce avian predation on listed juvenile salmon and steelhead. CRITFC DEIS Comments April 13, 2020 Page 15 of 59 In contrast, the CRSO DEIS contains parsimonious mitigation measures for predators, which are non-responsive to the broader guidance from the tribes and the Council. Thoughtful analyses of the Northwest Power Act requirements and the obligations to implement Councils Program regarding predator management are not to be found in the DEIS. We would have expected a more programmatic responses from the co-lead agencies, for instance committing to fund a Regional Predator Management Forum, with additional monitoring, that includes all funding and implementation partners to collaboratively and comprehensively evaluate and address predation (including piscivorous, avian, and pinniped predation) on salmon and steelhead from the river mouth to the spawning grounds. CRITFC DEIS Comments April 13, 2020 Page 16 of 59	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing regional management forums, common metrics, and implementation of measures that will aid in the reduction of predation impacts and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes and complies with all pertinent laws. Ultimately, it is beyond the co-lead agencies authorities and responsibilities to fund a Regional Predator Management Forum, with additional monitoring, that includes all funding and implementation partners to collaboratively and comprehensively evaluate and address predation (including piscivorous, avian, and pinniped predation) on salmon and steelhead from the river mouth to the spawning grounds. Specifically, under the ESA, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species such as addressing all predation (including piscivorous, avian, and pinniped predation) on salmon and steelhead from the river mouth to the spawning grounds. Ultimately, recovery, including any predation management actions that are need to achieve recovery, is a broader regional goal that is the role of NMFS and the USFWS and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on our analysis in the fish resources section of Chapter 7, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation, would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies.
31775	29	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	V. Proposed Alternative The Draft Proposed Alternative (PA) is based on 2021 operations under the Flex Spill Agreement, although it unilaterally incorporates significant modifications. While increasing spill to a 125 TDG flex spill operation, the numerous changes from the Flex Spill Agreement threaten to make the PA operation worse for salmon and steelhead than the 2020 operations under the Flex Spill Agreement a change in the wrong direction. Below are further detailed comments on individual measures presented in the Draft PA, however the following summary of our concerns paints a composite picture. In short, the benefits of a 125 Flex Spill Operation are systematically eroded by one power measure after another such that fish benefits are degraded to an unknown degree. In the end, the PA presents only slightly improved fish survival (if any) compared to the NAA, and those conclusions are based upon multiple layers of uncertainty. The charts below describe these effects in more detail. Among other things, the PA reduces spring flows through altered water management operations at Libby, Coulee and Dworshak. This means less spring flow for Upper Columbia stocks, and this would occur in all years, not just high flow years. At Dworshak, the additional winter drawdown would be based on unreliable and uncertain early season runoff forecasts, which could similarly reduce spring flows in the Snake to the detriment of Snake River salmon and steelhead stocks. The impacts to the Upper Columbia stocks are especially troubling due to their current condition and the limited benefits provided to them from Flex Spill operations.	In its analysis of effects, the Draft EIS used current high quality information and best science, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. Modifications to the No Action Alternative, such as changes in flows, were incorporated into the fish modeling. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that will assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It was the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. Chapter 7, Section 7.7. in the Draft EIS analyzes the effect of the Preferred Alternative on flow, relative to the No Action Alternative. While the comment is correct in that the new water management measures will result in less spring flow, the reductions are relatively minor. For example, flows at McNary Dam (Table 7-17) show relatively minor decreases, the largest being 2% (4.4 kcfs) in May at the 99% exceedance probability. Other spring flows are within 1% of the No Action Alternative.
31775	30	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	In addition to the spring flow changes, the PA includes several other measures with detrimental or unknown effects on anadromous salmonids: - Options for unrestricted turbine flexibility operations outside of peak efficiency with unknown levels of impact and no mitigation proposed;	The co-lead agencies are coordinating guidelines and limitations for operations outside the 1% operating range with the National Marine Fisheries Service and the US Fish and Wildlife Service (Services). During the fish passage season, the co-lead agencies will meet all required fish passage spill operations before operating above the 1% operating range. The proposed action in the Endangered Species Act consultation associated with the CRSO EIS includes monthly summaries of operations above the 1% operating range and an annual report on operations outside of the 1% peak efficiency range. After three years, the Services and the co-lead agencies will analyze data related to this operations and determine future operations.
31775	31	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Fall-time zero generation (zero flow) in the Snake (effects unknown on adult fall chinook, steelhead, and coho, and on juvenile fall chinook) with no mitigation proposed;	Extending the zero generation operation measure would not affect juvenile salmon or steelhead because they are not migrating in the late fall/winter timeframe when this measure occurs. However, impacts to adult passage (especially for Snake River steelhead) may be anticipated due to this operation. Because of the short overlap with the adult fish migration period, and limiting the operation to nighttime hours, this effect was considered to be minor. As with other operational measures in the Preferred Alternative, the impacts of the zero generation operation measure will be evaluated through the Regional Forum and adaptively managed as needed. In this EIS process, the co-lead agencies only develop mitigation for measures that result in moderate to major effects as compared to the No Action Alternative.
31775	32	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Reliance on already implemented or phased out actions (structural and avian) with no commitment to ensure benefits of those efforts are implemented and maintained over time;	The Preferred Alternative includes the actions in the No Action Alternative, unless specified otherwise. Structural improvements made over the past decades will continue to operate in the Preferred Alternative. The Preferred Alternative includes a large suite of predation mitigation measures, maybe of which are ongoing from the No Action Alternative. These include: maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary.
31775	33	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Options to reduce Fish and Wildlife Program with no metric or decision framework identified for evaluating that option;	Funding decisions for the Fish and Wildlife Program are not being made as a part of the CRSO EIS process. However, a range of potential Fish and Wildlife Program costs are included to inform the broader cost analysis for each alternative in the EIS. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments to the Fish and Wildlife Program would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements.
31775	34	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	and - No additional fish mitigation, other than JDA operations for birds; almost all mitigation measures are for power flexibility that will result in negative impacts to fish.	The Preferred Alternative includes actions that benefit fish species and habitat through additional measures, ongoing programs, mitigation measures, and ESA consultation. As described in Section 7.6.1, a number of measures that are carried forward, modified, or added from the alternatives in Chapter 2 are intended to improve survival of anadromous salmon and steelhead, lamprey, and resident fish. Some examples are structural measures for lamprey passage, juvenile fish passage spill operations, and predator disruption operations. Section 7.6.4.1 provides summaries of the ongoing programs that would be carried forwarded in the Preferred Alternative. The majority of those ongoing programs are mitigation currently being implemented. Additional mitigation measures identified to offset effects from measures in Section 7.6.1 are presented in Section 7.6.4.2 that include mitigation measures for fish effects (Plant Cottonwood Trees (Up to 100 Acres) Near Bonners Ferry

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					for resident fish and Temporary Extension of Performance Standards Spill Operation for adult salmonid passage delays). Section 7.6.4.3 describes the measures incorporated into the Preferred Alternative as a result of informal and formal ESA consultation. The Bull Trout Access to Perched Tributaries in the Kootenai River measure includes both completing an assessment and two projects for upstream passage. The Surface Spill to Reduce Take of Overshooting Adult Steelhead measure would provide an operational method to address the overshooting steelhead.
31775	35	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The PA action is then only fixed for one year, so all out year operations are highly uncertain. The PA points to the Adaptive Management Appendix for future year operations. This Adaptive Management Framework adds in significant additional uncertainty for fish benefits: - While written in the form of changes needed for fish, the appendix would allow for decreases in spill and other unknown actions that could have detrimental fish effects, with no real assurances that tribal or regional input would be adopted. Based on experience, it CRITFC DEIS Comments April 13, 2020 Page 17 of 59 is likely that the co-lead agencies will act in the interest of their primary agency missions (power, flood control, irrigation and navigation) without providing fish and wildlife equitable treatment in decision making.	The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. The co-lead agencies do not feel that the short-term nature of this operation is an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies will provide additional clarifying text in Appendix R to make these points more clearly.
31775	36	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	#NAME?	The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the Columbia River System Operations EIS. It was the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. Appendix R, Part 2 also contains the following principle to guide evaluation of the spill operations in relation to impacts on fish: Provide fish benefits, with the understanding that (i) in 2019, overall juvenile fish benefits associated with dam and reservoir passage through the lower Snake and Columbia rivers during the spring fish passage season must be at least equal to 2018 spring fish passage spill operations ordered by the Court, and (ii) in 2020 and 2021 , these fish benefits are improved further (as estimated through indices of improved smolt-to-adult returns, e.g., PITPH, reservoir reach survival, fish travel time)....
31775	37	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Moreover, the minimal fish benefits attributed to the PA rely on unknown benefits from reductions in latent mortality and are otherwise biased high. First, the base COMPASS model does not account for latent mortality and only shows benefit of the PA above the NAA when an its arbitrary range of latent mortality rates are employed in the model. Second , the CSS model results are biased high due to the selected model inputs, (i.e.; daily time steps in operations data rather than hourly time steps consistent with Flex Spill operations, operations data sets did not include fully loaded powerhouse operations like we see in reality, so spill proportion is weighted higher than reality). The PA fails to mention these important factors or take them into consideration.	The co-lead agencies do not agree that predicted fish benefits are minimal. Predictions vary by model and range from moderately negative to major beneficial. The Draft EIS acknowledges that the NMFS models incorporate latent mortality effects through a sensitivity analysis rather than direct estimation. The co-lead agencies do not agree that results are biased high due to hourly vs. daily time steps. These models will be used to assess relative changes so minor bias if present would not be enough to change relative magnitude of the effect. The co-lead agencies do not agree that powerhouse operations were modeled incorrectly. Powerhouse estimates reflect historic availability and known future outages. In practice, it is rare for all units at a project to be available simultaneously for long durations. Powerhouse units undergo planned and unplanned outages at a frequency that is reflected in the models.
31775	38	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Based on the above, additional elements will be needed for the PA to cushion or otherwise address the inherent uncertainty in the action. These may include: - More mitigation to offset measures for hydro flexibility and unknown benefit of Flex Spill; - Maintained or increased Fish and Wildlife Program spending in order to improve from 2016/NAA baseline and not just maintain status quo survival statistics; - A charter identifying side boards on the Appendix Flex Spill Workgroup and clear definition for decision making framework within it; and - Check-ins and/or off-ramps. The PA rests on significant uncertainty and degrading fish populations; the availability of immediate and significant action is required. The DEIS does not disclose or analyze these additional measures.	The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the CRSO EIS. The co-lead agencies intend to develop this more fully with regional experts to more clearly define the decision-making process, including those items that trigger the need for a decision to be made. Additionally, the Preferred Alternative includes the mitigation measure, "Temporary Extension of Performance Standard Spill Levels" to address to address potential adverse impacts to from increased juvenile fish passage spill operations.
31775	39	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	A. The PAs Assertions of Consideration of Tribal Interest in Fisheries and Tribal Resources is Unfounded The statements regarding respecting treaty rights are unsupported by the PA. There are numerous references to respecting treaty rights and tribal culture; yet, the PA is a deceptive approach to salmon and steelhead protection saying one thing and doing another by reducing current actions and suggesting future reductions to offsite mitigation based on results we will not see for 20 years. We find little or no evidence that our input has been incorporated within most sections of the DEIS. As discussed below, the PA fails to improve salmon survival, and fails to address whether conditions will meet the tribal goals described in the Tribal Perspectives document.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource.
31775	40	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	B. Water Management Measures Make PA Worse for Fish Than The 2020 Flex Operation The PA proposes to move water from spring into January at Coulee, Libby and Dworshak, creating a worse situation for many salmon and steelhead stocks than we currently have with the 2020 Flex Spill Agreement. While different rationales are given, primarily, these operations provide for more power flexibility. This additional power flexibility was not part of the 2020 Flex Spill operations under the Flex Spill Agreement. The new drafting operations are not limited to high flow years but would also occur in average and low flow years and would occur in 75% of all water years. Incredibly, at Libby, the operation states that they will draft deeper in January when inflow forecasts are less than 6.9 MAF, which is most years. From a fish perspective, this is backwards thinking. These new power flexibility operations will result in less spring flows for both Upper Columbia and Snake River stocks, likely resulting in higher water temperatures as well. Flow timing and volume have been proven to be two of the most important factors for juvenile migration, travel times and survival.	Chapter 7, Section 7.7. in the Draft EIS analyzes the effect of the Preferred Alternative on flow, relative to the No Action Alternative. While the commenter is correct in that the new water management measures will result in less spring flow, the reductions are minor. For example, flows at McNary Dam (Table 7-17) generally show minor decreases, the largest being 2% (4.4 kcfs) in May at the 99% exceedance probability. Other spring flows are within 1% of the No Action Alternative.
31775	41	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Deeper drafts at Dworshak (DWR) are included as a measure to help Total Dissolved Gas (TDG) issues at nearby hatcheries. However, TDG issues are only a concern during high flow events when large volumes of water need to be moved and turbine units are not available, as was witnessed in 2017. A deeper draft would not have helped in 2017 since turbine units were unavailable to move the water. The DWR drawdown is really another operation to increase power flexibility, but at the risk of not refilling the reservoir and/or decreasing spring flows both of which have salmon impacts. Failure to reach full pool reduces summer flow augmentation and lower Snake water temperature management capacity. Moreover, the decision timeframe of December/January for determining whether to drawdown DWR is not implementable; adequate information is not available at that time.	The comment is partially correct. The deeper early draft in high water years simply moves some of the draft into January and February, thus spreading it out and reducing TDG. It does result in increased power generation. In high water years that start building early, there is information to base the deeper draft on. It can potentially have a negative impact on refill, but the implementation rules would minimize that impact. 2017 is not a reasonable year to base analysis on since Unit 3 was not available. In most years, we have three turbines available but are only running one small unit instead of full power house. The current drawdown approach moves most of the flood risk management water in March and April when we have little additional capacity, resulting in more spill which elevates TDG. The deeper draft would really be best described as an earlier draft since it moves part of the flood risk management draft into January and February. Before the operation could be implemented, additional analysis, rule curves, and forecasting procedures would need to be approved for the reservoir. The comment is potentially is correct in that a information for a decision of December/January for determining whether to drawdown DWR may not be available at that time each year.
31775	42	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	While the flow changes from each of the above measures may not be large, their combined effects could add up to significant flow reductions in the river. Moreover, the actions are changes from the power flexibility operations agreed to for 2020 under the Flex Spill Agreement, therefore representing power benefits and fish detriments from the 2020 operations that fulfilled the Agreement. The DEIS failure to provide explanations, limitations, and mitigation are unacceptable.	Flows at McNary Dam should capture the combined effects of the changes to upstream reservoir releases. For the preferred alternative, flows at McNary Dam (Table 7-17) show minor decreases, the largest being 2% (4.4 kcfs) in May at the 99% exceedance probability. Other spring flows are within 1% of the no action alternative. The Flexible Spill operation measure is guided by the Fish Benefit Principle: provide fish benefits, with the understanding that (i) in 2019, overall juvenile fish benefits associated with dam and reservoir passage through the lower Snake and Columbia rivers during the spring fish passage season must be at least equal to 2018 spring fish passage spill operations ordered by the Court, and (ii) in 2020 and 2021, these fish benefits are improved further (as estimated through indices of improved smolt-to-adult returns, e.g., PITPH, reservoir reach survival, fish travel time). As with other operational measures, the Flexible Spill operation will be adaptively managed as needed through the Regional Forum. In this EIS process, the co-lead agencies only developed mitigation for moderate to major effects of action alternatives as compared to the No Action Alternative.
31775	43	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	C. Increased Turbine Pperation Flexibility Lacks Sideboards on Implementation The PA includes operation of turbines outside of the long-established 1% range. While some excursion is acceptable, the current way it is written is too broad and would allow excursions anywhere and for any reason. At some projects, operating outside of 1% have almost no impact since the turbines do not have capacity beyond 1%. However, other projects such as McNary could be operated 4-6 kcfs higher per turbine which equates to over 50 kcfs swing in flow moved from spill to the turbines. These matters are not disclosed in the DEIS. Meanwhile, the effects analysis assumes operation within the 1% bound. Specific alternative sideboards were not CRITFC DEIS Comments April 13, 2020 Page 19 of 59 disclosed or analyzed in the DEIS. The PA fails to demonstrate how the co-lead agencies will work with regional managers to come up with a mutually acceptable plan that considers individual project data and operations to create sideboards on turbine operations outside of 1% efficiency.	Operations that impact fish are reviewed and discussed within the Regional Forum groups and adaptively managed as needed. These groups will be utilized to review the impacts of operations above 1% peak efficiency.
31775	44	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	D. Structural Fish Measures Provide Little Benefit to Anadromous Salmonids Many of the PAs structural measures have little to no benefit for salmon and steelhead and should not be listed as beneficial to fish. Most of these fish measures appear to provide a hydro-power benefit instead, which is a step back from the Flex Spill Agreement. Those included in the PA are less than what was proposed in the multi-objective alternatives. For example, the Lower Granite Trap modifications and the Bonneville Serpentine Weir both have reduced scope providing almost no benefit above the NAA. In addition, most of the structural measures listed in the PA are already completed. Although they are additions to the NAA, their status towards completion should be clarified. The Columbia River Fish Management (CFRM) Program is characterized as being complete in 10 years since few new actions have been identified. The PA fails to accurately portray the minimal fish benefits associated with limited structural measures included in the PA and clearly identify that most have already been completed. Additional structural measures were not disclosed or analyzed in the mitigation toolbox to ensure NEPA coverage and to support appropriate commitments in the CRFM budget. The BA and DEIS fail include (but not be limited to) all actions currently on the SCT list. The scope of the DEIS must be sufficiently broad to provide NEPA coverage for all structural measures in the current Systems Configuration Team (SCT) spreadsheet analyses. The PA fails to provide for continued implementation of high priority measures from the SCTs analyses.	The co-lead agencies agree that the structural measures proposed in the Draft EIS provide small incremental benefits to fish survival when compared to increased spill or dam breach as modeled by CSS. There are two explanations for this: 1. Latent mortality, as modeled by CSS assigns a large survival benefit (Smolt-to-Adult return rates) associated with large reductions in powerhouse passage and 2. the overhaul of the four lower Snake and Columbia River dams is near completion. All the big structural fixes, such as surface flow bypass, juvenile bypass systems and improvements, spillway improvements, avian predation deterrence, adult ladder improvements, have been constructed. What remains in the CRFM budget and SCT spreadsheet is completion of that construction effort. Funding for operating and maintaining the facilities that were constructed under this overhaul will continue into the future. The remaining actions on the SCT list are almost exclusively recommendations from past BiOps, and as such are being carried into the Preferred Alternative from the No Action Alternative. Unless otherwise noted, all other actions that were planned or part of ongoing CRS operations and maintenance in 2016 when the EIS was initiated are included as part of the Preferred Alternative. Therefore, the items in the SCT sheet will have continued NEPA coverage.
31775	45	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	E. The DEIS Fails to Meaningfully Disclose and Analyze That Corps Reliance on O&M Funding to Meet its Fish Obligations Will Be Increasing but the Current Corps O&M Funding Trajectory is Negative. The PA indicates that most of the Corps actions will shift to an O&M (Operations and Maintenance) funding source, however Corps commitments to O&M funding are declining (per Ian Chaine, U.S. Corps of Engineers. See surpa FN7). Actions included in the PA that would rely on O&M funding include replacement and upgrades to existing system, continued implementation of existing management plans (e.g., avian predation plans), and multiple lines of research, among others. Most of these items are presumably subsumed as continuing actions	The Corps' operation and management budget has long been relatively flat, and in the past two decades the number and complexity of the fish passage facilities to maintain has grown, yet the Corps has managed to adequately operate and maintain those facilities. Much of the major overhaul of the CRS for the benefit of improved fish passage has already been constructed and turned over to our O&M budget. So we dont expect new growth to our O&M costs relative to what we had historically. We will request funding for the required actions, including funds to operate and maintain the CRS, however funding is never guaranteed and therefore all actions are contingent on funds being available.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				under the NAA, but they are not disclosed or analyzed, with continuing implementation assumed. The lack of certainty surrounding full implementation of these actions due to lack of funding is not disclosed or factored into the DEISs analysis	
31775	46	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	F. Fish Effects Analysis Depicts Minimal Improvements Based on High Levels of Uncertainty CRITFC DEIS Comments April 13, 2020 Page 20 of 59 The analysis in the PA does not determine what benefits to salmon and steelhead are expected or needed, nor does disclose a goal. The regional SAR goals are not discussed in the DEIS; the stated goals are merely any improvement without a quantitative goal. The analysis depicts almost little to no benefit for many of the stocks and when one considers confidence intervals (not shown in the summary chapters of the DEIS only in the appendix) there is not a statistical difference between the PA and NAA (base case). The following charts help to visual this point. Notably, the analyses do not indicate whether the measures result in increasing abundance trends towards the NPCC goal of 5 million salmon and increasing steelhead and SARs between 2 and 6 percent? The DEIS fails to disclose that progress towards achieving the NPCC goal should be one of the metrics to determine success of FCRPS hydro operations and mitigation measures. - Predicted survival benefits are minimal The following charts are used to compare the Preferred Alternative to the other Multiple Objective Alternatives and the NAA (Base Case) operation. The comparisions are based on SARs and juvnile reach survival generated from the fish models used in the DEIS. Figure 1 CSS SARs for yearling Snake River Chinook Comparison between DEIS Alternatives CRITFC DEIS Comments April 13, 2020 Page 21 of 59 Figure 2 CSS Yearling Snake River Chinook Juvenile Reach Survival from LGR to BON (Top Chart) and relative performance (Bottom Chart) compared to NAA (base case operation) using the cohort-specific model. CRITFC DEIS Comments April 13, 2020 Page 22 of 59 Figure 3 Snake River Steelhead SARs (top) and relative performance (bottom) using the cohort-specific model. The red dashed line in the upper panel represents NPCC average SAR goal of 4%. Figure 4 CSS Snake River Steelhead Juvenile Reach Survival from LGR to BON (Top Chart) and relative performance (Bottom Chart) compared to NAA (base case operation) using the cohort-specific model	Based on our analysis of the Preferred Alternative, it will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals like those mentioned in this comment are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council (Council) recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the 4% average SAR target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
31775	47	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- The DEIS fails to disclose that the PAs Flex Spill operation relies on latent mortality assumptions to show fish benefits The NOAA life cycle model analysis performed for the PA analysis relies heavily on assumptions regarding improvements in Latent Mortality to achieve any benefit when compared to the NAA (base case). Latent mortality is associated with powerhouse passage. Analyses have shown that juvenile fish that pass-through powerhouses experience a decrease in survival at later life stages compared to their spillway passed cohorts. Latent and delayed mortality refers to subsequent mortality at later life stages after the initial powerhouse passage experience. The CSS model is based on relationships built on SARs calculated from different passage routes from the long data time series of past years of adult returns (empirically based). CSS model analyses of CRSO EIS do not require any assumptions regarding delayed mortality. Delayed/latent mortality that occurs is captured in the SAR metric. NOAAs life cycle model (including its COMPASS component) does not include delayed/ latent mortality. Arrival time of juvenile salmon and steelhead to below Bonneville is the primary metric in COMPASS analyses used to access operational alternatives (including the PA). CRITFC DEIS Comments April 13, 2020 Page 23 of 59 The CSS model does show a slight improvement in SARs for the PA when compared to NAA (base case) since the PA reduces Pit-PH (powerhouse passages). Pit-PH is an index to estimate the number of fish passing powerhouses. However, the improvement described in the DEIS of 35% is a relative improvement however the resulting absolute SAR with the PA, is still small and below the regional 4% SAR goal. Conversely, the NOAA life cycle model does not show an improvement in the PA and actually shows it can be worse than the NAA (base case). NOAA modelers add a latent mortality adjustment factor into their model and arbitrarily used a range of values (0 50%). Once the latent mortality adjustment was used NOAAs Life Cycle Model did show a benefit when a 25% latent mortality reduction factor was added to the modeling, see appendix E. We agree that latent mortality is an important factor that needs to be considered, but the PAs use of the NOAA modeling relies solely on this assumed improvement to achieve even the modest improvements when compared to the NAA (base case). Any benefits of the PA in the NOAA analysis are questionable, because the NOAA latent mortality assumption lacks an empirical basis. If latent mortality improvements are less than this 25% threshold this could result in no benefit from the PA. The CSS analyses of the PA estimate that at low flow and poor ocean conditions, the predicted SAR with the PA is less than 1% which is less than population replacement levels. CSS analyses show that with implementation of the PA, predicted SARs are below the 1% SAR population replacement level, 36% to 39% of the time. For these reasons we believe that additional mitigation actions are needed to ensure benefits are realized. Furthermore, additional monitoring and research should be conducted to evaluate how the PA operation is performing. See recommended addition mitigation and actions below.	The model results presented in Section 3.5 and Chapter 7 address latent mortality and reservoir mortality. Multiple mechanisms of delayed mortality or 'carryover effects' between experiences in one lifestage influencing survival or physiology in subsequent lifestages (Gosselin et al. 2018). These include transportation related delayed mortality, injuries caused by passing multiple dams via any route, delays caused by reservoir and dam passage, and exposure to toxins. Latent mortality is captured directly in the CSS model for SARs and abundances. NOAA approached latent mortality as a sensitivity analysis, exploring the level of effect by latent mortality occurring via any mechanism - results of the Lifecycle Model are overlaid with several assumed values (10%, 25% and 50%) of reduction in latent mortality. Reservoir mortality is captured in the juvenile survival metrics presented in Chapter 3. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the Draft EIS. In their 2007 report the ISAB stated, "The ISAB concludes that the hydrosystem causes some fish to experience latent mortality, but strongly advises against continuing to try to measure absolute latent mortality. Latent mortality relative to a damless reference is not measurable. Instead, the focus should be on the total mortality of in-river migrants and transported fish, which is the critical issue for recovery of listed salmonids. Efforts would be better expended on estimation of processes, such as in-river versus transport mortality that can be measured directly." Gosselin, J. L., Zabel, R. W., Anderson, J. J., Faulkner, J. R., Baptista, A. M., & Sandford, B. P. (2018). Conservation planning for freshwater-marine carryover effects on Chinook salmon survival. Ecology and evolution, 8(1), 319-332. The results of third-party review, both the Corps' Independent Expert Peer Review as well as a recently released ISAB review of the CSS results have been included in the Final EIS. Initial review of the results of the peer review do not indicate fundamental flaws in either the CSS or NMFS approach and both models will continue to frame the potential outcomes associated with all MOs and the Preferred Alternative. Survival estimates from the University of Washington TDG model were not relied on for decision-making purposes but will be used to assess relative exposure indices. As noted by the ISAB in their review of the CSS model results generated for this EIS (ISAB 2020-1), changing climate conditions should be carefully assessed when considering potential impacts to salmon and steelhead, but the co-lead agencies note the concerns raised by the ISAB regarding the CSS's quartile range analysis and the likelihood or probabilities of SARs falling below 1 percent or above 2 percent. The co-lead agencies will evaluate that analysis as it evolves but are not relying on the probability analysis at this time.
31775	48	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Due to erroneous operating assumptions provided by the Co-Lead Agencies, the modeling analysis of fish benefits is biased high All analyses by NOAA and the CSS were based on 80-year water record model generated data sets from the USACOE. The PA represents an operation that is based on an hourly operation, but the data sets provided to analyze the PA were based on daily average operations. The anomalies in the PA data sets were identified in a memorandum to the federal co-lead agencies (discussed below). The discussion of the benefits of the PA does not address the effect of the disparity of the data sets relative to the proposed operations. Specifically, the implications of analyzing an hourly operation (the PA) on the basis of a daily average operation (the PA data set), is not discussed in the DEIS. The PA fails to account for the fact that the data sets provided to the CSS project were in daily average time steps, yet the proposed operation occurs on an hourly time step therefore raising doubts regarding the results. The CSS (memo January 24, 2020) highlighted their concern that the CSS predicted benefits are overestimates of predicted SARs. This creates a CSS analysis which shows more benefit to survival than is likely to occur (biased high). In addition, the hydraulic data sets have powerhouse operations that do not represent reality. Instead of fully loading the powerhouse when possible as is common practice, flow through the powerhouse reduced which results in more spill occurring then would actually occur. CRITFC DEIS Comments April 13, 2020 Page 24 of 59 This would bias the fish models into to predicting better survival then what would occur. The DEIS PA fails to mention this or take the biological effect into consideration.	The co-lead agencies do not agree that results are biased high due to hourly vs. daily time steps. These models will be used to assess relative changes so minor bias if present would not be enough to change relative magnitude of the effect. In practice, model estimates may not overestimate PITPH due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of nighttime spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. These examples of adaptive management will continue during implementation of selected operations. Regarding the statement that powerhouse operations were modeled incorrectly: powerhouse estimates reflect historic availability and known future outages. In practice, it is rare for all units at a project to be available simultaneously for long durations. Powerhouse units undergo planned and unplanned outages at a frequency that is reflected in the models.
31775	49	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- The level of improvement (50% increase in survival) for new turbines at Ice Harbor, McNary, and John Day are unfounded and not supported by past data and research. The PA assumes installation of new turbines at John Day, Ice Harbor, and McNary dams. However, these actions are already planned to occur in the base case so it is misleading that they are identified as new fish benefit in the PA. Furthermore, the DEIS arbitrarily assumed that these turbines would have a 50% improvement in juvenile migrant survival. This assumption is not supported by any available studies. See detailed comments below in our comments on Effects Analysis modeling. Moreover, the PA indicates that generation capacity at John Day and McNary will increase hydraulic capacity. This increase in generation capacity was not included in the hydraulic modeling that was provided to the fish model or the economic models and would impact the results from both models. With more water going through the turbines, economic impacts would be reduced. More importantly, juvenile survival would be decreased (see detailed discussion below). This information needs to be considered against the unsubstantiated survival improvement accredited to the new turbines, something the analysis fails to do.	The measures for Ice Harbor and McNary IFP turbines were included in the No Action Alternative based on the progress made in design, environmental compliance, and implementation. These measures were carried forward in the Preferred Alternative along with the John Day IFP turbine measure. Sensor fish have successfully identified and played a significant role in solving spillway passage injuries at both The Dalles and Ice Harbor. Although certainly not a perfect analogue for a fish, their motions are controlled by the hydraulics of the water and structure impact and do provide a measure of the physical environment fish are passing through. Less violent sheer and turbulence is obviously a benefit for fish. Balloon tags do best represent the potential for trauma to passing fish and not total mortality. Certainly, fewer traumatic injuries would lead to a lower mortality rate. The magnitude of the survival rate increase for naturally passing fish is unknown. Relying on the best available science, the co-lead agencies assumed mortality would be halved. The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Again, the magnitude is uncertain. Turbine intake screens would not be removed, unless a telemetry based survival study demonstrates survival would not be decreased. The opinion that more fish would pass the turbine because of the increase hydraulic capacity is not accurate. The amount of water passing through the powerhouse is actually controlled by operation decisions on spill levels, and is not solely dependent on the hydraulic capacity of the turbines. It should be noted that only turbines at McNary would have increased hydraulic capacity.
31775	50	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Additional bias or uncertainty in the PA analysis did not account for: Zero Generation in the Snake (as proposed for in the fall in the PA) has not been analyzed Avian losses are not accounted for (see below) Significant uncertainty from the Adaptive Management Appendix is not considered and all risk is on the fish side of the equation while minimizing risk on the hydro-power system. Looking at the PA data set in detail, spill plus powerhouse flows does not always equal daily average flow, by a lot. Sometimes water disappears and sometimes there is a lot of extra water (more than fishway flows for instance). Due to the uncertainties and modeling biases, significantly more fish mitigation measures should be considered to counter these uncertainties and allow the PA to be consistent with the NPCC goals of 5 million fish and 2-6% SARs. This was not disclosed or analyzed in the DEIS.	Zero generation operations will be constrained to periods of time when co-lead agencies expect fish impacts to be negligible. Additional analysis on the effects of this operation will be conducted by NMFS during the development of the 2020 Biological Opinion, which will be appended to the FEIS. Outflow through the dams are divided into multiple different types, mainly comprised of the powerhouse turbine flow and the spill. The spill flow has several different components. There is fish spill, powerhouse bypass channel, attraction spill, lack of market spill and forced spill due to lack of turbine capacity. In addition there is also miscellaneous flow, which includes lockages, leakage and other flows. For more information see Appendix B, Part 2: Spill Analysis. Contrary to statements in this comment, the Adaptive Management framework is not designed to increase risk for fish species, in contrast, it is anticipated to reduce overall risk and increase the region's knowledge of the effects of the Preferred Alternative and any reductions in latent mortality associated with passage through the CRS. Appendix R will be revised in the FEIS to clarify that point. Neither of the topics listed above require additional mitigation. In the event that model predictions from either model vary significantly, the co-lead agencies will coordinate with regional parties and consider modifying the associated mitigation package as appropriate. As noted the Northwest Power and Conservation Council's goals of 5 million fish and 2-6% SARs represent targets for broad-sense recovery and are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Even so, and with respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
31775	51	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	G. The DEIS fails to Disclose the Regional Importance of the Northwest Power Acts Fish and Wildlife Program or Analyze Whether the Actions Proposed in the DEIS are Consistent with the Program The DEIS discussion of the Northwest Power Acts Fish and Wildlife Program focuses on the cost of the program, fails to note its benefits, and does not disclose or analyze the individual measures within the Program for which the co-lead agencies have statutory obligations to take into account and implement. In various iterations the Program has been in existence since 1982. The region invests hundreds of millions of dollars in its implementation annually, but here is the thrust of the DEIS discussion. CRITFC DEIS Comments April 13, 2020 Page	Bonneville's Fish and Wildlife Program is first described in Section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. The fish and wildlife mitigation projects that Bonneville funds have been recommended by the Northwest Power and Conservation Council (Council) and either derive from, or have been incorporated into, the Councils Columbia River Basin Fish and Wildlife Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria. And for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Fish and Wildlife Program.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				25 of 59 Each year Bonneville funds projects with many local, state, tribal, and Federal entities to fulfill its Northwest Power Act fish and wildlife responsibilities and to implement offsite mitigation actions listed in various Biological Opinions for ESA-listed species. Offsite protection and mitigation actions, called enhancement, typically address impacts to fish and wildlife not caused directly by the CRS, but there are actions that can improve the overall conditions for fish to help address uncertainty related to any residual adverse effects of CRS management and climate variability on fish and wildlife	Funding decisions for the Fish and Wildlife Program are not being made as a part of the CRSO EIS process. However, a range of potential Fish and Wildlife Program costs are included with the alternative to inform the broader cost analysis for each alternative in the EIS. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments to the Fish and Wildlife Program would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements.
31775	52	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	DEIS 7-39. The benefits of the Fish and Wildlife Program are not adequately disclosed or analyzed. Offsite mitigation is intended to replace survival benefits that cannot be fully addressed through modifying operations of the hydropower system alone 16 USC 839b(h)(8)(A). Offsite protection and mitigation compensate for losses arising from the development and operation of the CRS hydroelectric facilities.	Many of the mitigation programs funded by the co-lead agencies consist of offsite mitigation. Bonneville's Fish and Wildlife Program is primarily an off-site mitigation or enhancement program. See, 16 U.S.C. 839b(h)(8)(A). The co-lead agencies consider actions not at the CRS dam and reservoir projects to improve conditions for fish affected by the CRS to be offsite mitigation actions. This is consistent with the co-lead obligations under various applicable Federal laws, including the ESA and the Northwest Power Act. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. The Northwest Power Act requires Bonneville to fund mitigation consistent with the Northwest Power and Conservation Councils (Council) Columbia River Basin Fish and Wildlife Program (Program) and the purposes of the Act. The Council develops its Program based largely on the recommendations and expertise of fish and wildlife managers. The mitigation projects that the Council recommends to Bonneville for funding derive from their Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under to certain statutory criteria that, for example, include examining whether projects are based on sound scientific principles and benefit fish and wildlife. 16 U.S.C. 839b(h)(10((D)(iv). These statutory processes for vetting and reviewing implementation of mitigation projects provide a reasonable basis for the co-lead agencies to rely on these projects being effective. In addition, for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Program, the underlying assumption being that the mitigation projects address appropriate obligations under the Council Program, and do so effectively. Further information about the policies and mandates of the Northwest Power Act and other statutes is in Chapter 5.1.2, and Chapter 8 discusses how the co-lead agencies complied with various laws, including the ESA and Northwest Power Act.
31775	53	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The NAA alternative assumes the 2016 Program. However, the DEIS fails to disclose and analyze the fact that BPA has reduced Fish and Wildlife Program funding since 2016, cutting the budget by $30M in 2018 due to spill surcharge and negotiated reductions. This reduction in mitigation spending is not accounted for in the PA analysis and creates bias in cost analysis as well as assumptions about the benefits of current mitigation actions. In addition, the co-lead agencies discuss reducing the off-site fish and wildlife mitigation funding if the benefits to fish are as anticipated. The DEIS fails to disclose or analyze what level of benefit (abundance, SARs, etc.) that will drive that discussion and decision. Nor does the DEIS disclose or analyze the process or timeline for consideration of that discussion and decision.	Funding decisions for the Bonneville F&W Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W Program costs are included to inform the broader cost analysis for each alternative in the EIS. In the case of the Preferred Alternative, Bonneville included a range of potential F&W Program costs to acknowledge the possibility that the Preferred Alternative could provide biological benefits to anadromous fish species (see Chapter 7 of the EIS, Preferred Alternative) and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville F&W Program. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. In 2016, Bonneville's F&W Program budget was $267,000,000, and the LSRCP budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP facilities, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17 percent, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative. see Appendix Q, Chapter 7 Summary of All Costs. Additional details concerning decision-making with regard to adaptive management for juvenile fish passage spill operations have been added to Appendix R.
31775	54	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	H. The Mitigation Package Contained in the DEIS is Lacking There is very little offered in the PA in terms of fish mitigation. Most fish mitigation is ongoing, and the discussions regarding this ongoing mitigation do not disclose its extent or effects on listed and non-listed species. (see Fish and Wildlife Program and Avian Predation discussions). With respect to new fish mitigation measures proposed in the DEIS: - The only new operational measure with fish benefit is JDA pool operations to aid with predation dissuasion. - The off-season surface spill study for Steelhead overshoots (and bull trout migration) has been reduced to studies only. This is an important mitigation action that needs to occur as soon as possible under any alternative and not wait for additional studies. - Tributary habitat restoration at a slower implementation pace than the NAA, due to budget cuts.	The Preferred Alternative includes actions that benefit fish species and habitat through additional measures, ongoing programs, mitigation measures, and ESA consultation. As described in Section 7.6.1, a number of measures that are carried forward, modified, or added from the alternatives in Chapter 2 are intended to improve survival of anadromous salmon and steelhead, lamprey, and resident fish. Some examples are structural measures for lamprey passage, juvenile fish passage spill operations, and predator disruption operations. Section 7.6.4.1 provides summaries of the ongoing programs that would be carried forwarded in the Preferred Alternative. The majority of those ongoing programs are mitigation currently being implemented. Additional mitigation measures identified to offset effects from measures in Section 7.6.1 are presented in Section 7.6.4.2 that include mitigation measures for fish effects (Plant Cottonwood Trees (Up to 100 Acres) Near Bonners Ferry for resident fish and Temporary Extension of Performance Standards Spill Operation for adult salmonid passage delays). Section 7.6.4.3 describes the measures incorporated into the Preferred Alternative as a result of informal and formal ESA consultation. The Bull Trout Access to Perched Tributaries in the Kootenai River measure includes both completing an assessment and two projects for upstream passage. The Surface Spill to Reduce Take of Overshooting Adult Steelhead measure would provide an operational method to address the overshooting steelhead. The Preferred Alternative is anticipated to benefit anadromous fish compared to the No Action Alternative, and therefore no additional mitigation is proposed. Chapters 2, 5, and 7 discuss the co-lead agencies' ongoing mitigation programs, and the co-lead agencies are unaware of the concern from the commenter that tributary habitat restoration is occurring at a slower pace currently.
31775	55	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	I. The DEIS Fails to Adequately Analyze the Current Avian/Predator Measures or Add New Measures CRITFC DEIS Comments April 13, 2020 Page 26 of 59 Predator management actions identified for the PA, while continuing, are actually at a lower level than the NAA due to budget cuts and lack of commitment by COE. Recent avian predation rates indicate that avian predation continues to be a major source of fish loss in both CRS reaches and the estuary. The extent of this fish loss is not adequately portrayed or accounted for in the EIS analysis. The DEIS proposes to continue current actions regarding avian predation, with the only new mitigation action identified being the John Day Pool operation. However, two of the three current plans have been declared complete and none of the plans have met their biological goals. More specifically, the DEIS discusses the continued implementation of three active management plans for avian predators: 1) the Double-Crested Cormorant Management Plan to Reduce Predation of Juvenile Salmonids in the Columbia River Estuary, 2) the Caspian Tern Management Plan to Reduce Predation of Juvenile Salmonids in the Columbia River Estuary, and 3) Inland Avian Predation Management Plan (IAPMP). Without specificity, the Corps also points to site specific management actions at many CRS dams. We support the Corps commitment to the existing plans, though each plan is fraught with problems, in their own ways.	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. This includes continued implementation of (1) dissuasion measures at the Corps hydropower facilities as described in the annual Fish Passage Plan and coordinated with the FPOM, (2) the Inland Avian Predation Management Plan (IAPMP), (3) CATE management plan for reduction in habitat at East Sand Island, and (4) the Double-crested cormorant (DCCO) management plan at East Sand Island. The goal of the CATE management plan was to reduce habitat at East Sand Island to a minimum of 1.0 acre following the creation/enhancement of habitat at alternative sites outside of the Columbia River basin. Habitat creation/enhancement was completed and habitat at East Sand Island reduced to 1.0 acre preceding the 2015 breeding season. The number of breeding pairs nesting on East Sand Island was used as a proxy to assess predation rates, but the stated goal of the plan was defined as an acreage of habitat and not the number of pairs in the estuary which has been met. The one acre of habitat will continue to be maintained through the Corps Operations and Maintenance group and coordinated with the FPOM. As described in the DCCO management plan, an average 3-year peak estimate of the breeding colony would be used to assess management objectives after implementation of Phase II activities (i.e. habitat modification). Actions would be considered successful when the average 3-year peak colony size estimate does not exceed 5,380 5,939 breeding pairs while no management activities are conducted. In coordination with USFWS, the Corps defines no management activities to mean non-lethal activities described in Chapter 5 of the FEIS. Specifically, Phase II activities are intended to consist of lower maintenance, non-lethal hazing and dissuasion actions that reduce the amount of human presence needs on East Sand Island to ensure colony size objectives are not exceeded. Hazing and dissuasion activities would be implemented as needed, and would continually transition to methods that are most effective, least impactful to non-target species, and require the least management effort and cost. Pending evaluation of the peak colony size during the 2020 breeding season, if the average three-year breeding colony is less than 5,939 breeding pairs, management objectives will be met and actions will transition long-term operation and maintenance of the colony. The Inland Avian Predation Management Plan (IAPMP) for the Corps and Bureau of Reclamation managed land on the Columbia Plateau has been focused on reducing predation by Caspian terns with initial efforts being implemented at Goose Island (Potholes Reservoir near Othello, WA) and Crescent Island (McNary Reservoir near Burbank, WA). The objectives of the IAPMP have been met at these two locations in recent years and as of 2019, there has been a 49% reduction in the total number of Caspian terns nesting on the Columbia plateau region since implementation of the IAPMP begun (Collis et al. 2020; http://www.birdresearchnw.org/2019%20GPUD%20Final%20Report.pdf). Adaptive management efforts to dissuade incipient colonies that have formed following implementation of the IAPMP have been implemented in Potholes Reservoir including at the NW Rocks starting in 2014 and at small islands in the northern portions of Potholes Reservoir starting in 2015. The co-lead agencies continue to monitor and adaptively manage all of Potholes Reservoir to dissuade terns from nesting on agency-managed lands in the area. However, the co-lead agencies recognize that some Caspian terns have moved to other locations and that some of these locations are managed by other entities where the AAs do not have authority and/or management responsibility. While it is recognized that the IAPMP goal of less than 2% predation at all Caspian tern nesting colonies within the Columbia River plateau has not been met to date, primarily due to the incipient colony within the Blalock Islands complex, the co-lead agencies will continue to work closely with these other entities in the region who have authorities and obligations to mitigate the impacts from avian predators to benefit ESA-listed salmonids.
31775	56	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Inland Avian Predation Management The co-lead agencies execution of the IAPMP has failed to keep colony specific avian predation rates less than 2% per ESU or to maintain breeding colonies at less than 40 pairs of nesting terns (e.g. Blalock Island). However, the greatest deficiency of the IAPMP is not in the execution of the plan, but the biological scope of the plan. At the time the IAPMP was written and implemented, we knew very little about other avian predator species and their impacts on ESA salmon and steelhead. The co-lead agencies have funded research and continues fund research that has added to our understanding of the impacts of avian predation and must be reflected in the IAPMP. For example, recent research has estimated Upper Columbia steelhead mortality by all species of avian predators to be as high as 53%. Gulls in the plateau region (e.g. Miller Island) are now known to contribute, largely, to the high steelhead and sockeye mortality estimates (Figure 5). For Miller Rocks the 2007 to 2019 average Gull predation on Snake River Sockeye has been 6.2%, Snake River Steelhead 7.2% and Upper Columbia Steelhead 8.2%. Hence, the IAPMP must be broadened to include all predatory avian species, not just Caspian terns. This predation is occurring in the affected area of the DEIS. The majority of this predation takes place in the tailrace of the dams and is directly related to presences and operation of the dams. CRITFC DEIS Comments April 13, 2020 Page 27 of 59 Figure 5 Upper Columbia River steelhead mortality from Rock Island to Bonneville, reprinted from System-wide Effects of Avian Predation on the Survival of Upper Columbia River Steelhead: Implications for Predator Management, Evans, A., 2019. Note, green bars with suffix LAXX refers to gull species (MRI LAXX refers to the gull colony on Miller Rocks). CATE is Caspian tern and DCCO is double-crested cormorant. 2020 marks the first year that the Bureau of Reclamation (BOR) has funded dissuasion efforts on Goose Island. In 2019, the Priest Rapids Coordinating Committee funded all of the dissuasion and vegetation effort. It is our understanding that BORs work represents a 50% reduction in effort from 2019. Were skeptical that BOR will produce the same results as the PRCC with only half the effort. Furthermore, the DEIS states, Reclamation will continue passive and active dissuasion efforts on Goose Island. There are dozens of islands in the Potholes reservoir area. All of the islands are in BORs jurisdictional authority and any of them could host the next colony of Caspian tern or another avian predator. BORs avian predation responsibility to all the areas in their jurisdiction, not only Goose Island, should be clearly stated in the DEIS.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation by avian predators, would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The primary driver for these benefits to anadromous fish is increased spill during the juvenile fish migration. The Inland Avian Predation Management Plan (IAPMP) has been focused on reducing predation by Caspian terns with initial efforts being implemented at Goose Island (Potholes Reservoir near Othello, WA) and Crescent Island (McNary Reservoir near Burbank, WA). The objectives of the IAPMP have been met at these two locations in recent years and as of 2019, there has been a 49% reduction in the total number of Caspian terns nesting on the Columbia plateau region since implementation of the IAPMP begun (Collis et al. 2020; http://www.birdresearchnw.org/2019%20GPUD%20Final%20Report.pdf). Adaptive management efforts to dissuade incipient colonies that have formed following implementation of the IAPMP have been implemented where the co-lead agencies have authority and management responsibilities which includes Potholes Reservoir including at the NW Rocks starting in 2014 and at small islands in the northern portions of Potholes Reservoir starting in 2015. The co-lead agencies continue to monitor and adaptively manage all of Potholes Reservoir to dissuade terns from nesting on co-lead agency managed lands in the area and this is anticipated to continue as described in the Draft EIS. However, the co-lead agencies recognize that some Caspian terns have moved to other locations and that some of these locations are managed by other entities outside of the co-lead agencies current management abilities. The co-lead agencies will continue to work closely with these other entities in the region who have authorities and obligations to mitigate the impacts from avian predators to benefit ESA-listed salmonids as well as implement a new reservoir management operation for the John Day reservoir to dissuade nesting Caspian tern as described in the Draft EIS. The IAPMP was developed with the best information available at the time and gulls were not identified as warranting directed management efforts at nesting colony locations by the co-lead agencies at agency-managed properties at that time. The co-lead agencies propose to continue, under the Preferred Alternative, predation reduction measures such as hazing at the agencies' CRS facilities as described in the Draft EIS to ensure the operation of the CRS does not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The co-lead agencies can only address certain types of predation by gulls, such as when they are foraging within the direct footprint of the co-lead agencies' CRS facilities where the agencies have management abilities. Other entities in the region have authorities and obligations to mitigate the impacts from avian predators as well and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Management of gulls at Miller Rocks just upstream of Miller Island is not feasible by the co-lead agencies as they do not own or manage this property and therefore do not have the authority or abilities to manage avian predation at this location.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The Bureau of Reclamation has been engaged with and funding actions associated with management of piscivorous waterbirds on the Columbia River plateau including at Potholes Reservoir since 2010. Starting in 2014 when the implementation of the IAPMP begun, BOR began funding their respective commitments associated with implementation of the IAPMP in coordination with the other co-lead agencies. While the Priest Rapids Coordinating Committee has funded additional avian predation efforts in the region, and agreed to fund all 2019 activities at Potholes Reservoir, the Bureau of Reclamation intends to continue implementing and funding future actions necessary to implement the IAPMP where they are the responsible agency.
31775	57	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Caspian Tern (CATE) Predation Management at East Sand Island The USFWS has not (e.g. will not) issued egg taken permits for non-managed satellite colonies on ESI. This means that if an egg is laid outside the managed colony, the nest becomes protected under the auspices of the migratory bird treaty act. Terns are colonial nesters and if one nest becomes protected, it will likely result in a new colony. At a minimum, egg take permits must be issued. Until 2019, the AAs, researchers and the adaptive management team targeted 3,125 nesting pairs on terns on the managed colony. That target was a widely accepted but never achieved. In 2019, CRITFC DEIS Comments April 13, 2020 Page 28 of 59 USFWS began citing the upper number in the range as the target (4,375) without explaining its rationale. This was a departure from the widely accepted management goal of 3,125. The CATE Predation Plan has not met its biological goals for nesting numbers in most years nor has it met its original biological goals, as stated in previous BiOps, of reducing CATE predation on steelhead to less than 6%. The COE has not moved to further reduce habitat at ESI to achieve the nesting pair goal and has moved funding away from this program to Operation and Maintenance, which has a negative funding trajectory. This calls into question the certainty of the future support and funding of these management operations.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation by avian predators, would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The primary driver for these benefits to anadromous fish is increased spill during the juvenile fish migration. The Corps Caspian Tern Management to Reduce Predation of Juvenile Salmonids in the Columbia River Estuary Final Environmental Impact Statement (FEIS) (2005) and Record of Decision (2006) (the Management Plan identified a Caspian tern population level goal of approximately 3,125 - 4,375 pairs at East Sand Island. This goal has been met in 2017 and 2019 respectively. The Management Plan stated tern nesting habitat could be reduced to (but not less than) 1.0 acre. Tern nesting habitat has been managed at 1.0 acre since 2015, and the nesting pair goal was met in 2017 and 2019. The co-lead agencies responsibilities under the Record of Decision will continue to be funded and implemented. At the conclusion of a 2020 Synthesis Report, and preliminary information from the 2020 season, the co-lead agencies will work with the Services through the appropriate Regional Forum workgroup(s) (e.g., FPOM) to determine need for and scope of future co-lead agency-sponsored Caspian tern management and monitoring
31775	58	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Double-crested Cormorant Predation Management at East Sand Island The DEIS predation section essentially restates the Corps responsibility to the DCCO ESI management plan. After modifying the terrain on ESI in a way that was consistent with the management plan, the COE stated that they have met the management objectives of this plan and are phasing this program out. However, the COE did not meet its biological goals of nesting pairs on ESI prior to making terrain modification. This has caused a majority of the colony to move further upstream and enhance and create new incipient colonies at such sites as Astoria-Megler Bridge (Figure 6), a location known as The Towers, various Navigation Markers, and the Longview Bridge. The COE can say they are closing out their management plan, but their actions to date have not meet the biological goals of reducing DCCO predation. Rather, they have moved the birds further upstream which will likely increase their predation impacts on listed salmon and steelhead stocks. Like the tern management plan, future funding for this program has been moved to the Corps of Engineers Operation and Maintenance budget which has a negative funding trajectory. This calls into question the certainty of the future support and funding of these management operations. CRITFC DEIS Comments April 13, 2020 Page 29 of 59 Figure 6. Double-crested cormorant breeding pair colony growth on Astoria-megler Bridge. Reprinted from data collected by Lawon, J. (ODFW), 2019.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation by avian predators, would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The primary driver for these benefits to anadromous fish is increased spill during the juvenile fish migration. Although the goal of the Double-crested Cormorant Management Plan to reduce the number of DCCOs nesting on ESI has been met in the last few years, avian predation on migrating salmon and steelhead in the lower Columbia River likely persists. The size of the DCCO colony on the Astoria-Megler Bridge has increased in every year since monitoring began in 2004 (with the exception of 2010), with the largest numerical increase in colony size [prior to 2020] occurring in 2018, when the colony more than doubled as compared to the size of the colony in 2017 (834 nests) (Turecek et al. 2018). The co-lead agencies authority to manage avian predators away from the CRS projects is limited to dredged material islands in the Columbia River estuary. Management of avian predators in the locations specified in the comment are beyond the authority of the co-lead agencies and therefore outside the scope of the Double-crested Cormorant Management Plan, and outside the scope of this EIS. Other entities in the region have authorities and obligations to mitigate the impacts from avian predators as well and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The implementation of all measures is dependent on funding availability. The co-lead agencies responsibilities under the Double-crested Cormorant Management Plan will continue to be funded and implemented. At the conclusion of a 2020 Synthesis Report, and preliminary information from the 2020 season, the co-lead agencies will work with the Services through the appropriate Regional Forum workgroup(s) (e.g., FPOM) to determine need for and scope of future co-lead agency-sponsored Caspian tern management and monitoring
31775	59	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Sea Lions While the California Sea Lion program has been successful (and presumedly continues), it is limited geographically to the Bonneville tailrace, and it is unclear if a Stellar Sea Lion program is included in the EIS.	Section 3.6 does consider the effects of the alternatives, including the No Action Alternative, on Steller Sea Lions. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped (California and Steller sea lions) and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped (both California and Steller sea lions) and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
31775	60	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	J. Lamprey Measures Are Incomplete in the DEIS and Their Funding is Uncertain The lamprey measures listed in the have been identified since 2016. They have not been implemented due to lack of funding commitment by the co-lead agencies. The lamprey measures disclosed in the DEIS represent only a portion of the list of needed lamprey actions even as identified in the Corps Lamprey Priority Matrix, which is itself just a start, and does not cover all lamprey needs. Recent funding commitments only provide funding through about 2022, and it unclear how that funding relates to this EIS and implementation of the lamprey measures identified for the DEIS. Future lamprey actions through the 25-year term of CRS EIS have not been identified, nor has their funding. With the reduction/phase out of the CRFM budget (also discussed above), funding for additional and future lamprey measures is uncertain. Including all actions in the matrix would demonstrate the importance of the actions, provide NEPA coverage, and assist with future funding requests.	The co-lead agencies recognize the importance of Pacific lamprey and will continue to work with CRITFC, CRITFC member tribes, and regional entities through existing frameworks such as the Corps-Tribal Lamprey Work Group, the Pacific Lamprey Conservation Initiative and the Corps Regional Forum workgroups (e.g., FFDRWG) to implement ongoing programs, as well as the lamprey measures described in the Preferred Alternative. The analyses completed and described in this Draft EIS were for the purposes of comparing the effects of the multiple objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs related to lamprey, such as habitat restoration, reintroduction and translocation, and other efforts. Measures identified in the Draft EIS do not include all lamprey passage improvements that could be potentially implemented at the lower Columbia and lower Snake River dams, but the Corps believes that potential actions contemplated in preliminary lamprey program planning discussions with CRITFC staff and others related to the 2018 Accords Extensions are consistent with the measures and analyses included in the Draft EIS. CRITFC is correct that actions beyond the scope of the measures included in the Draft EIS or ongoing activities would potentially require further NEPA analysis. Lamprey measures identified in the Draft EIS (and similar operational or structural measures) do not include research, monitoring or evaluation actions that may be needed to refine passage designs, inform operations, or address critical uncertainties. This includes the juvenile lamprey and adult lamprey migration behavior and fate studies identified in the 2018 Accords Extensions and in subsequent program planning and coordination discussions with CRITFC and others. For the purposes of the Draft EIS, measures must address known operational and structural issues, but this does not preclude development and implementation of future juvenile and adult lamprey studies. For Columbia River System dams, it is accurate to note that CRFM annual appropriations have declined over the past couple years and are projected to remain lower into the near future. However, a reduced reliance on the CRFM program into the future is a result of significant investments in construction of components of the dams for the benefit of improved salmon passage. The Corps CRS fish program is now transitioning to a program that is expected to be primarily sustained through long-term Operations and Maintenance funding. For future construction requirements aimed at improving anadromous fish passage throughout the CRS, the Corps will continue to express capability in the annual budgeting process. However, implementation of all measures including lamprey measures is dependent on funding availability. In 2020, the Corps did receive $20M in funding to implement actions contemplated in the 2018 Accords Extensions. As noted by CRITFC, and in similar comments from CTUIR, the Corps is currently refining cost estimates and developing a preliminary implementation plan for this $20M program. The Corps will continue to coordinate closely with CRITFC and other Accords tribes on prioritization of actions within this program and will continue to ensure consistency with measures identified and analyzed in the Draft EIS.
31775	61	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	K. Additional Measures Could be Added to the Mitigation Package in the DEIS The following list includes potential mitigation actions that could be implemented to mitigate for fish impacts. These actions were identified and suggested during the development of the mitigation toolbox but are not currently identified in the Draft EIS as potential mitigation. We were never told the disposition of our recommendation to add these items to the toolbox. With the uncertainty of the action moving forward, and the reliance on an adaptive management framework as identified in the Adaptive Management Appendix, it is important that these actions be included somewhere in the EIS analysis to provide the NEPA coverage for quick implementation and to assist with identifying funding. As noted above, these should be disclosed and analyzed in the PA, but were not as currently drafted. - Predation actions noted above; - Adult ladder temperature cooling pumps for McNary and John Day; - Vertical slot weir gates for adult steelhead fallback post spill make operation more cost effective; - Evaluate options to increase the number of RSW/TSW at dams to create the best possible surface passage attraction flow and increase the number of surface passage routes. (This alternative would require modifications of existing spill patterns and would need to be modeled); - Evaluate potential options to increase Kelt collection at projects in both Snake and lower Columbia; - Replace/place Cells at Little Goose Dam North Shore adult entrance; - Replace trunnion pin and wire ropes at The Dalles spillway; - Install additional Spillway Pit Detection (Ice Harbor, work collaboratively with Mid-Col to get detection there, possibly Wannapum, and location in lower Columbia); - Increase Pit Barges and other detection arrays below and at Bonneville Dam; - Implement shad reduction measures; - Look at ways to fund/implement 10-year Lamprey Plan (Strong need to get juvenile active tag study going); - During times when no adult ladders in operation, (ie LWG and LGS) run the RSW to assist overshot steelhead; - Work to increase funding through CRFM and O&M to ensure actions and maintenance will be completed; and - Continue to address measures under consideration in SCT analyses.	Appendix R, Part 3 presents the mitigation toolbox including rationales for not carrying forward mitigation measures. Potential actions as listed in this comment, especially the structural actions, may require further refinement for site-specific analysis under NEPA and other applicable laws. The commenter's proposed mitigation measures do not appear to offset impacts associated with implementing the Multiple Objective alternatives (MOs), including the Preferred Alternative. These mitigation measures were proposed in the workshop process and not selected because they did not offset identified effects of the MOs, and were not carried forward into the Preferred Alternative.
31775	62	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	L. The Adaptive Management Appendix Lacks Sideboards and Injects Significant Layers of Uncertainty Without Analysis - Flex Spill is only for one year, making outyear operations highly uncertain CRITFC DEIS Comments April 13, 2020 Page 31 of 59 The Adaptive Management Appendix essentially reduces the proposed action to a single year, with uncertainty of operation for the rest of the term of the EIS. The DEIS fails to analyze the single year commitment to Flex Spill and instead assumes a long-term commitment without regard to any consensus from all parties to deviate from that fixed operation.	The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. The co-lead agencies do not feel that the short-term nature of this operation is an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies will provide additional clarifying text in Appendix R to make these points more clearly.
31775	63	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	#NAME?	The co-lead agencies are currently in discussions with other federal agencies, the states, and Tribes on the structure of this forum. While the intent is to keep the spirit of the FSWG as previously utilized, there will be some modifications to the Draft EIS in this area based on our current discussions with these entities.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31775	64	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Fourth Pillar to test latent mortality opens wide uncertainty Appendix X unilaterally adds a Fourth Pillar to the Flex Spill Agreement pillars to require testing for latent mortality. Previous discussions have looked at a block study as this test. A block would decrease the PAs spill operation and constitute unanalyzed fish effects. Other potential tests could do the same. This was not disclosed in the DEIS. -	The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the Columbia River System Operations EIS. The latent mortality test is not specifically defined in the Draft EIS because it was the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process including development of a test to ensure effectiveness of the measure, utilizing their respective salmonid management and science expertise.
31775	65	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	#NAME?	The spill surcharge was removed from power rates in BP-20. See BP-20-E-Bonneville-19 Power and Transmission Rate Policy Testimony. Fredrickson et. al, page 15-17. The spill surcharge was included in BP-18 power rates due to the substantial cost recovery risk the court-ordered spill injunction created with little ability for Bonneville to model the impact without speculation. In BP-20, the circumstances surrounding the spill assumptions changed and allowed Bonneville to model planned spill in its rates, removing the need for the spill surcharge for cost recovery in the same way it did for BP-18 power rates. Future spending level decisions for Bonneville's Fish and Wildlife Program and rate provisions would be made in consultation with the region through Bonneville's processes and other appropriate forums.
31775	66	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Affected Environment and Effects Analysis A. Affected Environment is Not Meaningfully Depicted The discussions in the Affected Environment sections do not meaningfully depict the nature and extent of the impacts that the Basins hydro system has had on the Columbia Basins anadromous fish. Meaningfully depicting these impacts cannot be avoided. Under NEPA, regardless of the selection of the baseline, all cumulative effects must be revealed. The Affected Environment chapter fails to mention that the NPCC, consistent with the Northwest Power Acts statutory requirements, has identified a regional goal of 5 million salmon and steelhead with SARs in the 2-6% range. These are important benchmarks that the DEIS does not disclose or analyze.	The description of the affected environment and the effects analysis include the ongoing effects from the existence of the CRS and the continuing Federal action of the operation of the CRS. The focus of the EIS is system operations, not the existence of the system. To the extent the analysis considers the existence of the system, e.g., breach, the effects analysis captures the cumulative effect of project existence. The direct, indirect and cumulative effects to affected resources from CRS operations, maintenance and configuration are included in Chapters 3, 4, 6 and 7. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
31775	67	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	B. The DEIS Fails to Adequately Consider Tribal Cultural Resources The tribes continue to have fundamental disagreements with the co-lead agencies regarding the scope of the analysis of the CRSO DEIS for impacts to cultural resources. By selecting an arbitrary distance of one mile from the reservoirs, the agencies are taking an impermissibly narrow view of the human environment under NEPA, and failing to interpret it comprehensively to include the natural and physical environment and the relationship of people with that environment. 40 CFR 1508.14. As noted, this is a fundamental flaw in the analysis, a concern the tribes raised in scoping comments and in comments and emails to the draft Cultural Resources Chapter, such as the email of Catherine Dickson (CTUIR) on March 27, 2019. In conference calls and comments the tribes raised this concern again and again and yet the agencies retained the one-mile limitation on the analysis and even refused to acknowledge in the DEIS that there was a disagreement on this issue among the cooperating agencies. To quote the National Preservation Institute: - NEPA's concern is with the "human environment," defined as including the natural and physical (e.g., built) environment and the relationships of people to that environment. A thorough environmental analysis under NEPA should systematically address the "human" social and cultural aspects of the environment as well as those that are more "natural," and should address the relationships between natural and cultural. Culturally valued aspects of the environment generally include historic properties, other culturally valued pieces of real property, cultural use of the biophysical environment, and such "intangible" sociocultural attributes as social cohesion, social institutions, lifeways, religious practices, and other cultural institutions. These impacts are usually analyzed either as impacts on "cultural resources," or as "social impacts," or as both but many such impacts actually fall into the cracks between the "cultural resource" and "social impact" categories as usually defined.9 9 https://www.npi.org/what-are-cultural-resources CRITFC DEIS Comments April 13, 2020 Page 33 of 59 As noted in our comments, the easiest way to address cultural resource impacts is to use the whole basin as the study area. If the agencies will not do that, the agencies will need a carefully crafted argument as to why the study area selected meets each of the project purposes/changes proposed in the alternatives. The study area for irrigation and environmental justice are both much larger than the cultural resources study area, accounting for job losses for irrigation changes and impacts to communities distant from the projects themselves. Because changes to river operations affect cultural resources (farming practices impact native plants and animals for example), the study area should be broad as well. Similarly, the EIS suffers from insufficient analysis when certain study areas are broad if that furthers certain goals (such as keeping the dams because of importance to local farmers/shippers), but other study areas are small when it seems a larger area might highlight other goals. Fish are a cultural resource (in and of themselves, under NEPA, as opposed to fishing sites which are considered under the NHPA) and from Judge Simon's perspective, the primary point of this NEPA study is to determine impacts to the fish populations. Those fish migrate well beyond one mile from the edge of the reservoirs. The study area for aquatic habitat is virtually the whole basin. Figure 3-109, page 3-287, lines 6767-6768.	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources," as this is consistent with Federal laws and regulations, which focus on specific bounded properties. The co-lead agencies selected the size of the study area based on the area where the impacts from the proposed structural and operational measures are expected to occur. This study area is sufficient for the agencies to understand the effects of the different alternatives and to enable the agencies to make an informed evaluation of the alternatives. The co-lead agencies focused the evaluation on the locations where there were understandable direct and indirect effects that are reasonably able to be predicted as required by NEPA regulations. Tribal interests and holistic perspectives on the integration of Native American culture with the environment were addressed throughout the EIS and by inclusion of statements from the Tribes. The co-lead agencies note that many of the traditional cultural properties (TCPs) analyzed in the Draft EIS incorporate elements of the natural environment. Please see: Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas; Section 3.17.2 for Tribal Perspectives Summaries; and, Section 3.17.3 for Tribal Interests. Additionally, the EIS evaluates the impacts of the social and economic effects as well as effects to the natural and physical environment consistent with 40 C.F.R. 1508.14 and 1508.8.
31775	68	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The narrow scope of the CRSO DEIS study area is further impaired by a focus on archaeological resources while ignoring cultural resources (in the NEPA sense rather than archaeological resources under ARPA and the NHPA). From our participation as a cooperating agency in the teams reviewing drafts of the documents, it appears that the agencies were thinking only about archaeological sites (cultural resources team), TCPs (cultural resources team), Sacred Sites (likely cultural resources team, but possibly tribal liaison team), and Trust Assets (tribal liaison team). The other types of cultural resources we brought up in our scoping comments, such as cultural values (identity, traditional practices, first foods), social resources (community), and economic activity of tribal importance (by resource or geographic area) appear to have been relegated to the socioeconomics team. From our position on the socioeconomics team, we know that they exclusively focused on economic impacts, did not do work specific to tribes, and failed to consider social impacts at all. We feared that separating cultural resources into three different teams increased the likelihood that some concerns would be lost altogether, and further that all cultural resources would not get the thorough consideration they need and deserve. This is exactly what happened. The tribes believe that this is in part because the co-lead agencies cultural resources team consisted exclusively of archaeologists; the agencies representatives should have had the benefit of additional expertise in other types of cultural resources.	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources," as this is consistent with Federal laws and regulations, which focus on specific bounded properties. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Appendix P includes copies of tribal perspectives that were submitted by tribes and considered by the co-lead agencies. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section to summarize tribal issues by topic. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The co-lead agencies note that many of the Traditional Cultural Properties analyzed in the Draft EIS include aspects of the natural and social environment. Please see Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas, Section 3.17.2 for Tribal Perspectives Summaries and Section 3.17.3 for Tribal Interests in the Draft EIS. The EIS evaluates the impacts of the social and economic effects as well as effects to the natural and physical environment consistent with 40 C.F.R. 1508.14 and 1508.8. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. Section 3.15, Fisheries and Passive Use Section and, in particular, Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests, include discussions of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in Section 3.15.2.1, Fisheries and Passive Use, which includes subsections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
31775	69	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The analysis in the DEIS of sacred sites focuses exclusively on Executive Order 13007 and does not address the obligation to examine these sites under NEPA or other laws as cultural resources. Significantly, the DEIS does not address sacred sites under the NHPA as historic properties of religious and cultural significance to tribes, or under ARPA as sites of religious and cultural importance to tribes. By focusing narrowly on the authority of EO 13007, the agencies precluded open and honest discussions about sacred sites with tribes because information sent to agencies under EO 13007 does not have specific statutory protections from release under the Freedom of Information Act as does information sent under the NHPA or ARPA. The CTUIR specifically raised this concern about confidentiality of sacred site info in a December 6, 2018 call with the agencies. The CRSO addressed the concern by stating [w]here appropriate, agencies will CRITFC DEIS Comments April 13, 2020 Page 34 of 59 maintain the confidentiality of sacred sites. CRSO DEIS page 3-1355, lines 6098-6099. Tribes will not share sensitive sacred sites information if the agency will only commit to protect the confidentiality of that information as appropriate. For instance, when the CTUIR identified the Columbia River as a sacred site, the agencies made no response. We learned in the DEIS [t]he co-lead agencies believe this does not meet the definition in the Executive Order as it is not discrete or narrowly delineated. CRSO DEIS page 3-1355, lines 6116-6117. No discussion with the CTUIR on this subject was held. The CTUIR believes the site we identified meets the definition in the Executive Order. The agencies position also ignores the potential for analysis of this designation under either the NHPA or ARPA, both of which authorize the designation of lands of significance to the tribe. The tribes incorporate by reference all comments we have previously provided to the agencies.	The co-lead agencies requested information from the Tribes to identify sacred sites consistent with Executive Order (EO) 13007. While data collected to identify historic properties under the National Historic Preservation Act (NHPA) may be similar in nature to the data or information related to sacred sites, Federal agencies cannot make the assumption that this information can be used interchangeably without specific information provided by Tribes. The Traditional Cultural Property (TCP) information and data used to conduct the impact analysis described in the cultural resources Section 3.16.2.6 was largely derived from co-lead agencies efforts to comply with Section 106 of the NHPA through the ongoing efforts of the Federal Columbia River Power System (FCRPS) Cultural Resources Program. This information was gathered by the co-lead agencies in part to identify historic properties of importance to Tribes. Because of the requirements of EO 13007 the co-lead agencies could not make the assumption that any of the TCPs used in the Draft EIS analysis were also sacred sites and instead relied on information requested from the Tribes regarding sacred sites during the CRSO EIS process. The co-lead agencies determined that all Federal land within 1 mile of the lower Snake River and lower Columbia River Projects is neither discrete nor narrowly delineated, as required to meet the definition in EO 13007.
31775	70	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	C. Harvest, Hatcheries and Habitat - DEIS Fails to Analyze Harvest Opportunities for Treaty and Non-Indian Fisheries The DEIS repeatedly states that [d]ue to the complexity of fishery management, it is not possible to predict changes in fishery management that may result from changes in fish abundance. This statement is simply false. Coastwide, harvest managers in the United States and Canada regulate salmon fisheries based on abundance predictions. West coast ocean fisheries are for the most part managed based on one of two approaches, either aggregate abundance-based management or Individual stock-based management. Both approaches manage harvest based on anticipated salmon abundance.10 In the Columbia Basin, harvest is managed in accordance with the US v. OR 2018-2027 Management Agreement that sets forth harvest schedules from which changes in fisheries harvest regulations are regularly predicted and adopted.11 These harvest schedules have been analyzed for the effects on abundance, productivity,	The EIS recognizes the value of commercial as well as recreational fishing to the region. Section 3.15 describes the values associated with fisheries in the Pacific Northwest. Section 3.11 characterizes recreational fishing activities in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific effects of each alternative on these values. The effects are therefore discussed qualitatively. Fish harvest management is not within the scope and the co-lead agencies have no role or authority over fishing limitations or quotas. Fishing and harvest are subject to separate actions by federal, state, and tribal agencies outside the scope of this EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				spatial structure and diversity of affected salmon and steelhead populations. The lack of harvest opportunity analysis runs counter to the Tribal Perspectives of the Columbia River Treaty Tribes. The lack of harvest opportunity analysis also runs counter to the goals for non-Indian fisheries and the corresponding economic effects of these fisheries. There is no mention of Columbia River Chinook contributions to Canadian fisheries. The harvest rights and federal fiduciary obligations properly cabin any consideration of the Treaty right to harvest to the environmental baseline. Including Treaty harvest in the baseline is consistent with the purpose of the CRSO EIS, which is to examine different hydrosystem operation configurations. All alternatives studied in the CRSO EIS should have been analyzed for their effect on Columbia River fisheries and their ability to contribute to the recovery of stocks to harvestable levels that support tribal fisheries and communities. 10 https://archive.fisheries.noaa.gov/wcr/publications/fishery_management/salmon_steelhead/s7-_usvoregon_2018-2027_mgmagmnt__final_signed.pdf 11 https://wdfw.wa.gov/sites/default/files/publications/02085/wdfw02085.pdf CRITFC DEIS Comments April 13, 2020 Page 35 of 59	
31775	71	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- DEIS Analysis of Hatchery Effects is Incomplete The co-lead agencies fund hatchery programs that have the primary purpose to mitigate for impacts to fish from construction/operation of hydropower dams. Above Bonneville Dam, the AAs fund annual target releases of ~66 million salmon and steelhead. Regardless of how individual hatchery programs are managed (i.e., for harvest, supplementation, and/or reintroduction), every single program funded by the AAs serves the purpose of mitigation including the programs identified in table 2-18 (which only add up to a target release of 3.35 million). See Attachment D for an overview of Columbia River Basin Hatchery Programs. The DEIS baldly assumes that that termination of Lower Snake River Compensation Plan hatchery production will occur with the breaching of the Snake River Dams. The DEIS discloses no legal or factual analyses to support this position. The effects of the Snake River dams will persist in future populations of Snake River lamprey, sturgeon, salmon and steelhead. Tribal analyses indicated that hatchery production must continue until the impact of the dams has been mitigated, well beyond the 25-year scope of this EIS. The DEIS failure to disclose the facts regarding hatchery mitigation generally and the LSRCP specifically leaves the tribes with no reasonable analysis or factual basis to consider the veracity of the DEIS statements. We have provided additional comments regarding hatcheries in the sections of this document addressing the Proposed Action.	The Draft EIS acknowledges that with breaching of the Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, other mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer be possible. The rationale for this, as stated in the Draft EIS, is that Bonneville's funding is directly tied to the operation of the LSR dams. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. A summary of this qualitative discussion is provided for the reader for each Snake River species. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. A complete analysis of all hatchery programs and the status of maintenance/operations of each one is beyond the scope of this EIS.
31775	72	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Habitat Measures are Not Fully Analyzed in the DEIS The co-lead agencies do not state the anticipated level of funding for existing mitigation programs under the Preferred Alternative relative to the No Action Alternative. Accordingly, it is impossible to evaluate the potential biological benefit of proposed mitigation programs. A reader must infer the size and scale of mitigation programs based on the measures presented in the BA and assume that current fiscal year 2020 funding levels will persist to support these measures. Such inference and assumption are contrary to NEPAs requirement of informed public participation. We herein incorporate by reference the habitat comments of the Yakama Nation. They demonstrate the failure of the DEIS meaningfully disclose and analyze the extensive habitat mitigation measures that are ongoing as offsite mitigation for the impacts of the development and operation of the CRS.	This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. The analyses used in this EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Habitat mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs. For the purposes of comparing alternatives, however, a more detailed description is not needed. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative. The scope of this Draft EIS is the operation and configuration of CRS projects; a complete analysis of all habitat programs and the development to the specificity suggested in this comment is beyond this scope.
31775	73	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	D. Significant Errors Exist in the Biological Effects of Hydro Operations Analysis The following errors, omissions and inadequacies relate to modeling and underlying analysis of biological effects and apply to all MOs and the PA: - Third-party review of models is not yet available for consideration by the public during review of the DEIS CRITFC DEIS Comments April 13, 2020 Page 36 of 59 All models used in the DEIS are required to have a third-party review. We understand that this is ongoing as of the time of DEIS release, but the public will not be given a chance to see the third-party review for consideration in our comments.	The results of third-party review, both the Corps' Independent Expert Peer Review as well as a recently released ISAB review of the CSS results will be included in the Final EIS. Initial review of the results of the peer review do not indicate fundamental flaws in either the CSS or NMFS approach and both models will continue to frame the potential outcomes associated with all MOs and the Preferred Alternative. Survival estimates from the University of Washington TDG model were not relied on for decision-making purposes but will be used to assess relative exposure indices. Section 3.5 has been updated based on IEPR and ISAB reviews.
31775	74	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- The DEIS fails to adequately explain or consider significant errors relating to the CSS and Compass modeling The DEIS fails to adequately explain the differences between COMPASS and the CSS data and complexity. Broadly, COMPASS makes a large number of predictions that are not directly observed, and breaks survival into multiple individual route of passage survivals for each reach (spill, bypass, turbine, and other configuration routes for each dam), whereas the CSS models treat the entire hydrosystem as an aggregate of 2 routes of passage (number of powerhouses passed vs spilled on average). The CSS models are thus "cumulative effects" sensitive, whereas COMPASS looks for effects that may not be noticeable incrementally unless they are added up to full "accumulation".	While this is a fair description of distinctions between the two modeling approach, rather than calling this "error," the co-lead agencies consider this to simply be distinctions due to differences in model construction. All models must make assumptions; these assumptions led us to use both modeling approaches. The NMFS COMPASS/Life Cycle models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival numbers and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of operation of the CRS with respect to flow and spill. The Fish Technical Teams for the EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
31775	75	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	When comparing the predictions of the CSS models and the COMPASS model, the EIS draws attention to the fact that CSS models and COMPASS predict similar hydrosystem survivals, but do not predict similar SARs. This is misleading for two reasons. First there are two CSS models, which are different in nature, yet those two predict similar hydrosystem survivals and SARs. Secondly, both CSS models predict more variability in hydrosystem survival than the COMPASS model. See DEIS Sec. 3.5.	The NMFS COMPASS/Life Cycle models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under MO and Preferred Alternative scenarios of operations of the CRS projects with respect to flow and spill. The Fish Technical teams for the EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Appendix E contains results from all modeling efforts, including both CSS models. Section 3.5 will be updated based on IEPR and ISAB reviews and will address the elements of the two CSS models described in this comment.
31775	76	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	In the COMPASS (NOAA) model, NOAA used data from one Upper Columbia River (UCR) Spring Chinook population, as a surrogate to model UCR sockeye. However, they did not then use these data to model the actual, larger UCR Spring Chinook population, chosing to use McNary to Bonneville data for the UCR Chinook population. This begs the question: If this one population is not adequate to represent the entire UCR Spring Chinook how can it be used as a surrogate for UCR Sockeye. The selection of data appears arbitrary, and no explanation for the discrepancy is provided in the DEIS.	Rock Island to Bonneville survival rates are reported in Appendix E for NMFS COMPASS model results from the Upper Columbia Chinook ESU. When comparing levels of change in major metrics between the multiple objective alternatives vs. the No Action Alternative, adding the Rock Island to McNary segment does not significantly change the level of effect that one would interpret from spill operations or dam breach measures.
31775	77	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Water Temperature in COMPASS. The DEIS notes that the water temperature models that use flow relationships in COMPASS were not used for the CRSO scenario runs. Instead water temperature predicted by the Corps was used in COMPASS. No rationale was given for this change or any analyses or validation as to whether not this change to the COMPASS model runs decreased or reduced the efficacy or reliability of the COMPASS evaluations. (Appendix E, Section 1.2.1.4).	An 80-year historical water record with flows and water quality variables was generated with the Hydsim and ResSim models for use in the CRSO EIS. The models were able to simulate the effects of hypothetical operations included as measures in the multiple objective alternatives, such as monthly irrigation diversions, reservoir elevation changes, spill operations, etc. Climate change was also included as an additional trend. The co-lead agencies used temperature data sets that were developed by the water quality team as part of this EIS development.
31775	78	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Under COMPASS, mean and average survivals, migration, travel time, gas exposure, powerhouse passage, temperature and flow experience, number of bypasses, etc. appear to be used in modeling analyses. This homogenizes results and does not allow for examination of maximum and minimum ranges that fish might experience which can CRITFC DEIS Comments April 13, 2020 Page 37 of 59 have important consequences on overall stock viability. For example, low flows from poor runoff in 2001 caused single digit survivals for juvenile chinook from the Snake River to Bonneville Dam. This can cause a serious depression in that year class that echoed through several succeeding year classes. This is a serious limitation of the analysis and needs to be addressed in the PA and BA. See Appendix E, Tables 1-6; 1-7; 1-8, and 1-9 COMPASS Inputs and Data Fields	The COMPASS model was calibrated with mean and variance of observed PIT-based survival, travel time during two-week periods around the passage date, with temperature, flow, spill, day of passage, and travel time as input variables. FGE derived by studies, along with spill, was used to estimate number of bypass probabilities. The model does not use TDG effects, and this is left as a separate factor of secondary mortality, after survival through the CRS is calculated. Variations of spill, temperature and flow do capture the observed variation of PIT-based survival rates in the model fit. It is true that the travel time equations for NMFS' COMPASS model may not include very low flow years such as 2001 where nearly all smolts were diverted for transport and predation rates may have been anomalous. This is a suitable approach as more recent low flow years such as 2010 are more representative under most low flow/non-power emergency situations..
31775	79	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- The DEIS fails to adequately explain the role of latent mortality in CSS and COMPASS or the uncertainty it creates in the analysis The Executive Summary page 13 describes delayed or latent mortality as a key in explaining different predictions between the models. While this is true, the DEIS fails to explain the differences between the two models when it comes to latent mortality. The DEIS fails to mention that the two CSS models make statistical estimations of the effect of the freshwater hydrosystem on latent ocean mortality. The COMPASS life cycle model was expanded/revised to include latent mortality effects in the 2018 CRSO Biological Opinion and in this DEIS. This revision has not undergone extensive peer review and was the subject of debate within the CRSO anadromous technical team. The COMPASS modeling results include four arbitrary levels of assumed latent morality reductions (0, 10, 25, and 50%), which result in increased adult abundance, if true. The exploration of potential latent mortality impacts, in the COMPASS modeling, is positive; however, the COMPASS modeling does not link these latent mortality effects to specific CRS operations or fish powerhouse passage experience and is aspect open for criticism. There is ample research that fish that pass powerhouse experience some level of latent mortality.	The model results presented in Section 3.5 and Chapter 7 address latent mortality and reservoir mortality. Multiple mechanisms of delayed mortality or "carryover effects" between experiences in one lifestage influencing survival or physiology in subsequent lifestages. These include transportation related delayed mortality, injuries caused by passing multiple dams via any route, delays caused by reservoir and dam passage, and exposure to toxins. Latent mortality is captured directly in the CSS model for SARs and abundances. NOAA approached latent mortality as a sensitivity analysis, exploring the level of effect by latent mortality occurring via any mechanism – results of the Lifecycle Model are overlaid with several assumed values (10%, 25% and 50%) of reduction in latent mortality. Reservoir mortality is captured in the juvenile survival metrics presented in Chapter 3. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the EIS.
31775	80	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Significant bias exists and is unaccounted for in the modeling Following are examples of bias in the modeling which are due to the inputs used in the modeling COMPASS SAR results need further explanation for MO3 and MO4 alternatives. COMPASS SARs are similar for MO3-4 compared to MO1-2 because fish migrate in-river at a more natural rate of migration. The method COMPASS used for calculating SARs is heavily reliant on date of ocean entry. Therefore, in-river fish in MO3-4 enter the ocean a few days later than transported fish in MO1-2, so they are assumed to have poorer ocean survival. This caveat needs explaining in the text of the document since it is not obvious that transported fish would survive better in the ocean than in-river fish migrating at a more natural rate, based entirely on entry date into the ocean.	The co-lead agencies feel that the tradeoff between in-river survival and transportation are covered in the description of both the CSS and NMFS COMPASS models. Travel time and ocean entry time are both acknowledged as important variables in the COMPASS and NMFS Life Cycle models. The intent of the Preferred Alternative is to determine if salmon returns can be substantially enhanced as increased spill leads to higher survival, faster travel times and higher ocean survival due to reduced latent mortality as predicted by the CSS models, or whether changing the ratio of in-river migrating fish and transported fish has offsetting impacts as predicted by the NMFS models.
31775	81	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	There is CSS data available that was not incorporated in this report. Even though it was not generated specifically for this EIS, it represents the NAA and should be used as a reference. For example, CSS has calculated system survival for Upper Columbia stocks and could be used qualitatively to demonstrate potential impacts under each of the MOs.	The CRSO EIS analyzed the effects of operation, maintenance, and configuration of the CRS using current high quality information. CSS material generated for other purposes reflecting recent data trends was referenced in the CRSO EIS, but because CSS data that reflected the No Action Alternative, the multiple objective alternatives, and the Preferred Alternative were not available during the time this EIS was being developed, the co-lead agencies could not use that information to compare directly with the NMFS model predictions.
31775	82	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The H&H modeling did not include the proposed/necessary spill cap of 150 kcfs at Bonneville unless hydraulic capacity has been exceeded for MO4. This impacts analysis CRITFC DEIS Comments April 13, 2020 Page 38 of 59 of MO4, erroneously increasing the economic costs for this MO. This inaccuracy in datasets will result in overestimates of SARS and underestimates of power generation. Furthermore, the models were informed by	The detailed description of the measures for MO4 included spill to 125%, but a spill cap at Bonneville Dam to limit spillway erosion was not included. The perspective used in designing the alternatives was that these should serve as "bookend" scenarios. MO4 was intended to capture the high-end range of spill. The co-lead agencies can then interpret that a real world operation with a modified set of measures or limits such as the Bonneville 150 kcfs spill cap would modify economic costs or survival rates from the modeled bookend scenario.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				common hydrological datasets provided by the co-lead agencies. These datasets were not open to cooperating agency review and appear to have received insufficient validation.	
31775	83	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The DEIS states (Appx E Sec. 1.4.2) that summary statistics for SARs and return abundances for the CRSO were calculated differently that under the CSS modelers (McCann et al. 2017). For the CRSO, the co-lead agencies picked somehow (not stated how) random averages over the 80-year historical flow period for the two metrics, while the CSS modelers used the average of the last 10 flow years in the historical period. The CRSO authors do not provide a rationale for this change, however, given the overall reduction in flows over the last 10 years, the CRSO appears to bias for higher flows and thus higher survival rates. In any case, the CSS flow choice methodology should have remained for CRSO analyses for consistency.	The co-lead agencies do not agree with the claim that summary statistics were "picked somehow." Summary statistics were reported based solely on the data provided by the modeling teams. The co-lead agencies did not make any choices regarding which years of data to present or summarize. One should be cautious about interpreting the most recent 10 years as best representing the climate future. The actual climate trend in the future will not necessarily increase at the same rate as the past. The historical record could include periods of acceleration compared to 80 years ago. A similar issue was raised by the ISAB in its review of Chapter 2 of the 2019 CSS report and will be noted in the CRSO FEIS Section 3.5.
31775	84	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- The level of improvement (50% increase in survival) for new turbines at Ice Harbor, McNary, and John Day are unfounded and not supported by past data and research. High Capacity turbines are included as a measure in several of the DEIS alternatives. However, the data sets provided by BPA did not include increases in flow through the powerhouses due to the installation of high capacity turbines. The assumptions of increased survival through new turbines at John Day dam, McNary and Ice Harbor (fish friendly turbines) are not supported by any available studies. Survival estimates are, at best, equal to those of older turbine units (Skalski and Townsend 2005, Deng et al. 2019, Heisey et al. 2019). However, the higher flow through these turbines will cause higher absolute turbine passage, leading to lower overall dam survival and larger impacts of latent mortality.	The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Again, the magnitude is uncertain. The IFP turbines at John Day and Ice Harbor are not higher turbine capacity than those they are replacing. McNary turbines will have the ability to pass more flow, but will only do so based on the operation management decisions for spill levels.
31775	85	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	In Turbine Improvement Assumptions Final, the document used to justify increased survivals in the DEIS modelling based on bead strike studies, the underlying assumption is that 50% of fish would experience mortality due to both low pressures and strike/shear. While this number is useful for design it is not based on any biological study, data, or other form of evidence and should not be used in any survival estimates. The same document assumes equal improvements in direct and indirect turbine mortality. There is also no evidence provided for this assumption and it seems to be an example of optimistic estimate not based in reality.	The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Again, the magnitude is uncertain.
31775	86	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The interpretation of bead strike studies has resulted in an assumption of a 50% decrease in turbine mortality. This assumption has not been backed up by increased survival in studies with live fish at Wanapum or Ice Harbor Dams, both of which showed no detectable increase in survival.	The direct injury study of the IFP turbine at Ice Harbor in October 2019 did actually result in average of 48 hour survival of 98%, where the previous test of the original design unit was 95%. The comment is correct that this difference was not statistically significant. The assumption used in the COMPASS model was a 50% reduction in mortality, which translates into about 6% increase in survival rates. The actual magnitude that will be achieved is, of course, uncertain. However, given the extensive modifications throughout the turbine including the stay vanes, runner, and draft tube that create a passage environment with less violent sheer, significantly reduced chance of passing through gaps, elimination of very low pressures and great reduction of recirculation within the draft tube that would bring fish back to the turbine blades after passing most of the turbine an increased probability of both direct and indirect survival is reasonable. Again, the magnitude is uncertain.
31775	87	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Any increase in turbine capacity will increase the total number of smolts passing via the powerhouse. This will have impacts not only on concrete survival, but cumulative negative impacts throughout the hydrosystem.	The new John Day and Ice Harbor turbines will be designed to operate within the existing turbine operating range. McNary turbines will be designed with an increased range. Once installed, the new turbines will be tested and validated for fish survival. Although only the McNary turbines will be designed for an increased operating range, the overall level of spill at any given project is determined not by the individual turbine unit capacity but by overall project operations management decisions. These decisions will occur through the Regional Forum and guided by the Adaptive Management Plan. Adaptive management strategies will be used to assure no detrimental impact.
31775	88	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The PA assumes reduced turbine mortality with the installation of new turbines. The DEIS stated that these new turbines will improve fish passage conditions, lower TDG, and improve turbine efficiency and capacity. Turbine passage can directly cause fish mortality through blade strikes, rapid pressure changes, and other physical stresses. Turbine and powerhouse passage is also associated with delayed mortality, manifesting in the estuary or first year of ocean life. While direct mortality due to turbine passage has been studied primarily with models, sensor fish, and bead strike studies, tests with live smolts are relatively uncommon. Indirect and delayed mortality have been associated with powerhouse and turbine passage in a wide range of work demonstrating reduced estuary and first-year ocean survival for individuals who passed via one or more powerhouses during their outmigration (Haeseker et al. 2012, Petrosky and Schaller 2010, Tuomikoski et al. 2010, FPC 2010, FPC 2011a, FPC 2011b). Studies indicate delayed mortality from turbine passage can be substantial. For example, Ferguson et al. (2006) found that while direct mortality ranged from delayed mortality for juvenile chinook salmon that had passed through McNary Dam turbines operated within 1% peak efficiency ranged from 6.4-7%, delayed mortality ranged from 46-70%.	Survival estimates are based on the best available data. Once installed, the new turbines will be tested and validated for fish survival. Survival studies of the new Ice Harbor Turbine support the reduction in mortality estimates. Adaptive management strategies will be used to assure no detrimental impact. We concur that telemetry estimates such as Ferguson et al. (2006) capture both direct and delayed mortality component, and therefore are the inputs used for turbine survival estimates in the COMPASS model.
31775	89	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	There are few studies available to test the assumptions of increased turbine survival. In 2005, a comparison of turbine survival was done at Wanapum Dam, comparing one high-capacity turbine to single turbine of the old design (Skalski and Townsend 2005). In this study, balloon and radio-tagged smolts were released into the turbines under a range of conditions, making it difficult to interpret the results of the tests. Both balloon and radio tags have a number of methodological problems, including: a) requiring a minimum size that does not represent the run-at-large, b) releasing fish via tubes into turbines that cause large pressure differences that do not approximate actual passage conditions, and c) tag burdens that significantly impede swimming ability and, therefore, affect the probability of blade strikes and other injuries. For extensive comments on the difficulties of interpreting the results of balloon tag studies, see FPC (2004), FPC (2012), JTS (2004), and JTS (2005). Additionally, a complicated study design makes determining a biologically significant difference between turbines virtually impossible to detect. A significant three-way interaction effect between turbine type, flow, and entry depth means that any difference in survival between the turbines cannot be separated from the other factors in the study. Although the study results have been described as showing equal survival between the turbines, the study design makes it impossible to determine if this result is a product of study design or if direct mortality is equal between the two turbine designs. In 2019, sensor and balloon fish were deployed through the new turbine in Unit 2 of Ice Harbor Dam. The reports from these studies have not yet been made available, so a full review of their ability to address assumptions and interpretation of the results is not possible. However, the presentations at AFEP 2019 showed that severe shear or strike events were reduced only in two of four tested flows, and a reduction of 50% was only observed under one tested flow (Deng et CRITFC DEIS Comments April 13, 2020 Page 40 of 59 al. 2019). Survivals of balloon-tagged fish were not significantly different under any of the tested conditions (Heisey et al. 2019). These studies indicate the increases in survival developed from bead strike studies and physical modelling efforts are overstated.	The survival rates of juvenile salmon naturally passing through the IFP turbines is unknown; however, when taking into account the characteristics of the IFP turbines that eliminate very low pressures, decrease sheer and recirculation in the turbine, as well as physical model analysis of bead strikes, the co-lead agencies assumed mortality would be halved. Balloon tag methods do not measure all mortality. As the fish are not depth acclimated they suffer none of the barotrauma from low pressures, and they do not include predation in the tailrace which is the largest component of passage mortality (Ferguson et al. 2006). Therefore, only controlled telemetry estimates are used to represent turbine passage survival rates as inputs to the NMFS COMPASS model.
31775	90	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Modifications to the hydrosystem must be thought of in the context of the entire salmonid lifecycle, not just the concrete survival at each project. Even if the direct mortality of high-capacity turbines is shown to be no higher than that of the existing turbines, the increased turbine flow will lead to increase powerhouse passage of the run-at-large. This effect, compounded over multiple dams, will have a net negative impact on the smolt-to-adult returns. If the increased powerhouse flows are not included in the modeled datasets provided to the fish modelers, the increase in powerhouse passage will be lost.	Although only the McNary turbines will be designed for an increased operating range, the overall level of spill at any given project is determined not by the individual turbine unit capacity but by overall project operations management decisions. These decisions will occur through the Regional Forum and guided by the Adaptive Management Plan.
31775	91	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Not only is this additional TDG model redundant, but it has been developed and released without any chance for review by regional partners let alone peer reviewed. It is our understanding that the co-lead agencies will have an independent review of the models used in the DEIS but to date we have not seen any review thus we cannot review or comment on its findings. It appears by the time this review is complete there will be little to no opportunity to review nor incorporate any of its findings. What happens if they find a significant flaw, how will they be addressed?	The IEPR process involves addressing all of the IEPR panel comments and all the comments and their resolutions will be made public in the Final IEPR Report. The co-lead agencies consider all the IEPR comments and will determine if any further action is needed based on those comments.
31775	92	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	There is a wealth of empirical evidence from TDG levels and gas bubble trauma on juvenile and adult salmonids data collected at dams for many years from the Smolt Monitoring Program (SMP). The SMP is a requirement for fish spill under state water quality variances. In addition there is data from river field studies that captured juvenile and adult salmonids in reservoirs at depth that showed that any indication of gas bubble trauma in fish (if any) was less in the reservoirs where fish can compensate for TDG by migrating at depths then fish sampled in bypass systems which have no ability to depth compensate (see Backman and Evans 2002 and Backman et al. 2002 in McGrath et al. 2006). The co-lead agencies failed to use any of this data in estimating total dissolved gas effects on migrating fish, but instead relied on dated laboratory literature and numerical theoretical relationships to provide dissolved gas and model inputs. The CRSO incorrectly uses the term, gas bubble disease where the correct term is gas bubble trauma (see Weitkamp 2008 cited in CRSO). The CRSO failed to cite the important summary report on TDG that updates the existing CRITFC DEIS Comments April 13, 2020 Page 41 of 59 data and science on the relationship between TDG and gas bubble trauma in migrating fish (McGrath et al. 2006). This is surprising since the Corps funded the Pacific Northwest Laboratory to produce this report. The key point in the report: Review of recent work determined that newer research supports previous research indicating that exposure to up to 120% TDGS does not produce significant effects on migratory juvenile or adult salmonids when compensating depths are available.	The co-lead agencies are aware of the Smolt Monitoring Program gas bubble trauma monitoring and recognize that it will be valuable tool for adaptive management as we implement the Preferred Alternative. While we have seen 125% or even greater TDG in the river in past years, it has been due to high flow events that forced spill due to limited powerhouse capacity. The river conditions will be different in the Preferred Alternative with higher TDG levels over much longer periods of time and a smaller volumes of water in the river and higher portions of water being gassed. As there is no empirical data for the 125% TDG spill targets, we felt the need to model this and shed some light on possible effects. The UWs TDG model was already built, so we used that. This model does incorporate empirical data on fish behavior and survival, but the TDG-survival relationships are (necessarily) based on laboratory relationships. Because of the limitations of current models related to TDG and survival, those outputs from the TDG model were not used for decision making purposes. Experiments with confined fish will not accurately represent free swimming fish, which we know from telemetry studies of both adults and juveniles change depth regularly and can spend significant time at compensating depths, which reduce gas loading.
31775	93	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	E. The DEIS Fails to Adequately Consider its Water Temperature Effects Analysis High summer water temperatures in the Columbia River System are known to have detrimental outcomes on fish survival and recovery. These losses will only be intensified by a warming climate. It is essential to project how each EIS alternative will impact water temperature and thus fish survival in the Columbia system. Numerical modeling was used by the co-lead agencies to simulate the impacts of each EIS alternatives on water temperature and quality. The modeling results for MO3 show significant cooling in the river and correlated increases in SARs, but the DEIS fails to adequately consider this effect in its selection of a Preferred Alternative. The DEIS Executive Summary summarizes findings from the modeling efforts and recognizes that MO3 would have major benefits for anadromous fish survival: Model estimates for MO3 showed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze effects of the measures in each alternative on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. For species where qualitative analyses was used, such as sockeye salmon, the fish team developed metrics to look specifically at important parameters of the model results to evaluate specific effects to the relationships between these parameters and life history success of fish using Conceptual Ecological Models. For example, the percentage of days greater than 18 degrees Celsius during adult migration (June 21 to July 31) was used to evaluate upstream migration effects by looking at those exact parameters in the water quality modeling results for each alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				alternatives.12 In addition, DEIS Chapter 3 on Affected Environment and Environmental Consequences details results of the extensive modeling effort and analyses done to evaluate MO3 and reports significant improvements in water quality: Water temperature differences (up to 8.8 degrees Fahrenheit) between impounded (No Action Alternative) and non-impounded (MO3) river conditions would be greatest in the fall.Over the long term, MO3 would have moderate to major beneficial effects on water quality in Region C through the restoration of natural, river, and water quality processes; a substantial cooling effect in the fall; greater nighttime cooling and respite from warm water temperature conditions in the summer; and a reduction in overall system TDG.13 DEIS Chapter 3 presents the framework that was used to define the overall level of impact of water temperature outcomes for each CRSO EIS alternative. For water temperatures, the level of impact (negligible, minor, moderate, or major) was defined based on the absolute change in the maximum and minimum water temperatures as averaged over the 5-year simulation period (2011-2015)14. Taking a 5-year averaged approach to determine a single impact of each alternative fails the public by obscuring predictions of the numerical modeling effort which predicted hourly temperature changes for a wide range of hydrologic (wet, dry, average) and weather conditions (hot, cold, average). Appendix D presents more detailed predictions of MO3 actions on water temperature in graphics that clearly show between 2-10 F water temperatures 12 Executive Summary: Columbia River System Operations Draft Environmental Impact Statement, pg 24-25. 13 Columbia River System Operations Environmental Impact Statement Chapter 3, Affected Environment and Environmental Consequences, lines 6334 -6336, 6350-6353. 14 Chapter 3, 3.4.3.2 lines 5341-5345, Figure 3-108. CRITFC DEIS Comments April 13, 2020 Page 42 of 59 improvements for the Snake River during the critical summer and fall seasons for a wide range of hydrologic and weather conditions (Appendix D, Figures 6-23 to 6-27). In their decision framework, the DEIS defines water temperature changes of >2 degrees Fahrenheit to be a major impact15.	Regarding climate change, the climate science community is still developing models at the resolution necessary to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature to the Multiple Object alternatives (Section 4.2.3) and the Preferred Alternative (Section 7.8.4). Regarding water temperatures under dam breach scenarios, the analysis of MO3, which includes the measure to breach the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during high air temperature events. The models showed minor changes in the Columbia River under this alternative. There are many ways to look at water temperature impacts from the proposed EIS Alternatives. The co-lead agencies chose to use the daily maximum water temperature metric in our analysis since most state water quality standards for water temperature are based on this metric. The water temperature analysis specific to MO3 utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-dimensional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management, for 5 selected years (2011-2015). From these results, the co-lead agencies organized the EIS water temperature and TDG data using one methodology, but the agencies recognize that other techniques could be used. The methodology the agencies chose was used to bin results into negligible, minor, moderate or major categories based on the absolute change in water temperature, number of days that water temperatures exceeded state water quality standards and seasonality of change (based on whether anadromous fish are present or not). This methodology was reviewed by the EIS Fish Team and NMFS. In general, metrics were chosen based on: (1) absolute change in water temperature that the team considered to be a measurable; (2) change in the days that water temperature standards were exceeded that was determined to be more related to the EIS Alternative than seasonal/climatic variability. Hourly water temperature results for each five-year simulation are also provided in Appendix D. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3. However, the Preferred Alternative also meets all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The dam breaching alternative, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31775	94	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	In addition to the predicted cooling, diel temperature conditions predicted by the numerical models. The DEIS reports Average diel temperature differences seldom exceed 1 degree Fahrenheit under the no Action Alternative.Average differences would range from 2.5 to 3.5 degrees Fahrenheit for the same time period if MOE was implemented (Figure 6-29).16 Diel temperature fluctuation could provide thermal refuge for migrating adults even in the lower river. It is difficult to understand why the thermal benefits predicted by the numerical modeling for a free-flowing river were not part of the preferred alternative solution.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Diel cooling was reflected in the models as well as discussed and considered qualitatively. Overall, the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31775	95	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	EPAs used an alternative one-dimension model, RBM10, to evaluate the Columbia River system as part of the temperature TMDL process and also developed a model of a free-flowing river scenario. The DEIS reports EPA modeling results in Appendix D, Annex A that detail daily average temperature predictions with no Lower Snake River dams17. EPA also presented modeling results using RBM10 during the TMDL process18. The DEIS and EPA water quality models overlap geographically and temporally, and although the results may not be directly comparable, EPAs analysis offers comparison between a free flowing and impounded scenario that offers insights that supports the benefits of MO3. The free-flowing scenario results in a significantly cooler Lower Snake River by 1-2C during the period when the Snake River currently typically exceeds 20C (mid-July mid September). The free-flowing scenario significantly reduces the number of days that exceed a daily average of 20C. The cooler daily average temperatures in the summer and fall under the free-flowing scenario as noted above will result in cooler temperatures for a few migrating adult sockeye in July, for a significant number of adult steelhead in July, August, and September , and for a significant number of adult Fall Chinook in August and September19. Currently, in July and August the Snake River is warmer than the Columbia River by 2-3C at a time when Snake River temperatures exceed 20C. Adult steelhead may delay migration up the Snake and hold in the cooler Columbia River. In the MO3 scenario, the predicted cooling and 15 DEIS Chapter 3, line 5353, Figure 3-108. 16 DEIS Appendix D, line 4950-4954, Figure 6-29. 17 DEIS, Appendix D, Annex A, Figure 1-22, Table 1-22, line 481 18 EPA. 2019. Assessment of Impacts to Columbia and Snake River Temperatures using the RBM10 Model. Scenario Report. Phase 1. EPA Region 10. December 2019. 19 DART Adult Passage Fish Counts for All Species http://www.cbr.washington.edu/dart/query/adult_daily CRITFC DEIS Comments April 13, 2020 Page 43 of 59 diel fluctuations during this time could reduce or eliminate this potential thermal impediment to migration. The cooler summer and fall temperatures would provide less stressful migration conditions for adult steelhead and fall Chinook salmon migrating up the Lower Snake River. The DEIS process should have also included an alternative that combined optimized Dworshak releases to regulate water temperature with a free free-flowing Lower Snake River. The options that were only evaluated in MO1 which proposed releasing more Dworshak water in June/July, less in August, and more again in September/October. This schedule would release cold water during the peak of the sockeye and S/S Chinook migrations in June/July and again during the peak of fall Chinook and steelhead migrations in September and October. This option should have been combined with an evaluation of a free-flowing lower Snake River to fully evaluate the best options for fish survival.	There are a few key differences between EPA's RBM-10 model and the models used in the development of this EIS that should be made clear. First, the RBM-10 (TMDL) model predicts a daily average water temperature, while the CE-QUAL W2/RAS (EIS) model predicts a daily maximum value. The co-lead agencies chose the daily maximum water temperature metric since most water quality standards are based on this metric. Second, the RBM-10 model uses weather data from airport weather stations with the longest records, whereas the co-lead agencies used weather stations with the most spatial coverage and spatial representation (airport and AgriMet weather stations). Lastly, RBM-10 was utilized for a free-flowing scenario. The free-flowing scenario includes the absence of Grand Coulee, Chief Joseph, the five mid-Columbia PUD dams, the lower four Columbia River and the lower four Snake River dams. Dworshak Dam, however, was included in EPA's "free-flowing" scenario as a boundary condition and uses observed flows and temperatures. 2010 channel bathymetry is utilized throughout the system. The TMDL assessment focused on quantifying the thermal load of the dams by comparing existing conditions to a "free-flowing" scenario where Dworshak Dam is still in place. The co-lead agencies used HEC-RAS (1-dimensional model)for MO3 for the lower Snake River; CE-QUAL W2 (2-dimensional model) was used for the other mainstem CRS dams. MO3 includes breaching the four lower Snake River dams in which the earthen embankments of each dam are removed, leaving the concrete sections in place. All other CRS dams remain in place. Dworshak Dam uses modeled flows and temperature. 1934 (pre-dam) channel bathymetry is utilized throughout the lower Snake River; 2010 geomorphology used for elsewhere in the system. The CRSO EIS assessment focused on predicting water temperature and TDG conditions under MO3 . Given the differences between efforts, direct comparisons between the two assessments are not appropriate. Both models have been reviewed extensively by the agencies and concluded that both temperature models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As stated in EPA's review letter (#16-0059), EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS. The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used current high quality information and best resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. The water temperature analysis specific to MO3 utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-dimensional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. Specifically, 2016 No Action Alternative Dworshak operations were used in the MO3 analysis. The alternatives are evaluated in terms of change from the No Action Alternative, which is the baseline condition of 2016 when the development of the EIS began. The co-lead agencies defined the No Action Alternative consistent with NEPA and implementing regulations. In the case of an ongoing action, such as operation of the CRS, the no action alternative represents no change in current management direction or level of management intensity. The No Action Alternative thus assumes the existence of the CRS projects and does not attempt to hypothesize the direct and indirect costs of each of Congress's decisions to construct CRS projects. The EIS analyzing the effects of the No Action Alternative on resources, environmental and socioeconomic, at present and into the future. However, the EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. Thus the EIS did realistically and clearly analyze, to the extent practicable, whether the hydrosystem is causing or contributing to compliance with the water quality standards as compared to historic river temperatures.
31775	96	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	F. Power/Economics: The DEIS Power and Economics Analyses Are Deeply Flawed and Fail to Incorporate and Analyze Important Information Sources. Early in the DEIS development process, tribal staff urged the co-lead agencies to adapt their power analyses to recognize the rapid evolution of western energy markets and the role of the CRS in this setting. The ever-increasing integration of the Western electricity grid creates opportunities and threats for both fish and power. Independently from the DEIS process the co-lead agencies, state and tribal parties entered into a Flex Spill Agreement for an interim period of three years. Unlike the DEIS, the process for developing the Flex Spill agreement was forward-looking, innovative and collaborative. It was not and is not a comprehensive agreement and its limits are clearly described within the Agreement itself. Nevertheless, the Agreement was founded on innovations in analytical methods that assisted the parties collaborative dialogue. For instance, the Flex Spill Agreement is based on hourly spill operations in attempt to accommodate time-of-day pricing that occurs in Western energy markets.	The comment suggests that the EIS should have adapted its power analysis to recognize the rapid changes occurring in the western energy markets. The comment is not clear, though, as to what aspect of the western energy market the EIS omitted. The EIS recognizes that the energy market is constantly changing. To that end, the EIS included updated information concerning coal retirements, demand response, resource integration, and other factors that could affect the power analysis. Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, pages 3-829-841 in the Draft EIS. In addition, in response to comments, the Final EIS includes the data used in estimating replacement resources costs for solar and batteries using publicly released draft information from development of the Northwest Power and Conservation Council's 8th Power Plan. This is included as rate sensitivities in the Final EIS. The Final EIS also includes the de-escalating cost curves prepared by National Renewable Energy Laboratory (NREL) that will likely be used by the Council in the 8th Power plan. The EIS analysis also considers emerging technologies in the resources analysis, though it recognizes that most of these new resource options have not reached the scale needed in the EIS to be cost-effective. Section 3.7.3.5, Replacement Resource Options, pages 3-907-910 in the Draft EIS. The co-lead agencies are proposing an adaptive implementation framework for juvenile fish passage spill operations, which builds off the lessons learned from the 2019-2021 Spill Operation Agreement. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the CRSO EIS. The co-lead agencies intend to engage regional, state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects.
31775	97	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The selection of analytical methods was carried out solely by the co-lead agencies, despite offers of assistance from the tribes. As an example, CRITFC has extensive capability to perform analyses with a HYDSIM based analytical tool it developed for just this kind of setting. Called CIS, the analytical tool is capable of modeling and comparing multiple operation scenarios for CRS projects, quickly and easily. It has been used by the 15 tribes in the U.S. portion of the Columbia Basin to analyze the potential effects of modernizing the Columbia River Treaty. An explanation of CIS provided to the co-lead agencies is attached. CRITFCs offer went into a void. In the case of anadromous fish, the development of future system scenarios were not iterative. Rather it was based on a one-way information flow.	The cooperating agency assistance is very much appreciated throughout the NEPA process. As for the modeling of system operations the co-lead agencies have existing capabilities to represent complex operations of the system that allow feed-back and coordination between various resource areas. Hydroregulation (regulating water) is the process planners and operators use to make decisions about routing water through a series of dams in a river system. Computer hydroregulation modeling is used to simulate operations for the system of dams that operate for multiple purposes, including flood risk management, hydropower, irrigation, navigation, recreation, water supply, and fish and wildlife purposes. Two hydroregulation models were used to simulate operations in the basin in support of the Hydraulics and Hydrology (H&H) analysis: Hydro System Simulator (HYDSIM) and Hydrologic Engineering Center Reservoir System Simulation (ResSim) software. The models mesh together through multiple steps to simulate operations in the Columbia River Basin. More information on these models is available in Section 3.2 and in Appendix B of the Draft EIS.
31775	98	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Energy is important to certain economic sectors in the region, but overall the economy of the region is highly dependent on the natural capital provided by the Columbia River and its tributaries and other factors that is far larger than CRS energy outputs and which the DEIS failed to disclose or analyze. The DEIS should have disclosed to the public the broader natural capital values of the Columbia River Basin, which are described in The Value of Natural Capital in the Columbia River Basin: A Comprehensive Analysis by Earth Economics. https://ucut.org/wp- CRITFC DEIS Comments April 13, 2020 Page 44 of 59 content/uploads/2017/12/ValueNaturalCapitalColumbiaRiverBasinDec2017.pdf. This broader context of natural capital management is important economic context for changes in CRS configuration and operations, which are minor in comparison. The DEIS also fails to consider the effects of built capital resources on the natural capital of the Basin. In many cases, such as the CRS, the built capital has degraded the natural capital of the basin. This degradation is described in the Earth Economics report, the 1999 Tribal Circumstances report and the 2019 Tribal Perspectives document. The loss of the Basins natural capital has profoundly damaged the tribes cultures and economies. Restoring the natural capital lost to the tribes is not disclosed or analyzed in the DEIS. Moreover, future sustainability of the natural capital of the Columbia River Basin is not analyzed in the DEIS.	The EIS recognizes the environmental, social, and economic values of the natural resources of the Columbia River Basin and the focus of the EIS is on how the CRSO EIS Alternatives affect these resources. For example, Section 3.5 evaluates effects of the alternatives on fish and Section 3.15 describes the values that people hold for salmon, including for commercial fishing, ceremonial and subsistence purposes, and passive use (e.g., existence values); Section 3.11 describes the effects on recreation, including fishing and other types of recreation; and Section 3.17 provides information on the cultural significance of the salmon to regional Tribes. Beyond the effects on fish, the EIS additionally evaluates potential effects on wildlife species and habitats (Section 3.6), agricultural productivity (Section 3.12), and air quality (Section 3.8). The EIS also recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The Fisheries section (Section 3.15) as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries analysis (Section 3.15.2.1), which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. The Draft EIS acknowledges the information in the Earth Economics. In particular in Section 3.15 the EIS states, "[a] report by Earth Economics applied the mathematical model provided by Richardson and Loomis (2009) to estimate the existence values for salmon under present and hypothetical future conditions in the Columbia River (Flores et al. 2017). This study estimates an aggregate existence value across all 2.8 million households in the Columbia River Basin of $38.4 million annually for the current scenario versus $1.1 billion annually for a scenario where salmon populations increase by 51 percent. There is some uncertainty about the method used to estimate the 51 percent increase salmon population levels for the future scenario. Moreover, the study describes these estimates as existence values (i.e., synonymous with passive use values) that are additive with other types of values quantified and described in their report, including commercial fishing, recreational fishing, and cultural values. Based on the method employed to quantify these values, however, they are more likely reflective of a TEV estimate and should not be summed with other types of values."
31775	99	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	. Our prior comments urged the co-lead agencies to consider the Tribes Energy Vision for the Columbia River. It was originally published in response to the energy crisis of 2001, when the federal dams violated their ESA operation requirements.20 These violations were the result of regional utilities assumptions that spot market power supplies would be adequate to address the regions needs. These faulty assumptions cost BPA hundreds of millions of dollars.	Bonneville is aware of the Draft Energy Vision for the Columbia River cited by the commenter. This document was developed by external parties, and based on discussions with the Yakama Nation. It has not been finalized. The Tribes Draft Energy Vision document is discussed in more detail in other comments from the Yakama Nation (6299 and from CRITFC (31775). Many of the elements of this draft document are incorporated in the EIS. As described in Appendix H, Power and Transmission and Section 3.7.3.1, Base Case Methodology, the EIS employs a variety of industry standard models such as GENESYS, HYDSIM, AURORAxmp, GridView and powerflow modeling to assess the potential power and transmission effects of the alternatives and the replacement resource portfolios.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31775	100	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The 2003 Energy Vision for the Columbia River described solutions to address conflicts between peak power production and Columbia Basin salmon. Against the backdrop of fish problems associated with serving loads, the plan identified less harmful and less expensive ways to provide electricity for peak loads. A win-win combination. The CRITFC 2013 Energy Vision for the Columbia River builds on the recommendations made in 2003. Like its predecessor, the 2013 plan recommended measures to reduce the pressures of the regions energy demands on the Columbia River and its ecosystem. The Vision included the following recommendations: Reduce peak demands on the system. - Implement time-of-use pricing of power to reflect the full cost of generating and distributing power at different times of the day and year. - Implement programs to store power off peak to serve on-peak loads. - In water heaters; - In existing and added mass in buildings; and - In electric vehicles controlled to use off-peak power. - Implement fuel switching where appropriate Expand programs to improve energy efficiency. - Secure all cost-effective conservation - Ensure that utilities meet the Northwest Power and Conservation Councils energy-efficiency targets. - Expand low-income programs. - Expand commercial building programs. Meet the renewable performance standards established by states. - Develop wind energy. - Develop solar energy. - Develop a comprehensive plan to site renewable resources 20 Notably, FERC licensed dams on the Columbia River did not violate their fish operating requirements in 2001. CRITFC DEIS Comments April 13, 2020 Page 45 of 59 Site strategically located resources. Take additional actions to address emergencies and dry year strategies. Improve ecological function for fish and wildlife and reduce flood control costs as part of the review of the Columbia River Treaty.	The comment lists a variety of potential energy technologies and conservation efforts as well as other objectives recommended for the EIS and co-lead agencies to consider. Regarding conservation and other technologies to reduce peak demand, the EIS included all cost-effective conservation identified by the Northwest Power and Conservation Council and included demand response in the renewable energy portfolios to address peak demand. See Appendix H, Power and Transmission, Section 2.2, H-2-3; Section 3.7.3.1, Demand Response Analysis for CRSO, at 3-837 in the draft EIS. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, as is forecast in MO3. The EIS also considered wind and solar energy as replacement resources. Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at 3-904-910; see also Table 3-160 in the draft EIS. Many of the other recommendations are broad regional goals, which while not exclusively analyzed in the EIS are discussed in the EIS power analysis in Sections 3.7.2, Affected Environment and 3.7.3, Environmental Consequences as well as in the greenhouse gas analysis (Section 3.8) of the Draft EIS (for example, the importance of renewable energy for state clean energy goals, see Section 3.8.2.2 State Renewable Energy Targets). The EIS identifies the Preferred Alternative as striking a balance as suggested by the comment. As described in Chapter 7, the Preferred Alternative met the objectives of improving survival for ESA-listed fish species by including measures designed to benefit ESA-listed fish species, including structural measures (Section 7.6.2), operational measures (Section 7.6.3), and mitigation measures (Section 7.6.4). The Preferred Alternative also met the objective of ensuring an adequate, reliable, and economic supply of power. Overall, the Preferred Alternative results in a small power rate increase to power customers of Bonneville compared to the No Action Alternative. See Section 7.7.9, Table 7-32 of the Draft EIS.
31775	101	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The DEIS fails to disclose and analyze the tribes concerns and recommendations to evolving nature of the regions energy demands and the pressures they place on the Columbia Rivers ecosystem, including its anadromous fish. We are pleased that the DEIS recognizes the NW Councils regional energy plan, but the tribes Vision goes beyond the Councils regional energy planning. We specifically incorporate by reference herein the power and economics comments of the Yakama Nation. The analyses reported by the Yakama Nation were developed with input and support from the technical staff of CRITFC. Rather than repeat this content in CRITFCs comments, we are specifically incorporating the Yakama Nations power and economics analyses by reference.	Bonneville is aware of the Draft Energy Vision for the Columbia River cited by the commenter. This document was developed by external parties, and based on discussions with the Yakama Nation. It has not been finalized. The Tribes Draft Energy Vision document is discussed in more detail in other comments from the Yakama Nation (6299 and from CRITFC (31775). Many of the elements of this draft document are incorporated in the EIS.
31775	102	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	G. The DEIS Fails to Consider Additional Related and Important Effects - Effects of the Mid-Columbia PUDs were not adequately considered The DEIS generally ignores the Mid-C PUD dams in description of the Upper Columbia salmon and steelhead stocks. These dams are important, particularly for cumulative effects, but also because upriver CRS operations directly impact survival through the mid-Columbia reach (flow timing and volume, temperature and TDG). It is important to observe how upriver operations affect system survival and system travel time for Upper Columbia stocks for each MO.	Impacts from Mid-Columbia Public Utility District (Mid-C PUD) projects are acknowledged. Mid-C passage effects were considered in Smolt-to-Adult return rates (SARs) and PIT tag powerhouse passage (PITPH). A quick analysis of relative change in survival between the No Action Alternative and Multiple Objective alternatives (MOs) shows that nearly all of the change occurs in the lower Columbia River projects. Upstream operations in the MOs compared to the No Action do not appear to be changing the PUD passage response. Rock Island to Bonneville survival rates are reported in Appendix E for National Marine Fisheries Service COMPASS model results from the Upper Columbia Chinook ESU. When comparing levels of change in major metrics between the MOs and the No Action Alternative, adding the Rock Island-to-McNary segment does not significantly change the level of effect that one would interpret from spill or dam breach. Moreover, the EIS analyzes generation changes for the Mid-C PUD projects in Appendix J, Exhibits 3 through 6.
31775	103	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Alternative flood risk management regimes and the Columbia River Treaty should have been considered in the DEIS analysis The tribes envision the need for new flood risk infrastructure in the U.S. to minimize the consequences of high flows. A domestic regional flood risk management review for the Columbia Basin was recommended in the U.S. Entity Regional Recommendation on the Future of the Columbia River Treaty after 2024. A regional flood risk study is needed to determine what levee system upgrades, lower value floodplain reconnections, and floodplain management changes are needed to minimize the risk of damaging floods while providing greater flexibility in operations of U.S. and Canadian reservoirs to integrate ecosystem-based function into Columbia River flow regimes. The DEIS fails to disclose or analyze the tribes recommendations.	The current operations of the Columbia River System, including current Treaty-related operations, are included in the EIS analysis. If Treaty-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary. Section 2.5.10 of the Draft EIS explains why re-evaluating system flood risk management was screened out from further consideration in this EIS. Section 2.5.10 also explains that while the U.S. Entity Regional Recommendation stated support the pursuit of Congressional authorization and appropriations for a region-wide public process to assess potential changes to the current level of flood risk protection, no such authorization or appropriation was provided. As such, a study for this purpose was determined to be outside of the scope of this EIS.
31775	104	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The effects of the Columbia River Treaty are briefly described in Chapter 3, but much more could have been disclosed to the public. The Columbia Rivers ecosystem functions and values were not considered in shaping and implementing the Treaty. This lack of consideration caused serious degradation of the ecosystem and undermined historical tribal economic and social resources that depend on it. Goth the U.S. and Canada recognize that a modernized Treaty needs to be adaptable to climate change and the corresponding changes in basin meteorology and hydrology. The tribes believe a comprehensive CRITFC DEIS Comments April 13, 2020 Page 46 of 59 study should be undertaken pursuant to a modernized Treaty to investigate water management options and structural changes at dams that could mitigate the anticipated changes in hydrology and water quality that are already problematic with the current system of dams. https://www.critfc.org/wp-content/uploads/2014/12/ecosystem-booklet-single-page.pdf	The current operations of the Columbia River System, including current Treaty-related operations, are included in the EIS analysis. If Treaty-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary.
31775	105	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The cumulative effects of the Columbia River Treaty merited mention in Chapter 6 in three brief sentences. Likewise, the adequacy and health of existing regional coordination, alignment, and planning actions will not be assessed for the purposed of this EIS, but nonetheless merits mention for context. The United States and Canada began negotiations in 2018 to modernize the Columbia River Treaty regime. The negotiations are currently ongoing, therefore any potential effects on the environment that may result from that effort are not reasonably foreseeable. The co-lead agencies chose not to disclose Canadian reservoir operations, which has frustrated systemwide comprehensive evaluations. In the context of the Columbia River Treaty, the tribes have evaluated total U.S. and Canadian system operations using the CIS modeling tool that incorporates HYDSIM logic and functions. These have been presented in widely distributed publications, including in a publication entitled: Ecosystem-Based Function Integration Into the Columbia River Treaty. Unfortunately, the DEIS does not disclose or analyze this information. https://www.critfc.org/wp-content/uploads/2014/12/ecosystem-booklet-single-page.pdf.	The comment appears to be asking for Canadian reservoir operations to be in the Draft EIS as well as inclusion of ecosystem analysis completed by the Tribes on the U.S. and Canadian System operations. The HEC-WAT and HEC-ResSim model documentation appendix (Appendix B, Part 3) and the Hydroregulation appendix (Appendix I) provide an overview of the operating assumptions used to represent Canadian operations. Because operational changes to Canadian reservoirs were not considered in the EIS, the description of No Action operating assumptions include ecosystem analysis of current Canadian operations. The current operations of the Columbia River System, including current Treaty-related operations, are included in the EIS analysis. If Treaty-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary.
31775	106	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Analysis of reservoir ecology should be included in the DEIS. There are important extant regional models to assist in defining anadromous salmonid mainstem and estuary habitat that were not utilized but should have been in the CRSO DEIS. This is surprising because the co-lead agencies and basin tribal and state sovereigns used them to assist in better defining ecosystem function attributes during the 2012-2014 Columbia River Treaty Sovereign Review process. These include the USGS chinook and sturgeon spawning habitat models. References below: - Hatten, J.R., Parsley, M.J., 2009. A spatial model of white sturgeon rearing habitat in the lower Columbia River, USA. Ecological Modelling 220:36383646. - Hatten, J.R., K.F. Tiffan, D.R. Anglin, S.L. Haeseker, J.J. Skalicky, and H. T. Am. Fish. Soc. 122, 217e227. - Parsley, M.J., Beckman, L.G., 1994. White sturgeon spawning and rearing habitat in the Lower Columbia River. N. Am. J. Fish. Manag. 14, 812e827. - And the Coastal Zone Margin and Prediction estuary salmon habitat preference model sand near ocean plume relationships: Buria et al. 2010. The influence of the Columbia River plume on the survival of steelhead (O. mykiss) and Chinook salmon (O. tshawytscha) a numerical exploration. Canadian Journal of Fisheries and Aquatic Sciences, 2010, 67(10): 1671-1684, https://doi.org/10.1139/F10-083.	Given the time constraints on developing the EIS, the co-lead agencies had to rely on existing models that were ready to be utilized for the analysis. In the case of the USGS reservoir model, it was not in the right format for evaluating the measures the multi-objective alternatives in this EIS and needed substantial further development to be utilized.
31775	107	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	H. The Effects of Climate Change Are Not Adequately Evaluated The DEIS lack of quantitative regulated flow and river operations modeling based on the RMJOC II 160 climate change projections is a significant flaw. The DEIS states that the approach BPA used to examine four of the RMJOC II climate change scenarios does not meet the policies or technical guidance of the Corps or Reclamation under the time frame of the EIS. This is a significant failing of the DEIS to adequately evaluate the DEIS alternatives for climate change impacts as required by ESA and NEPA. We anticipate that Phase II of the RMJOC II project will contain the Phase I climate change scenarios with regulated flows and river operations based on updated flood risk and irrigation data is necessary to fill this inadequacy. The DEIS notes that having quantifiable understanding how future climate may impact EIS alternatives is important to BPAs understanding of impacts to generation and revenue in the future. It is no less important and is vital to understanding the other metrics examined in this EIS such as flood risk, ecosystem function with respect to anadromous and resident fish, water quality, recreation and water supply. In this section, the DEIS notes that the four climate change scenarios BPA chose to evaluate for power generation provide a general spread of future climate scenarios, but they are not adequate considering the full suite of 160 climate scenarios in the RMJOC II study.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
31775	108	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The approach used to estimate and compare power generation and review four RMJOC I unregulated climate change scenarios by regulating them through HYDSIM runs is an interesting preliminary first look but lacks adequate daily flood risk rule curves and appears to lack validated modified flows. The details of how the DEIS established data sets used to replace the 80-year modified flow data set and the volume forecast data sets used in all of the alternatives are not provided. Assumptions are provided as to how BPA established URCs for the four climate change scenarios, but they are not the approach that is required for robust flood risk evaluations. The revised URCs are based on the HYDSIM 14 period time step and do not have the precision of the daily time steps that the Corps uses when generating flood risk curves and URCs. In addition, the four climate scenarios chosen were based on the spread of 160 scenarios, culled down to 19 scenarios and based on annual runoff. It would much more informative to examine a fuller suite of scenarios culled by seasonal volumes for each metric considered (i.e. spring and early summer volume forecasts for fish; winter volume forecasts for flood risk).	Thank you for these comments and observations. Technical details on how the climate change streamflows compare to historical datasets and water supply forecasts developed for the hydroregulation studies will be available in the forthcoming RMJOC-II, Part 2 publication. The commenters correctly state that HYDSIM runs on a 14-period time step. While this temporal resolution is adequate for longer-term hydropower analyses, and intercomparisons between the alternatives with respect to the selected climate change scenarios, the temporal resolution of HYDSIM is too coarse for robust flood risk and biological assessments, which typically require reliable daily flow and temperature inputs. For the purposes of this Draft EIS, the four climate change scenarios examined, which capture a wide range of possible climate change outcomes, were informative vis-a-vis the alternates, as described in Appendices I and J.

31775	109	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	In Appendix J Hydrogeneration, the summary section that provides the results of the model comparisons between historical climate (80-year historical record) and the four RMJOC II climate scenarios for all of the DEIS alternatives. These results indicate there were negligible differences between historical climate and future climate change scenarios for all DEIS alternatives with respect to power generation and revenue. Dynamic changes to potential load demand and market shifts from winter generation to summer generation, new generation resources and conservation technologies are all important uncertainties under current examination by BPA and the Northwest Power and Conservation Council. These uncertainties need to be assessed, weighed and accounted for in revised EIS modeling to establish a more robust approach to examining climate change effects on future power needs.	Section 4.2.5.2 in the Draft EIS describes the projected effects of increasing temperatures on demand (load) and projected effects on reliability (e.g., if climate change is expected to exacerbate or ameliorate reliability issues) for each alternative. This analysis relies on current, best available studies by the Northwest Power and Conservation Council and PNNL. Issues surrounding shifts in loads and markets, resource development, and reliability are, as the commenter points out, uncertain and under ongoing evaluation by multiple entities in the region. Further analysis would be speculative and highly uncertain at this time, so was not included in this EIS.
31775	110	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	VII. Mitigation The CEQ regulations concerning mitigation describe several types of mitigation actions at 40 CFR 1508.20. As pointed out in the DEIS, these include rectifying the affected environment and compensating for the impacts to resources of concern. The DEIS fails to adequately consider ongoing mitigation programs and irrationally limits the scope of proposed mitigation.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure.
31775	111	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	A. Continuing Mitigation Actions Are Not Adequately Described or Considered Within the Affected Environment and Analytical Framework While the DEIS NAA assumes a 2016 Baseline, the discussions in the Affected Environment sections do not meaningfully depict the nature and extent of the cumulative impacts that the Basins hydrosystem has had on the Columbia Basins anadromous fish. The NAA carries with it substantial unmitigated salmon and steelhead losses due to the CRSO dams configurations and operations. The broad scope of these impacts is described in multiple sources, including the Tribal Perspectives submitted by Warm Springs, Umatilla, Nez Perce and Yakama tribes in June 2019. In an effort spanning multiple years with numerous public hearings in a notice and comment style, the NW Power Planning Council considered the extent of hydropower related salmon and steelhead losses and concluded by adopting Program goals in 1987. The effort is described in multiple volumes. https://www.nwcouncil.org/reports/2014-columbia-river-basin-fish-and-wildlife-program/appendix-b-estimates-hydropower-related-losses. Costs for Implementing the Fish and Wildlife Program are approximately $300 million annually, recently reduced to $282M. Program implementation is a key factor in the overall balance of activities that fulfills the equitable treatment mandates that apply to the co-lead agencies pursuant to 16 USC 839b(h)(11). The cost analysis in Appendix Q suggests reducing Fish and Wildlife Program funding and proposes funding cuts that are so substantial that they represent major shifts in regional governmental activities and policies. Appendix Q describes a $105 million/year (37%) reduction of Program spending associated with MO3 and MO4. Appendix Q describes a metric, benefits, that would evidently justify this 37% reduction in Program funding. There is, however, no actual appraisal in the DEIS of the biological benefits of the BPA actions implementing the Fish and Wildlife Program, let alone an analysis placing such benefits in the context of the full extent of the CRS dams effects. Without more, it is simply irrational to assume that co-lead agencies statutory obligations under the Northwest Power Act can be met using such gross assumptions. Unless the DEIS contains a thorough, accurate and meaningful discussion of the Fish and Wildlife Programs implementation, including progress toward its goals and mitigation objectives, there is no basis to assume a 37% funding reduction in Program implementation should accompany MO3 and CRITFC DEIS Comments April 13, 2020 Page 50 of 59 MO4 While federal agencies are given latitude in establishing their objectives in a NEPA analysis, that latitude does not relieve the agencies from considering cumulative actions, cumulative impacts as well as direct and indirect effects. In this regard, the DEIS fails to accurately consider the context and intensity of the dams historic and long-term effects as well as this context for establishing appropriate mitigation measures. This situation is again symptomatic of the structural flaws that flow from an inadequate analysis of the CRSO dams cumulative baseline effects and a DEIS scope that only seeks improvement in juvenile and adult passage. Since reductions in Fish and Wildlife Program funding are beyond the stated scope of the DEIS objectives, the DEIS should not purport to analyze such measures.	The co-lead agencies disagree with the supporting documentation for the statement regarding substantial unmitigated salmon and steelhead losses. The Northwest Power and Conservation Councils (Council) anadromous fish loss assessments are often mischaracterized. The mischaracterization is in that the assessments were for the impacts of all the hydroelectric projects in the Columbia River basin, all 137 dams existing at the time, not just the 14 CRS projects considered in the EIS. 1/ Moreover, the assessments state that, [i]n several parts of the discussion, there are references to the approximate contributions of groups of projects to salmon and steelhead losses. These are included only for the purpose of estimating system hydropower-related losses, not to determine particular responsibilities within that system for mitigating the losses. 2/ Thus, the Councils anadromous fish loss assessments do not provide a reliable basis for establishing the CRS contribution for those losses, which also makes it impractical to track the degree to which the co-lead agencies mitigation efforts have addressed the goals and objectives that incorporate these broader losses. The loss assessments also use a baseline that predates the effects of commercial fishing, industrial pollution, mining, logging, irrigation withdrawals, and other development. The effects of those sources drastically reduced anadromous fish runs well before construction of the first CRS dams began. In considering appropriate mitigation baselines under the Federal Power Act, with mitigation provisions for non-Federal dams similar to those for the Federal projects under the Northwest Power Act, courts have rejected pre-project baselines. For example, in a licensing proceeding for a mid-Columbia dam, FERC found that because the extent of losses to fish and wildlife due to project development [was] virtually undocumented . . . fish and wildlife mitigation based on pre-project resource levels [was] unrealistic and unwarranted. Pub. Util. Dist. No. 1 of Chelan County., Wash., 15 FERC 62,168, 63,280 (1981); see also City of Tacoma, Wash., 98 FERC 61,274,62,095 (2002) (we do not attempt to recreate pre-project conditions or to hypothesize an environmental baseline that assumes that the project does not exist. Thus, our starting point must be the Cowlitz Project as it is currently configured . . .). Similarly, the Ninth Circuit has found that it defies common sense and notions of pragmatism to develop a 50-year-old baseline in an attempt to guide present day decision making. American Rivers v. FERC, 187 F.3d 1007, 1018 (9th Cir. 1999). Another court rejected pre-project baselines, stating: The statutory words fish and wildlife . . . affected by the project seems to refer to the fish and wildlife currently existing [and . . .] surely cannot refer to the animals inhabiting the area in 1899, when the project came into being. Conservation Law Foundation v. FERC, 216 F.3d 41, 46 (D.C. Cir. 2000). The Councils anadromous fish loss assessment and the goals based upon it do not consider the status of fish resources when the CRS dams were first built or distinguish the effects of the CRS from over 100 non-federal hydroelectric projects or other causes of fish mortality such as fishing, pollution, or water withdrawals. Therefore, the assessment and goals provide little useful guidance to the co-lead agencies efforts to manage the CRS in a manner that fulfills their Northwest Power Act mandates. The comment also raises concerns about equitable treatment stating that the statutory mandate applies to Bonneville's off-site mitigation program implemented to fulfill its Northwest Power Act section 4(h)(10)(A) responsibilities. As discussed in Section 5.1.2, the section 4(h)(11) equitable treatment standard applies to Federal Columbia River Power System (FCRPS) management and operation only, and it does not apply to Bonneville's section 4(h)(10)(A) mitigation funding responsibilities. Next, the comment questions the adequacy of the analysis in the EIS because it does not include a comprehensive review demonstrating the efficacy of Bonneville's Fish and Wildlife Program. The description of the affected environment throughout the relevant sections in Chapter 3 of the EIS by definition reflects the effects of past and ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. 3/ The comment also questions the analysis of reduced Fish and Wildlife Program funding under MO3 and Multiple Objective alternative 4 (MO4). Funding decisions for the Fish and Wildlife Program are not being made as a part of the CRSO EIS process. However, a range of potential Fish and Wildlife Program costs are included to inform the broader cost analysis for each alternative in the EIS. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. In the case of MO3 and MO4, Bonneville included a range of potential Fish and Wildlife Program costs to acknowledge the possibility that the alternatives could provide biological benefits to anadromous fish species and that this could, in turn, reduce the need for some offsite mitigation funded through the Bonneville Fish and Wildlife Program. With respect to anadromous fish, the Northwest Power Act calls for improved survival at the dams and flows of sufficient quality and quantity . . . to improve [their] production, migration, and survival. The co-lead agencies demonstrate throughout the EIS how they meet these statutory objectives. The Columbia River Basin Fish Accord Extensions (Fish Accords) and Bonneville's comments to the Council on its 2020 amendment process also highlight the actions the Agencies have taken to fulfill this anadromous fish mandates of the Act.5/ Under MO3 or MO4, operational, structural and mitigation measures would substantially benefit anadromous fish. This would allow, if not necessitate, reductions in off-site mitigation funding. Future budget adjustments to the Fish and Wildlife Program would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Moreover, the co-lead agencies note that through the 2008 Fish Accords and the 2018 Accords Extensions, six tribes, one tribal association, and two states voluntarily affirmed the legal and biological adequacy of CRS operations as well as the off-site mitigation done through Bonneville's Fish and Wildlife Program. Several of the Accord partners published a 10-year review of its Accord-related mitigation accomplishments and the biological benefits obtained. In that report, the entity found Bonneville's $261 million annual funding level during the Accords and mitigation effort was consistent with the Northwest Power Act. 1/The Council says there are now 274 dams in the basin (with 19 of those in Canada). See https://www.nwcouncil.org/reports/columbia-river-history/damshistory) versus 136 (with 10 in Canada) that were considered in hydrosystem impacts of 1986 loss assessments (see Council, 2014 COLUMBIA BASIN FISH AND WILDLIFE PROGRAM, App. D at 137). 2/Council, 2014 COLUMBIA RIVER BASIN FISH AND WILDLIFE PROGRAM App. E at 1, Numerical Estimates of Hydropower-Related Losses. 3/Draft EIS, Appendix V, 2020 CRS Biological Assessment, Appendices D and E. 4/See 16 U.S.C. 839b(h)(6)(E). 5/ See Bonneville, Recommendations to the Council on Amending the 2014 Fish and Wildlife Program (Dec. 13, 2018) https://app.nwcouncil.org/uploads/2018amend/recs/765/Bonneville%20Recomendations%20to%20Council%20FW%20Program%20Amendment%2012.13.2018.pdf; Final Comments on Draft Addendum Part II (Oct. 18, 2019) https://app.nwcouncil.org/uploads/2018amend/comments/1341/Final%20Bonneville%20Comments%20on%20Draft%20Council%20Addendum%202019.10.18.pdf 6/Columbia River Inter-Tribal Fish Commission, COLUMBIA BASIN FISH ACCORDS 10-YEAR REPORT (Aug. 2018) https://www.critfc.org/wp-content/uploads/2018/08/accords-10yr-summary_spread.pdf. 7/ Id. at 5.
31775	112	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	B. Proposed Mitigation Measures Fail to Mitigate for Identified Impacts The mitigation chapter does not reflect the significant input requested of, and provided by, the Cooperating Agencies. The mitigation measures were intended to be a toolbox approach where numerous measures could be identified and then applied as needed to the Preferred Action. The approach taken in the DEIS was to only apply limited to no mitigation to the MOs, thereby limiting the mitigation available to the PA. The DEIS fails to identify adequate mitigation for affected resources. Specific impacts are identified in Affected Environment, but there is no reference to those impacts in Mitigation chapter. There are several affected environments where a significant impact is identified, yet no mitigation action is recommended. For example, adult impacts are identified in MO1 and MO4, yet there are little and not mitigation for this impact identified by the alternatives. Another example, the DEIS notes a likely increase in Northern Pike predation but the mitigation section only calls for continuation of the current predation programs and not looking at enhancing the program to deal with the predation issue.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. Regarding northern pike, the co-lead agencies recognize and appreciate the importance of northern pike invasion as a regional issue, and did include analysis where alternative operation, maintenance, and configuration of CRS projects could affect them. An analysis of northern pike invasion in Region B, resident fish noted minor effects to northern pike in the Lake Roosevelt/Chief Joseph Dam area due to a minor change in boat ramp access for ongoing suppression efforts in wet years. In this EIS process the co-lead agencies only develop mitigation for moderate to major effects of the multiple objective alternatives as compared to the No Action Alternative. The assertion that no mitigation is included for resident fish is inaccurate. In most cases, effects to resident fish were either beneficial or minor. Mitigation for the resident fish effects is included in the Preferred Alternative as follows: Line 1263: Plant native wetland and riparian vegetation (up to 100 acres) on the Kootenai River downstream of Libby. Line 1281: Spawning habitat augmentation at Lake Roosevelt Line 1330: Bull trout access to perched tributaries in Kootenai River Line 1344: Study offseason surface spill for downstream passage of adult steelhead (and bull trout)
31775	113	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	For salmon and steelhead, the mitigation section is wholly inadequate and does not appear to make sense. The DEIS uses the NAA as the baseline for mitigation responsibility, but the NAA was determined to be inadequate to avoid jeopardy by the court.21 It would follow that any alternative that does not produce a moderate improvement to the NAA should therefore carry significant mitigation actions to demonstrate a cumulative benefit that exceeds historic survival values. The DEIS does the opposite it provides little to no fish mitigation in all alternatives, 21 Under the No Action Alternative, COMPASS predicts that in-river survival of juvenile Snake River Chinook and steelhead from the Lower Granite to Bonneville Dams would be 50 and 43 percent, respectively. These values are lower than historic values of 53 and 56 percent from recent years (Widener et al. 2018). Similarly, COMPASS modeling predicts survival of upper Columbia River Chinook salmon and steelhead for the No Action Alternative would be 70 and 66 percent, respectively. These values are also below the historic values of 84 and 74 percent. CRITFC DEIS Comments April 13, 2020 Page 51 of 59 and if fact, no mitigation is provided for upper Columbia stocks where every alternative provides a worse condition than the NAA: For MO1, the summary tables of anadromous fish effect in Table 6-20 indicate that MO1 would be similar to the base case which was found to not be sufficient to meet jeopardy standards. However, MO1 has little to no additional mitigation actions. The mitigation proposed for salmon and steelhead is to revert backwards to the operation proposed in the NAA for Little Goose Dam and continue existing predator management programs. No other mitigation is proposed. As discussed with the PA, continuing existing predator management programs at NAA funding levels is not an improvement over the NAA. Rather than reverting to NAA spill levels to encourage adult migration, at the expense of juvenile migrants, the co-lead agencies should propose improvement of the	The mitigation identified in the EIS is to offset impacts of each Multiple Objective alternative compared to the No Action Alternative, which was the scope of analysis for this EIS. NEPA does not require identification of mitigation for the continuation of the No Action Alternative. Each alternative, including the Preferred Alternative, has a number of proposed measures intended to benefit fish. Multiple Objective alternative 1, Multiple Objective alternative 3, Multiple Objective alternative 4 and the Preferred Alternative all meet the objectives for adult and juvenile ESA-listed fish, as well as resident fish, with an overall beneficial effect over the No Action Alternative, and did not have an overall adverse effect to fish; therefore additional mitigation was not warranted. Additionally, Chapter 5 in the final EIS has been updated to include information previously included in the draft EIS in Sections 3.7 and 3.19 that Bonneville's Fish and Wildlife Program would increase under MO2 to address potential additional impacts to fish and wildlife.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				adult fish ladder at Little Goose Dam or construction of a second ladder. This mitigation action was recommended by the tribes for the mitigation toolbox. For MO2, the co-lead agencies propose no mitigation actions for salmon and steelhead because even though the alternative is stated to decrease survival for both juveniles and adult abundance. If the NAA poses jeopardy for salmon and steelhead, there should be a significant mitigation package attached to this alternative. For MO3, the co-lead agencies propose short term mitigation to offset short term impacts caused by breaching the lower Snake dams. They propose constructing or improving trap and haul facilities to get fish out of the river and transport them around the zone of breaching. They also propose to rear more hatchery fish during the construction phase of breaching to replace two lost year classes of salmon and steelhead. The effect of this mitigation action does not offset the impact but reduces the number of fish impacted. No other mitigation is proposed. For MO4, again the co-lead agencies propose to revert backwards to the operation proposed in the NAA for Little Goose Dam and rely on existing predator management programs as described under MO1. No other mitigation is proposed. As with MO1, with adult passage identified as a concern, a second fish ladder at Little Goose (and possibly Lower Granite) should be considered as an appropriate mitigation action. For All MOs and the PA, the DEIS proposes continuation of current (NAA) predator control measures without addition or enhancement, however this fails to recognize: avian predation measures are not meeting biological goals or have been deemed complete without meeting such goals. See discussion under PA comments. likely increase in Northern Pike Minnow predation, which the DEIS does recognize but keeps the program at current levels. increases in pinniped predations, which the DEIS also recognizes as likely or uncertain, but fails to mitigate. CRITFC DEIS Comments April 13, 2020 Page 52 of 59 Many examples exist for additional Affected Environments (e.g.; Water supply, Navigation, etc.) but due to time constraints we have limited our comments to salmon and steelhead. The Draft fails to present a single plausible MO alternative that would meet judicial muster.	
31775	114	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	C. Offsite Mitigation is Lacking The Offsite Mitigation Package (DEIS 5-29, 5-33) is lacking in several areas: - Habitat Research Monitoring &Evaluation. This section is woefully inadequate with regards to habitat condition, implementation of habitat restoration, and evaluation of biological responses. Tributary habitat restoration projects are implemented to reduce the impacts of limiting factors and increase the survival and productivity of focal species of interest. There should be a strong commitment to protecting and improving tributary habitat and implementing monitoring programs for assessing the impacts of limiting factors and effectiveness restoration actions. This will help to inform critical additional habitat improvement needs. The DEIS does not discuss significant regional habitat strategies in progress: the Habitat RM&E Strategy and the Habitat Implementation Strategy. Both strategies are attempting to synthesize standardized metrics (or indicators) of habitat conditions, habitat implementation and the impact on biological response. In addition, the DEIS fails to discuss the Northwest Power Planning Councils Research Plan regarding tributary habitat uncertainty research (2017-4). The following are key RM&E questions or uncertainties from this document. The EIS fails to disclose or analyze these important habitat questions. Question 1. Do investments in tributary habitat restoration mitigate for degraded mainstem habitat and passage conditions? 1.1. To what extent do tributary habitat restoration actions improve the survival, productivity, distribution and abundance of native fish populations? 1.2. How much does improving habitat and eliminating barriers (removing dams and culverts, or transporting migrating fish above dams) increase carrying capacity and contribute to recovering important fish populations? 1.3. To what extent is an increase in carrying capacity usurped by non-native invasive species, preventing recovery of native fish and wildlife populations? 1.4. To what extent do restoration efforts provide resilience to buffer against climate events and recover native species of interest? Question 2. What additional habitat restoration projects should be implemented to benefit fish and wildlife? 2.1. Are the cumulative suites of restoration actions benefiting populations of fish and wildlife in tributary watersheds? 2.2. How can habitat restoration actions support or enhance cold water habitat to provide thermal refuges?	Please see the response to Comment 6894-55 from the Confederated Tribes of the Umatilla Indian Reservation.
31775	115	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Habitat Restoration. Offsite mitigation should include increased floodplain restoration actions in tributaries. CRITFC member tribes and others are aggressively assessing and addressing primary limiting factors which are causing significant juvenile fish loss in tributaries. The degree of stream channelization in some Columbia Basin tributaries exceeds 75 percent therefore floodplain restoration must be aggressively embraced as offsite mitigation in the DEIS. Recent Columbia Basin Partnership Task Force modeling determined that tributary juvenile fish mortality in the mid- Columbia sub-region accounts for the highest level of fish mortality in all salmon and steelhead life history phases. The DEIS should recognize and be informed from this effort. For instance, CTUIR is implementing a science-based approach to restore floodplains to naturally functioning and sustaining ecosystems. It is paramount that this work be maintained or increased to continue address the most limited fish life history stages.	This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. The analyses used in this EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Habitat mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs. For the purposes of comparing alternatives, however, a more detailed description is not needed. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative. The scope of this Draft EIS is the operation and configuration of CRS projects; a complete analysis of all habitat programs and the development to the specificity suggested in this comment is beyond this scope.
31775	116	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Lamprey Restoration Since at least 1995, the tribes have worked hard to develop and implement tributary lamprey restoration projects. Beginning in 2000, tribal efforts focused on translocation of adult lamprey as a means to re-establish extirpated segments to the lamprey population of which we are just now beginning to see lamprey benefits. The CRITFC member tribes have collectively developed and implemented the Tribal Pacific Lamprey Restoration Plan (CRITFC 2011) and more recently the Master Plan: Pacific Lamprey Artificial Propagation, Translocation, Restoration, and Research (CRITFC 2018). These guiding documents provide the pathway for recovery actions in the mid to upper Columbia River and Snake River basins. These plans have had review and support from our federal and state partners and provide significant detail regarding needs, schedule and funding for lamprey recovery. The DEIS should recognize and embrace these efforts. Additionally, the USFWS Lamprey Conservation Agreement has over 140 signatories in support of lamprey recovery throughout their historical range. Off-site mitigation for lamprey will need to occur to ensure that recovery actions are able to be fully funded and implemented, without it would be unacceptable and would not be aligned with tribal recovery goals and efforts.	Under the No Action Alternative (Page 3-400) the Draft EIS recognizes these efforts in summary with There are numerous actions to benefit Pacific lamprey, including projects like the Pacific Lamprey Conservation Initiative and the Tribal Pacific Lamprey Restoration Plan. These plans improve understanding of Pacific Lamprey status and limiting factors, implement high-priority habitat restoration actions, increase populations through reintroduction and translocation efforts, and conduct artificial propagation research with plans to release hatchery juveniles in select areas pending an environmental assessment. These actions are expected to continue under each of the multi-objective alternatives, so for the purpose of this Draft EIS were not described in further detail. This does not at all diminish the co-lead agencies' intention to continue recognizing and embracing the efforts of the Tribes as future activities are coordinated within the frameworks established in the Region under these plans and the USFWS Pacific Lamprey Conservation Initiative. The measures in the Preferred Alternative to meet the objective of improving conditions for Pacific lamprey were designed to work in concert with the ongoing mitigation programs such as the habitat restoration, reintroduction and translocation, and other efforts in full collaboration with these forums.
31775	117	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	#NAME?	The scope of this Draft EIS is the operation, maintenance, and configuration of fourteen CRS projects. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative. A complete analysis of all hatchery programs and the status of maintenance/operations of each one is beyond the scope of this EIS.
31775	118	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The introduction to the Mitigation chapter of the DEIS describes the NEPA framework of the DEIS, including the mitigation requirements specific to NEPA. Throughout the DEIS development process the foregoing objectives framed the analysis conducted by the co-lead agencies as well as the mitigation considered in the DEIS. NEPA and the case law interpreting it do not require this constrained analysis. As part of the NEPA process, Federal agencies consider appropriate mitigation measures to avoid, minimize, rectify, reduce or eliminate, and/or compensate for specific impacts (CEQ 2011). The mitigation measures summarized in this chapter are intended to reduce the duration and severity of impacts from implementing a specific action. DEIS Page 5-1. Importantly, mitigation measures are only proposed in the DEIS in those instances where the proposed alternative worsens or impacts juvenile survival or adult migration in the CRSO from where it was estimated to be under the No Action Alternative. E.g. DEIS, page 5-24, section 5.4.2.2. As a related matter, effects are categorized to include minor, moderate and major effects for NEPA purposes. As a result, the analyses segmented conditions and effects occurring before and existing in 2016 from those that would occur as a result of the actions contained in the DEIS alternatives. This segmentation is akin to the existence versus operations segmentation that was contained in NOAAs 2004 BiOp for the FCRPS and that was struck down by Judge Redden in May 2005.	Mitigation in NEPA is intended to address environmental effects of the proposed action if that alternative is implemented. Here, the proposed action is the continued operation and maintenance of the CRS. However, mitigation for the identified alternative would include actions that are within the co-lead agencies' authorities that address the effects of the selected alternative, as compared to the No Action Alternative. New mitigation is not proposed to mitigate for the existence of the system, but rather to ameliorate the effects of the operations and maintenance of the CRS as identified in the alternative. NEPA does not require identification of mitigation for the No Action Alternative.
31775	119	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Appendix V, which is the Biological Assessment for ESA compliance is framed somewhat differently, but it acknowledges the different statutory frameworks as follows: It is important to note that NEPA and the ESA establish different standards for legal compliance and have different approaches to the analysis of the effects of the action. Because of these differences, the analyses performed in the draft EIS and in the BA are tailored to the requirements of each regulatory process. The mitigation chapter of the DEIS includes conclusory discussions of Bonnevilles Fish and Wildlife Program funding commitments under the Northwest Power Act in subsection 5.2.1.1 as well as a similar conclusory statement of the Northwest Power Acts equitable treatment requirements in section 5.2.1. The mitigation discussion fails to disclose and analyze the effectiveness of the ongoing mitigation actions required by the Northwest Power Act, Endangered Species Act or other federal laws. Compared to the narrow improvement and mitigation framework of the DESI, the June 2019 Tribal Perspective document describes a much different set of objectives that should have framed at least some of the analyses in the DEIS. It includes discussion of tribal plans to effectuate treaty reserved fishing rights as well as the Northwest Power Acts fish and wildlife obligations. Its frame of reference is based on tribal well-being, as opposed to improvement from the status quo. The DEIS fails to disclose and analyze whether the alternatives would achieve those objectives described in the tribal Perspectives report. The EIS omitted analysis of ESA and NWPA compliance and other plans. Contrary to the assertions in the DEIS, there is no evidence that the co-lead agencies considered the NPCCs Fish and Wildlife Programs specific goals, objectives and measures with regard to anadromous fish. While some disclosure and analysis of wildlife Program obligations is set forth in the DEIS, such disclosure and analysis does not occur for anadromous fish. Without that disclosure and analysis there is no evidence in the DEIS that the co-lead agencies have provided equitable treatment for fish and wildlife. Similarly, neither the DEIS nor the Biological Assessment in Appendix V contain a holistic analysis of whether any of the alternatives would meet ESA requirements. Many federal ESA jeopardy analyses on the CRS (or FCRPS) have preceded the DEIS. They are the subject of many technical and legal publications, but this history not disclosed in the DEIS. There is also no disclosure and analysis of survival metrics or recovery metrics from previous BiOps. Nor does the DEIS contain a discussion of	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Regarding Northwest Power Act compliance, the comment asserts inadequate analysis in the EIS as to the efficacy of mitigation funded through Bonneville's Fish and Wildlife Program. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that would continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and present, ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the survival and recovery metrics from NOAA Recovery Plans or the Interior Columbia Technical Review Team. Perhaps the most salient disclosure is contained in a paragraph in Chapter 3 and it does not bode well for future salmon and steelhead returns: On February 4, 2020, the co-lead agencies viewed a presentation prepared by NMFS regarding returns for the 2019 fish passage season and the Adaptive Management Implementation Plan. Although not all returns occurred prior to the presentation, NMFS utilized current return numbers to project return numbers if current return rates continued in 2020 and 2021. These projections signaled that returns are low, especially for Snake CRITFC DEIS Comments April 13, 2020 Page 56 of 59 River steelhead. The co-lead agencies are currently evaluating the information provided by NMFS and will have a more detailed discussion of this information in the final EIS, including any updates that NMFS may provide once all returns have occurred, if appropriate. DEIS Page 3-301. Notably, the information disclosed by NMFS to the co-lead agencies on February 4, 2020 is not disclosed in the DEIS. The discussion of recovery plans in the Biological Assessment (Appendix V) is only aimed at ensuring the consistency of tributary habitat programs and safety net hatcheries with recovery plans. There is no analysis of recovery per se or its likelihood under any of the alternatives. The absence of such analysis frustrates public consideration of the alternatives and their consequences	Power Act, particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. Although the Northwest Power Act requires Bonneville to fund mitigation consistent with the Northwest Power and Conservation Councils (Council) Columbia River Basin Fish and Wildlife Program (Program) and the purposes of the Act, no statutory provision requires the co-lead agencies to undertake separate analyses regarding the efficacy of such mitigation. Rather, the structure and processes of the Act create a presumption that mitigation measures and projects recommended for implementation by the Council are indeed an effective means for addressing mitigation under the Act. First, the Council develops its Program based largely on the recommendations and expertise of fish and wildlife managers. The mitigation projects that the Council recommends to Bonneville for funding derive from their Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under certain statutory criteria that, for example, include examining whether projects are based on sound scientific principles and benefit fish and wildlife. 16 U.S.C. 839b(h)(10((D)(iv). These statutory processes for vetting and reviewing implementation of mitigation projects provide a reasonable basis for the co-lead agencies to rely on these projects being effective. In addition, for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Program, the underlying assumption being that the mitigation projects address appropriate obligations under the Council Program, and do so effectively. The comment also asserts that the agencies did not consider the Councils Program goals, objectives, and measures for anadromous fish. First, the co-lead agencies note that the Councils Program goals, objectives, and measures have been under a revision process for a substantial portion of this EIS analysis, and that revision remains ongoing. Bonneville submitted comments in the Councils amendment process, including fundamental questions about the legal basis of many of the Programs goals and objectives. 1/ However, even under the Councils prior 2014 Program, the overarching anadromous fish goal includes a smolt-to-adult return of 2-6%. The EIS analyzed SAR implications of the various alternatives. In addition, the CSS model predicts that certain smolt-to-adult return rates under the Preferred Alternative would increase from 2.0% to 2.7%, within the range included in the Council Program goal for anadromous fish. The comment further claims that there is no evidence in the EIS of the agencies adherence to the equitable treatment mandate of the Act. The equitable treatment provision of the Act directs the agencies management and operation of the Columbia River System provide equitable treatment for fish and wildlife with the other authorized purposes for which the system is managed, such as flood risk management, hydropower generation, irrigation, navigation, and recreation. See 16 U.S.C. 839b(h)(11)(A)(i). The co-lead agencies provide fish and wildlife with equitable treatment on a system-wide basis. See NW. Envtl. Def. Ctr. v. Bonneville Power Admin., 117 F.3d 1520, 1533-34 (9th Cir. 1997) (While each power marketing action that affects the system implicates the equitable treatment provisions, Bonneville may properly exercise its obligation by insuring equitable treatment for fish on a systemwide basis.); Confederated Tribes of the Umatilla Indian Reservation v. Bonneville Power Admin., 342 F.3d 924, 931 (9th Cir. 2003) (The equitable mandate of [the Northwest Power Act] does not require every Bonneville decision to treat fish and wildlife equitably. For example, Bonneville may make some decisions that place power above fish, so long as on the while, it treats fish on par with power.). Through this EIS process, the co-lead agencies have considered management and operation of the Columbia River System for its multiple authorized purposes. And, as noted above, CSS analysis of the Preferred Alternative predicts an increase in smolt-to-adult return rates as compared to the no action alternative. The co-lead agencies inclusion of alternatives MO3 and MO4 which are focused on benefiting fish, plus the incorporation of measures specifically designed for improved benefits to fish and wildlife, as balanced against other purposes, reflects equitable treatment of fish and wildlife consistent with the Northwest Power Act. 1/ See Bonneville Power Administration Comments on Draft 2020 Addendum to the Columbia River Basin Fish and Wildlife Program (Oct. 18, 2019), available at https://app.nwcouncil.org/uploads/2018amend/recs/765/Bonneville%20Recomendations%20to%20Council%20FW%20Program%20Amendment%2012.13.2018.pdf; Bonneville Power Administration Comments on Revised Part One of the 2020 Addendum to the Columbia River Basin Fish and Wildlife Program (Jun. 22, 2020) available at https://app.nwcouncil.org/uploads/2018amend/comments/1392/Final%20Council%20Addendum%20Pt%201%20Cover%20Ltr%20and%20Comments%202020.06.22.pdf. See also response to 6844-56 and 6929-8. Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and the Northwest Power Act.
31775	120	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	I. Biological Assessment/ Attachment V The Preferred Alternative (PA) was used as a foundation to construct the Biological Assessment (BA) contained in Appendix V of the DEIS. The BA attached to the DEIS in Appendix V while providing more detail compared to the PA, does not introduce any new actions towards improving survival for listed species. Our prior comments on the PA apply with equal force to BA. As previous noted in our comments, the PA provides little to no improvement for many of the ESA stocks. The PA relies solely on improvements in Latent Mortality and John Day dam reservoir operations to reduce nesting of avian predators to gain any improvement over the NAA (base case). Nor does the BA include any sort of check-in to verify that the current actions are producing the anticipated results. If these latent mortality assumptions are wrong, which the agencies admit may be the case since the adaptive management plan outlines a fourth pillar that would require some evaluation to better understand how operations affect latent mortality, then additional actions are needed to provide a safety net for this unknown. As written, if the latent mortality assumptions are over stated as the NOAA Life cycle model latent mortality alludes to, then the Proposed Action would be worse for fish than the No Action Alternative due to all the tradeoffs in the BA intended to offset the power costs incurred by the proposed action.	Thank you for your comment. Please refer to our response to comment ID 31775-20.
31775	121	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	Similar to the PA, the BA relies on the smallest improvement in projected juvenile survival to meet an Improve Juvenile Survival objective. For some species, this is less than 1% improvement. Furthermore, the BA fails to acknowledge that the AMIP Safe-Guards under the current Biological Opinion have been triggered for several of the ESA species (Upper Columbia Steelhead and Chinook, and Snake River wild steelhead). In spite of this no major additional mitigation actions have been sought. The BA mentions that avian deterrent programs (including upgrades to existing facilities such as bird wires at McNary Dam and sprinklers at Ice Harbor Dam) will be coordinated through the FPOM and included in the Fish Passage Plan. Due to a negative trajectory of funding in the Fish Passage Operation and Maintenance program budget, however, it is highly uncertain if even these modest improvements could occur.	With respect to the comment on AMIP safeguards, please refer to our response to Comment ID 31775-20. The increased levels of spring spill included in the Preferred Alternative are intended to provide a more effective passage method to avoid direct injury from turbine or bypass passage and an indirect benefit to reductions in latent mortality that is modeled to increase adult returns. Funding of operations and maintenance has been a challenge with decreasing budgets; however, the co-lead agencies will annually review critical failures that have interrupted operations from adhering to FPP criteria, and make recommendations to the prioritized non-routine fish needs by project prior to the next budget request.
31775	122	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The DEIS fails to analyze or provide a safety net until there is certainty that the assumptions about latent mortality are indeed being realized. As discussed previously, the DEIS fails to consider actions such as: - An expanded predation program that would include management of avian, piscivorous fish and sea lions - Expanded Kelt collection and reconditioning - Fund mainstem habitat actions at tributary river mouths to create transition zones and coldwater refuges for migrating fish - Evaluate options to increase the number of RSW/TSW at dams to create the best possible surface passage attraction flow and increase the number of surface passage routes thus CRITFC DEIS Comments April 13, 2020 Page 58 of 59 decreasing Pit PH and further reducing Latent Mortality (LM) effects. The larger the reductions in LM the easier it is to detect them. - Increases in the Hatchery Safety Net Program - Additional Habitat Measures and funding	Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the CRSO EIS. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns (SAR) of 35% and 28%, respectively. The SAR ratio is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that are within the recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the Life Cycle model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. With respect to some of the areas highlighted in the comment, such as AMIP safe-guards and kelt reconditioning, please refer to our response to Comment ID 31775-20. The predation management measures proposed to carry forward were shown in the Draft EIS (Chapter 7, Table 7-5), which included avian, piscivorous fish and pinniped predation management, as well as habitat, operational, and hatchery measures. The BA also includes proposed and continued non-operational actions that include predation management of avian, piscivorous fish and pinniped species (refer to Section 2.6.1.3, Predation Management).
31775	123	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	The BA does include additional information on Hatcheries and Tributary Habitat Actions. We provide the following initial comments on these sections: - Non-operational Conservation Measures for ESA-listed Salmon and Steelhead Hatcheries This section highlights a small sub-set of co-lead agency funded hatchery programs in the Columbia Basin, of which there are more than 170. By not accounting for all of the hatchery programs in the Basin, the future of the hatchery programs that have not been identified herein is opaque and should be elucidated. The six programs identified in table 2-18 represent only ~5% of the hatchery production funded by the AAs (above Bonneville Dam). The AA-funded hatchery programs include both ESA-listed and non-listed salmon and steelhead. Of only ESA-listed production that the AAs fund (~17 million annually), table 2-18 represents only 20% of those programs that are managed to supplement natural populations and use local broodstock (do these not count as conservation and safety net hatchery actions?). If the purpose of this section and table 2-18 is to identify only the ESA-listed programs that are managed as supplementation programs (i.e., conservation/safety net), then the table does not come close to capturing the number of existing programs that should be listed.	The co-lead agencies note the continued existence of their respective independent, congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee Dam mitigation, John Day Dam mitigation, Dworshak Dam mitigation, and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. All of the hatchery programs funded by the co-lead agencies for both conservation or harvest mitigation purposes have completed Section 7 consultations, so their effects will be captured in the environmental baseline of the biological opinion. The conservation and safety-net hatcheries that are listed in Table 2-18 are hatchery programs that the co-lead agencies specifically wanted to highlight where the primary objective is to reduce short-term extinction risk and promote recovery of ESA-listed stocks. These programs are a component of and/or in addition to other congressionally authorized hatchery mitigation actions included in the baseline
31775	124	golc@critfc.org	Columbia River Inter-Tribal Fish Commission	- Habitat (Appendix D) There needs to be a clear distinction among habitat implementation, habitat condition, and biological response metrics. Furthermore, the relationship between the three types of metrics needs to be explicit (i.e., what habitat condition will implemented actions affect, and how will [or how do we expect] the new conditions to impact focal populations?). Currently the Appendix mixes several of these together in various tables, excludes them from others, and does not resolve the linkages between them. An example of a habitat implementation metric is miles (or acres) of riparian vegetation planted or protected. This describes the work that was done by implementors regardless of the works impact. Examples of associated habitat conditions include the height or density of riparian vegetation, stream temperature response, or change in effective shade. This information comes from research, monitoring, and evaluation conducted at various spatial and temporal scales (sites, tributaries, and watersheds on a 5- or 10-year basis depending on the type of metric). An example of associated biological response includes the focal populations response to the (presumably) improved habitat condition, such as increase in productivity survival rates or abundance of summer parr to fall emigrant life stage. We recognize that biological responses cannot be measured everywhere for each habitat treatment, but the expected causal pathways among habitat implementation, habitat condition, and biological response should be articulated. This has already been accomplished in several research CRITFC DEIS Comments April 13, 2020 Page 59 of 59 programs and restoration prioritization frameworks in the region. This could be accomplished here by presenting a table of the three types of metrics showing the linkages.	The co-lead agencies acknowledge the commenters perspective on the distinction between metrics resulting from implementation, status and trends and action effectiveness, with the latter two categories extending to both habitat-environmental variables and fish response. The co-lead agencies will report ESA progress based on the presented implementation metrics with the understanding that the second two categories will be further evaluated through the Columbia Basin RME strategy in collaboration with basin stakeholders.
31779	1	Karl Dye	Tri-City Development Council	Energy Both Benton PUD and Energy Northwest have recently completed studies which indicated that the Pacific Northwest region will need gigawatts of additional power generation in the next decade. The region will be facing a significant challenge in providing enough electricity to meet the demand, and to do so without significantly increasing costs or carbon emissions. Removing the four lower Snake River dams non-carbon-emitting electrical generation from the grid at this critical time will make that task much more difficult. The Tri-City community is committed to leveraging the capabilities of the Pacific Northwest National Laboratory (PNNL), the highly skilled local workforce, and local business expertise to grow the Tri-Cities presence as the Energy Hub of the Pacific Northwest. As part of that effort, there is a desire to develop, demonstrate and install a variety of new energy generation technologies, some of which are likely to be intermittent. Without the baseload capacity and load balancing capabilities of the four lower Snake River	The statements in the comment are consistent with the findings and discussion in the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, 3-905-907 in the draft EIS. Section 2.3 of Appendix H, Sensitivity of LOLP to Assumptions about Coal Capacity in the draft EIS also provides additional details on the effects of coal retirements on required replacement resources.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				dams it would be much more difficult, if not impossible, to fully pursue and deploy these emerging technologies. With the Clean Energy Transformation Act (CETA), the State of Washington has set very aggressive clean energy goals. Even with CETA, there is a strong possibility that new natural gas power plants will have to be built in order to meet regional energy needs. Without the dams, new carbon-emitting generation in the region would be a near certainty, which runs counter to the goals of the legislation	
31779	2	Karl Dye	Tri-City Development Council	A key element of successful economic growth in the Tri-Cities is the reliability of the communitys power supply. Breaching the four lower Snake River dams could double the loss of load probability in the region, making it significantly more challenging to recruit and retain companies and industries that require a reliable power supply. Notably, many of these industries provide higher-than-average wages to their employees. Therefore, the loss of these jobs, or the inability to recruit similar companies to the community in the future, would have an outsized negative economic impact on the Tri-City area.	The statement that regional power reliability would decline under MO3 is consistent with the findings of the EIS, without resource replacement. See Section 3.7.3.5, Effects on Power System Reliability, at 3-903 in the Draft EIS; see also Appendix H, Table 2-1. However, the EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. See Section 3.7.3.5, at 3-904-910 in the Draft EIS. Under these replacement portfolios, regional power rate pressure increases. In addition, consistent with the statements in the comment, the EIS discusses the importance of lower power costs for the regional economy in Section 3.7.2.11, Regional Electricity Rates.
31779	3	Karl Dye	Tri-City Development Council	Environment The Tri-City community, along with many other stakeholders, share the goal of increasing the salmon, steelhead and lamprey population throughout the Columbia and Snake river system. There is significant concern, however, that breaching the dams would not have the desired effect of restoring the populations of these species. There are numerous other factors that likely impact fish numbers, including predation below Bonneville Dam, ocean conditions, harvest, and the lack of fish passage into tributaries in Oregon and Idaho. Moreover, salmon populations worldwide are struggling, including in undammed rivers such as the Fraser River in British Columbia. This data suggests that simply breaching the four lower Snake River dams is not the appropriate solution. Before releasing the final EIS, TRIDEC encourages the federal agencies to perform a more in-depth analysis of salmon population changes in the Columbia-Snake river system compared with other river systems in order to provide important context regarding the impact (or lack thereof) of the four lower Snake River dams.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. Predation management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. The other items listed in this comment are beyond the scope of this EIS. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Recognizing ocean conditions are a major driver in juvenile survival and adult returns. As such two of the models used in these analyses, NMFS and CSS Lifecycle Models, use metrics of ocean productivity to predict adult returns.
31779	4	Karl Dye	Tri-City Development Council	In addition to healthy fish populations, orca survival is a top priority for people throughout the Pacific Northwest. The connection between the struggles of the orca population and the four lower Snake River dams, however, is tenuous at best. Addressing pollution in the Puget Sound and in the ocean, restoring fish passage and fish habitat in Puget Sound tributaries, and increasing hatchery fish production are far more likely to increase the orcas food supply than breaching the four lower Snake River dams.	The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
31779	5	Karl Dye	Tri-City Development Council	All options for replacing the electricity produced by the four lower Snake River dams would have substantial negative environmental impacts. For example, it is estimated that replacing the power with natural gas generation would result in 3.3 million metric tons of carbon emissions. Alternatively, building out the necessary renewable energy generation (primarily wind and solar) would require the development of tens of thousands of acres of land, which could create environmental impacts which should also be identified in the final EIS.	The statement that replacing hydropower from the four lower Snake River dams with natural gas would increase carbon dioxide emissions by 3.3 million metric tons is consistent with the findings of the draft EIS. The EIS acknowledges the potential effects of land development needed to replace lost hydropower capacity from the four lower Snake River dams with solar energy; however, given the uncertainty of where these resources may be built, the specific impacts to natural and cultural resources are currently unknown, and thus, too speculative to identify in the final EIS. See Section 3.7.3.5, Zero-Carbon Replacement in the draft EIS. If an alternative is selected that requires replacement resources, whether solar, wind, or other resource, additional environmental review would be required. Appendix H, Section 2.2.4 in the Final EIS discusses the process for potentially acquiring new resources.
31779	6	Karl Dye	Tri-City Development Council	Navigation It is well known that there would be a significant increase in carbon emissions if the four lower Snake River dams were breached and rail or trucks replaced barging. Importantly, the dramatic increase in trucking could also have a significant negative impact on the Tri-Cities and other communities. For example, if barging were to be replaced by trucks, it would result in an estimated 435 additional trucks per day coming through the Tri-Cities. This would have a substantial negative impact on traffic and the quality of life in the community. It would also result in additional road maintenance costs for local municipalities. Switching from barge to rail would also have significant negative impacts on small towns in the Columbia River Gorge, many of which already struggle with the impact of existing rail traffic through their communities.	Environmental and human health impacts associated with increased emissions to shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (3.8), and increase health and safety concerns due to increased truck traffic on roadways and potential for increased accidents, as well as other social effects, are described in the Navigation and Transportation Section (Section 3.10.3.5). Potential increases in road maintenance cost are provided in the "Regional Economic Effects" subsection of Section 3.10.3.5.
31779	7	Karl Dye	Tri-City Development Council	Economy Low-cost power has been critical to economic development in the Tri-Cities for decades. In highly competitive efforts to attract companies to the community, or to expand existing operations, it is often the deciding factor. This competitive advantage has already decreased significantly with the prevalence of low-cost natural gas generation, but the potential of 50% higher electricity costs if the dams were breached would be extremely detrimental to the Tri-City economy. It would be much more difficult to attract large energy users (which often provide family-wage jobs) to the community, and existing businesses may relocate to regions with more affordable power. The resulting residential rate increases would also reduce discretionary spending, impacting families and businesses alike. The local agricultural industry, which already operates with minimal margins and uses substantial amounts of power for irrigation would face significant challenges because of the rate increase as well.	The EIS did not identify Multiple Objective 3, which includes breaching the four lower Snake River dams, as the Preferred Alternative. Consistent with the concerns voiced by the comment, the EIS finds that increased power costs would have adverse regional economic effects, including reduced employment and income under MO3. The EIS used the IMPLAN model to examine effects on regional sales and employment. The EIS did not directly analyze the competitive advantage of low-cost electricity; however, the EIS acknowledges its importance for the regional economy in Section 3.7.2.11 - Regional Retail Electricity Rates.
31779	8	Karl Dye	Tri-City Development Council	The DEIS estimates that approximately 48,000 acres of irrigated agriculture land would be lost if the four lower Snake River dams were to be breached. This land is some of the most productive agricultural land in the world and leads to the direct employment of thousands of people in the Tri-City area. There are thousands of other regional jobs in ancillary industries such as food processing, agriculture equipment suppliers, vendors, and more that also rely on the irrigated agriculture the dams provide. Without the dams some farmland would likely move to dryland wheat production (with a much smaller economic impact), but much more would likely not be viable at all. The resulting impact would be very harmful to the economy of the Tri-Cities and smaller communities in Central and Eastern Washington. It would also be devastating to families that have farmed the land for generations, along with the people they employ.	In Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports, as it is not within their current authorities. See Chapter 3 for analysis of the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion. This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
31779	9	Karl Dye	Tri-City Development Council	Tourism and recreation would also be negatively impacted by breaching the four lower Snake River dams. The Port of Clarkston estimates that approximately 25,000 passengers participate in river cruises annually, with many of those cruises stopping in the Tri-Cities. (This number is substantially higher than the one used in the DEIS, and the federal agencies are encouraged to reassess their estimate.) When river cruises stop in the Tri-Cities, passengers visit local retailers, eat at local restaurants, and travel to local tourist attractions, resulting in a substantial economic benefit that would not exist without the dams.	The EIS includes a discussion of community concerns about the potential impacts of MO3 in the navigation section in Section 3.10.3.5, in the subsection under Regional Economic Effects called "City/Local Effects Associated with Changes in Commercial Navigation, Cruise Lines, and Ferry Operations," as well as under the Other Social Effects subsections. The most recently available data was used to characterize cruise line passengers when the analysis was undertaken. These sections describe potential regional economic as well as social and community impacts associated with dam breach. The EIS recognizes the short-term adverse effects to recreation visitation and values, including cruise and tour boats, and the associated impacts to the regional economy under MO3, which includes breaching the four lower Snake River dams, which are described in Sections 3.10.3.5 and 3.11.3.5.
31781	1	Jay Inslee	State of Washington, Office of the Governor	As noted in my recent letter requesting an extension to the public comment period on this DEIS, it is unconscionable, in the midst of the COVID-19 emergency, to hold to the original 45-day public comment period. Even if there had been no emergency, this truncated comment period would have been insufficient to provide for adequate public review and comment of such a voluminous and complex document.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9 that they should plan to submit comments by the close of the comment period.
31781	2	Jay Inslee	State of Washington, Office of the Governor	I reserve the right to provide more specific recommendations on this issue at the appropriate time, when we are no longer in the middle of an active public health emergency. Thank you again for considering the enclosed comments. Very truly yours, Jay Inslee Governor	Thank you for your comment.
31781	3	Jay Inslee	State of Washington, Office of the Governor	As noted in our February 2017 scoping comments, Washington envisioned a CRSO EIS that is more visionary and provides more context for informed policy making than is afforded by the draft EIS. We have the following concerns, which build on concerns Washingtons cooperating agencies have conveyed throughout the CRSO NEPA process: The draft EIS does not contain a restoration bookend alternative that optimizes salmon and steelhead survival. Multiple Objective Alternative 3 (MO3) and Multiple Objective Alternative 4 (MO4) include powerful new fish recovery actions (breaching and higher spill, respectively), but they also include new actions that may harm salmon survival. The lack of a bookend fish-friendly alternative compromises the ability of the region to place the Preferred Alternative in context. The draft EIS does not furnish a basis that allows the reader to analyze the effect of various individual components of the multiple objective alternatives, which makes it impossible to determine how much an individual action helps or hinders achieving the documents various goals. The goal the draft EIS is working to meet for salmon and steelhead recovery is vague. It appears to be aiming for improvement well short of the State of Washingtons healthy, harvestable goal (see Washington scoping comments, footnote 1 for more background), which is compatible with the Northwest Power and Conservation Councils goal of a 2-6% smolt-to-adult return ratio, with an average of	The co-lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies (including Washington), and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				4%, and provisional population goals developed by the collaborative Columbia Basin Partnership. As noted above, NEPA affords a much-needed opportunity to consider a full range of federal laws and policy goals. As touched on above, in important respects the draft EIS does not represent adequately, or adequately accommodate, a long-term vision for the basin. There is no attempt to incorporate or recognize ongoing tribal and Northwest Power and Conservation Council 3 efforts to pursue phased reintroduction of salmon and steelhead above Chief Joseph and Grand Coulee dams, no strategy proposed for tying in the outcome of the current Columbia River Treaty negotiation, and there are only hints of how fishery and dam managers might work together to optimize the system for energy, transportation, and agriculture along with environmental concerns including salmon and southern resident orca recovery. Washingtons Lower Snake River Stakeholder Report1and associated panel discussions highlighted a hunger to better understand what it will take to optimize the system, and now is the time to convene a dialogue around how the region can achieve this goal. Flexible spill can be a first step, but not if it is largely locked in place for fifteen years as proposed. The multiple objective alternative (MOA or MO) concept is useful in theory (especially if accompanied by the bookend alternatives urged above), but in practice the MOAs in this draft are not all serious policy alternatives. For instance, rather than explaining the impact of spring spill and summer spill as part of a menu of discrete operational choices with different costs and benefits for fish and power during the different seasons, MO4 seeks to maximize spill for the entire salmon migration season. The result is that a more affordable fish-friendly alternative that focuses spill to 125% TDG in the spring only is not analyzed for its effectiveness for fish or its impact on Bonneville Power Administration revenue. In addition, generally fish friendly MOAs, including MO3 and MO4, include large new irrigation withdrawals from Lake Roosevelt and other measures to incrementally improve hydropower production that partially counteract their fish benefits.	used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Additionally as stated in the CRSO Draft EIS, the information about CRT-related operations available in 2016 is applied in the Draft EIS analysis as the best-available information. The CRSO Draft EIS evaluated the implications of the CRS alternatives using the Treaty coordinated operations, including their relationship to hydropower, ecosystem, and flood risk management, with the best available information. As is also noted in the Draft EIS, if CRT-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary. Moreover, measures to reintroduce salmon above Grand Coulee and Chief Joseph were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. Finally, the co-lead agencies analyzed spill to 125% in the spring only in the Preferred Alternative.
31781	4	Jay Inslee	State of Washington, Office of the Governor	The cumulative impacts of Lake Roosevelt withdrawals and other upper river water management changes are not adequately analyzed, especially in terms of how those changes may affect juvenile fish survival past the non-federal dams on the mid-Columbia and rearing flows for the natural fall Chinook population in the Hanford Reach.	The cumulative action analysis methods are based on the policy guidance and methodology originally developed by CEQ.(1997a). This method includes identifying affected resources and associated direct/indirect effects; establishing the geographic and temporal boundaries of the analysis; identifying the cumulative action scenario; and analyzing the cumulative effects. The Environmental Consequences sections in Chapter 3 of the EIS present the direct and indirect effects of the Columbia River System Operations (CRSO) Environmental Impact Statement (EIS) No Action Alternative and Multiple Objective Alternatives 1, 2, 3, and 4 and Chapter 7 for the Preferred Alternative on each resources affected environment as presented in the Affected Environment sections of Chapter 3. The resource conditions described in those sections account for the effects to resources related to past and present actions. In these sections, the resources mentioned in the comment were analyzed. Juvenile fish survival metrics such as SARS and PITPH past the non-Federal dams on the Mid-Columbia (Mid-Columbia PUD projects) were included in the NMFS COMPASS and Lifecycle Model outputs. The relative change in survival between the No Action Alternative and MOs, including the Preferred Alternative shows that nearly all of that change occurs in the lower Columbia projects; upstream impacts do not appear to be changing the Mid-Columbia PUD projects response. Results were summarized in the EIS as survival from McNary to Bonneville, but full results are available in Appendix E. Likewise, rearing flows for the natural fall Chinook population in the Hanford Reach were analyzed qualitatively using hydrology model results for each alternative that incorporated all upstream effects. On the mainstem Columbia and Snake Rivers, the vast majority of water diversions for irrigation and municipal and industrial water supply are captured in the direct and indirect effects section of Sections 3.12 and 7.7.14. Chapters 6 and 7 further consider the cumulative effects of each alternative combined with reasonably foreseeable future actions (RFFAs) and conditions for all resources. RFFAs with the potential to impact water supply are listed in Table 6-37 and 7-54, along with a description of the effects of these actions. RFFAs are considered in the cumulative effects analysis for each resource in Chapters 6 and Section 7.9.
31781	5	Jay Inslee	State of Washington, Office of the Governor	Little consideration is given to finishing the job when it comes to fish stocks like mid-Columbia steelhead which are positioned for de-listing if there is a focused effort to address a limited number of limiting factors to recovery (e.g., implementation, not testing, of surface flow bypass routes at all projects during non-spills for pre-spawn steelhead adults).	Section 7.6.4.3 describes preliminary measures agreed to by the co-lead agencies during informal ESA consultation with NMFS and USFWS on the Preferred Alternative. Due to the fact that the consultation is ongoing, the measures in this Section may be modified or expanded prior to the Final EIS. In the case of steelhead overshoots (and kelts), this Section includes the following: To reduce the take of overshooting adult Middle Columbia River and Snake River Basin steelhead, the co-lead agencies, beginning in 2020, would implement offseason surface spill as a means of providing safe and effective downstream passage for adult steelhead that overshoot and then migrate back downstream through McNary Dam and the Snake River dams during months when there is no scheduled spill for juvenile passage. The co-lead agencies would implement this measure within the October 1 to November 15 and March 1 to March 30 timeframes based on the analysis already included in this EIS for MO4. The commenter is correct that the model analyses do not accurately or fully capture the effect of the dams on the escapement of adult steelhead overshoots and kelts. These effects of dams on escapement of adult steelhead overshoots and kelts are discussed qualitatively in the Draft EIS.
31781	6	Jay Inslee	State of Washington, Office of the Governor	The comment period on the draft EIS was too short considering the burden placed on the public due to the COVID-19 pandemic. This will significantly compromise the quality and quantity of feedback you receive on this important document.	See response to Comment 31781-1.
31781	7	Jay Inslee	State of Washington, Office of the Governor	In spite of the concerns voiced above and below, the general thrust of the Preferred Alternative represents a potential pathway for progress over past dam operations and can provide a path to additional future progress if the final EIS calls for a flexible spill operation that adaptively builds on salmon survival improvements from the 2019-21 Flexible Spill Agreement to be in place for three to five years rather than 15. This shorter timeline can enable the region to move forward, while pivoting toward additional actions that increase the probability of achieving Northwest Power and Conservation Council recovery goals and metrics. During this three-to-five period, an adaptive management framework must in place to optimize the flexible spill approach and to respond quickly to fish returns that are below science-based adaptive management thresholds, such as the region is currently experiencing with low upper Columbia and Snake river steelhead returns. While the juvenile salmon and life cycle survival improvements attainable through the flexible spill are, according the draft EIS, less than those that could be obtained through MO3 or MO4, flexible spill to 125% total dissolved gas can be expected to provide significant (over 50% according to the Comparative Survival Study model) improvements to Snake River spring/summer Chinook and steelhead SARs. However, it appears doubtful that even the improvements from flexible spill can bring about the SARs necessary to consistently achieve the Councils long-term recovery goals for either Snake River or upper Columbia River stocks. Near-term flexible spill operations must continue to build and improve upon the 2019-2021 Flexible Spill Agreement, which is evidence of the potential for collaboration among different regional entities. Momentum from the flexible spill collaboration will have the best chance to endure and strengthen if the final EIS provides the necessary space for discussion and agreement on a strategy to move toward stronger salmon recovery actions as feasible. Washington urges that the final EIS call for a continuation of a full tributary, estuary, and hatchery mitigation program and an enhanced predation control program, updated as needed according to the most recent Fish and Wildlife Program from the Northwest Power and Conservation Council. The final EIS and its PA should directly reference the reintroduction efforts in the blocked areas upstream of Chief Joseph and Grand Coulee dams and the Columbia River Treaty negotiations as key processes associated with salmon recovery efforts. The final EIS and its PA should not endorse or include new power-friendly actions that could harm salmon and steelhead, such as installation of high capacity turbines that could increase powerhouse encounters for juvenile migrants and removal of fish screens from turbine intakes, at least absent solid new scientific evidence that these actions would not counteract some of the benefits and assumptions of the flexible spill operation or more aggressive salmon recovery measures. Flexible spill must also be adaptively managed toward increasing its power to improve fish survival; retreating from the 2020 flex spill operation to a block spill operation or a weaker flex spill operation would be going backwards.	The Draft EIS Preferred Alternative includes an adaptive management plan (Appendix R, Part 2). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the flexible spill measure on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. Since the adaptive part of this framework would enable changes as warranted (i.e., via information from the frameworks monitoring plan), it is not clear to us how reducing the timeframe from 15 years to 3-5 years would provide a better path to additional future progress. We think the adaptive management part of the plan already allows this, regardless of the timeframe. In reference to your request to continue habitat, tributary, and hatchery actions, the co-lead agencies intend to carry forward habitat restoration and predation actions from the No Action Alternative and continue meeting our hatchery obligations (see Table 7.5 in the Draft EIS). Reintroduction in blocked areas and the Columbia River Treaty review are both discussed in Chapter 1 of the Draft EIS. Measures related to these ongoing efforts were considered, but eliminated from further consideration in the EIS. Regarding your comment on not including new actions that could harm salmon and steelhead, the co-lead agencies generally concur. In the case of fewer fish screens and new turbines, the Biological Assessment in the Draft EIS states that the co-lead agencies propose consideration of cessation of deployment of turbine intake bypass screens at Ice Harbor, McNary, and John Day dams following replacement of existing turbine unit runners with new IFP designs (see Section 2.3.3.4). In addition to further coordination with NMFS, USFWS, and other regional sovereigns, the co-lead agencies anticipate that any proposed changes in the configurations or operations at these dams will require biological monitoring and evaluations. If the study results demonstrate a neutral or beneficial effect, the co-lead agencies will consider cessation of turbine intake bypass screen installation. The Improved Fish Passage turbines at Ice Harbor and John Day dams will be designed to operate within the existing turbine operating range. McNary turbines will be designed with an increased range. Although only the McNary turbines will be designed for an increased operating range, the overall level of spill at any given project is determined not by the individual turbine unit capacity, but by overall project operations management decisions.
31781	8	Jay Inslee	State of Washington, Office of the Governor	Energy In Washingtons comments to the Action Agencies on the power and transmission analysis during the cooperating agency process, including the review of the administrative draft of the PA, we expressed concern about the draft EISs analysis of replacement resources. Of particular concern was the lack of inclusion of energy efficiency (EE) resources beyond those identified in the Northwest Power and Conservation Councils Seventh Power Plan. If the replacement resource options had included additional EE, as would be expected in an optimized analysis, the cost impacts would be lower for alternatives requiring replacement resources such as MO3 and MO4. The Action Agencies should incorporate relevant analytical tools and assumptions, such as those used by the Northwest Power and Conservation Council in resource planning, to inform the analysis of replacement resource options. Action Agencies should also incorporate, when available, an updated reliability analysis from the Council.	The EIS uses the Northwest Power and Conservation Councils (Council) GENESYS model for LOLP modeling and to identify potential replacement resources as suggested by the comment. The EIS power analysis included all cost-effective conservation identified by the Council in the load forecasts analyzed in the power analysis (See Section 3.7.3.1 Methodology and Appendix H, Power and Transmission, Section 2.2, H-2-3 in the draft EIS). The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3. All cost effective conservation in the region is assumed to be acquired consistent with existing law and mandates regardless of the status of the four lower Snake River dams. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS.
31781	9	Jay Inslee	State of Washington, Office of the Governor	Additional resource retirements and changes in state level energy policy since the initial scoping of the CRSO EIS has changed the context in which the draft EIS and its analyses of the alternatives were conducted. During the CRSO cooperating agency meetings the resource adequacy analysis of the alternatives illustrated the potentially large Loss of Load Probabilities (LOLPs) that could occur, especially when coupled with accelerated retirements of coal resources around the region. While the PA satisfies the criterion set within the NEPA process for defining an adequate system, and while the associated LOLP was not severely out of alignment with the Northwest Power and Conservation Councils resource adequacy standard of five percent LOLP or less, additional resource retirements outside the Federal Columbia River Power System have been announced and state standards requiring the phase-out of coal resources were adopted after the CRSO NEPA process formed its baseline assumptions. An updated regional analysis is needed as part of the ongoing adaptive management plan for implementing the final DEISs PA as well as the regional conversation Washington is requesting.	Consistent with the comment, the EIS acknowledges that the regional resource mix is changing rapidly. As the EIS power analysis was underway, new announcements about coal-plant retirements and announcements about accelerated timelines for previously announced coal-plant retirements were made. And in May 2019, Washington State passed the Clean Energy Transformation Act. To assess the impact of these additional and accelerated coal-plant retirements, the EIS analysis included an assessment of the Loss of Load Probability (LOLP) with the coal plant retirements. See draft EIS, Section 3.7.3.1, Base Case Methodology and Cost Sensitivity Analysis at page 3-816; see also Id. at page 3-823. Specifically, accelerated coal retirements were taken into consideration in development of the Rate Sensitivity Analysis for each Multiple Objective (MO) Alternative. See draft EIS, Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis at pages 3-829-830 and Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842. Through this analysis, the EIS identifies the incremental impact of accelerated coal retirements on each regional reliability under each MO. For the Preferred Alternative, the EIS analysis shows that the LOLP rises slightly more slowly than that of the No Action Alternative when more coal plants are removed in the analysis discussed above. See draft EIS, Section 7.7.9.1, Table 7-30. In this study, the amount of resources needed for regional reliability for the Preferred Alternative was about the same as the need for the No Action Alternative. Consequently, while the region will need to continuously evaluate the need for new resources due to coal-plant retirements, changes in Columbia River System operations under the Preferred Alternative would not affect that need substantially.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31781	10	Jay Inslee	State of Washington, Office of the Governor	Climate Change Washington appreciates the draft EISs analysis of the different alternatives impacts on carbon-free energy production, with the caveats raised in Section D of these comments. We also appreciate the documentation of likely climate change impacts in the Columbia Basin and the analysis of how each alternative will perform under climate stressors. However, it would be useful to see, integrated into the bookend fish-friendly alternative Washington asked for in our scoping comments, more work to identify and package a set of operations that will be most resilient to climate change. Without such an alternative, it is difficult to clearly understand how the PA, for instance, stacks up against other alternatives from a climate adaptation and resilience perspective.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS.
31781	11	Jay Inslee	State of Washington, Office of the Governor	Transportation Please see the attached spreadsheet (Attachment A) from the Washington State Department of Transportation. WSDOT points out that the analysis for MO3 (the only alternative with significant implications for transportation) appears to rely on outdated information, and thus it may not accurately reflect the costs and benefits of upgrading rail, highway, grain elevator, and lower Columbia shipping infrastructure to adapt to an alternative that includes breaching the lower Snake River dams.	Individual comments from the spreadsheet are addressed in the appropriate comment response. The demand for waterway transportation is influenced by many factors, both related to the river operations and competing modes of transportation. In many cases, that demand is affected by private sector choices (investments by Class I railroads, construction of shuttle rail elevators by grain companies) that are largely difficult to predict into the future. This EIS combined existing information with a new survey of shippers to create an updated transportation optimization model that was as up to date and accurate as possible within the constraints of the study. The study addresses all of the costs and benefits described in this comment.
31781	12	Jay Inslee	State of Washington, Office of the Governor	Water Quality/Temperature The draft EIS illuminates some issues and opportunities related to controlling warm water temperatures to create better conditions for migrating salmon in the summer (and even late spring in years like 2015). At D-3-36, the draft notes that there is mild stratification of water temperature behind McNary and John Day dams on the lower Columbia. Temperatures at both projects can increase mortality for adult and juvenile salmon, and even set up thermal barriers to upstream migration, as occurred with sockeye in 2015. Washington requests that the action agencies analyze with regional fish managers, and recommend in the final EIS if appropriate, installation of pumps, similar to those at Lower Granite Dam, to cool the fish ladders at John Day and/or McNary dams. For MO3, it is important for the region to understand the water temperature effects of lower Snake River dam breaching on existing temperature issues as well as how breaching would perform under future climate scenarios. To this end, it would be helpful if the final EIS used both the Corps HEC River Analysis System and the Environmental Protection Agencys temperature model, as the draft EIS does on the fishery side by using the competing Comparative Survival Study model and the NOAA COMPASS lifecycle model. EPA has been studying temperature in the Columbia-Snake system for years, and the region will depend on EPAs analysis in other upcoming regulatory processes, so it only makes sense that the EPA model should be relied upon in this EIS as well. Also relevant to the potential effects of breaching, and missing from the MO3 analysis, is how Dworshak Dam releases might be optimized under this alternative. We urge that the final EIS explore in detail how Dworshak releases might be reshaped from status quo releases to maximize the occurrence of healthy water temperatures in a free-flowing lower Snake River, how far downstream effects would extend, and what quantitative impact that operation might have on salmon and steelhead returns. Finally, the fish-friendly bookend alternative we have consistently requested since our scoping comments should explore what if any changes to federal storage dam operations would be capable of cooling the mid- and lower Columbia River. It would also explore how changes in the shape and quantity of releases might benefit water quality in the estuary. We continue to 7 believe a fish-friendly bookend alternative is necessary for analytical purposes and to complement the power-friendly MO2.	The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally, high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Drier and warmer years such as 2015, as summarized in NOAAs 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the EIS. In addition, the co-lead agencies are actively working on implementing the recommendations identified in NMFS's 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision making and reduce, to the extent practicable, the negative impacts of high summer temperatures on migrating salmon, including adult sockeye salmon. The water temperature analysis specific to MO3 (the dam breaching scenario) utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-demesional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. No Action Dworshak operations were used in the MO3 analysis. Results were provided to the fish team for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. Future dam breaching analysis may provide an opportunity to investigate Dworshak Dam operations further, but this would need to occur outside of the EIS process and under a more appropriate study framework. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The co-lead agencies chose to develop a 2-dimensional model of the mainstem CRS reservoirs rather than use the 1-dimensional RBM-10 model. The co-lead agencies felt it important to capture hourly, rather than daily average water temperature data, as well as the thermal stratification that is observed in some of the CRS reservoirs. Both models used in the EIS analysis - CE-QUAL W2 and HEC-RAS - have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. The EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. Thus the EIS did realistically and clearly analyze, to the extent practicable, whether the hydrosystem is causing or contributing to compliance with the water quality standards as compared to historic river temperatures. In addition to investigating the operational impacts on water temperature, the co-lead agencies have taken other actions to address water temperature impacts on fish passage.
31781	13	Jay Inslee	State of Washington, Office of the Governor	The Washington Department of Ecologys Office of Columbia Rivers (OCR) has been working since its inception in 2006 to carefully balance development of new out-of-stream water supplies with protection and enhancement of instream flows in the Columbia River and its Washington tributaries. The full build out of the Columbia Basin Project proposed in several of the draft EIS MOAs, absent significant new water storage releases to augment instream flow, would be inconsistent with the balance Washington has sought to achieve through the OCR. We urge the action agencies to ensure that even the smaller withdrawals proposed in the PA from Lake Roosevelt and Lake Rufus Woods should they be adopted in the final EIS are subject to OCRs rules and full environmental review on a project level.	Early in the EIS process, the co-lead agencies evaluated Washington's RCW 90.90.020(1)(a) and determined that ,in developing the Water Supply measures, the statutory provision for instream flow allocation does not apply because the water is not to be obtained through the development of new storage facilities, nor is it being funded through the State. Nevertheless, the co-lead agencies respect OCR's role and will continue to coordinate with OCR to ensure compliance with applicable laws.
31781	14	Jay Inslee	State of Washington, Office of the Governor	Regarding lower Snake River irrigation affected by lower Snake River dam breaching, Washington suggests including more information in the final EIS on the cost of replacing irrigation from the reservoir behind Ice Harbor Dam and/or compensating landowners for diminished value of dryland acreage or acreage that would require deeper wells. That is more realistic and desirable than simply assuming, as does the draft EIS, that irrigated agriculture in that area will simply vanish.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. The MO3, Region C discussion begins on page 3-1267, line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. Replacing irrigation infrastructure is discussed in Chapter 5 as potential mitigation as NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. However, the mitigation requested is not within the co-lead agencies' current authorities.
31781	15	Jay Inslee	State of Washington, Office of the Governor	The draft EIS provides insufficient analysis of economics of commercial, tribal, and recreational fishing in terms of geographic scope and quantitative analysis. Future management of the Columbia River will have profound impact on the West Coast and Alaskas commercial fishing economy (much of which uses Washington as a home base), and recreational and tribal fishing well inland into eastern Washington, eastern Oregon and central Idaho. More information on the impact of the more restorative alternatives on inland recreational fishing economies and tribal economies would be helpful to informed decision-making, as would be more information on the benefits for commercial fisheries of the additional Snake River fall Chinook habitat that would be made available through dam breaching.	The co-lead agencies utilized up-to-date, high-quality information to analyze effects to fisheries. The EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific effects of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River). Recovery goals set under ESA Section 4(f) are separate and distinct from goals associated with the analysis of alternatives under NEPA. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids. It also meets the EIS objectives for resident fish, lamprey, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
31781	16	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section MODEL OVERVIEW Line number(s) Figure 3-1 and Table 3-1 Both the Figure and Table indicate there are 5 shuttle rail elevators, when actually only four (4) were used in the model. Is this a typo or were five used?	There are five shuttle rail facilities, but only four of them are included in the model as a shipment alternative. One of the shuttle facilities located near Plymouth, WA, is utilized to bring corn/soybean shuttle trains from the Midwest.
31781	17	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section MO3 Scenarios discussion Line number(s) Figures 3-8 through 3-10 These figures are used to indicate utilization of the highways for shipping, however there is no way of telling which highways are seeing the increased use. The figures could be improved by labeling the main highways or indicate in the text which highways are seeing the increased use.	The density of highway flows are indicated by colors and size of the highway lines. Given the size of the area it is difficult to label the highways and show the volumes at the same time. Figure 3-2 is more useful for identifying highways as it does not include volumes..
31781	18	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section SCENARIO 1 Line number(s) 439-440 The "Endicott Facility" is not located in LaCrosse as indicated here and throughout this Chapter. It is located in Endicott.	This was an error that has been corrected in the FEIS.
31781	19	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section COSTS TO AGRICULTURAL OPERATIONS Line number(s) 663-685 The Endicott facility is closer to Colfax than McCoy. It seems logical the Colfax area farmer would utilize Endicott before McCoy. Consider reexamining the data and revising as necessary.	The choice of facility is based on total transportation costs rather than distance alone. In this particular situation, given that the McCoy facility is a circular/loop track facility and the Endicott facility in not, the pricing is slightly better at the McCoy facility.
31781	20	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section COSTS TO AGRICULTURAL OPERATIONS Line number(s) Figures 3-11 through 3-16 The rail shuttle facility is located in Endicott not LaCrosse	This was an error in the figures that has been corrected in Appendix L in the FEIS.
31781	21	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 755-759 The 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report were completed so long ago that they should not be considered as a guide for estimating the present-day costs of necessary infrastructure upgrades, even when corrected for inflation. Modeling and analysis may need to be redone if updated costs vary significantly from original estimates.	Estimates were developed for these costs based on input from local stakeholders during this study period, as well as using published reports as information sources, including the 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report. To the extent possible, the CRSO EIS navigation and transportation model structure reflects the best available current information based upon input from both shortline and mainline rail representatives. The model deals with current transportation rates to determine the expected flows and impact on shipper costs. Infrastructure needs are discussed outside of the model, and are based on the most recent estimates, updated for inflation.
31781	22	Jay Inslee	State of Washington,	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 804-805 The author references Figure 3-16 as illustrating increased traffic on Highways 12 and 395, however the graphic doesn't show any highways.	Figure 3-8 provides traffic for the highway system. Figure 3-16 indicates the relevant highway segments for comparison with other scenarios. This has been clarified in the FEIS.

			Office of the Governor		
31781	23	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 803-804 The author mentions potential highway congeston, but does not elaborate or discuss associated costs. Increases in truck traffic and shifts in traffic patterns could warrant significant capacity and safety improvements in addition to the maintenance costs mentioned. State and local agencies would bear most of the costs for these improvements. These costs should be calculated and incorporated into the transportation analysis.	Potential increases in congestion and re-routing responses, increased risk to safety, and increased road maintenance costs are provided in the "Regional Economic Effects" subsection of Section 3.10.3.5.
31781	24	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 808 Per ton-mile estimates for road resurfacing costs in Eastern Washington were based on literature from 1998 and inflated to 2019 dollars. The author assumes this is a linear correlation, however regulations, requirements, and materials can change greatly in 22 years that can effect base estimates. More up-to-date estimates should be obtained from WSDOT and local agencies.	The co-lead agencies had discussions with WSDOT colleagues during this preparation of the EIS. WSDOT's input was received, and they agreed with the estimates produced by extrapolating for inflation.
31781	25	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 850 Cost estimates for port and terminal expansions and decommissions should be included in the analysis.	Port and terminal capacity needs and decommission costs are described in the subsection "Regional Economic Effects" in Section 3.10.3.5.
31781	26	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 851-854 The cost to construct a new shuttle facility is $25 million per year? This statement doesn't make sensedo you mean the cost to operate? Also, please cite your source.	As described in Appendix L, "[b]ased upon input from local shuttle rail facility operators the cost to construct a new shuttle rail facility with the ability to move 25 million bushels of wheat/barley per year is approximately $25 million (personal communications with shuttle rail manager). Based upon this its estimated that 1 to 2 shuttle rail facilities could be needed at a cost of $25 to $50 million." The estimate of $25 to $50 million is a one time cost for constructing additional rail facilities.
31781	27	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 868 Please cite WSDOT source used here.	A citation has been added in response to this comment in Appendix L.
31781	28	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 874 Costs of maintaining and upgrading rail infrastructure have likely changed significantly since the 2002 EIS, even if inflation is accounted for. A new analysis of rail infrastructure costs should be conducted to reflect these changes and the methodology for estimating these costs should be included in the appendix.	Estimates were developed for these costs based on input from local stakeholders during this study period, as well as using published reports as information sources, including the 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report. To the extent possible, the CRSO EIS navigation and transportation model structure reflects the best available current information based upon input from both shortline and mainline rail representatives. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. As described in Section 3.10.3.5, increases in infrastructure demands could vary widely following dam breach, depending on factors such as the changes in rail rates, which influence the mix of alternative transportation modes that are utilized. In the EIS scenarios, the largest demands on rail would occur under Scenario 1, when rail rates are assumed not to increase and rail transit would be relatively more attractive. In contrast, increased highway use would be highest under Scenario 3, when rail rates are assumed to increase by 50 percent. The EIS also notes that the high rail demand scenario and the high highway demand scenario would not both occur. The EIS also acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road maintenance costs may occur. In addition, infrastructure investments are transitional costs, and would primarily be borne by private entities, including rail lines and grain shippers. Ultimately, rail infrastructure investments would be at the discretion of the railroads. Over time, prices should adjust to cover these costs. Some highway costs would be transferred to the trucking industry through fees, though most costs would likely be borne by public entities. The EIS states in Section 3.10.3.5 that, due to the high level of uncertainty surrounding these costs, interpretation should be done with caution.
31781	29	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 874-877 Private short lines often rely on government funds for necessary improvements. It is more accurate to state that necessary improvements would likely require both public and private investment. The analysis should include a more detailed and accurate projection of what these costs would be and what would happen if funding was not available.	The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. As described in Section 3.10.3.5, increases in infrastructure demands could vary widely following dam breach, depending on factors such as the changes in rail rates, which influence the mix of alternative transportation modes that are utilized. In the EIS scenarios, the largest demands on rail would occur under Scenario 1, when rail rates are assumed not to increase and rail transit would be relatively more attractive. In contrast, increased highway use would be highest under Scenario 3, when rail rates are assumed to increase by 50 percent. The EIS also notes that the high rail demand scenario and the high highway demand scenario would not both occur. The EIS also acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road maintenance costs may occur. In addition, infrastructure investments are transitional costs, and would primarily be borne by private entities, including rail lines and grain shippers. Ultimately, rail infrastructure investments would be at the discretion of the railroads. Over time, prices should adjust to cover these costs. Some highway costs would be transferred to the trucking industry through fees, though most costs would likely be borne by public entities. The EIS states in Section 3.10.3.5 that, due to the high level of uncertainty surrounding these costs, interpretation should be done with caution.
31781	30	Jay Inslee	State of Washington, Office of the Governor	Appendix L Chapter 3 Section INFRASTRUCTURE COSTS Line number(s) 881-887 The author is using data and information from a study conducted in 2002 to reach their conclusions. It is safe to assume that much has changed between then and now. For example, WSDOTs data shows that the BNSF mainline operated at Level-of-Service E in 2016, and rail traffic is expected to increase regardless of any changes to barge traffic on the Lower Snake River (2019 State Rail Plan). The analysis should include information attained from more current interviews with the mainline as well as the shortline operators.	Estimates were developed for these costs based on input from local stakeholders during this study period, as well as using published reports as information sources, including the 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report. To the extent possible, the CRSO EIS navigation and transportation model structure reflects the best available current information based upon input from both shortline and mainline rail representatives.
31781	31	Jay Inslee	State of Washington, Office of the Governor	The draft CRSO EIS contains the seeds for meeting this purpose, but it lacks analytical clarity and falls short in setting forth an ambitious vision for advancing salmon recovery in a manner that optimizes the value of the Columbia River System for the region as a whole. The draft EISs Preferred Alternative (PA) flexible spill operation represents progress for salmon survival compared to past dam operations, but additional actions on top of those proposed by the PA will likely be needed to achieve regional salmon recovery goals. For example, the draft EIS does not lay out a clear pathway toward regionally discussing, vetting, and adopting additional measures. Instead, it endorses an unspecified degree of improvement for Endangered Species Act (ESA)-listed salmon and steelhead only. This falls short of Washingtons expectations for the NEPA process, which provides an opportunity to restore salmon and steelhead consistent with regional goals and that meets other applicable federal laws such as the Northwest Power Act (not only the ESA jeopardy standard). In addition, the range of NEPA alternatives considered may be broad, but does not present a full range of options thanks to complex multiple objective alternatives that all have a mix of new positive and new negative impacts on salmon. The document calls for adaptive management, but the scope of that adaptive management lacks a road map for adopting stronger measures as needed. To succeed in the mid- to long-term, flexible spill must be accompanied, starting as soon as possible, by an active, collaborative, and visionary regional conversation. That conversation should seek to optimize, beyond that achieved in the draft EIS, system operations with a high likelihood of restoring salmon and steelhead to healthy, harvestable populations that also contribute toward a reliable prey base for southern resident orcas; provide clean, reliable, and affordable energy to support achievement of the regions climate and clean energy goals; and a healthy agricultural sector including a reliable water supply and transportation network. To show support for, and faith in, this conversation, the action agencies should maintain the preferred alternative as currently envisioned (with adaptive management) in place for three to five years, at which point the region should assess the feasibility of implementing more aggressive salmon restoration measures, including direct and off-site mitigation. The issues the CRSO EIS is intended to address are too dynamic for a 15-year plan of action to be appropriate, 2 especially without built-in check-ins that anticipate substantial changes in direction as necessary and as supported by a collaborative management process.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species or plan for additional actions needed to achieve regional recovery goals.. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Chapter 8 of the EIS demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and Northwest Power Act.
31786	1	csimpson@ecbid.org	East Columbia Basin Irrigation District	Page 2-73, Line 2231; Authorization is for the Columbia Basin Project, not Basin, I believe. - Page 2-73, Line 2237; The 256,475 acres and 1,154, 138 AF mentioned does not sync with the 336,300 acres and 4.1 AF/AC water duty (1,378,830 AF) mentioned in Appendix A, Line 453, Table 1-8. Page 2-73, Line 2238; The CBP has not developed 772,572 acres, the number is closer to 675,000. CBP is authorized for 1,029,000 acres, if 336,300 are left then 692,700 acres are developed which is much closer to the 675,000 acres commonly referred to. - Page 2-7 4, Line 2249; As Alternatives are reviewed further the statement that " ... diversion flow from Lake Roosevelt would be reshaped to prevent substantial drafting of Banks Lake ... " causes concern if this new focus has the potential to adversely impact the CB P's ability to draft Banks Lake for O&M purposes.	The analysis does not contemplate the operations of Banks Lake and does not address concerns with operations and maintenance (O&M). The Columbia Basin Project has four water rights and developed acres associated with conserved or groundwater pumping, for a total of 772,525 acres supported with water from existing water rights; of this, 693,863 have been developed. However, this number changes annually as new acres are developed under the existing water rights. The additional acres were calculated using the total number of acres supported with existing water rights since they already have "authorization" to divert water from the Columbia, regardless of if they have done so to date.
31786	2	csimpson@ecbid.org	East Columbia Basin	- Page 3-1243, Line 2490; ECBID comprises over 10% of the land irrigated from the Columbia River. We participated in some open houses but were not contacted, as appears to have occurred for other, smaller irrigation entities (page 7-2) which, if done with us, could have lead to better initial information	The co-lead agencies implemented a robust public scoping process to provide an opportunity for the public to help identify significant issues that should be evaluated in the EIS. The public scoping period extended from September 30, 2016, through February 7, 2017. During this time, the co-lead agencies conducted 16 public meetings across the region and two webinars.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
			Irrigation District	for this draft. - Page 3-1244, Line 2509; Lincoln County lands can also receive CBP water. - Page 3-1248, Line 2614; Change "these" to "this", only Lake Roosevelt is mentioned. - Page 3-1248, Line 2627; Change Region "D" to" B". - Page 3-1248, Line 2628; 16,860 not equal to Table 3-269's total of 16,100.	Thank you for your review and suggested edits. We implemented most of these suggested changes. Table 3-271 includes acre-feet from surface, 760 acre-feet, and groundwater, 16,100 acre-feet, consistent with the the total 16,860 acre-feet presented in the text.
31786	3	csimpson@ecbid.org	East Columbia Basin Irrigation District	- Page 7-32, Line 954; Maintaining an elevation of 1222. 7 not only increases pumping efficiency but may allow more flexibility for the operation of Pumps 1-6 of the Keys Plant, which is beneficial to the CBP as it continues to develop. - Page 7-32, Line 976; ECBID supports the additional water supply above the No Action Alternative as described. - Page 7-32, Line 979; As written, 15,000 AF of M&I water appears connected to the OSSS which is not included in the OSSS water supply. If associated with the Lake Roosevelt Incremental Releases Program (LRIRP) then the 30,000 AF of additional supplies, for OGWRP should be noted also. - Page 7-77, Line 1933; Lower Lake Roosevelt elevations increase concern for Banks Lake pumping as we continue to complete development of the CBP. With increased acreage to be served the need for more water supply, earlier in the irrigation season, should be expected and not negatively impacted by reservoir operations. Let's not lose sight that Grand Coulee Dam and Lake Roosevelt are primarily constructed as the diversion dam and reservoir for the Columba Basin Project.	Evaluations for this EIS included consideration of pump efficiency given the elevations of Lake Roosevelt and Banks Lake. Though pump efficiency decreases as Lake Roosevelt decreases, analysis confirmed that the total demand as currently supported by water rights can be delivered to Banks Lake without decreasing the elevation of Banks Lake beyond elevations that have been considered in Odessa Subarea Special Study NEPA analysis. Appendix N provides more detail information on the irrigation and water supply analysis.
31786	4	csimpson@ecbid.org	East Columbia Basin Irrigation District	- Page A-1-11 , Line 453; Please refer to earlier comments regarding discrepancies in acreage, water diversion totals and CBP drawdown of Banks Lake for OM&R needs.	Columbia Basin Project has four water rights and developed acres associated with conserved or groundwater pumping for a total of 772,525 acres supported with water from existing water rights; of this, 693,863 have been developed. However, this number changes annually as new acres are developed under the existing water rights. The additional acres were calculated using the total number of acres supported with existing water rights since they already have "authorization" to divert water from the Columbia, regardless of if they have done so to date.
31786	5	csimpson@ecbid.org	East Columbia Basin Irrigation District	- Page N-1-11, Line 222-226; This should mention how much from the CBP is returned to the river,~ 116th of the amount diverted to the CBP annually(~ 500KAF). - Page N-1-2, Line 240; Same as previous comment about including Lincoln County. - Page N-3-2; Line 546; Change "countries" to "counties". - Page N-3-18; Line 81 O; "Lake Roosevelt Water Supply effect", note that with future CBP development will come increased early season diversions by the Keys Plant. Availability of pumps decrease as elevations decrease toward elevation 1208. The need for more pump availability in the future is probable. - Page N-5-23, Line 1442; Note that below a certain Lake Roosevelt elevation, maybe 1222', Pumps 1-6 cannot be started, they need to be running before the elevation drops. This becomes a critical issue as longer drawdowns occur and CBP development requires larger spring deliveries.	The alternative analysis utilizes hydrologic data and studies to compare operational impacts to flows and water quality. As part of these evaluations, return flows from current irrigation practices are captured through the use of 2010 Modified Flows. Evaluations for this EIS included consideration of pump efficiency given the elevations of Lake Roosevelt and Banks Lake. Though pump efficiency decreases as Lake Roosevelt decreases, analysis confirmed that the total demand as currently supported by water rights can be delivered to Banks Lake without decreasing the elevation of Banks Lake beyond elevations that have been considered in Odessa Subarea Special Study NEPA analysis.
31795	1	kimmyweerts@gmail.com	N/A	The Columbia and Snake River dams contribute 90% of renewable energy produced in the Pacific Northwest. Removal would produce additional pollution by increasing carbon emissions from truck and rail traffic, defeating the work that has been done to lower carbon emissions and lowering Washingtons reputation as an energy steward as well as increasing the cost of electricity.	The EIS does find that MO3 would increase carbon emissions from the power sector while increasing the cost of electricity, and by shifting barge-based shipping through the lower Snake River dams to road and rail transportation. While MO3 is estimated to increase greenhouse gas emissions by 3.5%-8.9% or 1.3-3.3 million metric tons (depending if replacement generation resources are gas or zero-carbon); the Preferred Alternative is estimated to increase greenhouse gas emissions by 1.5% or 0.54 million metric tons.
31795	2	kimmyweerts@gmail.com	N/A	Barging is the cleanest, safest method of transportation of goods from eastern Washington to the rest of the world. The sheer number of trucks on the roads that would be needed to replace water transportation would cause ever-increasing dangers on roads traveled by our local population, students, faculty, and families from both Washington State University and the University of Idaho. Roads would need continual and higher priority maintenance and repair increasing the tax burden on our local and state population.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear-and-tear costs may occur. Safety concerns with the increase in truck trips under MO3 is discussed in Section 3.10.
31795	3	kimmyweerts@gmail.com	N/A	Research has been constant over the years and data-driven studies show that dam breaching does little for the fish. Resources have been and continue to be funded for already successful projects that demonstrate ever-increasing success rates for juveniles. Fish are declining for other real reasons such as mandated increased spills and higher TDGs, along with oceanic conditions which are the two most highly correlated factors to tanked endangered salmonid SARs (smolt to adult returns), increasing out migrating smolt delayed mortality, and increased smolt physiological maladies associated with high river TDG levels.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Specifically, TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring is required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Further, the Preferred Alternative includes a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored. Regarding ocean conditions, the co-lead agencies recognize that ocean conditions are a major driver in juvenile survival and adult returns. As such two of the models used in these analyses, NOAA and CSS Life Cycle models, use metrics of ocean productivity to predict adult returns. A number of metrics that monitor ocean temperature and productivity are reported annually and are used to predict salmon returns. These metrics can be seen at: https://www.nwfsc.noaa.gov/research/divisions/fe/estuarine/oeip/g-forecast.cfm.
31799	1	Gary Frommelt	American Queen Steamboat Company	In 2019, the American Empress brought over 12,000 passengers to the Clarkston and the surrounding area by way of the Snake River and the associated lock and dam systems that make these trips possible. Industry statistics show that this translates into an economic contribution of over $4 million dollars. This contribution results in close to 150 jobs for local citizens based on the variety of services used. These include but are not limited to local shops, museums, tourist attractions, supplies for the vessel such as food and beverage, fuel and all items required to support a floating city of over 300 people. Many small shops and tourism venues owe their livelihood to the continued stream of visitors brought in by the American Queen and other passenger carrying riverboats. 222 PEARL STREET, NEW ALBANY, IN 47150 I TEL (901) 654-2600 I FAX (901) 654-2541 I WWW.AQSC.COM ~ AMERICAN QUEEN 9 STEAMBOAT COMPANY Uniquely American River Cruises American Queen Steamboat Company strongly agrees with the DEIS Preferred Alternative which avoids dam breaching and aims to improve fish habitat through continued programmatic actions. Removal of the Snake River dams would prevent us from sailing on the Snake River and eliminate the economic benefits and jobs stated above; we are clearly against removal of any dams in the system. We also believe that the environmental benefits of hydro-electric power and commercial shipping by barge far outweigh the alternatives. Loss of hydro power and losing grain and other cargo shipments by barge would have a major negative impact on the environment in the entire region.	Cruise ship visitation is characterized in Section 3.10, Navigation and Transportation. Section 3.10.3.5 describes the contribution of cruise ships as providing demand for approximately 230 jobs in the region, which would include employment in the industry itself as well as increased demand for services at ports of call. The statement in the comment that the loss of capacity and energy would negatively affect regional electricity costs and Bonneville customers is consistent with the findings of the EIS. Regarding the funding of the fish and wildlife program, funding decisions for the Bonneville Fish and Wildlife program are not being made as part of the CRSO Draft EIS. A range of costs are included to inform the broader cost analysis and any future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums.
31808	1	tjones@rmecon.net	N/A	As an economist I anticipated the DEIS and was prepared to discuss and submit comments on the merits of BPAs economic arguments. Sadly, in this case, that is a trivial exercise because BPA did not do a legitimate analysis. A legitimate analysis would have presented one or more potential alternatives that restored the fish to agreed upon population levels. The best alternative, the ultimately Preferred Alternative (PA) in BPA jargon, would presumably be the one that was least disruptive, produced recovery levels of fish in the least costly fashion. But, BPA did not do that. The judge ordered the Breach Alternative to be investigated because that is the alternative that all legitimate non-BPA parties have historically deemed the most likely to succeed at restoring the fish. The breach option is the only option historically viewed as capable of achieving Idaho Fish and Game Commission and the Northwest Power and Conservation Councils SARs in the range of 2-6% with an average of 4%. In fact, the breach alternative, MO3 in the executive summary, is the only alternative that the BPA unarbitrarily says, … would meet the objectives of Improve Juvenile Salmon, Improve Adult Salmon, Improve Resident Fish, and Improve Lamprey. All other alternatives, including the preferred alternative, equivocate on that subject. BPAs best other alternative, the preferred alternative, looks to increase SARs to about 1% for spring/summer chinook from the current 0.8% and to about 2.1% from the current 1.6% for steelhead. It is the equivocation on that subject that renders the DEIS fatally flawed. The judges order to BPA was to provide an alternative, or a list of alternatives that result in restored fisheries. Faced with that order the rules of economic analysis, and simple reasoning, mandate that it is not acceptable to choose an alternative that fails to achieve the objective, regardless of how difficult or personally undesirable that might be for BPA management. In laymans terms, BPA was ordered to investigate alternatives that restore fish and to do so in apples to apples fashion. Instead BPA made a mockery of the process by comparing apples, to oranges, to tomatoes. In summary, the Breach alternative is the only alternative in the DEIS that complies the judges order. Therefor, the breach alternative, by standard economic protocol, must be the chosen option.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The rationale for not selecting MO3 is discussed in Chapter 7.
31812	1	N/A	N/A	1. Benefits from dam breachings multiplication of wild fish returns are poorly estimated or excluded entirely: The dam breaching option (Mixed Objective Alternative 3, or MO3) would deliver substantial improvement of wild fish survival, passage and productivity, regardless of which of two fish forecasting models used in the DEIS produces the estimates. Yet the multitude of benefits from dam breachings multiplication of wild fish returns are poorly estimated or excluded entirely.	Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase (Smolt-to-Adult returns (SARs) for steelhead were not modeled). SAR is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. Under the Comparative Survival Study (CSS) model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. Specific details of the Federal obligation: The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
31812	2	N/A	N/A	2. The DEIS excludes available data from prior studies showing substantial economic benefits of dam breaching. The DEIS analysis states that its economic analysis approach is worse than other available methods but fails to utilize more the accurate estimating techniques and excludes available data from prior studies showing substantial economic benefits of dam breaching.	It is important to note that the EIS has undergone a third party neutral Independent Expert Peer Review on the tools used (including economic models), as well as the assumptions and conclusions in the EIS. The EIS Recreation Section 3.11 describes the methodology under MO3: "Potential increases in visitation associated with the new river recreational opportunities in the long-term (e.g., fishing, rafting, paddling, as well as land-based activities) are evaluated through a review of previous studies and similar river reaches." The recreation evaluation uses the Unit Day Value method to apply consumer surplus values to recreation visitor days, which is a USACE-approved approach. The procedures described in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (Water Resources Council 1983) (Principals and Guidelines) outline three generally accepted methods for measuring recreational benefits: the unit day value (UDV), the travel cost method, and contingent valuation. Although a current site specific travel cost or contingent value approach would be a preferred method, a more detailed analysis at this geographic scale was not possible under the timeline of the study. The EIS does not indicate that the UDV method is worse; it is an approved approach that relies on expert and informed opinion to assign relative values to recreational visits based on the quality of recreational opportunities supported by individual recreation areas. The UDV approach provides a consistent approach across all sites in the evaluation. The post dam breach effects on visitation uses a potential range in non-fishing visitation from the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Study and EIS to estimate long-term visitation along the lower Snake River, including rafting and kayaking. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with river recreation post dam breach were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users.
31812	3	N/A	N/A	The DEIS fails to assign an economic value to wild fish recovery and increased angling activity that dam breaching and wild fish recovery would bring. The analysis vaguely suggests that new opportunities for angling and recreation may offset other changes, then wrongly concludes that dam breaching, the most robust strategy for fish recovery, does not deliver economic benefits.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS Section 3.15.3.5 describes the potential for economic benefits under MO3 associated with recreation in the long-term. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
31812	4	N/A	N/A	The DEIS also minimizes benefits from increased post-dam breaching fishing activity by using comparisons with existing activity from two other rivers, the Clearwater and Hanford Reach of the Columbia, but then admits that those comparisons may considerably under-estimate future recreation activity on a restored natural river and the major tributaries (e.g., Salmon River, Middle Fork Salmon River, Grand Ronde River, etc.) that flow into it. For example, the DEIS notes that rafting is a popular activity on other undammed river reaches, including Hells Canyon and the Salmon River, but fails to account for the high economic value of rafting and related recreational activities. The DEIS entirely omits discussion or valuation of the 63 historically named rapids that breaching the lower Snake River dams would reveal. The DEIS also does not recognize the higher per-trip value of non-motorized boaters who would make up the bulk of recreational users on a restored river. A 2019 report by ECONorthwest, Lower Snake River Dams Economic Tradeoffs of Removal, cites 15-115% greater per trip for whitewater recreation compared to reservoir-based recreation, and a higher ($228 per day) recreational user value. Restoring 140 miles of free-flowing river and revealing 14,000 acres of currently inundated riparian and riverside land, would provide an amazing recreation resource to the region. Today, Washington state does not have a multiple day destination whitewater river. A restored lower Snake River would provide such a resource benefitting Lewiston, the Tri-Cities, and small communities all along the river. Breaching the four lower Snake River dams would create new long-term jobs in the outdoor recreation and tourism sectors, and other types of businesses would inevitably move to the area due to an increased quality of life associated with a restored river and restored fisheries. Salmon recovery would benefit commercial, sport and tribal fisheries, thereby benefitting local communities. Salmon recovery would benefit the Southern 4 Resident orca population and associated tourism economies in Puget Sound and along the west coast.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The evaluation uses a potential range in non-fishing visitation from the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Study and EIS to estimate long-term visitation along the lower Snake River, including rafting and kayaking. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with river recreation post dam breach were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users. In addition, the timeline of the EIS precluded an extensive survey of post dam breach recreation. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries subsection and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries subsection of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Most Section of chapter 3 include a Tribal Interests Section at the end that attempts to summarize issues by topic. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
31812	5	N/A	N/A	In its analysis of cultural impacts, the DEIS downplays benefits of a restored natural river associated with public and tribal access, and instead emphasizes the potential threats to cultural resources from increased erosion and possible looting. A responsible plan for river restoration must include broad riparian restoration, along with careful management of access and use of restored riparian areas to ensure improvement of habitat and protection of cultural sites and resources. The analysis does acknowledge the preference for dam breaching among tribal communities, an evaluation that comes as close as any in the DEIS to an accurate assessment and one we wholeheartedly support: Most tribes support breaching the four lower Snake River dams…as it represents the only alternative that substantially attempts to restore the river to a more natural environment (emphasis added) and some could interpret dam breaching as a meaningful milestone in salmon restoration efforts (p. 3-1414).	The co-lead agencies agree with the commenter that many tribes may support MO3, which includes the measure to breach the four lower Snake River dams. The co-lead agencies disagree with the commenter's assessment that the Draft EIS downplays the benefits of a more normative river and emphasizes threats to cultural resources from increased erosion and possible looting. The Draft EIS Multiple Objective alternatives were evaluated in accordance with the National Environmental Policy Act and effects are discussed in Chapters 3, 4, 5, 6, and 7, including effects to Cultural Resources. The Draft and Final EIS include information about mitigation for MO3 in Chapter 5 Mitigation. Section 5.4.3, includes riparian mitigation measures for planting in the areas affected by breaching the four lower Snake River dams.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31812	6	N/A	N/A	In contrast, the Preferred Alternative (PA) offers an uncertain range of impacts for wild fish, ranging between negative or possible positive benefits, with the positive only occurring with optimistic assumptions in one of the two fish population models. The PA analysis also admits that its approach is experimental, that its aim would be to collect data on effectiveness rather than offering a proven effective solution. The PA emphasizes structural measures at dams that were part of other alternatives, spill and adaptive changes to fish transport, while leaving power operations largely unchanged. From that mixture of impacts, it appears the PA is intended to protect the status quo of operations, rather than actually achieve a significant improvement in wild fish survival through the hydrosystem. The PA is a patchwork of half measures, relies on experimentation and contingencies in modeling, fails to invest in significant changes to the dams or dam operations to benefit wild fish survival, and will fail to achieve the goal of restoring self-sustaining runs of salmon, steelhead and other imperiled fish species in the Snake and Columbia basins.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The Preferred Alternative complies with the ESA (see Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information). The co-lead disagree with the the comment that power generation was elevated over our legal obligations. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used current, high quality scientific information the in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Finally, the co-lead agencies disagree the Preferred Alternative is a continuation of the status quo. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
31812	7	N/A	N/A	Detailed Comments on the DEIS 1) Wild Fish Recovery: The DEIS fails to recognize that only breaching the lower Snake River dams would deliver significant benefits in wild fish survival, returns and recovery. The DEIS concludes that based on its model results, breaching of the lower Snake River projects is expected to have major beneficial effects on juvenile outmigration and upstream migration of wild salmon and steelhead, particularly those fish that originate in the Snake River (p. 3-593). Operational changes in the dam breaching option would increase Snake River spring/summer Chinook juvenile survival between 19-25.9% compared to the no-action alternative, decrease travel times (up to 31% vs no action), and decrease turbine passage (-71-4%) and associated mortality (Table 3-88, p. 3-559). The analysis assumes that hatchery releases that are mitigation for the lower Snake River dams would end, and cautions that reduction of hatchery fish could reduce numbers of juvenile Snake River Chinook salmon by as much as 85 percent and that the reduction in hatchery fish could increase predation of wild juveniles and reduce juvenile survival. For adult spring/summer Chinook, improvements compared to the No-Action Alternative would also be dramatic: 14-170% Smolt-to-Adult-Return (SAR) improvement from Lower Granite Dam and to Lower Granite Dam. Abundance would improve between 9-107% from the No-Action Alternative (Table 3-89, p. 3-560). For Snake River steelhead, juvenile survival would improve 23-46% compared to the No-Action Alternative, travel time would decrease 32-45%, and powerhouse passage would decline by 76-77%, with a 178% increase in SAR, from the current return rate of 1.8% to 5% (p. 3-562-3). The other MOs tend to have negative or mixed impacts on wild salmon and steelhead. Those that would deliver improvements still fall far short of achieving meaningful recovery for threatened fish. MO2 reduces spill, resulting in more turbine mortality and increased migration time for juvenile fish. Most alternatives include the same improvements to lamprey passage and survival, so suggest they could benefit lamprey. MO2 could reduce Snake River Chinook survival up to 7%, reduce juvenile steelhead survival by up to 22%, and cause a 30% reduction in SAR for Chinook and steelhead (pp. 3-515 to 3-517). MO4 results vary widely by model, from negative to positive depending on the model and assumptions. It predicts 1-10% juvenile survival improvement for Snake River spring/summer Chinook, 8-14% reduction in travel time, and 64-81% reduction in transported fish because of additional spill, but increased risk from Total Dissolved Gas (Table 3-96, p. 3-610). SAR and abundance changes vary widely by model, from -12% to +75%, but with the higher rate only achieving 3.5% SAR, far less (almost 50%) than the SAR under the dam breaching alternative. Abundance could range from -32% to + 99% vs. the no-action alternative (Table 3-97, p. 3-612). For Snake River steelhead, MO4 could increase juvenile survival 1-30%, decrease travel time up to 10%, reduce transported fish by 82%, and reduce powerhouse passage 80-86% (Table 3-98, p. 3-614). SAR could improve by 72% to a rate of 3.1% (Table 3-99, p. 3-616).	The co-lead agencies agree with the summarization of the model predictions from Chapter 3, but emphasize that these are model-based predictions of change relative to the No Action Alternative, not guaranteed outcomes. The co-lead agencies do not agree with the characterization that the CRSO EIS failed to recognize the predicted effects to salmon and steelhead that would result from each Multiple Objective alternative, as well as the Preferred Alternative. The co-lead agencies acknowledge in the Draft EIS that implementation of MO3 would have benefits to salmon and steelhead. However, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31812	8	N/A	N/A	Most of the structural improvements targeting lamprey should be implemented regardless and could be included with the dam breaching alternative. MO2 could increase risk of injury or impingement for lamprey because of increased powerhouse flow and passage. MO3 would 6 improve lamprey survival and production substantially by easing upstream and downstream migration without the lower Snake River dams.	The structural improvements for lamprey are included in every alternative, including MO3 (the alternative that includes the measure to breach the lower Snake River dams), and the Preferred Alternative. The increased risk of injury or impingement for lamprey due to increased powerhouse flow and passage is included in the sentence However, most of the water management and water supply operational measures have no benefit and might make migration conditions worse for juvenile lamprey compared to the No Action Alternative. This sentence was intended as a summary statement and was inadvertently placed at the end of the Adult Migration/Survival Section in MO2. The substantial benefits to lamprey under MO3 are described starting on page 3-572.
31812	9	N/A	N/A	In contrast, the Preferred Alternative offers uncertain anadromous fish impacts, and relies upon unproven practices unlikely to actually achieve recovery. The PA suggests it may have some positive fish benefits, but also declares that its spill strategy is essentially experimental and would prioritize the value of power sales to determine when spill would occur (p. 7-21). The PA fish benefits range from negative to somewhat positive, with the possible increased fish returns predicated on unreliable model assumptions of reduced delayed mortality, so are highly contingent. The DEIS acknowledges the range of potential outcomes predicted by the models used to estimate impacts to anadromous fish, including a study to evaluate the potential benefits and unintended consequences of a flexible spill operation. Survival rates of juvenile spring/summer Chinook under the PA would be very similar to the No-Action Alternative, between 1-5% higher, decreasing travel time 7 percent (Table 7-24, p. 7-100). SAR impact would range from a decrease of 7.5% to an increase of 35% compared to the No-Action Alternative, with adult abundance ranging from -24 to +58% (Table 7-25, p. 7-102). For Snake River steelhead, juvenile survival and travel time would not change from the no-action alternative, with SAR increasing 28% but to a rate of only 2.3%, far below the level produced by dam breaching.	See response to Comment 31812-7.
31812	10	N/A	N/A	2) Implementation Costs: Breaching the four Lower Snake River dams represents a cost-effective investment, given that the implementation costs of MO3/Breach are comparable or less than other alternatives, including No Action and PA. MO3, the dam breaching alternative, competes favorably in cost with the other MOs and preferred alternative, with lower costs for structural measures, operational actions, and fish and wildlife mitigation programs compared to the MOs and PA. Annual equivalent costs for MO3 would range between $896M and $1.001B, a reduction of between $159M with low fish and wildlife costs to $54M with high fish and wildlife costs, compared to the No-Action Alternatives annual cost of $1.055B, a reduction of between 5-15% (Table 3-308 and 3-309, p. 3-1481). The Preferred Alternative would cost between $1.014-1.063B, between a 3.9% reduction to a 0.6% increase compared to the No-Action Alternative (Table 7-51, p. 7-199).	Considering hydropower costs and values, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
31812	11	N/A	N/A	3) Economic Benefits: The DEIS does not fully capture the benefits of dam breaching, nor does it reasonably count the economic benefits of wild fish recovery, associated recreation and economic activity that LSR dam breaching would deliver. In particular, the DEIS recreation impact analysis: a) Declares that the unit day value method used was less accurate than preferred site-specific travel cost or contingent value approaches (p. 3-1880) but that the more detailed analysis was not possible under the timeline of the study.	Section 3.11.3.5 describes the potential for visitation in the lower Snake River post dam breach in the long-term. The EIS describes that the visitation in the lower Snake River, including rafting, kayaking, and recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with this visitation were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users. In addition, the timeline of the EIS precluded an extensive survey of post dam breach recreation.
31812	12	N/A	N/A	b) Emphasizes the loss of existing activity based on boat ramp data (p. 3-1177) quantitatively at reservoirs only and are described qualitatively for river reaches where dam breaching would improve recreational access and quality.	Visitation data included both reservoir and river locations, although the commenter is correct, that most of the existing conditions visitation data was associated with reservoirs. Section 3.11.2.2 describes gaps in the recreational visitation data. Data were not available for all sites, notably along river reaches. A quantitative analysis was undertaken to estimate the range in river-based visitation post dam breach in the long-term, based on previous analysis conduced for the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Study and EIS and fishing visitation in similar river reaches.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31812	13	N/A	N/A	c) Assigns monetary values to short-term lost recreation activity (p. 3-1222) amounting to 83% of visitor spending under the No-Action Alternative.	Losses in reservoir recreation, visitation, consumer surplus, and regional economic effects were estimated because data was readily available for the evaluation. The EIS Section 3.11.3.5 describes the potential for river-based visitation in the lower Snake River post dam breach in the long-term. The EIS describes that the visitation in the lower Snake River, including rafting, kayaking, and recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with this visitation were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users. In addition, the timeline of the EIS precluded an extensive survey of post dam breach recreation.
31812	14	N/A	N/A	d) Contains only qualitative estimates of fishing benefits, with no assigned monetary value: Fishing Activities, as well as other recreation types, would be considerably reduced in the short term during and immediately following breach, but could rebound in the long-term as anadromous fish populations improve. The largest increases in the number of Snake River salmon and steelhead are projected under MO3. Therefore, fishing for these anadromous species could increase in the long term relative to the No Action Alternative. The value of trips could also increase due to the increased abundance and diversity of wild fish. (p. 3-1214) The DEIS also notes new opportunities for land and water-based river recreation and possibly anadromous recreational fishing may offset visitation lossesand recreational opportunities may even increase in the long-term relative to the No-Action Alternative (pp. 3-1222 3-1223). But because the DEIS fails to assign monetary value estimates, the dam breach option does not have an assigned economic benefit.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
31812	15	N/A	N/A	e) Entirely excludes the monetary value of post-dam breach salmon and steelhead fishing, based on claims that fishing value is limited by uncertainties related to Endangered Species Act restrictions, and because those estimates were excluded from the 2002 Final Lower Snake River Juvenile Salmon Migration Feasibility Report/Environmental Impact Statement by the Walla Walla District US Army Corps of Engineers (2002 FEIS) analysis that was used as the primary basis of this economic impact estimate for the breach option (p. 3-1219).	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
31812	16	N/A	N/A	f) Declares that the methods to estimate potential fishing visitors (comparing with fishing visits to Hanford Reach and Clearwater data) may considerably underestimate future recreation activity in the Lower Snake River.	For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The evaluation uses a potential range in non-fishing visitation from the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Study and EIS. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively.
31812	17	N/A	N/A	g) Notes that rafting is a primary recreation interest in upstream reaches including Hells Canyon and Salmon River, but includes no discussion or valuation of the 63 historically named rapids that breaching the lower Snake River Dams would reveal. The DEIS also does not recognize the higher per-trip value of non-motorized boaters who would make up the bulk of post breach recreation. A 2019 report by ECONorthwest, Lower Snake River Dams Economic Tradeoffs of Removal, cites 15-115% greater per trip for whitewater recreation (p. 97) and a $228 per day recreational user value (p. 99).	Section 3.11.3.5 describes the potential for visitation in the lower Snake River post dam breach in the long-term. The EIS describes that the visitation in the lower Snake River, including rafting, kayaking, and recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with this visitation were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users. It is true that rafting would likely have a much higher consumer surplus value per day compared to other types of activities.
31812	18	N/A	N/A	h) Other than referencing the 2002 FEIS, the DEIS fails to evaluate or incorporate numerous published analyses of economic impacts related to dam breaching. Several studies by the Idaho Department of Fish and Game and others between 1996-2005 estimated the value of 8 a recovered fishery could be worth $148M for a single species to $342M for recovered populations of salmon and steelhead, up to $734M if direct and indirect benefits are included (summarized in Laughy, Linwood. The Economic Impact in Idaho of Snake River Salmon and Steelhead Fisheries, March 2020).	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
31812	19	N/A	N/A	The DEIS also considers, but then declines to assess non-use, also known as passive use values, of restored salmon and steelhead runs in the Columbia Basin. Other economic studies have shown strong passive use values associated with salmon recovery exist among Pacific Northwest residents. A 1999 study by John Loomis, Passive use values of wild salmon and free-flowing rivers, assigned non-use value of increased anadromous salmon and steelhead related to Snake River dam breaching between $66M and $879M, with an additional $420M in passive use related to the return of the lower	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. As described in the EIS, Section 3.15.2.2, "Best practices for benefit transfer identified in OMB Circular A-4 describe that meeting all criteria is difficult and that professional judgment is required in determining

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Snake River to a natural condition. While acknowledging that passive use values could be considered, the DEIS instead summarily excluded these values, even though some passive use values were included in 2002 FEIS and they are commonly used elsewhere to benchmark economic estimates. The DEIS vaguely concludes instead that Given the limitations of the existing literature, this EIS does not include a quantitative benefit transfer of passive use values (DEIS p. 3-1322).	whether a particular transfer is too speculative (OMB 2003, 26). Given the limitations of the existing literature, this EIS does not include a quantitative benefit transfer of passive use values. This analysis acknowledges that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching.
31812	20	N/A	N/A	A 2019 evaluation by ECONorthwest, Lower Snake River Dams Economic Tradeoffs of Removal, suggests a potential value of $1.04B in recreation benefits and an additional $10.97B non-use. Removing the Lower Snake River Dams will result in a net increase of $505 million in output, $492 million in value added, $408 million in labor income, and 317 average annual job-years. Within those totals, Spending from visitors in the area results in an increase of $179 million in total output, an increase of $104 million in total value added, an increase of $56 million in total labor income, and an increase of 49 average annual job-years (ECONorthwest p. 124). Since the DEIS assigns no dollar values to its qualitative analysis of fishing and recreation benefits, dollar values from Idaho Fish and Game studies, the ECONorthwest report and others should be considered as offsets against estimated negative financial impacts.	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. This is consistent with NEPA guidance, which describes that the EIS should not be a cost-benefit analysis if there are important tradeoffs that are not quantified. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS has a different charge than the ECONorthwest study. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. The study used a very limited sample of 20 trips to the region. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.
31812	21	N/A	N/A	4) Energy and Power Impacts: The investments in energy conservation and carbon neutral replacement generation that could accompany LSR breaching would make the regions energy system stronger, more climate resilient, and contribute to broader sustainability in ways that the PA will not. As with other segments of the DEIS, the analysis of power replacement costs and ratepayer impacts associated with dam breaching are inaccurate and incomplete. The DEIS exaggerates the costs of replacement power, given the ongoing evolution of power markets and declining cost of emerging renewable and storage technologies, and omits additional available efficiency and demand side energy resources in the analysis of MO3s power replacement scenarios. Based on an unnecessarily narrow evaluation of energy replacement options and scenarios, excluding wind, solar-storage hybrids, and additional energy efficiency, the DEIS assigns a significant range of additional cost to power replacement related to lower Snake River dam breaching, from about $380M - $1.1B. Potential wind, energy efficiency, and storage resources are currently available and have steadily declined in cost. Studies by the Northwest Energy Coalition (NWEC) and others indicate that a realistic, forward projection of solar costs would allow replacement of generation from the lower Snake River dams at 15-30% less than the DEIS estimates. NWEC estimates that using a more accurate cost estimate for solar, storage, and other distributed energy resources would reduce the capital cost of replacement power by a quarter or more (NWEC DEIS comments p. 31). Incorporating an optimized and realistic, cost-effective replacement portfolio that includes more accurate cost assumptions for wind, solar, energy efficiency and storage investments would reduce projected replacement cost and rate impacts associated with lower Snake River dam breaching. Consequently, because the DEIS fails to provide accurate information needed to make an informed decision, a new and more rigorous study is warranted.	The EIS analyzed the effects on regional reliability if the four lower Snake River dams are breached as discussed under Multiple Objective Alternative 3 (MO3). To maintain regional power reliability at the No Action Alternative levels, the EIS found that additional replacement resources would be necessary. The EIS considered a range of resource portfolios to replace the output of the four lower Snake River dams. That range is reflected in two portfolios used to describe the potential resource options: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Section 3.7.3.5, at 3-904-910 in the draft EIS. The costs of these resource portfolios were developed from the Northwest Power and Conservation Councils (Council) 7th Power Plan and Mid-Term Update. The purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. See draft EIS Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, at Section 2.2. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for MO3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. All cost effective conservation identified by the Councils 7th Power Plan is included in the load forecast. See Appendix H, Power and Transmission, Section 2.2, H-2-3 in the draft EIS. The comment mentions various renewable power resources and incorrectly states the EIS excluded these. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options; however, to avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, at Section 2.2 in the draft EIS. The EIS also examined the use of storage technologies considered a long-term resource of the 7th Power Plan, but has become more commercially available since the release of the 7th Power Plan, and will likely now be considered a primary resource in the Councils 8th Power Plan. Wind generation was considered, but the EIS analysis found that solar was more cost-effective for lowering the LOLP. The MO3 potential replacement resource portfolio did include a combination of solar and storage. Regarding the potential for additional efficiency, the EIS included all cost-effective conservation identified by the Council in their 7th Power Plan, which is the current power plan. Cost effective conservation in the region would be acquired under Washington and Oregon law regardless of the status of the four lower Snake River dams. In addition, demand response was included in the renewables portfolio as a demand-side resource, consistent with the 7th Power Plan target. See Section 3.7.3.1, Demand Response Analysis for CRSO, at page 3-837 in the draft EIS. Conservation was not considered a potential resource replacement to avoid double-counting. As described in the draft EIS in Appendix H, Power and Transmission, and Section 3.7.3.5, the EIS considered the Northwest Energy Coalition study cited in the comment, but it is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. See Section 3.7.3.1, Step 3, at 3-820; Section 3.7.3.5, Related Study, at 3-913; Appendix H, Power and Transmission, Section 2.4 in the draft EIS.
31812	22	N/A	N/A	These smart, available infrastructure investments would lead to a modernized, sustainable, net zero carbon energy system that doesnt drive wild salmon and steelhead to extinction. A revised system that integrates additional conservation and renewables with post-dam breach hydropower is healthier in the long run for its climate/carbon impacts, wild fish and natural river recovery, so that the investment in a more resilient system is worth it for a sustainable future. The DEIS omits maintenance and upgrade costs associated with leaving the lower Snake River dams in place. Based on typical 50-year maintenance cycles, 21 of 24 turbines would need upgrade or replacement; yet the cost of doing this maintenance/upgrade cycle, which could cost $1 billion or more, is omitted from both the No Action and Preferred Alternatives (NWEC DEIS comments, p. 55). Inclusion of these costs would also expand the differential between the breaching alternative, which would avoid upgrade and maintenance costs for lower Snake River dam turbines, and NA/PA in which those costs would be necessary.	All cost effective conservation identified by the Northwest Power and Conservation Councils Seventh Power Plan is included in the load forecast. Appendix H, Power and Transmission, Section 2.2, H-2-3 in the Draft EIS and more detail in the Final EIS. Under existing law, all cost effective conservation must be acquired regardless of the status of the Federal Columbia River Power System (FCRPS). Therefore, conservation was not considered a potential resource replacement to avoid double-counting. All capital and expense (operations and maintenance, O&M) costs for the four lower Snake River dams are included in the Draft EIS analysis. Under the Draft EIS analysis, Bonneville expects to fund approximately $47 million per year in capital and $53 million per year in expense totaling approximately $100 million per year for the four lower Snake River dams combined. Under MO3, the four lower Snake River dams O&M and capital investments were removed from Bonneville's costs before calculating rates. In the Draft EIS, please see Section 3.7.3.5, Table 3-166, and pages 3-920-924. These costs were also removed from MO3 under the Net Present Value analysis. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1 in the Draft EIS) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1 in the Draft EIS). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary Dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecast between the 2040s and 2060s, which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary. As described in Appendix H, Power and Transmission and Section 3.7.3.5, in the Draft EIS considered the Northwest Energy Coalition study cited by the commenter, but that study is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data.
31812	23	N/A	N/A	The DEIS also fails to properly evaluate power customers willingness to pay additional costs in order to recover salmon and steelhead. Studies of regional willingness-to-pay related to wild salmon recovery indicate a range that would support potential increases from dam removal ranging from $3.42-$7 per month (ECONorthwest p. 111). Although we believe the DEIS over-estimates potential rate increases, if necessary, the likely rate increases would fall within regional willingness-to-pay ranges, so represents a strength rather than a weakness of the dam breaching option.	Section 3.15.2.2 of the Draft EIS summarizes existing research regarding the publics willingness-to-pay for salmon conservation and restoration. This section specifically describes the ECONorthwest study referenced in this comment, highlighting the objective of the study and the approach to surveying rate payers to estimate willingness-to-pay for salmon restoration. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. The findings of the ECONorthwest report that the benefits of salmon restoration outweigh the costs (increased power rates) of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. However, the anadromous fish effects analysis in Section 3.5 of the Draft EIS does not find that MO3 would result in recovery of salmon or steelhead populations or restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3.
31812	24	N/A	N/A	5) Irrigation: Irrigation costs and impacts associated with dam breaching are inaccurate, because the DEIS ignores prior analysis from the 2002 FEIS, which concluded that irrigated agriculture could continue along the Snake River. One of the key points that underpins the approach taken in the DEIS regarding irrigated agriculture is that if the dams are breached (MO3), there will be no more agriculture on the 10 lands adjacent to the Snake River. However, the 2002 FEIS 1 by the same agency clearly found a viable path for continuing to irrigate these same lands. In 2002, the analysis found that an alternative, Option 32, could technically work and met the criteria desired by the analyst: operational prior to breaching of the Ice Harbor reservoir function through a full range of river stages without interruption able to handle a potentially large quantity of suspended sediment No reason is provided as to why something that was true in 2002 fails to be true in 2020. The only source given is conversations with several extension agents in Washington and Oregon. These conversations are without other reference such as date or even information regarding what was said. So, we are left to	In Region C (lower Snake River) and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, the MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				assume that these may be the same conversations mentioned in the 2002 FEIS where, under Farmland Value in Section 5.11, it states: This analysis based the determination of economic effects to irrigators under Alternative 4 Dam Breaching on a change in farmland values that would occur with elimination of the current water supply. Typical land values for farm properties near Ice Harbor were used. This information was compiled through discussions with farm managers, cooperative extension agents, farmland appraisers, agricultural economics professors, and the use of published enterprise budget sheets for a number of crops. In 2002 Appendix I, Economics, estimated that modifying the irrigation pumps in 1998 (Option 3) cost $291,481,000 and also estimated the land value at $127,940,000. The conclusion was that private landowners would not pay for modifications. American Rivers supports the continued irrigation of these lands and will support including the costs to modify the irrigation systems while the lower Snake River is restored. We believe solutions can be found that meet the need for salmon and people for a restored river, and for farms to continue to irrigate their land from that same river.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. In Region C, under the MO3 alternative this analysis accordingly concludes that pumps are unable to deliver water to an estimated 48,000 acres.
31812	25	N/A	N/A	6) Transportation: The DEIS analysis of transportation impacts from dam breaching is incomplete and overestimates costs to replace current barge-based agricultural commodity shipping. Throughout the DEIS the analysis is limited. Key points and prior analysis by the USACE and others are missing. Overall, there is not adequate consideration of the benefits of dam breaching to the region, nor a close look at solutions and mitigation measures that can cost 1 Lower Snake River Juvenile Salmon Migration Feasibility Study, Final Feasibility Report and Environmental Impact Statement, 2002. US Army Corps of Engineers, Walla Walla District. 2 2002 FEIS, Appendix D, Natural River Drawdown Engineering and Technical Appendix D, Existing Systems and Major System Improvements Engineering. effectively replace services provided by the four lower Snake River dams. Similar deficiencies are present throughout the DEISs transportation analysis.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. Under MO3, construction of new infrastructure to replace the lost purposes of the existing infrastructure or to mitigate for the loss of Federal benefits was considered where there are existing Federal authorities. However, in order to regain the full benefits of these lost Federal services, the co-lead agencies identified mitigation measures that are outside the authority of the co-lead agencies that would need to be taken by other entities to alleviate the loss associated with de-authorization of Federal projects.
31812	26	N/A	N/A	The analysis of the impacts under MO3 in Appendix L, Navigation and Transportation, appears to rely on a belief that there are not significant opportunities for additional investments in rail infrastructure which could increase rail capacity.	The navigation analysis does not provide a position on investment opportunities, but attempts to describe when infrastructure investments may be needed. Ultimately, rail infrastructure investments would be at the discretion of the railroads.
31812	27	N/A	N/A	The DEIS focuses on the present and on limitations. But what is limited in 2019 where commenters have further stated it is difficult to secure a unit train on short notice (L-3-14, comments of Idaho Cooperating Agencies, December, 2019) becomes possible when public investment shifts from maintaining an aging system of locks and barges, and towards further investment in rail infrastructure. Wheat farming existed in the Inland Northwest prior to the construction of the four lower Snake River dams, and farming will continue to thrive after the dams are breached. When the four lower Snake River dams and their barge transport system were put in place between 1962 and 1981, farmers moved from shipping via rail to using either rail or barge, based largely on price and location. The existing rail system in the region declined, grain elevators were abandoned or removed, tracks were either left to degrade or were removed. Those are investments that can be made again. We support transportation improvements that give farmers options for shipping.	The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
31812	28	N/A	N/A	In the area of transportation, the DEIS falls short in key ways: The DEIS ignores a rail line, the WATCO-Union Pacific line from Lewiston to Lyons Ferry. This is a primary alternative for grain shipping. This, and the lack of information regarding Washington States Grain Train and transportation plans, is a surprising oversight.	The choice to limit those types of movements in modelling assumptions was after consultation with grain shippers and WATCO. The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID, to Ayer Junction, WA. Research conducted as part of the EIS suggested that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers. The EIS also discusses the potential for rail car shortages. The Washington State's Grain Train was not mentioned in the EIS but could be used to partially address these potential rail car shortages.
31812	29	N/A	N/A	The DEIS should have included data and information from relevant reports on transportation, among them: Washington State Department of Transportation (WSDOT)s 2019 Draft Rail Plan 2019 2040 WSDOTs 2017 2017 2027 Grain Train Strategic Plan WSDOTs 2015 Palouse River and Coulee City Rail System Strategic Plan WSDOTs 2015 Short Rail Line Rail Inventory and Needs Assessment	Assumptions made in the EIS and within the transportation optimization model are informed by plans released by WSDOT. In particular, a discussion with several experts at WSDOT is cited in Section 3.10.3.2 in which WSDOT provided input on the future of the Palouse River and Coulee City Rail (PCC), which are also presented in the WSDOT 2019 Draft Rail Plan. Additional insights into the capacity of Eastern Washington's short line capacity were also provided by WSDOT that informed the EIS.
31812	30	N/A	N/A	The DEIS assumption that barge volume will decrease substantially on the Columbia River is faulty. It would make sense to consider expansion at the Port of Pasco with barge transport originating there. The 2002 FEIS assumed that this would happen and that grain transport would shift to the Tri-Cities. This would reduce rail miles and shipping costs. Expanding rail to the Port of Pasco for grain shipment should be fully explored, starting by updating the earlier analysis in the 2002 FEIS by the Corps.	The EIS does not assume that all freight will cease to travel on the Columbia-Snake Navigation system under MO3. As described in the Summary of Effects Section for MO3 under Section 3.10.3.5, navigation operations would continue for the Columbia Shallow and Deep Draft portions of the Columbia Navigation Channel. The river ports still operating on the Columbia River will likely experience a large volume increase from commodities arriving via rail and/or truck. The outcomes of the flows that end up on the Columbia River terminals are the product of all shippers in the area minimizing transportation costs. Expansion of rail facilities is outside of the authorities of the co-lead agencies, and such an effort would need to be undertaken by others.
31812	31	N/A	N/A	The DEIS measures truck trips not by miles but by each trip leaving the farm. The most immediate and noticeable impact comparing the No-Action Alternative to MO3 is that the number of truck trips going to the river ports decreases by 80,086 trucks as farmers now choose the next least cost option, which would be shuttle rail under Scenario 1. 12 That would result in an additional 46,638 trucks going from the farm to elevators with rail access instead and an additional 32,495 trucks to elevators with rail access and an additional 892 trucks going from the farm to elevators without rail access. Also, under Scenario 1, an additional 498 truck trips would occur for trans-shipments between elevators without rail to those with rail that didnt occur under the no-action scenario. The net additional trips under Scenario 1 is 13,515 truck trips compared to the No Action Alternative. Given the distance of many farms to the river ports, and the location of rail elevators, and the potential to add elevators with an expanded rail system, we recommend an analysis that looks at miles driven rather than truck trips so decision makers and the public have an accurate understanding of impacts.	Both truck trips and miles are calculated and reported in Section 3.10.3.5. The Commercial Navigation and Transportation subsection provides a total estimate ton-miles by transportation mode, and the Highways and Highway Congestion section under the Regional Economic Effects provides additional information about number of truck trips by origin and destination.
31812	32	N/A	N/A	Changes to the current rail infrastructure seem likely to occur and that this be analyzed to understand the true benefits, costs and impacts: more elevators will be built, connected by rail lines, especially in places that once had more rail and more grain elevators. This is happening today and the trend is likely to continue. Such upgrades of elevator and rail infrastructure may mean that fewer truck miles are driven, and that rail options become increasingly available for transportation of agricultural commodities to market. If public investments are shifted from maintaining an aging barge/lock system and to rail that includes public or farmer-cooperative owned rail, the result may be good options at fewer miles driven.	The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
31812	33	N/A	N/A	An assumption is made that grain shipped on the Columbia will drop from 65% to 32% of all grain shipped with no explanation why. It seems reasonable to assume, just as the 2002 FEIS did, that under MO3 grain would arrive at the Tri-Cities via rail or truck and loaded onto barges from there, and that grain that originates farther from the river is likely to continue on via rail to lower Columbia ports.	The figures cited by the commenter are the results of the modeling effort, rather than any assumption. As such, this is what is predicted to happen when grain shippers choose the least cost of moving grain to market under each alternative.
31812	34	N/A	N/A	The DEIS assumes that all grain shipped on the river arrives via truck but this conflicts with assumptions in the 2002 FEIS. It seems reasonable to analyze how much grain can also arrive via train to the Tri-Cities. This impacts the costs and the overall truck miles and if it was deemed viable in 2002 it should be considered. The 2020 model assumed that all grain loaded onto a rail car would continue to Portland via rail yet in 2002 it was assumed that grain would also be shipped from the Tri-Cities.	The regulations on Class I railroads related to Positive Train Control are different today than they were in 2002, which prevents shortlines from operating on the Class I lines.
31812	35	N/A	N/A	The transportation model assumes that there will be no expansion of rail lines (and in fact, overlooks a rail line.) In the years since the publication of the 2002 FEIS there has been public and private investment in short rail and increased options and shuttle facilities. It is reasonable to assume that this trend will continue and that rail will be more available, especially if the removal of barge past Pasco makes investment in rail for grain transport more appealing.	Given that it is the Class I railroads that decide where they will invest in their infrastructure and when, there was no reasonable process for predicting how and where they choose to invest to maximize profits on a national rail network that moves far more products than wheat from the northwest. Research conducted as part of the EIS suggested that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers.
31812	36	N/A	N/A	The 2002 Final Lower Snake River Juvenile Salmon Migration Feasibility Report/Environmental Impact Statement by the Walla Walla District US Army Corps of Engineers (2002 FEIS) stated that It is judged possible that additional transportation capacity could be made available with no significant increase in unit cost 3 yet the 2020 DEIS failed to fully consider or update this analysis. It also failed to analyze a surprising finding of the 2002 FEIS, that the current transportation is NOT the least cost option. Transportation was analyzed in the 2002 FEIS and the USACE found solutions that would allow grain transportation once the four lower Snake River dams were breached. Their solution was a mix of improved rail capacity and expanded grain storage at the Tri-Cities.	The general findings of the 2002 and current EIS are consistent. The current EIS reviews likely transportation scenarios under MO3, which includes breaching the four lower Snake River dams, using a transportation optimization model, and finds that a mix of transportation options, including rail, truck, as well as barge below Ice Harbor Dam, are likely.
31812	37	N/A	N/A	The 2002 FEIS discovered while modeling transportation costs that the existing system wasnt the least cost. They stated there wasnt enough time to analyze that further but this should have been looked at in the DEIS: A fundamental assumption made for this analysis is that the existing transportation of grain represents the least-cost condition. Therefore, it was assumed that the cost of all movements of grain with dam breaching should be at least as costly as under the base condition. Actual operation of the model, however, showed that this was not the case. The model results showed that a number of grain movements were found to be less costly with dam breaching than with the existing transportation system. (Emphasis added.)4	This EIS relies on more up to date information regarding shipping rates and conditions than were included in the 2002 EIS. Going shipping rates were estimated using a new survey of shippers, and used as the basis of the transportation optimization model.
31812	38	N/A	N/A	The 2002 analysis should have been the starting point for the DEIS in order to build on the earlier work, particularly the sections we provide below: If dam breaching were to occur, the Tri-Cities area would become the alternate port area.5 The FEIS goes on to estimate the costs to range from $58.7-million to about $335.4 million depending on the type of facility and capacity added at Pasco. These estimates included rail and access roads. The 2002 FEIS also estimated that there were sufficient country elevators to shift grain from the Snake River but that improvements to loading facilities and railcar handling tracks would be needed. (Appendix I, I3-109) The 2002 FEIS considered whether it made sense to maintain the river ports, and add rail from them to the Tri-Cities, It would be appropriate to consider converting some of the existing 12 river elevators (which handled over 100-million bushels of grain in 1998) to railroad loading facilities that would then ship grain by rail to the Tri-Cities.6 They believed this had the potential of being less costly than other approaches. The 2002 FEIS found that while there may need to be some rail upgrades, they also found that concerns about railroad pricing may	The general findings of the 2002 and the current EIS are consistent. Infrastructure costs were developed based on input from local stakeholders, as well as published reports including the 2002 Lower Snake River Feasibility Study/EIS (2002 EIS), and the 1999 Lund Report. Please refer to Section 3.10.3.5 and that sections discussion of infrastructure costs.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				not be accurate. While some specific route segments might require substantial incremental expenditures to accommodate additional traffic, the adverse rate effects of these expenditures would be largely offset by the efficiencies gained through expanding the capacity of related route segments. At 3 2002 FEIS, Appendix I, I3-88 4 2002 FEIS, Appendix I, I3-90 5 2002 FEIS, Appendix I, I3-89 6 2002 FEIS, Appendix I, I3-89 14 least in the case of the diversion of lower Snake River traffic, concerns regarding terminal congestion and the adverse effects this congestion may have on railroad pricing are unfounded. 7	
31812	39	N/A	N/A	7) Sediment: Sediment related impacts from dam breaching are overstated in the DEIS and could be reduced through potential mitigation strategies. a) The DEIS suggests sediment from breaching would degrade conditions between 2-7 years following the deconstruction. However, the study does not adequately contextualize the volume of sediment that would potentially mobilize in comparison to the receiving waters of both the Snake and Columbia rivers and their capacity for handling a short-term increased sediment load. In their guidelines for assessing sediment for dam removal consideration, the Federal Interagency Advisory Committee on Water Information Subcommittee on Sedimentation, led by the U.S. Bureau of Reclamation, acknowledges that the probability of sediment impact is based on the relative reservoir sediment volume (small, medium, or large). The relative reservoir sediment volume is based on the ratio Ts, which represents the years of upstream sediment supply trapped within the reservoir. The years of trapped sediment is representative of the reservoir sediment volume and the rivers capacity to transport it. Additionally, studies analyzing sediment transport following the removal of dams like the Marmot Dam on Oregons Sandy River indicate sediment transport and distribution can happen much more quickly, with sediment redistributed in the first year the river recovering its pre-dam conditions and most sediment redistributed in 2-3 years. Sediment quality and chemical components may be more of a concern than in the Sandy River, but the distribution time could be far less than estimated. The Condit Dam on the White Salmon River in Washington impounded 2.3 million cubic yards of sediment. When considering sediment management alternatives, the project investigators weighed the long-term gains against short-term impacts to aquatic species, as well as the capacity of the receiving waters to transport the sediment. The final 401 water quality certification indicated that the project would cause brief exceedances of water quality criteria in the White Salmon River and the Columbia RiverHowever, dam removal will provide permanent benefits to fish, other aquatic life, and recreational uses. The U.S. Fish and Wildlife Service found salmon redds upstream of the Condit Dam within one year of the dams demolition. The DEIS also assumes passive transport of all sediment available behind the dams. It does not acknowledge that moving forward with a dam breach alternative would analyze a number of sediment management and mitigation alternatives, including but not limited to mobilizing sediment behind the dams in consideration. The discussion of sediment in MO3 focuses almost exclusively on impacts to aquatic species if sediment were released and does not consider the current impacts of sedimentation to 7 2002 FEIS, Appendix I, I3-105 habitat within the dam impoundments and the flood risk associated with the reservoir sediment deposit behind Lower Granite Dam under the other alternatives. Full consideration of the dam breach alternative should account for the benefits associated with re-establishing a more natural sediment transport regime, including the restoration of habitat within the former impoundments that would result from the clearing of fine sediment from those impoundments	The formulation of the MO3 measure for drawdown and embankment removal plan for the four lower Snake River dams mirrored that developed in the 2002 Lower Snake River FR/EIS. This plan includes incremental reservoir drawdowns prior to breaching combined with the stepped approach of embankment breaching which are specific best management practices intended to reduce suspended sediment and turbidity in the lower Snake River under MO3. There is approximately 180 million cubic yards (Mcy) of sediment retained behind the four lower Snake River dams, that has accumulated over the last 59 years since Ice Harbor Dam was completed in 1961. This is nearly 80 times greater than the sediment behind Condit Dam on the White Salmon River in Washington. Sediment-related impacts for the MO3 Breach Snake Embankments plan were estimated using numerical modeling to simulate erosion, transport, and deposition in the Snake and Clearwater Rivers, as well as the McNary reservoir pool as detailed in Appendix C.3.4. Similar to the 2002 FR/EIS, this analysis approach was utilized to estimate reservoir erosion rates, downstream concentrations, and deposition-induced flood risk in response to drawdown and bypass of the four lower Snake River dams. Modeling predictions of dam breach sediment processes are inherently probabilistic due to the rapidly varied hydraulics and complex interactions that effect both sediment supply and sediment transport capacity. If MO3 is identified as the selected alternative in the ROD, the co-lead agencies would further study the potential impacts and refine the elements of the removal plan (means, methods, and timing) as well as implementation measures to insure that suspended sediment and turbidity were appropriately mitigated in accordance with applicable laws and regulations. Immediately following removal of the four lower Snake River embankments, rapid scouring of sediments within the active Snake River channel was predicted to result in an annual deposition rate in McNary reservoir between 8.6 and 12.0 Mcy/year depending on watershed hydrology for the near-term response period with an approximate gradation of 4/5 fines (silt and clay) and 1/5 sands. The McNary reservoir trap efficiency for the legacy dam deposit loading averages 40% for clay, 82% for silts, and 100% for sands. In the following long-term period, the average annual deposition rate in McNary reservoir is predicted to equilibrate and average 2.3 Mcy/year, as watershed sediment yield that had previously been retained in Lower Granite reservoir would now be routed downstream. The approximate gradation of this material is 2/3 silts and 1/3 sands. The McNary reservoir trap efficiency for the long-term watershed sediment load averages 4% for clay, 64% for silts, and 100% for sands. Total depositional volume of these sediments was compared with the McNary reservoir volume to determine the percentage of infill due to increased sediment loading under the MO3 Breach Snake Embankments measure. Sediment loading associated with the initial removal and near-term response period was estimated to reduce the McNary reservoir volume less than 2%; over the following years, the long-term sediment loading was estimated to incrementally reduce the reservoir volume an additional 0.2% per year. Regarding sedimentation impacts to flood risk upstream of Lower Granite Reservoir. The four lower Snake River dams are not authorized for flood risk mitigation and there is no elevated risk to flooding in the lower Snake River reach for any of the EIS Alternatives. Furthermore, the Walla Walla District (Corps) constructed eight miles of levees around Lewiston as part of the Lower Granite project to help protect lives and property from potentially destructive high-water conditions after the dams were built. Unlike freely flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. The most recent dredging in the Lewiston area, has been to maintain a 14-foot depth in the navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan. Dredging outside of the navigation channel limits to maintain conveyance capacity has not been conducted since 1992. Dredging for channel conveyance capacity would only occur in the future if there were an observed accelerated rate of sediment accumulation and a heightened risk of levee overtopping, which does not appear to be the current trend.
31812	40	N/A	N/A	b) The DEIS provides little discussion on the fact that MO3 is the only alternative that would result in marked improvements to lethally warm water temperatures. Unimpounded flowing water is better able to maintain cooler water temperatures necessary for increased survival of native riverine aquatic life. Water quality improvements need to be considered as part of the alternatives analysis.	All EIS alternatives were analyzed using the same methodology. Water temperature results can be found throughout Section 3.4, Chapter 7, and the Water Quality Appendix D. Regarding water temperatures in the lower Snake River, it is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact.
31812	41	N/A	N/A	8) Cultural Resources: The DEIS emphasizes risk and potential degradation to cultural resources in the dam breaching alternative and fails to recognize significant cultural benefits that a natural river would restore. Functioning natural rivers are and have always been at the heart of Pacific Northwests culture. The restoration of natural conditions in the lower Snake River through dam breaching represents an unparalleled opportunity to expand cultural opportunities, for both tribal and non-tribal communities, yet the DEIS fails to recognize or give sufficient value to the cultural value of lower Snake River restoration.	The co-lead agencies have defined cultural resources as property-based and composed of three sub-categories: archaeological sites, traditional cultural properties (TCPs), and the historic built environment. In regards to these cultural resource property types, the co-lead agencies disagree the Draft EIS omits the positive or beneficial effects of breaching the four lower Snake River dams to cultural resources. Section 3.16.3.6 discusses impacts from the MO3 to the cultural resources property types, to include TCPs. In the Draft EIS, lines 7054-7060 describe the benefits of the alternative on TCPs, such as increased access to the river and the ability to experience the river in a pre-inundation condition. The co-lead agencies state in the Draft EIS on page 3-1388, "In the long term, this would be expected to have a beneficial effect to TCPs." Within many of the resource analysis areas in Chapter 3, a specific section is provided to explicitly consider tribal interests, including the effects of MO3. Please see in the Draft EIS Sections 3.3.4, 3.4.4, 3.5.4, 3.6.4, 3.7.4, 3.8.4, 3.9.5, 3.10.4, 3.11.3.7, 3.15.4 and lines 3911-12 in Section 3.13.3.4.
31812	42	N/A	N/A	The DEIS emphasizes risk, primarily in the exposure and erosion potential of various alternatives on archeological sites and Traditional Cultural Properties, the latter encompassing both historic and modern features in the built environment, including the dams themselves. It downplays or omits the benefits of restored natural river conditions that would result from breaching.	The co-lead agencies have defined cultural resources as property-based and composed of three sub-categories: archaeological sites, traditional cultural properties (TCPs), and the historic built environment. The co-lead agencies do not consider Traditional Cultural Properties as encompassing historic and modern features in the built environment. The co-lead agencies disagree the Draft EIS omits the positive or beneficial effects of breaching the four lower Snake River dams to cultural resources. Section 3.16.3.6 discusses impacts from MO3 to the cultural resources property types, to include TCPs. In the Draft EIS, lines 7054-7060 describe the benefits of MO3 on TCPs, such as increased access to the river and the ability to experience the river in a pre-inundation condition. The co-lead agencies state in the Draft EIS, on page 3-1388, "In the long term, this would be expected to have a beneficial effect to TCPs." The cultural resources impact analysis does not compare impacts or benefits from the alternatives on the other resources analyzed in this EIS. Within many of the resource analysis areas in Chapter 3, a specific section is provided to explicitly consider tribal interests, including the effects of MO3. Please see in the Draft EIS Sections 3.3.4, 3.4.4, 3.5.4, 3.6.4, 3.7.4, 3.8.4, 3.9.5, 3.10.4, 3.11.3.7, 3.15.4 and lines 3911-12 in Section 3.13.3.4.
31812	43	N/A	N/A	MO3 analysis assigns potential major adverse impacts to dam breaching associated with exposure of 14,000 acres now covered by lower Snake River reservoirs, citing the example of a 2014 drawdown at Wanapum Dam as an example. The DEIS suggests the major impacts would be potential erosion damage, threats of looting and casual collection of artifacts (p. 3-1386), and a 915% increase in acre-days of exposure, using the spatial extent of Lower Granite dams reservoir as a proxy for the lower Snake River area (pp. 3-164-5, 3-1383).	The co-lead agencies acknowledge this comment is an accurate reflection of the cultural resources impact analysis of Multiple Objective alternative 3 as provided in Section 3.16.3.6 in the Draft EIS.
31812	44	N/A	N/A	The benefits of additional tribal access and restored cultural use are referenced, but given little weight as benefits. The notion of tribal use is mentioned in a footnote in analysis of exposure, (p. 3-1378) stating that short term risk is expected to shift to beneficial effects in the period after (breaching) due to increased access to these properties by tribal communities. And later, Restoration of a natural river would allow tribal communities that attach importance to those areas to access them and, in the long term, experience the river as it was prior to inundation (p. 3-1388). The analysis notes that 293 archeological sites encompassing 2,125 acres exist within the lower Snake reservoirs (p. 3-1383), and that 16 based on improved survey techniques would likely expand to over 500 sites after breaching (p. 3-1387).	The co-lead agencies have described the effects of the alternatives using the best available information. The co-lead agencies did not conduct a comparative analysis of impacts and benefits between cultural resource types, nor did they attempt to impose values on different resource types or effects for weighting purposes. Instead, the cultural resources impact analysis compared the impacts between the alternatives on the three different types of cultural resources: archaeological sites, Traditional Cultural Properties, and the historic built environment. The summary of effects for each Multiple Objective in Sections 3.16.3.3 through 3.16.3.7 addresses impacts to each property type equally.
31812	45	N/A	N/A	The summary of effects acknowledges that exposure of Traditional Cultural Properties would allow resumption of some traditional uses that have not been possible since the dams were built, and this is viewed as a beneficial effect but continues to note that the partial removal of dams would be major effects to these built resources and would reduce their historic value (p. 3-1391). The DEIS acknowledges that MO3 was specifically identified by several tribes as preferable and Most tribes support breaching the four lower Snake River dams...as it represents the only alternative that substantially attempts to restore the river to a more natural environment and some could interpret dam breaching as a meaningful milestone in salmon restoration efforts (p. 3-1414). Exposure of the currently inundated area represents an extraordinary opportunity for people to reconnect with the land and river, one in which public agencies would need to play a significant management role. Any serious strategy to restore natural river conditions in the lower Snake River would include plans for ecological restoration, as well as management of access and measures to protect significant cultural sites and resources. The DEIS fails to consider such restoration plans and protection as elements of its mitigation strategies, and in doing so fails to recognize both federal agencies responsibility in post-breaching land management and the significant cultural value that breaching would offer.	The co-lead agencies disagree the Draft EIS omits the positive or beneficial effects of breaching the four lower Snake River dams to cultural resources. Section 3.16.3.6 describes effects from MO3 to the cultural resources property types, including Traditional Cultural Properties (TCPs). In the Draft EIS, lines 7054-7060 describe the benefits of the alternative on TCPs, such as increased access to the river and the ability to experience the river in a pre-inundation condition. The co-lead agencies state on page 3-1388 in the Draft EIS, "In the long term, this would be expected to have a beneficial effect to TCPs." The co-lead agencies also respectfully disagree the Draft EIS fails to consider protection as part of mitigation strategies for impacts to cultural resources. Section 5.4.3.8 in the Draft EIS describes activities the co-lead agencies would undertake for cultural resources under MO3. These activities include: increased law enforcement patrols, reservoir bank stabilization, data recovery, protective signage, reseeding of exposed areas, and a public outreach campaign to deter looting. The measure to breach the four lower Snake River dams was not included in the Preferred Alternative identified in the Draft EIS.
31812	46	N/A	N/A	9) Environmental Justice: The DEIS downplays or dismisses the significant, disproportionate negative Environmental Justice impact that continued operation of lower Snake River dams and reservoirs imposes upon tribes and downplays the restorative justice value of a natural river. In its analysis of Environmental Justice (EJ) impacts, the DEIS claims that changes to vegetation and wildlife associated with dam breaching would be adverse, including the potential to adversely affect plants used for ceremonial and subsistence gathering activities by tribal communities although in the long term, following re-establishment of vegetation, target species are expected to return and be available be available for traditional hunting and trapping activities. Still, the DEIS considers the EJ effect related to vegetation to be minor with no disproportionately high and adverse effects on minority, low income or tribal people (p. 3-1428).	The commenter is concerned that the Environmental Justice analysis downplays the restorative impacts and value of a naturally flowing Lower Snake River. In particular the commenter is concerned that the Draft EIS finds no disproportionate impact to minority, low income, or tribal people as a result of adverse effects of the alternatives on vegetation including plants used for ceremonial and subsistence gathering activities, The commenter is correct that the Draft EIS (Section 3.18.3.2) finds that effects on minority, low-income and tribal populations related to vegetation, wildlife, wetlands and floodplains would be minor under MO3 after reestablishment of vegetation; this is due to the expected magnitude of the effects of the Alternatives relative to the No Action Alternative.
31812	47	N/A	N/A	On fish, the EJ analysis emphasizes short term adverse effects to most species but then acknowledges that long-term increases in abundance in anadromous species due to dam breach are expected to occur, particularly Snake River runs of Chinook salmon and steelhead. And that All species of salmon and steelhead are culturally important to Indian tribes and increased salmon and steelhead returns could result in a major beneficial change. It notes potential adverse impact to resident fish harvest that would adversely impact opportunities for tribes, low income and minority subsistence fishers (p. 3-1460)	The comment is consistent with the Environmental Justice analysis presented in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31812	48	N/A	N/A	The EJ section acknowledges that return of this portion of the Snake River to riverine conditions would allow practitioners of traditional lifeways the chance to return to locations that have been inaccessible for decades, a benefit most recognized in tribal communities (p. 3-1463).	The comment is consistent with the EIS, which identifies a cultural resource benefit that would be most recognized by tribal communities under MO3.
31812	49	N/A	N/A	We strongly recommend that your agencies integrate additional investment and mitigation actions, based on comprehensive analysis that utilizes existing methods, studies, data and strategies that were excluded from the DEIS, to develop a recovery plan that restores natural river conditions in the lower Snake River. A well-developed dam breaching and investment plan can recover federally endangered salmon and steelhead runs, and also initiate a transition to modernized sustainable infrastructure for power conservation and generation, transportation, irrigation and water supply, as well as diversified recreation and cultural resource preservation. The DEIS and especially the Preferred Alternative fail to recognize or comprehensively analyze impacts to wild fish populations, implementation costs, economic values, energy, irrigation, transportation, sediment, cultural, and environmental justice aspects of the alternatives, consistently diminishing or excluding benefits associated with dam breaching and a restored natural lower Snake River. Consequently, we do not believe the analysis in the DEIS meets the standard for a hard look at all reasonable alternatives as required by the National Environmental Policy Act. Improved, comprehensive analysis and mitigation planning would produce a cost-effective strategy for lower Snake River dam breaching, natural river restoration, and infrastructure modernization. Capturing the opportunity to restore the lower Snake River and the thousands of miles of salmon-bearing tributaries that flow into it represents a unique path to ecological recovery that will bolster the future of the Pacific Northwest economy, its cultural integrity, climate resilience and sustainability	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Moreover, in Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3, which includes the measure to breach the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River that could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia rivers could dredge new channels within the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions or build infrastructure to extend pumps or water supply access. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The Federal co-lead agencies would not mitigate for these impacts to water users or ports. Chapter 3 analyzes the social and economic effects of implementing MO3 and Chapter 5 discusses mitigation.
31818	1	portdave@portoflewiston.com	Port of Lewiston	See Attached Documents	While no attachments were received with this submission, the Port of Lewiston also submitted comments that are listed as letter 31766 with attachments. Please refer to comments and responses that are listed under 31766. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
31819	1	N/A	N/A	While the Action Agencies briefly discuss the Southern Resident orcas in the DEISs review of Alternatives, the DEIS vastly underestimates the impacts of the CRSO on this endangered population due to limited prey availability and fails to take a hard look at the science and impacts on Southern Resident orcas and the importance of Columbia Basin Chinook salmon to the orcas. In the DEIS, the Action Agencies provided, at best, a cursory examination of the direct, indirect, and cumulative impacts of the Preferred Alternative selected, and largely ignored indirect effects on Southern Residents and key cumulative impacts from climate change. Additionally, the DEIS fails to respond to contrary scientific publications that do not support the selection of the Action Agencies Preferred Alternative.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a negligible to minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The co-lead agencies analyzed the direct and indirect impacts of each of the alternatives on SRKW in Section 3.6, cumulative effects in Chapter 6, and climate change in Chapter 4. Based on the fish analysis in Section 7.7.4 of the Draft EIS, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. The co-lead agencies utilized current high quality information to analyze the impacts of operation, maintenance, and configuration of the CRS projects even that information that is contrary to the findings for the Preferred Alternative.
31819	2	N/A	N/A	(iv) Agencies must respond to contrary expert comments. NEPA also requires agencies to address responsible opposing viewpoints and explain their rationale for choosing one viewpoint over the other.16 Federal courts have set aside NEPA analyses where an agency failed to respond to scientific analysis that called into question the agencys assumptions or conclusions. Indeed, the DEIS is invalid because the Action Agencies have failed to respond to opposing scientific viewpoints objectively and in good faith, including those of the governments own experts like the Fish Passage Center.17	The Draft EIS uses current, high quality information and modeling in order to evaluate both the benefits and adverse effects of the range of alternatives. In doing so, the CRSO EIS teams present opposing scientific information. For example in Section 3.5 and Chapter 7, results from both anadromous fish models from the NMFS and Fish Passage Center are used to determine a potential range of results based on opposing viewpoints. Ultimately, the co-lead agencies are responsible for selecting and implementing an alternative. The rationale for doing so is presented throughout Chapter 7, which identifies a Preferred Alternative based on weighing the benefits in achieving the Purpose and Need Statement and EIS objectives while considering the potential adverse effects to the human and natural environment. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The CRSO EIS technical teams included experts from across over 30 cooperating agencies. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers from other experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of Sections 2034 and 2035 of the Water Resources Development Act of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
31819	3	N/A	N/A	B. The Endangered Species Act NEPAs implementing regulations require that, to the fullest extent possible, agencies must prepare draft environmental impact statements concurrently with and integrated with environmental impact analyses and related surveys and studies that are required by the Endangered Species Act, 16 U.S.C. 1531 et seq. (ESA).18 The ESA aims to conserve species of 10 See, e.g., Robertson v. Methow Valley Citizens Council, 490 U.S. at 350-51. 11 See NRDC v. Evans, 168 F. Supp.2d 1149 (N.D. Cal. 2001). 12 Navajo Nation v. U.S. Forest Serv., 479 F.3d 1024, 1056 (9th Cir. 2007). 13 40 C.F.R. 1508.25(c); Colo. Envtl. Coal., 185 F.3d at 1176. 14 40 C.F.R. 1508.8; see also Utahns for Better Transp., 305 F.3d at 1174. 15 40 C.F.R. 1508.7. 16 40 C.F.R. 1502.9(b). 17 W. Watersheds Project, 632 F.3d at 492-93 (agency violated NEPA by giving short shrift to a deluge of concerns from its own experts and other federal and state agencies). 18 40 C.F.R. 1502.25. fish, wildlife, and plants facing extinction as well as the ecosystems upon which endangered and threatened species depend.19 The ESA also requires each agency to use the best scientific and commercial data available.20 Under section 7 of the ESA, federal agencies must consult with the U.S. Fish and Wildlife Service or the National Marine Fisheries Service (NMFS) (collectively, the Services) on the impacts of any action that may affect listed species or their critical habitat.21 Specifically, section 7 requires federal agencies to insure that any action authorized, funded, or carried out by such agency . . . is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designed critical habitat.22 To jeopardize the continued existence of a species means to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species.23 At its essence, the ESA prohibits federal action that is likely to result in harm of listed species or critical habitat. The ESA defines critical habitat as the physical and biological features that are essential to the conservation of listed species.24 For example, in the Columbia Basin, migratory corridors are considered critical habitat defined by several primary constituent elements such as water temperature, water quantity, water quality, and safe passage.25 Along with the other alternatives analyzed in the DEIS, the Preferred Alternative certainly may affect several ESA-listed species, including salmon and orcas, as well as the critical habitat for these species, triggering the ESAs requirements. The Action Agencies operation and maintenance of the CRSO directly impacts 13 distinct salmon and steelhead evolutionarily significant units (ESUs) listed under the ESA within the Columbia-Snake watersheds. ESA-protected salmon and steelhead species that the Preferred Alternative will affect include: 1) Snake River fall Chinook salmon; 2) Snake River spring/summer Chinook salmon; 3) Snake River steelhead (Oncorhynchus mykiss); 4) Upper Columbia River spring Chinook salmon; 5) Upper Columbia River steelhead; 6) Middle Columbia River steelhead; 7) Snake River sockeye salmon (Oncorhynchus nerka); 8) Columbia River chum salmon (Oncorhynchus keta); 9)	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Chapter 8 describes how the co-lead agencies complied with the ESA, among other laws. As stated in Chapter 8, a biological assessment (Appendix V) was submitted to both NMFS and USFWS dated December 20, 2019, to support development of biological opinions. The NMFSs and USFWSs biological opinions are completed to coincide. The biological opinions will be addressed in the Record of Decision and, if adopted by the co-lead agencies, would supersede previous biological opinions. The population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be minor. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Lower Columbia River Chinook salmon; 10) Lower Columbia River coho salmon (Oncorhynchus kisutch); 11) Lower Columbia River steelhead; 12) Upper Willamette River Chinook salmon; and 13) Upper Willamette River steelhead.26 NOAA Fisheries has designated critical habitat for 12 of these 13 19 16 U.S.C. 1531(a)(4), 1531(b). 20 16 U.S.C. 1536(a)(2). 21 Id. 22 Id. 23 50 C.F.R. 402.02. 24 16 U.S.C 1532(5)(A). 25 Critical Habitat for 15 Distinct Population Segments (DPSs) of salmon and steelhead (Oncorhynchus spp.) in Washington, Oregon and Idaho, 50 C.F.R. 226.212. 26 Washington Dept of Fish and Wildlife, ESA Listed Washington Salmonids, available at: http://wdfw.wa.gov/conservation/endangered/esa/wa_esa_listed_map.pdf. salmonid species. In addition, the CRSO indirectly impacts the endangered Southern Resident orca Distinct Population Segment (DPS) that depends on the Basins salmon populations as a vital prey source.27 In consultation over the DEIS under section 7 of the ESA, NMFS must rely on the best available scientific information and data about salmon or orcas.28 Because the DEIS does not present or analyze the most comprehensive scientific information on these species, consultation will be impaired. Because the CRSO may affect ESA-listed species and their critical habitat, both directly and indirectly, the Action Agencies must consult with NMFS on the Preferred Alternative. After consultation, investigation, and analysis, NMFS must prepare a new biological opinion to evaluate the effects of the proposed actions on the survival and recovery of listed species and designed critical habitat. Under the ESA, recovery means improvement in the status of listed species to the point at which listing is no longer appropriate.29 NMFSs biological opinion should include a summary of the science-based information upon which the opinion is based, an analysis of the effects of the agency actions on listed species and critical habitat, and whether the actions are likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat30 Minor changes to the current maintenance, operation, and configuration of the CRSO will certainly continue to appreciably reduce the likelihood of both the survival and recovery of these listed species. Indeed, because current management efforts have hastened the decline of salmon populations, thus contributing to the alarmingly low number of Southern Resident orcas, the Preferred Alternative that does little more than perpetuate the status quo approach of managing the CRSO will likely cause jeopardy to both Snake River salmonids and Southern Resident orcas. If NMFS determines that the Preferred Alternative may jeopardize the survival of ESA-listed species or adversely modify a species critical habitat, the action must be modified or eliminated. Therefore, NMFSs biological opinion must specify all reasonable and prudent alternatives that avoid jeopardy and make recommendations that promote the conservation of the listed species or species critical habitat.31 27 NOAA Fisheries, Killer whale (Orcinus orca), https://www.fisheries.noaa.gov/species/killer-whale. 28 16 U.S.C. 1536(a)(2). 29 50 C.F.R. 402.02. 30 50 C.F.R. 402.14(h)(3). 31 16 U.S.C. 1536(b)(3)(A).	
31819	4	N/A	N/A	Analysis I. The DEIS does not take a hard look at the impacts and science on Southern Resident orcas. The Southern Resident orca DPS has been listed as endangered under the ESA since 2005 and under Canadas Species at Risk Act (SARA) since 2003.32 This community of orcas is genetically distinct from all other orca populations, does not interbreed and rarely interacts with other orcas, and is the only ESA-listed orca population.33 They are part of the fish-obligate Resident ecotype, and rely almost exclusively on salmon as their primary prey.34 As the only Resident population to inhabit the California Current ecosystem and frequent the outer coasts of Washington, Oregon, and Northern California, the Southern Resident orcas spend over half the year in coastal waters.35 Despite the research and conservation efforts initiated after their ESA listing, the Southern Residents have continued to decline and now number just 73 individuals, their lowest population abundance in over 40 years, and have likely lost at least one additional orca since the most recent census at the end of 2019.36 NMFS has recognized them as one of nine marine species most at risk of extinction, and considers them a recovery priority #1: a species whose extinction is almost certain in the immediate future because of a rapid population decline or habitat destruction.37 Throughout their range, the Southern Residents face significant threats to their survival, including prey depletion, high toxicant loads, anthropogenic noise, vessel impacts, and oil spill risk.38 A lack of their preferred prey, Chinook salmon, is widely recognized as the primary limiting factor to their immediate survival and future recovery, with increased mortality and decreased fecundity shown to be correlated with coastwide indices of Chinook salmon abundance.39 For their immediate survival and future recovery, the Southern Resident orcas need abundant, diverse, and accessible Chinook salmon prey throughout their range.40 32 National Marine Fisheries Service, Endangered Status for Southern Resident killer whales. 70 FR 69903; DFO (Fisheries and Oceans Canada). 2017. Species in the Spotlight: Southern Resident Killer Whale DPS. 38 National Marine Fisheries Service. 2008. Recovery Plan for Southern Resident Killer Whales (Orcinus orca). 39 Ford, J.K.B, G.M. Ellis, and P.F. Olesiuk. 2005. Linking prey and population dynamics: Did food limitation cause recent declines of 'resident' killer whales (Orcinus orca) in British Columbia. Fisheries and Oceans; Ford J.K.B et al. 2010. Linking killer whale survival and prey abundance: food limitation in the oceans apex predator? Biology Despite the wealth of information available on Southern Resident orcas and updated information available since the scoping period, the DEIS only includes three referenced sources of information on the Southern Residents, does not include the most recent population estimate of 73 orcas from the Center for Whale Research and NMFS (as of December 31, 2019), and does not include any peer-reviewed studies from independent scientists or data from NMFS regarding the orcas presence in coastal habitat or the importance of Chinook salmon to the orcas survival.41	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies utilized current high quality data and best available science in order to analyze the effects of operation, maintenance, and configuration of the CRS projects in the CRSO EIS. Recovery of ESA-listed salmon and SRKW is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their designated critical habitats. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31819	5	N/A	N/A	During the initial scoping period for this review, OSA and many other commenters provided the Action Agencies with scientific information regarding the presence of the Southern Resident orca population off the mouth of the Columbia River and their reliance on Columbia Basin Chinook. The Action Agencies failed to include any of this information in the DEIS. OSA provided extensive studies by NMFS of the Southern Residents movements in coastal waters, which highlight the mouth of the Columbia River as a high-use area;42 studies indicating the orcas preference for Chinook even when other species (e.g. sockeye and pink salmon) are present in greater abundance;43 and information on the correlation of coastwide Chinook abundance to Southern Resident mortality and fecundity rates.44	The Final EIS has been updated based on the National Marine Fisheries Service (NMFS) 2020 Biological Opinion and the information cited by the commenter. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. The revised information on Southern Resident killer whales can be found in Section 3.6 (Wildlife) in the final EIS. Additional details on the most crucial Chinook salmon prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
31819	6	N/A	N/A	Since the scoping period, additional science has been published that further substantiates the importance of Columbia Basin Chinook to Southern Resident orcas, including a comprehensive review of available data from NMFS, published with the agencys draft critical habitat revision for Southern Resident orcas (which would provide federal protection to their coastal habitat).45 Although the DEIS recognizes and mentions this proposed critical habitat revision and the Letters, 6:139142; Ward E.J, E.E. Holmes, and K.C. Balcomb. 2009. Quantifying the effects of prey abundance on killer whale reproduction. Journal of Applied Ecology, 46: 632640; National Marine Fisheries Service 2008. Journal of Applied Ecology, 46: 632-640. 45 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries Service, September 2019. Available: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killer-whale. Federal Register publication (page 3-685), none of the considerable information provided in the proposed rule and accompanying Biological Report were included in the DEIS, nor does the DEIS note that prey species of sufficient quantity, quality, and availability to support individual growth, reproduction and development, overall population growth is an established essential feature for current and proposed critical habitat.46 This recent review of research from NMFS presents a new summary of information regarding the Southern Resident orcas diet and habitat use during the non-summer months.47 As mentioned above, Southern Resident orcas frequent the outer coasts of Washington, Oregon, and Northern California, spending more than half the year in coastal waters, with highest use of this habitat occurring in the winter and early spring.48 The	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The co-lead agencies utilized current high quality information and best available science in analyzing the effects of operation, maintenance, and configuration of the CRS projects. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). Changes to this portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				data compiled by NMFS from dedicated surveys, satellite-tagging, and passive acoustic monitoring indicate that the timing of the Southern Residents presence near the mouth of the Columbia River coincides with peak spring Chinook salmon returns.49 NMFS itself has noted this area to be a high use foraging area, and approximately 50% of the time spent by the orcas in coastal waters is between Grays Harbor and the Columbia River.50	
31819	7	N/A	N/A	The DEIS misuses and misinterprets the Priority Stock Report developed by NMFS and the Washington Department of Fish and Wildlife. The DEIS also does not fully consider the caveats and assumptions built into the model, described in the Report itself.51 First, the list of stocks and prioritization reflects the observed diet of Southern Resident orcas.52 Second, the Priority Stock Report states the caveat that there was no spatial correction factor for sample collection (stocks originating from near the sample locations are more likely to be collected), and no correction factor for abundance (more abundant stocks are more likely to be identified in the 46 National Marine Fisheries Service: Proposed Rulemaking to Revise Critical Habitat for Southern Resident Killer Whale Distinct Population Segment. 84 FR 49214. 47 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. June 22, 2018. Available: https://archive.fisheries.noaa.gov/wcr/publications/protected_species/marine_mammals/killer_whales/recovery/srkw_priority_chinook_stocks_conceptual_model_report___list_22june2018.pdf; See NOAA Fisheries Chinook Salmon https://www.fisheries.noaa.gov/species/chinook-salmon-protected. 52 Ibid. diet).53 Sampling effort in Puget Sound and other inland waters of Washington State is much greater than on the outer coast due to logistical constraints for researchers.54	Without specifically identifying how the CRSO EIS misuses and misinterprets the Priority Stock Report and its modeling, the co-lead agencies cannot respond to this comment. The CRSO EIS considered the caveats and assumptions in its analysis. Pursuant to NMFS and WDFW's prioritized list of Chinook salmon within their range that are important to SRKW, the CRSO EIS considered that list in assisting to prioritize actions to increase prey availability for the whales. This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. (NOAA and WDFW 2018). Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on current high quality information and the best available science as stated in Section 3.1.1. There are gaps and assumptions in the SRKW diet that are still not understood and the co-lead agencies considered the two most important Chinook stocks of the Lower Snake River system in their assessment: the Spring and Fall Chinook. The diet of the SRKW is varied depending on available fish stocks and consists of chum as well as Fall Chinook in the Fall. SR Fall Chinook population is increasing and has been considered for delisting.
31819	8	N/A	N/A	The DEIS and Priority Stock Report also do not take into account restoration potential of these stocks. This critical step would provide better direction as to which stocks to focus restoration efforts. NOAAs own recovery plan for Southern Resident orcas states, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin.55 Finally, the Priority Stock list reflects the full range of Chinook consumed by the Southern Resident orcas throughout the year. While Puget Sound Chinook are high-priority during the summer and fall, Columbia and Snake River Chinook are high-priority during the winter and early spring. The DEIS does not consider the seasonal importance of the different stocks presented in the Priority Stock Report.56 Ignoring key findings and scientific reports, the DEIS does not fully take into account these factors when drawing conclusions on their Preferred Alternative, improperly diminishing the importance of Columbia/Snake River salmon as a prey resource for Southern Resident orcas.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. As mentioned in the comment, NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). "Restoration" or recovery of ESA-listed species is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their designated critical habitats. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31819	9	N/A	N/A	II. The DEIS fails to address the direct effects on salmon and indirect effects of CRSO to Southern Resident orcas. The Action Agencies consistently disregard both the direct effects of system operations to ESA-listed salmonids and the subsequent reduction in quantity and quality of available prey for Southern Resident orcas. By failing to include sources that clearly show the crucial relationship between Columbia Basin Chinook salmon and Southern Resident orcas in the DEIS, the Action Agencies do not adequately assess the indirect effects of prey depletion as a result of CRSO on the Southern Resident orcas.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife ,and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).

Recovery Plan for Snake River Spring/Summer Chinook Salmon and Snake River Basin Steelhead. natural river flow important for out-migrating smolts, increased water temperatures, altered sediment flow, and changed the composition of fish communities, resulting in increased predation on salmon.58 Additionally, the physical features of dams such as turbines, bypass systems, and sluiceways directly kill both adult and juvenile salmon.59 Survival of spring/summer Chinook in the Snake River is lower compared to salmon returning to tributaries lower in the river system that travel past fewer dams.60 Out-migrating smolts not directly killed by the hydropower system may succumb to delayed mortality in the estuary and ocean due to hydropower system-related impacts.61 Decreased water velocities prolong the in-river experience of out-migrating juvenile fish and decrease the survival of Snake River Chinook in multiple life stages, including smolt to adult returns.62 These impacts to salmon survival result in fewer spring Chinook returning to the Columbia Basin as adults, decreasing the available prey for Southern Resident orcas. As previously noted, the orcas continue to target Chinook salmon even when other species are more abundant, and regardless of the overall Chinook salmon abundance.63 The orcas rely on multiple stocks of Chinook, depending on availability at different times of the year and in different parts of their range.64 Prey and fecal samples indicate that Chinook still comprise the majority of the orcas diet in coastal waters, and over half of the Chinook consumed by Southern Residents in this part of their range originate in the Columbia Basin.65 Studies analyzing the health and nutritional status of these orcas indicate that these spring Chinook runs are particularly important for the Southern Residents.66 The Southern Resident orcas need to maintain a 58 Ibid. 59 Ibid. 60 Schaller, H. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. The co-lead agencies have existing mitigation commitments to address the impacts that occurred to habitat from the construction of the dams. Where adverse effects to habitat are anticipated as a result of implementing an alternative, habitat restoration was proposed. For instance, the Preferred Alternative added habitat mitigation along wetlands and riparian areas in the John Day reservoir and around Lake Roosevelt. The Preferred Alternative also carries forward certain ongoing actions including habitat measures that are described in Section 7.6.4.1 with examples listed in Table 7-5 in the Draft EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
31819	11	N/A	N/A	Early spring Chinook returning to the Snake and Columbia Rivers provide a unique nutritional value to the orcas in the late winter and early spring. These salmon are known to be large and have a high fat content, and can deliver extra nutritional benefit to endangered orcas.69 Upon their return to historic summer habitat (Salish Sea) in the early spring, elevated triiodothyronine (T3) values indicate the orcas were recently foraging on especially rich, fatty food spring Chinook returning to the Columbia Basin.70 Research assessing the changing nutritional status of the orcas indicates that the conservation of these early spring runs may be especially important to recovery efforts for the Southern Residents.71 The 2016 NMFS Status Review for the Southern Resident orcas one of the only three references included in the DEIS for orcas agrees with this point, clearly stating that these elevated T3 levels in early spring indicate that the whales are foraging on prey with high nutritional value before returning to inland summer habitat, suggesting the importance of coastal early spring run salmon.72	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a negligible to minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
31819	12	N/A	N/A	A lack of sufficient prey causes nutritional stress for Southern Resident orcas, which has been linked to negative health metrics including reductions in growth rates, adult length, and social cohesion.73 Photogrammetry analysis on the body condition of individuals, along with fecal 67 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. Quantifying the effects of prey abundance on killer whale reproduction. Journal of Applied Ecology, 46: 632640; Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National hormone analysis on nutritional and reproductive status, provides additional insight into the impacts of prey depletion: the orcas exhibit a decline in body condition between October and May, when they are more likely to be in coastal waters; in recent years, 69% of detected pregnancies have failed, a loss that has been linked to nutritional stress from variations in inland and	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.

				coastal salmon abundance, particularly from the Columbia Basin.74 It is evident that the current abundance of Columbia Basin Chinook is not sufficient to meet the nutritional needs of the Southern Resident orcas and any failure to increase salmon availability above a modest or negligible increase, i.e. under the No Action or Preferred Alternative, during the late winter and early spring season when they are most reliant on these stocks would lead to further declines and the potential extinction of the orca population.	
31819	13	N/A	N/A	By incorrectly asserting that Snake River and Columbia Chinook constitute a small portion of their overall diet and failing to include any scientific studies on the impacts of prey depletion, particularly of Columbia Basin salmon, on Southern Resident orcas, the Action Agencies vastly under-represent the indirect effects of CRSO on Southern Residents.75 The Action Agencies also contradict themselves in the DEIS: it notes that a change in operations (MO3) may result in a moderate to major increase in smolt-to-adult returns and overall abundances of adult salmon and steelhead over the long term with an increase in prey availability from the Columbia Basin, subsequently changing the short- and long-term behavior of the orcas, but also consistently asserts that the change in prey availability would have a negligible impact on the orcas.76 Not only do actions that change the orcas behavior have impacts that are far more significant than negligible, but the Action Agencies do not fully analyze these indirect effects - i.e. changes in behavior of the orcas - that they themselves note in the DEIS. III	The key to the co-lead agencies' usage of differing levels of "effects" is provided in Chapter 2 of the Draft EIS and includes "no effect", "negligible effect", "minor effect", "moderate effect", and "major effect." As indicated in this chapter, the No Action Alternative describes the baseline condition at the time the Notice of Intent to prepare the EIS was issued (September 2016). This baseline condition serves for comparison of the level of effects of the other alternatives. For MO3 the overall effect to SRKW would be minor. Changes to this portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The effects are further described in Table 3-106 under Southern Resident killer whale DPS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
31819	14	N/A	N/A	III. The DEIS fails to assess the cumulative impacts of region-wide declines in salmon abundance. Southern Residents need available, accessible, and abundant food sources throughout their range to sustain them year-round and support individual and population growth. While the Southern Residents have some seasonality in their movement throughout their range, historically using the inland waters of the Salish Sea during the summer and fall and moving into coastal waters in the winter and spring, their habitat use is dynamic, with foraging, breeding, calving, traveling, and resting occurring throughout their range.77 Marine Fisheries Service, September 2019. Available: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killer-whale. 74 Fearnbach, H. et al. 2018. Population growth is limited by nutritional impacts on pregnancy success in endangered Southern Resident killer whales (Orcinus orca). PLoS ONE 12(6): e0179824, https://doi.org/10.1371/journal.pone.0179824 75 Columbia River System Operations Draft Environmental Impact Statement at 7-151. 76 Columbia River System Operations Draft Environmental Impact Statement at 3-758 and 3-759. 77 National Marine Fisheries Service. 2008. Recovery Plan for Southern Resident Killer Whales (Orcinus orca). National Marine Fisheries Service, Northwest Region, Seattle, Washington; Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries As previously noted, the orcas movement is tied to seasonal returns of salmon runs to rivers in the Pacific Northwest and California, and they depend on different runs of salmon in different seasons.78 The Action Agencies incorrectly assume that Columbia Basin Chinook salmon is a minor part of Southern Resident orcas diet because they are comparing it to year-round diet information. The Action Agencies must consider that salmon from all rivers within the orcas range are not available to the orcas on a year-round basis, but instead are critical to the orcas survival in specific seasons.79 The spatiotemporal distribution of Chinook runs within the orcas range means that different runs are more available, and therefore more important, to the Southern Residents at different times of the year.80 Columbia Basin Chinook are important not only for immediate survival in the late winter and early spring, but for supporting pregnancies and population growth, and sustaining the orcas as they shift into summer foraging grounds.81 The Action Agencies fail to consider the seasonal role of Columbia Basin Chinook in providing the Southern Residents with a key source of food and nutrition during the late winter and early spring.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The cumulative effects analysis associated with SRKW has been added to the cumulative effects section (Chapter 6 for the MOs and Chapter 7) for the Preferred Alternative. A portion of the Chinook population throughout their foraging range, as well as other fish (halibut, lingcod, and big skate), contribute to the overall diet of the SRKW.
31819	15	N/A	N/A	The Action Agencies also fail to assess the cumulative effects of region-wide reductions in salmon abundance on the Southern Resident orcas, and the further reductions in prey availability from the expected impacts of climate change. Pacific salmon have been extirpated from at least 40% of their historic habitat, and populations return at less than 3% of their historic numbers each year.82 This decline and failure to recover salmon directly impacts Southern Resident orcas: according to NMFS, existing management and recovery actions for Service, September 2019. Available: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killer-whale. 78 Ibid; NMFS. 2014. Portland State University, Portland, Oregon; Levin, P. and M. Schiewe. 2001. Preserving salmon biodiversity. Am. Sci. 89, 220-227. salmon has not been sufficient to increase availability to support Southern Resident population growth.83 The development and alteration of watersheds, estuaries, and nearshore environments is one of the primary causes of salmon decline, and increasing ocean warming and acidification compound stressors on salmon and can impede their survival.84 Climate change impacts are expected to cause an additional 22% loss of current salmon habitat.85 Increasing ocean warming and acidification compound stressors on salmon and can limit their survival. The Cascade Mountains have had a 25% decrease in snowpack since 1950 due to increasing global temperatures, and summer streamflow has decreased up to 15%.86 Lower streamflow in the summer can increase water temperatures to levels deadly for salmon, decrease suitable habitat, and impede migration.87 For example, drought conditions in 2015 were amplified by changes to river flows caused by dams, resulting in a massive die-off of sockeye salmon in the Columbia River, and the marine heat wave of 2015/2016 increased water temperatures in inland Washington, causing the loss of an estimated 1.5 million juvenile fish in overheated streams and rivers.88	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory project purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The cumulative effects analysis methods are described in Chapter 6 and follow CEQ guidance, which includes establishing the geographic and temporal boundaries of the analysis, identifying applicable cumulative actions, identifying affected resources and direct/indirect impacts, and analyzing the cumulative impacts. Cumulative effects of the Preferred Alternative are presented in Section 7.9. The EIS analysis considers the cumulative effects of reasonably foreseeable future actions. Climate change, for example, is described in Chapters 4 and 7.8, but can also be considered an effect of past, present, and future actions that may have a cumulative effect on certain resources in the analysis area. Based on the cumulative effects analysis, the co-lead Agencies determined that implementing the Preferred Alternative would result in a negligible effect to SRKW. See Section 7.7.8. The EIS acknowledges, however, that climate change could exacerbate the effects from the Preferred Alternative on wildlife, such as SRKW. See Section 7.9.9. However, the effect would likely remain negligible.
31819	16	N/A	N/A	8 Despite these projected climate change impacts on salmon, the DEIS does not provide any information about efforts to mitigate lethal water temperatures on salmon, and the models used to predict climate impacts on water temperatures and salmon do not accurately assess how water temperatures will differ under the Preferred Alternative. In addition, the DEIS does not consider that current and continued declines of Chinook salmon stocks in the Columbia Basin and throughout the range of the Southern Resident orcas increases year-round nutritional stress on the orcas and impedes	Regarding climate change, the climate science community is still developing models at the resolution necessary to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature to the Multiple Objective alternatives (Section 4.2.3) and the Preferred Alternative (Section 7.8.4).

Available: https://www.governor.wa.gov/sites/default/files/OrcaTaskForce_FinalReportandRecommendations_11.07.19.pdf. similar analyses on the impacts of hydrosystem operations on prey availability for Southern Resident orcas, NMFS concluded that the loss of a single individual, or the decrease in reproductive capacity of a single individual, is likely to reduce the likelihood of survival and recovery of the species.89 The current low abundance of Columbia Basin Chinook, and the minor increase projected for the Preferred Alternative, directly reduces the likelihood of survival and recovery for Southern Resident orcas.	The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Life cycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS. Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
31819	17	N/A	N/A	Many Chinook salmon runs identified as priority stocks for Southern Resident orcas are also listed as endangered under the ESA;90 spring-run salmon appear to be disproportionately impacted by human use and development of river systems because of the extended time juveniles and adults spend in river systems.91 Assessing changes in prey availability for Southern Resident orcas on a river-by-river basis disregards the effects of declining salmon abundance throughout their range and the subsequent year-round nutritional stress, which further limits their immediate survival and future recovery. NMFS has identified [p]rey species of sufficient quantity, quality, and availability as an essential habitat feature in both current and proposed critical habitat areas including Salish Sea and coastal habitat and noted that the availability of key prey stocks is essential for the orcas survival.92 The DEIS does not consider that restoring Columbia and Snake River spring Chinook runs could greatly increase a critical seasonal food source for Southern Resident orcas and therefore increase their chances of survival and recovery.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
31819	18	N/A	N/A	IV. The Preferred Alternative is environmentally inadequate and offers only a minor change to status quo conditions for Chinook salmon and Southern Resident orcas. The Preferred Alternative offers only a minor change to status quo conditions, which have been inadequate for salmon and orca recovery. According to a review by the Fish Passage Center, the Preferred Alternative does not meet the regional recovery goal for Chinook salmon, and has only slightly better fish survival metrics compared to the No Action Alternative.93 The DEIS 89 NMFS. 2009. Biological Opinion and Conference Opinion on the Long-Term Operations of the Central Valley Project and State Water Project, at 573. 90 NOAA Fisheries West Coast Region and WDFW Southern Resident Killer Whale Priority Chinook Stocks Report. Comparative Survival Study of PIT-tagged Spring/Summer/Fall Chinook, Summer Steelhead, and Sockeye. 2019 Annual Report, Chapter 2. Available: https://www.fpc.org/documents/CSS/CRSO/CRSO-84.pdf. neglected to even mention this report, let alone respond to its conclusions, which were contrary to those of the DEIS.94 The DEIS itself, as well as additional independent studies and reviews have concluded that the most effective and quickest action to recover ESA-listed salmon populations in the Columbia Basin and increase prey availability for Southern Resident orcas is to restore unobstructed passage through this area.95 Restoring salmon productivity to the Snake River Basin in particular is vital due to the recovery potential for spring/summer Chinook salmon in the remaining high-quality habitat.96	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies conclude there could be a minor beneficial effect to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. But, the overall impact of MO3, including the fact that the operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. There are many factors that effect salmonid populations that are outside the authority of the co-lead agencies. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Section 7(a)(2) does not require the co-lead agencies to recover ESA-listed species. However, the co-lead agencies included objectives in the EIS to benefit ESA-listed species. The Preferred Alternative meets the requirements of Section 7(a)(2) and meets the objectives of the CRSO EIS.
31819	19	N/A	N/A	While the DEIS wrongly asserts that any change in prey availability resulting from the Preferred Alternative would have a negligible impact on Southern Resident orcas, it also notes that Alternative MO3 would lead to an increase in prey base available to marine mammals foraging in the Columbia River or offshore from the mouth of the Columbia River, such as the killer whale and that changes in prey availability could impact the behavior of the population in both the short and long term.97 If Columbia Basin Chinook continue to decline, the orcas may be forced to spend more time and energy searching for other sources of food. In either case - searching for other food sources or responding to improved prey availability near the mouth of the Columbia actions that change the orcas behavior have impacts that are far more significant than negligible. With the continued coastwide decline of Chinook salmon and the historically low numbers returning to the Columbia Basin in recent years, status quo conditions or the very minor changes of the Preferred Alternative will continue to negatively impact Southern Resident orcas by reducing a vital seasonal source of available prey.98 94 See W. Watersheds Project, 632 F.3d at 492-93. 95 Columbia River System Operations Draft Environmental Impact Statement Executive Summary, page 24; see also: Budy, P. et al. 2002. Using population projection matrices to evaluate recovery strategies for Snake River spring and summer Chinook salmon. Conservation Biology 17:782-794. 96 Ibid. and Bonar, Scott (American Fisheries Society Western Division). Letter to Dr. Jane Lubchenco (NOAA). May 4, 2009. Available at: https://s3-us-west-2.amazonaws.com/fisheries/website+pdfs/AFS+POLICY+LETTER+-	The CRSO EIS analyzes the effects of each alternative approach to operation, maintenance, and configuration of the CRS projects in comparison to the No Action Alternative. Under the No Action Alternative, or baseline condition, SRKW are opportunists and follow the Chinook runs along the Pacific Northwest coast. As defined in Chapter 2, the effect of an alternative is "negligible" when the effect as compared to the No Action Alternative is not able to be detected. The Preferred Alternative would result in negligible (undetectable) effects to SRKW because changes to the SRKW's behavior would be undetectable compared to the No Action Alternative. SRKW's range is large making effects of operations of the CRS lesser in comparison to other species, such as sea lions. Effects to sea lions are greater because sea lions have a behavioral predatory advantage by concentrating their fishing efforts at the dams. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

				+Lubchenco+Letter+on+Hydro+Projects+and+Dams+(pdf).pdf. 97 Columbia River System Operations Draft Environmental Impact Statement at 3-758 and 3-759. 98 See: Fish Passage Center. Adult Chinook Returns to Bonneville Dam: https://www.fpc.org/webapps/adultsalmon/R_dailyadultcountsgraph_resultsV6.php; See: Washington Department of Fish and Wildlife 2020 Salmon Forecast. Presented February 28, 2020: https://wdfw.wa.gov/sites/default/files/2020-02/2020_north_of_falcon_forecast_presentation_22820_reduced_file_size.pdf. The DEIS did not consider the high recovery potential of Columbia Basin Chinook and the potential for selecting any other alternatives that maximize salmon survival for a significant positive impact on prey availability for Southern Resident orcas.99 Instead, the Preferred Alternative fails to fully achieve the Action Agencies environmental objectives to improve juvenile and adult salmon survival, and fails to fulfil the Purpose and Need Statement to ensure conservation of fish and wildlife resources, including threatened, endangered, sensitive species such as Southern Resident orcas.	
31819	20	N/A	N/A	V. The Action Agencies must consult with NMFS under section 7 of the ESA to ensure that their actions and the conclusions of the DEIS do not jeopardize listed species or adversely modify critical habitat. The Action Agencies have an independent duty under the ESA to ensure that their selection of the Preferred Alternative does not jeopardize listed species or adversely modify critical habitat.100 To accomplish this, the Action Agencies must consult with NMFS, and the agencies conclusions must be based on the best scientific information available.101 As explained above, to the extent the Action Agencies intend to rely on the limited information and incomplete science presented in the DEIS, the information is inadequate to meet the ESAs high standard. OSA expects the Action Agencies to revisit these inadequacies before releasing the final EIS for the Columbia River System Operations, which will inform consultation with NMFS under section 7 of the ESA.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The co-lead agencies understand their responsibilities under the ESA and documented this compliance in Chapter 8.
31819	21	N/A	N/A	Conclusion The EIS and the Action Agencies Preferred Alternative must support salmon and Southern Resident orca recovery and present a comprehensive, ecosystem-based recovery strategy to improve river flow, temperature, and habitat conditions through all system operations. By failing to take a hard look at the best available scientific information about Southern Resident orcas, which clearly shows the connection between orcas and Columbia Basin salmon, the direct impacts of CRSO on salmon, the reduction in available seasonal prey and other indirect impacts on Southern Resident orcas, and the cumulative impacts of climate change and insufficient prey throughout the orcas range, the DEIS is incomplete and legally insufficient. Thus, OSA expects the Action Agencies to revise this analysis to take a hard look at these impacts, present the best available science, and address contrary scientific information that supports the selection of an alternative that will recover Southern Resident orca and Columbia Basin salmon populations.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their designated critical habitats. Based on the fish analysis in Section 7.7.4, the co-lead agencies utilized current high quality information and best available science to reach the conclusion that the Preferred Alternative is expected to provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31821	1	colleen.weiler@whales.org	Whale and Dolphin Conservation	I. The DEIS fails to satisfy National Environmental Policy Act requirements. The National Environmental Policy Act (NEPA) requires that to the fullest extent possible all federal agencies must complete a comprehensive environmental impact statement in connection with actions that significantly affect the environment. 2 In enacting NEPA, Congress recognized the profound impact of human activities, including resource exploitation, on the environment and declared a national policy to create and maintain conditions under which man and nature can exist in productive harmony. 3 NEPA has two fundamental goals: (1) to ensure that the agency will have detailed information on significant environmental impacts when it makes decisions; and (2) to guarantee that this information will be available to a larger audience. 4 To advance its clear policy objectives, NEPA establishes action-forcing procedures that require agencies to take a hard look at environmental consequences. 5 A hard look requires a 1 Nat'l Wildlife Fedn v. Nat'l Marine Fisheries Serv., 184 F. Supp. 3d 861, 876 (D. Or. 2016). 2 42 U.S.C 4332. 3 42 U.S.C. 4331(a). 4 Envtl. Prot. Info. Ctr. v. Blackwell, 389 F. Supp. 2d 1174, 1184 (N.D. A world where every whale and dolphin is safe and free meaningful comparison of the environmental consequences of all alternatives, including the proposed alternative. 6 A hard look does not allow the agency to take a soft touch or brush-off of negative effects. 7 To have taken the required hard look, the Action Agencies must utilize public comment and the best available scientific information. 8 By focusing agency attention in this way, NEPA ensures that the agency will not act on incomplete information. 9 In analyzing the Preferred Alternative, the No Action Alternative, and all other reasonable alternatives, the Action Agencies failed to take a hard look at the environmental consequences and properly consider the three types of impacts: direct, indirect, and cumulative. 10 Direct effects are caused by the action and occur at the same time and place, such as those to salmon; while indirect effects are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable, 11 such as reduction in prey availability for Southern Resident orcas. Cumulative impacts include impacts on the environment resulting from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, by any person or agency, and impacts resulting from individually minor but collectively significant actions taking place over a period of time. 12	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), as well as meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is most likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The agencies evaluated the direct, indirect and cumulative effects to resources affected by CRS operations, maintenance and configuration in Chapters 3, 4, 6, and 7. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKWs), along with vessel traffic and noise, and toxic contaminants. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
31821	2	colleen.weiler@whales.org	Whale and Dolphin Conservation	NEPA also requires agencies to address responsible opposing viewpoints and explain their rationale for choosing one viewpoint over the other.13 Federal courts have set aside NEPA analyses where an agency failed to respond to scientific analysis that called into question the agencys assumptions or conclusions. Indeed, the DEIS is invalid because the Action Agencies have failed to respond to opposing scientific viewpoints objectively and in good faith, including those of the governments own experts like the Fish Passage Center.14	The Draft EIS uses current, high quality information and modeling in order to evaluate both the benefits and adverse effects of the range of alternatives. In doing so, the CRSO EIS teams present opposing scientific information. For example in Section 3.5 and Chapter 7, results from both anadromous fish models from the NMFS and Fish Passage Center are used to determine a potential range of results based on opposing viewpoints. Ultimately, the co-lead agencies are responsible for selecting and implementing an alternative. The rationale for doing so is presented throughout Chapter 7, which identifies a Preferred Alternative based on weighing the benefits in achieving the Purpose and Need Statement and EIS objectives while considering the potential adverse effects to the human and natural environment. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The CRSO EIS technical teams included experts from across over 30 cooperating agencies. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers from other experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of Sections 2034 and 2035 of the Water Resources Development Act of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available..
31821	3	colleen.weiler@whales.org	Whale and Dolphin Conservation	While the Action Agencies briefly discuss the Southern Resident orcas in the DEISs review of Alternatives, the analysis does not include the best available scientific information, not does it meaningfully compare the environmental consequences of the Alternatives. Thus, the DEIS fails to take a hard look at the science and impacts on Southern Resident orcas and the importance of Columbia Basin Chinook salmon to the orcas, and therefore vastly underestimates the impacts of the CROS on this endangered orca population. In the DEIS, the Action Agencies provided, at best, a cursory examination of the direct, indirect, and cumulative impacts of the Preferred Alternative selected, and largely ignored indirect effects on Southern Residents and key cumulative impacts from climate change. Additionally, the DEIS fails to respond to contrary scientific publications that do not support the selection of the Action Agencies Preferred Alternative. WDC cannot support the DEIS or the Preferred Alternative selected by the Action Agencies, as it is not the environmentally-preferable alternative and is not supported by the best scientific information and data available.	The co-lead agencies relied on high quality, current information in the development of the CRS. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKWs), along with vessel traffic and noise, and toxic contaminants. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. The FEIS includes additional information on SRKWs in Section 3.6 and 7.7.8.

31821	4	colleen.weiler@whales.org	Whale and Dolphin Conservation	II. The DEIS does not take a hard look at the impacts and available science on Southern Resident orcas. The Southern Resident orca DPS has been listed as endangered under the ESA since 2005 and under Canadas Species at Risk Act (SARA) since 2003.15 This community of orcas is genetically distinct from all other orca populations, does not interbreed and rarely interacts with other orcas, and is the only ESA-listed orca population.16 They are part of the fish-obligate Resident ecotype, and rely almost exclusively on salmon as their primary prey.17 As the only Resident population to inhabit the California Current ecosystem and frequent the outer coasts of Washington, Oregon, and Northern California, the Southern Resident orcas spend over half the year in coastal 6 Ctr. for Biological Diversity v. WDC, 7 Nelson Street, Plymouth, MA, 02360 T +(508) 746-2522 F +(508)746-2537 E contact@whales.org W whales.org WDC is a registered 501(c)3 non-profit organization. A world where every whale and dolphin is safe and free waters.18 Despite the research and conservation efforts initiated after their ESA listing, the Southern Residents have continued to decline and now number just 73 individuals, their lowest population abundance in over 40 years, and have likely lost at least one additional orca since the most recent census at the end of 2019.19 The National Marine Fisheries Service has recognized them as one of nine marine species most at risk of extinction, and considers them a recovery priority #1: a species whose extinction is almost certain in the immediate future because of a rapid population decline or habitat destruction.20 Throughout their range, the Southern Residents face significant threats to their survival, including prey depletion, high toxicant loads, anthropogenic noise, vessel impacts, and oil spill risk.21 A lack of their preferred prey, Chinook salmon, is widely recognized as the primary limiting factor to their immediate survival and future recovery, with increased mortality and decreased fecundity shown to be correlated with coastwide indices of Chinook salmon abundance.22 For their immediate survival and future recovery, the Southern Resident orcas need abundant, diverse, and accessible Chinook salmon prey throughout their range.23	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies utilized current high quality data and best available science in order to analyze the effects of operation, maintenance, and configuration of the CRS projects in the CRSO EIS. Recovery of ESA-listed salmon and SRKW is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their designated critical habitats. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31821	5	colleen.weiler@whales.org	Whale and Dolphin Conservation	Despite the wealth of information available on Southern Resident orcas and updated information available since the scoping period, the DEIS only includes three referenced sources of information on the Southern Residents, does not include the most recent population estimate of 73 orcas from the Center for Whale Research and NMFS (as of December 31, 2019), and does not include any peer-reviewed studies from independent scientists or data from NMFS regarding the orcas presence in coastal habitat, the importance of Chinook salmon to the orcas survival, or the seasonal significance of Columbia Basin Chinook.24 WDC, along with multiple other concerned organizations and individuals, submitted substantial scientific information regarding the presence of the Southern Resident orca population off the mouth of the Columbia River and their reliance on Columbia Basin Chinook during the initial scoping period for the DEIS. However, the Action Agencies failed to include any of this information: NMFS research on the presence of the Southern Residents in coastal waters, which highlights the mouth of the Columbia River as a high-use area;25 studies indicating the orcas preference for Chinook even when other species (e.g. sockeye and pink salmon) are present in greater abundance;26 and information on the correlation of coastwide Chinook abundance to Southern Resident mortality and fecundity rates.27	The Final EIS has been updated based on the National Marine Fisheries Service (NMFS) 2020 Biological Opinion and the information cited by the commenter. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. The revised information on Southern Resident killer whales can be found in Section 3.6 (Wildlife) in the final EIS. Additional details on the most crucial Chinook salmon prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
31821	6	colleen.weiler@whales.org	Whale and Dolphin Conservation	Since the scoping period, additional science has been published that further substantiates the importance of Columbia Basin Chinook to Southern Resident orcas, including a comprehensive review of available data from NMFS published 18 Krahn, M.M. et al. 2004. 2004 status review of southern resident killer whales (Orcinus orca) under the Endangered Species Act. WDC, 7 Nelson Street, Plymouth, MA, 02360 T +(508) 746-2522 F +(508)746-2537 E contact@whales.org W whales.org WDC is a registered 501(c)3 non-profit organization. A world where every whale and dolphin is safe and free with the agencys draft critical habitat revision for Southern Resident orcas (which would provide federal protection to their coastal habitat).28 Although the DEIS refers to the proposed critical habitat revision and the Federal Register publication (page 3-685), none of the considerable information provided in the proposed rule and accompanying Biological Report were included in the DEIS, nor does the DEIS acknowledge that prey species of sufficient quantity, quality, and availability to support individual growth, reproduction and development, overall population growth is an established essential feature for current and proposed critical habitat.29 By failing to include this information, the DEIS underrepresents the importance of Chinook salmon to Southern Resident orcas throughout their range, including the coastal waters off the mouth of the Columbia. This recent collection of research from NMFS summarizes information available regarding the Southern Resident orcas diet and habitat use during the non-summer months (although we also note the information has been with NMFS well before the scoping period and available in publications and presentations from the Agency).30 As noted, Southern Resident orcas frequent the outer coasts of Washington, Oregon, and Northern California, spending more than half the year in coastal waters, with highest use of this habitat occurring in the winter and early spring.31 The data compiled by NMFS from dedicated surveys, satellite-tagging, and passive acoustic monitoring indicate that the timing of the Southern Residents presence near the mouth of the Columbia River coincides with peak spring Chinook salmon returns.32 NMFS itself has noted this area to be a high use foraging area, and approximately 50% of the time spent by the orcas in coastal waters is between Grays Harbor and the Columbia River.33	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The co-lead agencies utilized current high quality information and best available science in analyzing the effects of operation, maintenance, and configuration of the CRS projects. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). Changes to this portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
31821	7	colleen.weiler@whales.org	Whale and Dolphin Conservation	While the DEIS does include one recent publication regarding Southern Resident orcas the Priority Chinook Stock Report developed by NMFS and the Washington Department of Fish and Wildlife the DEIS does not account for the assumptions and caveats noted in the report itself. 34 The Priority Stock list reflects the full extent of different salmon stocks available to Southern Resident orcas throughout the year. While stocks available during seasons the orcas are food-limited (October-May) are weighted higher and correlation factors are applied for the degree of spatiotemporal overlap, the Priority List does not otherwise differentiate the seasonal availability of different stocks not all stocks are available at all times. We do not dispute the DEIS statement that Puget Sound Chinook stocks are one of the most important salmon stocks for the orcas, but the DEIS must also note that these stocks are not available year-round.35 Other sources of food are critical in different seasons, including Chinook salmon returning to the Columbia Basin in the late winter and early spring. Orcas need to maintain a balance of energy year-round to support daily activities, as well as gestation, lactation, and growth. 36 They need food on a regular basis, and rely on seasonally available prey to 28 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries Service, September 2019. Available:	Without specifically identifying how the CRSO EIS misuses and misinterprets the Priority Stock Report and its modeling, the co-lead agencies cannot respond to this comment. The CRSO EIS considered the caveats and assumptions in its analysis. Pursuant to NMFS and WDFW's prioritized list of Chinook salmon within their range that are important to SRKW, the CRSO EIS considered that list in assisting to prioritize actions to increase prey availability for the whales. This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. (NOAA and WDFW 2018). Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on current high quality information and the best available science as stated in Section 3.1.1. There are gaps and assumptions in the SRKW diet that are still not understood and the co-lead agencies considered the two most important

A world where every whale and dolphin is safe and free fulfill that need. 37 The DEIS wrongly assumes that only the top-rated salmon stock in the Priority List significantly impact Southern Resident survival and recovery, thus underrepresenting the effects of the CRSO on a critical, seasonal source of food.	Chinook stocks of the Lower Snake River system in their assessment: the Spring and Fall Chinook. The diet of the SRKW is varied depending on available fish stocks and consists of chum as well as Fall Chinook in the Fall. SR Fall Chinook population is increasing and has been considered for delisting. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Also, see response to Comment 6110-16.
31821	8	colleen.weiler@whales.org	Whale and Dolphin Conservation	The Priority Stock Report and the DEIS also do not consider the restoration potential of Columbia Basin Chinook. This critical step would provide a better understanding of how changes in abundance could impact seasonal prey availability for the orcas, particularly during seasons they are currently food-limited. NOAAs own recovery plan for Southern Resident orcas states, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin.38 In the same plan, NMFS went on to note that the Columbia-Snake River Basin had the largest potential for increasing Chinook salmon abundance throughout the Southern Residents range.39 If the decline of Columbia Basin Chinook has caused the greatest change in food availability, an increase in abundance would have a similar, beneficial, effect. Ignoring key findings and scientific reports, the DEIS does not fully take into account these factors when drawing conclusions to support their Preferred Alternative, improperly diminishing the importance of Columbia and Snake River salmon as a prey resource for Southern Resident orcas.	The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Also, see response to Comment 6110-16.
31821	9	colleen.weiler@whales.org	Whale and Dolphin Conservation	III. The DEIS fails to address the direct effects on salmon and the indirect effects on Southern Resident orcas of the CRSO. The Action Agencies consistently disregard both the direct effects of system operations to ESA-listed salmonids and the subsequent reduction in quantity and quality of available prey for Southern Resident orcas. By failing to include sources that clearly show the crucial relationship between Columbia Basin Chinook salmon and Southern Resident orcas in the DEIS, the Action Agencies do not adequately assess the indirect effects of prey depletion as a result of the CRSO on the Southern Resident orcas.	The co-lead agencies utilized current high quality information and best available science in its analysis of the effects (direct, indirect, and cumulative) of the operation, maintenance, and configuration of the CRS projects.The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. 31821	10	colleen.weiler@whales.org	Whale and Dolphin Conservation	The CRSO has substantially impacted the natural ecology and function of the Columbia River Basin, one of the largest watersheds in North America. 40 Hydropower development and ongoing operations have significantly altered and destroyed salmon habitat and watershed health, resulting in widespread impacts to salmon populations.41 Dams have greatly reduced or eliminated historically accessible habitat, reduced natural river flows vital for out-migrating smolts, increased water temperatures, altered sediment flow, and changed the composition of fish communities, resulting in increased predation on salmon.42 In addition, the physical features of dams such as turbines, bypass systems, and sluiceways have direct and indirect impacts to both adult and juvenile salmon.43 Survival of spring/summer Chinook in the Snake River is lower compared to salmon returning to tributaries lower in the river system that travel past fewer dams.44 Out-migrating smolts not directly killed by the hydropower system may succumb to delayed mortality in the estuary and ocean due to hydropower system-related impacts.45 Decreased water velocities prolong the in-river 37 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. A world where every whale and dolphin is safe and free experience of out-migrating juvenile fish and decrease the survival of Snake River Chinook in multiple life stages including smolt to adult returns.46 Despite decades of protection and management, most ESA-listed salmon stocks in the Columbia Basin remain in poor condition and at high risk of extinction. 47 NMFS has recognized that dam presence and operations in the Columbia Basin directly and indirectly contribute to the majority of mortalities of juvenile and adult salmonids migrating through the system.48 These impacts to salmon survival result in	The co-lead agencies utilized current high quality information and best available science to analyze the effects of operation, maintenance, and configuration of the CRS projects in the CRSO EIS, including for its Southern Resident Killer Whale (SRKW) analysis. The overall health and condition of the SRKW depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. There are many effects to salmon and steelhead populations outside the operation and maintenance of the dams (see Chapters 6 and 7 for more information). Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.

				fewer spring Chinook returning to the Columbia Basin as adults, decreasing the available prey for Southern Resident orcas. A lack of sufficient prey causes nutritional stress for Southern Resident orcas, which has been linked to negative health metrics including reductions in growth rates, adult length, and social cohesion.49 Photogrammetry analysis on the body condition of individuals, along with fecal hormone analysis on nutritional and reproductive status, provides additional insight into the impacts of prey depletion: the orcas exhibit a decline in body condition between October and May, when they are more likely to be in coastal waters; in recent years, 69% of detected pregnancies have failed, a loss that has been linked to nutritional stress from variations in inland and coastal salmon abundance, particularly from the Columbia Basin.50 Up to a third (33%) failed relatively late in gestation or immediately postpartum, when the energetic cost to the mother orca is especially high, putting her at increased risk.51 It is evident that the current abundance of Columbia Basin Chinook is not sufficient to meet the nutritional needs of the Southern Resident orcas and any failure to increase salmon availability above a modest or negligible increase, i.e. under the No Action or Preferred Alternative, during the late winter and early spring season when they are most reliant on these stocks would lead to further declines and the potential extinction of the orca population. As previously noted, the orcas continue to target Chinook salmon even when other species are more abundant and regardless of the overall Chinook salmon abundance.52 The orcas rely on multiple stocks of Chinook, depending on availability at different times of the year and in different parts of their range.53 Prey and fecal samples indicate that Chinook salmon still comprises the majority of the orcas diet in coastal waters, and over half of the Chinook 46 Schaller, H. A world where every whale and dolphin is safe and free consumed by Southern Residents in this part of their range originate in the Columbia Basin.54 Studies analyzing the health and nutritional status of these orcas indicate that these spring Chinook runs are particularly important for the Southern Residents.55 The Southern Resident orcas need to maintain a balance of energy year-round to support daily activities, as well as gestation, lactation, and growth.56 The size of individual salmon and their caloric content vary by species, geographic area, season, and year, and therefore have different value to Southern Resident orcas.57 Early spring Chinook returning to the Snake and Columbia Rivers provide a unique nutritional value to the orcas in the late winter and early spring. These salmon are known to be large and have a high fat content, and can deliver extra nutritional benefit to endangered orcas.58 Upon their return to historic summer habitat (Salish Sea) in the early spring, elevated triiodothyronine (T3) values indicate the orcas were recently foraging on especially rich, fatty food spring Chinook returning to the Columbia Basin.59 Research assessing the changing nutritional status of the orcas indicates that the conservation of these early spring runs may be especially important to recovery efforts for the Southern Residents.60 The 2016 NMFS Status Review for the Southern Resident orcas one of the only three references included in the DEIS for orcas supports this point, clearly stating that the elevated T3 levels detected in the orcas in early spring indicate that the whales are foraging on prey with high nutritional value before returning to inland summer habitat, suggesting the importance of coastal early spring run salmon.61 By incorrectly asserting that Snake River and Columbia Chinook constitute a small portion of their overall diet and failing to include any scientific studies on the impacts of prey depletion, particularly of Columbia Basin salmon, on Southern Resident orcas, the Action Agencies vastly under-represent the indirect effects of CRSO on Southern Residents.62 The Action Agencies also contradict themselves in the DEIS: it notes that a change in operations (MO3 breaching the Snake River dams) may result in a moderate to major increase in smolt-to-adult returns and overall abundances of adult salmon and steelhead over the long term with an increase in prey availability from the Columbia Basin, subsequently changing the short- and long-term behavior of the orcas, but also consistently asserts that the change in prey availability would have a negligible impact on the orcas.63 Not only do actions that change the orcas behavior have impacts that are far more significant than negligible, but the Action Agencies do not fully analyze these indirect effects changes in behavior of the orcas that they themselves note in the DEIS.	
31821	11	colleen.weiler@whales.org	Whale and Dolphin Conservation	IV. The DEIS fails to assess the cumulative impacts of region-wide declines in salmon abundance. Southern Residents need available, accessible, and abundant food sources throughout their range to sustain them year-round and support individual and population growth. While the Southern Residents have some seasonality in their movement throughout their range, historically using the inland waters of the Salish Sea during the summer and fall and moving into coastal waters in the winter and spring, their habitat use is dynamic, with foraging, breeding, calving, traveling, and resting occurring throughout their range.64 54 Ward, E. et al, NWFSC Science to Inform SRKW Distribution and Diet, Presentation to Pacific Fisheries Management Council SRKW Working Group, May 2019: available at https://www.fisheries.noaa.gov/webdam/download/92840008. 55 Ayres KL, et al., 2012. National Marine Fisheries Service, Northwest Region, Seattle, Washington; Proposed Revision of the Critical Habitat WDC, 7 Nelson Street, Plymouth, MA, 02360 T +(508) 746-2522 F +(508)746-2537 E contact@whales.org W whales.org WDC is a registered 501(c)3 non-profit organization. A world where every whale and dolphin is safe and free As previously noted, the orcas movement is tied to seasonal returns of salmon runs to rivers in the Pacific Northwest and California, and they depend on different runs of salmon in different seasons.65 The Action Agencies incorrectly assume that Columbia Basin Chinook salmon is a minor part of Southern Resident orcas diet because they are comparing it to year-round diet information. The Action Agencies must consider that salmon from all rivers within	The cumulative effects associated with SRKW has been added to the cumulative effects section. A portion of the Chinook population throughout their foraging range, as well as other fish (halibut, lingcod, and big skate), contribute to the overall diet of the SRKW. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the orcas range are not available to the orcas on a year-round basis, but instead are critical to the orcas survival in specific seasons.66 The spatiotemporal distribution of Chinook runs within the orcas range means that different runs are more available, and therefore more important, to the Southern Residents at different times of the year.67 Columbia Basin Chinook are important not only for immediate survival in the late winter and early spring, but for supporting pregnancies and population growth, and sustaining the orcas as they shift into summer foraging grounds.68 The Action Agencies fail to consider the seasonal role of Columbia Basin Chinook in providing the Southern Residents with a key source of food and nutrition during the late winter and early spring.	
31821	12	colleen.weiler@whales.org	Whale and Dolphin Conservation	The Action Agencies also fail to assess the cumulative effects of region-wide reductions in salmon abundance on the Southern Resident orcas, and the further reductions in prey availability from the expected impacts of climate change. Pacific salmon have been extirpated from at least 40% of their historic habitat, and populations return at less than 3% of their historic numbers each year.69 Many Chinook salmon runs identified as priority stocks for Southern Resident orcas are also listed as endangered under the ESA;70 spring-run salmon appear to be disproportionately impacted by human use and development of river systems because of the extended time juveniles and adults spend in river systems.71 Assessing changes in prey availability for Southern Resident orcas on a river-by-river basis disregards the effects of declining salmon abundance throughout their range and the subsequent year-round nutritional stress, which further limits their immediate survival and future recovery. NMFS has identified [p]rey species of sufficient quantity, quality, and availability as an essential habitat feature in both current and proposed critical habitat areas including Salish Sea and coastal habitat and noted that the availability of key prey stocks is essential for the orcas survival.72 The myopic approach of only considering salmon abundance from one watershed ignores both the region-wide decline of salmon and the orcas need for abundant and available prey resources throughout their range. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Changes to this portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The cumulative effects associated with SRKW have been added to the cumulative effects section. A portion of the Chinook population throughout their foraging range, as well as other fish (halibut, lingcod, and big skate), contribute to the overall diet of the SRKW. The impacts to SRKW from food sources from other areas aside from the area impacted by the operation, maintenance, and configuration of the CRS projects are outside of the scope of what the federal action can address in this EIS. However, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
31821	13	colleen.weiler@whales.org	Whale and Dolphin Conservation	The development and alteration of watersheds, estuaries, and nearshore environments is one of the primary causes of salmon decline, and increasing ocean warming and acidification compound stressors on salmon and can impede their survival.73 Climate change impacts are expected to cause an additional 22% loss of current salmon habitat.74 Increasing ocean warming and acidification compound stressors on salmon and can limit their survival. The Cascade Mountains have had a 25% decrease in snowpack since 1950 due to increasing global temperatures, and summer streamflow has decreased up to 15%.75 Lower streamflow in the summer can increase water temperatures to levels deadly for salmon, decrease suitable habitat, and impede migration.76 For example, drought conditions in 2015 were amplified by changes to river flows caused by dams, resulting in a massive die-off of sockeye salmon in the Columbia River, and the marine heat wave of 2015/2016 increased water temperatures in inland Washington, causing the loss of an estimated 1.5 million juvenile fish in overheated streams and rivers.77 Despite these projected climate change impacts on salmon, the DEIS does not provide any information about efforts to mitigate lethal water temperatures on salmon, and the models used to predict climate impacts on water temperatures and salmon do not accurately assess how water temperatures will differ under the Preferred Alternative. In addition, the DEIS does not consider that current and continued declines of Chinook salmon stocks in the Columbia Basin and throughout the range of the Southern Resident orcas increases year-round nutritional stress on the orcas and impedes immediate survival and future recovery of the population. In a similar analysis on the impacts of hydrosystem operations on prey availability for Southern Resident orcas, NMFS concluded that the loss of a single individual, or the decrease in reproductive capacity of a single individual, is likely to reduce the likelihood of survival and recovery of the species.78 The current low abundance of Columbia Basin Chinook, and the minor increase projected under the Preferred Alternative, continues to directly reduce the likelihood of survival and recovery for Southern Resident orcas.	A full assessment of considerations of climate change and water temperatures are in section 3.4 Water Quality, Chapter 4 Climate, and Chapter 7 of the Preferred Alternative of the analysis. Regarding effects on killer whales, the agencies have considered the effects of each of the alternatives on the Southern Resident Killer Whale in their wildlife analysis, which is summarized in Chapter 3.6 and Chapter 7 the EIS and described in greater detail in Appendix F and Appendix V. While the largest change to Snake River Salmon may result from implementation of alternative MO3, the co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW. CSS and NMFS Life Cycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. 31821	15	colleen.weiler@whales.org	Whale and Dolphin Conservation	The Action Agencies failed to adequately evaluate all reasonable alternatives to reduce the impacts of the CRSO to avoid jeopardy on ESA-listed species. More effective actions, including breaching dams and/or modifying operations, are necessary to eliminate or reduce the adverse impacts to listed species and change the status quo. The dam breaching Alternative, MO3, would result in significant increases in salmon populations and aide in the long-term restoration of the Columbia watershed. Instead, the DEIS wrongly asserts that any change in prey availability resulting from the Preferred Alternative would have a negligible impact on Southern Resident orcas, yet also notes that Alternative MO3 would lead to an increase in prey base available to marine mammals foraging in the Columbia River or offshore from the mouth of the Columbia River, such as the killer whale and that changes in prey availability could impact the behavior of the population in both the short and long term.82 If Columbia Basin Chinook continue to decline, the orcas may be forced to spend more time and energy searching for other sources of food. In either case - searching for other food sources or responding to improved prey availability near the mouth of the Columbia actions that change the orcas behavior have impacts that are far more significant than negligible. Indeed, the Action Agencies conclude without citation or analysis that the effect for the prey-limited orcas would be only minor. 83 We agree that MO3 would result in the greatest increase in overall abundance of adult salmon over the longer term; however, we cannot agree that the impact on the Southern Residents that a moderate to major increase in adult salmon returns over the long term would be minor. The DEIS did not consider the high recovery potential of Columbia Basin Chinook and the potential for selecting any other alternatives that maximize salmon survival for a significant positive impact on prey availability for Southern Resident orcas.84 Instead, the Preferred Alternative fails to fully achieve the Action Agencies environmental objectives to improve juvenile and adult salmon survival, and fails to fulfil the Purpose and Need Statement to ensure conservation of fish and wildlife resources, including threatened, endangered, sensitive species such as Southern Resident orcas. With the continued coastwide decline of Chinook salmon and the historically low numbers returning to the Columbia Basin in recent years, status quo conditions or the very minor changes of the Preferred Alternative will continue to negatively impact Southern Resident orcas by continuing to impact a vital seasonal source of available prey.85	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKWs), along with vessel traffic and noise, toxic contaminants, and other health risks (e.g., inbreeding). The operation of the Columbia River System directly affects Snake River and Columbia River Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of abundance of Chinook salmon available to SRKW for prey, populations of some Snake River adult Chinook salmon stocks are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS scientists maintain that recovering Chinook salmon stocks for SRKW goes beyond the Columbia River Basin, and that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW. (NMFS BiOp 2020). The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit deferentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
31821	16	colleen.weiler@whales.org	Whale and Dolphin Conservation	VI. The DEIS does not adequately assess the Alternative of breaching the four Lower Snake River dams While there are many actions necessary in different parts of their range to support Southern Residents orcas, leading orca scientists agree that if the four Lower Snake River dams are not breached, recovering this iconic and unique population may not be possible. 86 Under status quo conditions, the orcas and the salmon they depend on will continue to decline. The Preferred Alternative does not provide the comprehensive plan needed to transition the region to a free-flowing Snake River. It offers only a minor change to status quo conditions, and is projected to result in half as many salmon returning to the Columbia Basin as there would be under MO3. 87 The DEIS itself, as well as additional independent studies and reviews, have concluded that the most effective and quickest action to recover ESA-listed salmon populations in the Columbia Basin and increase prey availability for Southern Resident orcas is to restore unobstructed passage through this area.88 Restoring salmon productivity in the 82 Columbia River System Operations Draft Environmental Impact Statement at 3-758 and 3-759 83 Columbia River System Operations DEIS at 3-758. 84 Fish Passage Center. 2019. A world where every whale and dolphin is safe and free Snake River Basin in particular is vital due to the recovery potential for spring/summer Chinook salmon in the remaining high-quality habitat.89 The Action Agencies did not fully assess the environmental benefits of MO3, breaching the four Lower Snake River dams, or take a meaningful look at the environmental consequences of the other Alternatives. Removing dams is an increasingly common management strategy for watershed restoration throughout the U.S.90 The DEIS should analyze the potential ecosystem benefits that occur under MO3, including salmon recovery, habitat and estuarine restoration, improved water quality and temperature, and improved physical conditions of tributaries and mainstem habitat.91 The DEIS also does not consider that restoring Columbia and Snake River spring Chinook runs could greatly increase a critical seasonal food source for Southern Resident orcas and therefore increase their chances of survival and recovery. We urge the Action Agencies to conduct a more extensive and accurate assessment of breaching the four Lower Snake River dams and a management alternative that maximizes salmon survival through the CRSO. The Action Agencies must consider the direct, indirect, and cumulative impacts that management actions have on salmon, Southern Resident orcas, and other wildlife. As written, the DEIS does not completely or accurately assess the feasible alternatives for restoring the Lower Snake River, and the assessment of investments needed to accompany dam breaching and meet additional management objects is limited and does not include key findings in energy sector reports. 92 The Pacific Northwest region is in need of an innovative plan that takes bold action to identify long-term, inclusive solutions to support healthy ecosystems, wildlife, and communities.	The CRSO EIS focuses on alternatives to CRS operations, maintenance and configuration and not on restoring the lower Snake River. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

31831	1	nanm3@yahoo.com	N/A	I feel that the removal of the Snake River dams would be detrimental to the Pacific Northwest. Barge travel hauling farm products to port cities would not be possible. This add many,many trucks to our roads and increase wear and tear. The barges also carry fuel for cars and trucks which would be added to the traffic load, a very potential hazard to the roadways.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. Under MO3, barge navigation would not be possible on the lower Snake River. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Similarly, Section 3.10 also describes increased safety concerns from the additional truck traffic resulting from MO3.
31831	2	nanm3@yahoo.com	N/A	The loss of cheap hydro power would open the door for expensive wind and solar, which are not as reliable as the energy provided by these dams. Also the installer of the wind machines would benefit from tax credits while the consumers foot the actual bill. Consumes would probably see their energy bills increase. Wind energy is very unreliable.	The comment that replacing lost hydropower capacity with new, variable renewable resources would increase system costs is consistent with the findings of the EIS. See Section 3.7.3.5, Table 3-166 in the draft EIS. However, it should be noted that the EIS did not identify wind as a cost-effective replacement in any alternative, though in Multiple Objective Alternative 2 wind in Montana was identified for the avoided build relative to the No Action Alternative. See EIS, Section 3.7.3.5, at pages 3-904-910 and Appendix H, Chapter 2 in the draft EIS for additional detail.
31834	1	rarusnak62@gmail.com	N/A	All billions in restoration efforts have failed, recline is accelerating, while agencies keep trying the same failed techniques. Specifically, here is how I support my critiques against this political unscientific un economically valid DEIS: 1. The plan ignores avoided costs and future savings by restoring the lower Snake River: The DEIS ignores the anticipated savings of more than $1 billion by eliminating the rising capital, operations and maintenance costs for the four Snake River dams. The cost of maintaining the dams, and replacing turbines is significant.	The cost analysis, described in Section 3.19, Chapter 7, and Appendix Q, describes the implementation and system operations costs under the MOs and compared to the No Action Alternative. The cost analysis estimates the capital and O&M costs savings that would occur under MO3 (see Tables 4-1 and 5-1 in Appendix Q). The capital costs include additional construction and capital requirements that would be needed in the future to maintain the lower Snake River dams. The cost analysis shows that MO3 would result in cost savings between $53 and $158 million as compared to the No Action Alternative.
31834	2	rarusnak62@gmail.com	N/A	2. This DEIS presents a false choice between maintaining affordable utility bills and restoring healthy salmon and steelhead. It overstates the cost of replacing power from the Snake River dams with clean energy, and suggests replacing their power with fossil fuels, a step we know is unnecessary.	The EIS analyzed the effects on regional reliability if the four lower Snake River dams are breached as part of Multiple Objective Alternative 3 (MO3). To maintain regional power reliability at the No Action Alternative levels, the EIS found that additional replacement resources would be necessary. The EIS considered a range of resource portfolios to replace the output of the four lower Snake River dams. That range is reflected in two portfolios used to describe the potential resource options: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Section 3.7.3.5, at pages 3-904-910 in the draft EIS. The costs of these resource portfolios were developed from the Northwest Power and Conservation Councils (Council) 7th Power Plan and Mid-term Update. The purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, at Section 2.2 in the draft EIS. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for MO3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. All cost effective conservation identified by the Councils 7th Power Plan is included in the load forecast. See Appendix H, Power and Transmission, Section 2.2, at H-2-3 in the draft EIS. Under Washington and Oregon law, all cost effective conservation must be acquired regardless of the status of the Federal Columbia River Power System. Therefore, conservation was not considered a potential resource replacement to avoid double-counting. To address concerns about potential reductions in resource costs, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the Final EIS. The Final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan.
31834	3	rarusnak62@gmail.com	N/A	3. Science must be a foreign language to this plan. The DEIS deems irrelevant and outright dismisses the volumes of peer reviewed scientific research across multiple fields, that restoring the lower Snake River will provide salmon and steelhead with their best chance to recover. It ignores the benefits of increasing those runs for critically endangered orcas and struggling fishing communities.	The co-lead agencies used the best available science and current high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation. The CRSO EIS analyzes the effects of operations, maintenance, and configuration on orcas (Section 3.6 and 7.7.8) and on fishing communities (Section 3.15 and 7.7.17).
31834	4	rarusnak62@gmail.com	N/A	4. The DEIS fails to acknowledge the impacts of climate science, absent conciderations for dwindling snowpack. Epic fail is the plans recommendations including w/I the flexible spill at the federal dams will not deliver sufficient survival benefits for endangered salmon and steelhead, and ignores the fact that any potential benefits will be eroded by climate impactssomething river restoration can help mitigate.	Chapter 4 describes the latest projections of climate change for the region. These include projections of weather, snowpack, streamflow, and sea level rise. The amount that an alternative may exacerbate or ameliorate the effects of climate change is discussed in Section 4.2. As discussed in Section 7.6.4 the ongoing Columbia River Tributary Habitat Program will continue under the Preferred Alternative, this program funds, designs, and implements tributary habitat improvements for anadromous fish, including lamprey, in specified Columbia River sub-basins.
31834	5	rarusnak62@gmail.com	N/A	5. Yet again the DEIS ignores another major factor, the tribal populations and historic treaty rights, as it ignores the economic impact that has already been made on Native peoples: The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices already made by Tribes and rural communities in terms of lost fishing opportunity, reduced jobs and incomes, impacts on Tribal cultures and diets, and other socio-economic effects.	Tribal input was received throughout development of this EIS and those concerns, rights and interests, including treaty rights, were considered and incorporated throughout this EIS. Please see the Tribal discussion in the Executive Summary, the Tribal Perspectives Section of 3.17 and their submittals in full in Appendix P. The alternatives are evaluated in terms of change from the No Action Alternative, which is the baseline condition of 2016 when the development of the EIS began. The co-lead agencies defined the No Action Alternative consistent with NEPA and implementing regulations. In the case of an ongoing action, such as operation of the CRS, the no action alternative represents no change in current management direction or level of management intensity. The No Action Alternative thus assumes the existence of the CRS projects and does not attempt to hypothesize the direct and indirect costs of each of Congress's decisions to construct CRS projects. The EIS analyzing the effects of the No Action Alternative on resources, environmental and socioeconomic, at present and into the future. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. The Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
31834	6	rarusnak62@gmail.com	N/A	Basically and overwhelmingly this DEIS ignores the economic and community benefits of salmon recovery and the investments and jobs that river restoration activities will generate. Many new jobs would be created with a free-flowing river. Fishing and recreation opportunities would improve, and about 4,000 acres of land currently flooded by the dams would become available for farming, recreation and would improve habitat.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. Regarding the potential for agricultural development on currently inundated lands under MO3, the co-lead agencies would no longer operate project lands after the projects are deauthorized. Under MO3, it is anticipated that the Corps would retain jurisdiction over the land holdings throughout the implementation period and biological evaluation process and that public control of a portion of public lands would be necessary to protect the environmental and natural benefits to salmon associated with dam breaching. Post dam breaching, the lands may be disposed to another Federal or state agency, or even a private entity. It is uncertain if lands would be available for agriculture. If MO3 were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to implement the alternative.
31838	1	lauren.druash@gmail.com	N/A	As an Idahoan, sportsman, and passionate conservationist, I have several concerns regarding the preferred alternative in the DEIS. This DEIS directly impacts our economy, culture, and ecosystem. Here are some of the key issues identified: 1. MO3, the dam beaching alternative, is the only option that adequately eliminates the risk of extinction for endangered Snake River species of salmon. It is the only proposed alternative that achieves meaningful recovery and reverses the extinction trend by improving SAR to an average of 4%. To achieve recovery, smolt-to-adult ratios must achieve a 4% average. (1) The preferred alternative does not achieve a high enough SAR to meet the regional recovery goals of the species. Research from the Fish Passage Center(FPC) has consistently demonstrated that removal of the Lower Four Snake River Dams is the most effective strategy for improving SAR and	The co-lead agencies used the best available science and current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				survival of ESA listed Snake River salmon and steelhead.(2) Based on FPC research and the DEIS itself, MO3 alternative is the only alternative that adequately achieves the recovery of ESA-protect salmon.	involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
31838	2	lauren.druash@gmail.com	N/A	2. The preferred alternative, as with previous management plans, is likely in violation of the Endangered Species Act: The preferred alternative within the DEIS recycles 20 years of plans and management strategies, which have been consistently deemed illegal and in violation of the Endangered Species Act. Section 9 of the ESA dictates that it is illegal to take (defined also as kill within Section 3) endangered species. Section 7 is clear that federal agencies may not jeopardize the existence of endangered species, and that agencies must use their authority to conserve both endangered and threatened species. The preferred alternative in the DEIS is only a slight deviation from previous illegal management plans and does not achieve meaningful recovery of Snake River salmon. Therefore, it should be considered that the preferred alternative is likely also in violation of the Endangered Species Act.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The Preferred Alternative complies with the ESA (see Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information). The co-lead agencies used current, high quality scientific information the in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Finally, the co-lead agencies disagree the Preferred Alternative is a slight deviation from previous operations. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
31838	3	lauren.druash@gmail.com	N/A	3. The DEIS lacks an appropriate and thorough cost-benefit analysis of dam removal, salmon and steelhead recovery, and loss of salmon and steelhead fisheries due to the continued decline of the species due to low SAR. The analysis contains an inaccurate representation of a.) Lower 4 Snake River Dams operations and maintenance, and b.) economic impacts of the coastal and inland fishing industry. In Idaho alone, outdoor recreation - including fishing - is a $2.3 billion dollar industry. In a year of high salmon and steelhead returns, steelhead anglers have spent $8.6 million a month engaging in sportfishing. Placing no monetary value on an industry directly impacted by the Lower Snake River Dams and failure to recover salmon and steelhead to abundant numbers while including the monetary value and impacts of other industries - such as energy and shipping- is deeply concerning. This demonstrates a total and complete disregard for the recreation, angling, and coastal commercial fishing industries, which are directly impacted by the Lower Four Snake River dams. Juvenile and adult salmon survival is directly impacted by these dams, as has been demonstrated by analysis of juvenile salmon survival and salmon and steelhead returns both before and after the construction of the dams (3), as well as evaluations of juvenile salmon survival through each of the dams in the hydrosystem. It is a flawed assessment and inaccurate representation of the full range of impacts of the hydrosystem. Additionally, the study severely underestimates the cost of continued repair and maintenance of the Lower Snake River dams. A full cost-benefit analysis on each of the Lower Four Snake River Dams has yet to be produced, despite the financial state of BPA and cost of BPA-sourced power (which far exceeds the cost of power on the open market), impacts on both inland and coastal fishing industries, and impacts on endangered species. This is long overdue, and should be included in the DEIS. It is deeply concerning that this plan, once again, fails to stop the decline of salmon and steelhead in Idaho. Salmon are central to Idahos ecosystem and economy, and carry deep cultural and economic value. By ignoring the fishing industry entirely while discussing the impacts on other industries of dam breaching, this plan is alarming in its failure to adequately address the needs of our communities.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. Considering the costs and benefits of hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $156 million and $417 million and the benefit-cost ratios are between 2.9 and 6.1. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $57 million and the benefit-cost ratio would fall to 1.7. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes directed funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
31839	1	N/A	N/A	I appreciate the efforts made and am concerned about breaching any of these dams or increasing the spill. Certainly we want to continue to produce clean energy. Removing this clean form of energy could not only increase our power costs, but require harmful alternatives to avoid shortages. These dams have already helped us avoid blackouts in my area - the Tri-Cities. Why would we want to do either of breach or increase the spill, especially in the times we now live in?	The comment about implications of Multiple Objective (MO) Alternative 3, which includes breaching the four lower Snake River dams and MO4, which includes spill up to 125% TDG 24 hours per day during spring and summer on regional power reliability and rates are consistent with findings of the EIS. See Section 3.7.3.5, Effects on Power System Reliability, at 3-903 and Appendix H, Table 2-1 in the draft EIS. The EIS also describes the importance of the four lower Snake River dams, particularly Ice Harbor, for stability in the Tri-Cities area. See Section 3.7.3.5, Bonneville Transmission System Reliability and Operations in the draft EIS.
31839	2	N/A	N/A	These dams are just one factor in salmon and orca survival. Given that survival rates through the dams are as high as 97%, it seems like a better use of time and effort would be to protect the environment of the Puget Sound Chinook salmon. I support the preferred alternative of the draft EIS. I also hope the majority of the effort will be placed where the majority of the fish survival problems occurin the ocean and Puget Sound.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.

31840	1	NOPVoices@att.net	N/A	Attached is a document to help with determining what to do other that sticking to the status quo. http://www.klamathrenewal.org/definite-plan/	Thank you for your input. The co-lead agencies do not believe we are sticking to the status quo. The Preferred Alternatives spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. In our analysis of effects, the co-lead agencies used current high quality data and best available science, including models and studies published in peer review science journals. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% as a result of the Preferred Alternative.
31843	1	nbelsby42@gmail.com	N/A	Water Quality:. This section states that there are elevated water temperatures in the Columbia River Basin due to regular climatic events and climatic variability. It also states that there is regional controversy regarding the role that the federal agencies may play in higher water temperatures. Any conclusion regarding causation for water temperatures must be based upon scientifically proven, evidence based science, not blanket statements of fault.	The co-lead agencies are complying with NEPA, and using current, high quality information in which to make conclusions. Water temperature results can be found throughout Section 3.4, Chapter 7, and the Water Quality Appendix D.
31855	1	N/A	N/A	In the face of climate change, it is no small thing to remove hydroelectric dams. But the Lower Snake dams supply a fraction of the regions power, at the cost of a culturally, economically, and ecologically essential species. Further, removing these dams will allow more migratory fish to access some of the most pristine stream habitat that remains. The EIS takes too narrow a scope on the impacts of the dams. Salmon and other native fish are integral to ecosystems and communities from the Pacific to inland forests. The report fails to account for the impact of dwindling populations on orcas, forest health, and rural and indigenous communities.	The agencies evaluated the direct, indirect and cumulative effects to resources affected by CRS operations, maintenance and configuration in Chapters 3, 4, 6, and 7. Through on-going regional climate change studies and related work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for use in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change at the appropriate resolution (river-scale vs. regional- or global-scale), and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. The same is true for projecting changes to TDG. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures would warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams would result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures would remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River would be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions would result in even more difficult challenges. The co-lead agencies relied on high quality, current information in the development of the CRS. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKWs), along with vessel traffic and noise, and toxic contaminants. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. The FEIS includes additional information on SRKWs in Section 3.6 and 7.7.8. The average annual costs to operate and maintain the four lower Snake River projects is $75M (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32M (Appendix Q, Table 4-1). The annual hydropower (Table 3-171) and navigation (Table 3-244 & Table 3-246) benefits alone for these projects are estimated at $284M to $588M in the base case analysis for MO3. These hydropower values include the effect of other measures in MO3, but the majority of this value stems from generation at the four lower Snake River dams. This estimate is derived from what the hydropower analysis called the base case and does not account for the full characteristics of the lower Snake River projects generation such as sustained peaking capability and fast ramping ability to integrate variable renewable energy sources. Fully replacing the generation capabilities of the four lower Snake River dams could roughly double estimated replacement resource costs (see Section 3.7.3.5). As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of capability in certain months of the year. While the increase in solar and wind generation is consistent with the EIS discussion in 3.7.2.1 Power Generation, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under MO3. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Finally, tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
31858	1	baca.andrew@epa.gov	Environmental Protection Agency	The EPA appreciates the continued cooperation that has occurred, and continues to occur, between the Co-Lead agencies and the EPA, concerning the different watershed-scale models used by the agencies. As you know, the EPA used its RBM-10 model in the development of a Draft Total Maximum Daily Load for the Columbia and lower Snake Rivers and the Co-Lead agencies used their CE-QUAL W2 and HEC RAS models to develop the Draft EIS. Agency discussions on these models have involved a team of individuals from the EPA and each of the Co-Lead agencies who were involved in the development, use, and application of the agencies respective models. The participants from each agency identified and evaluated similarities and differences in the modeling assessments and concluded that both temperature model predictions provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the Co-Lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS.	Thank you for your comment. The co-lead agencies appreciated the collaboration between their staff and EPA staff to compare the similarities and differences of each model, and the different purposes of each.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31858	2	baca.andrew@epa.gov	Environmental Protection Agency	The Draft EIS identifies and evaluates a No Action Alternative and five alternatives for operations, maintenance, and configuration of the 14 Federal dam and reservoir projects in Idaho, Montana, Oregon, and Washington, called the Columbia River System. The alternatives include different system operations and additional structural modifications to existing projects such as breaching the embankments at the Lower Granite, Little Goose, Lower Monumental, and Ice Harbor Projects; modifying fish ladders; or adjusting storage operations to affect the timing of flows for various purposes. The alternatives explore a range of spill levels to support juvenile fish passage, varying levels of hydropower generation by seasonal changes in flows, and differing actions to support the needs of Endangered Species Act-listed anadromous and resident fish. After evaluating the potential effects of the five alternatives on resources, such as flood risk management, water supply, hydropower generation, fish, vegetation, wildlife, wetlands, floodplains, climate, navigation, cultural resources, tribal interests, recreation, and other environmental, social, and economic resources, the EPA believes that the Co-Lead agencies identified a Preferred Alternative that balances multiple, sometimes competing, river resource needs and Co-Lead agency mission requirements.	Thank you for your comment.
31858	3	baca.andrew@epa.gov	Environmental Protection Agency	The EPA offers that the discussion of the Preferred Alternative could benefit from building a more robust analysis of several issues that we would be happy to discuss with the Co-Lead agencies in greater detail. For example, we recommend discussing measures or additional analysis of measures that could help address temperatures, including evaluating whether there are feasible operational measures to cool the John Day and Ice Harbor reservoirs. In addition, the Co-Lead agencies may want to consider providing additional discussion on the fate and transport of other water quality parameters that may be affected by the alternatives. In this regard, the Draft EIS could be strengthened by referencing available data on the cycling of nutrients, primary production, mercury methylation, methane production, and on dissolved oxygen and pH.	Thank you for your comment. The co-lead agencies look forward to continued collaboration with the USEPA. Additional information was added to portions of the EIS based on the collaboration between the co-lead agencies and USEPA. The EPA is the lead agency on developing a water temperature TMDL for the Columbia and Snake Rivers, and in doing so will evaluate the impact of all anthropogenic and natural sources of heat in the Columbia and Snake rivers. The EIS, in contrast, analyzed, to the extent practicable, whether the hydrosystem is causing or contributing to compliance with the water quality standards as compared to historic river temperatures. While there is little opportunity to change bulk river water temperatures through operational or structural technologies at run-of-river dams, passageways within the structures such as fish bypass channels and fish ladders can be influenced by project operations when the river is thermally stratified. The development of such structures were analyzed under the CRSO EIS and on-going evaluations continue. In addition, other ideas have been suggested, including the construction of off-channel cold water refuge in the John Day or The Dalles reservoirs (EPA 2019). While the feasibility of this specific idea is unknown, the Corps encourages continued dialogue with the EPA, States and other federal partners to brainstorm water temperature improvement opportunities that exist in the basin, and document such initiatives as we move into the implementation phase of the TMDL. Available data regarding cycling of nutrients, primary production, mercury methylation, methane production, etc. can be found in supporting documents on the CRSO website. These are referenced throughout Chapter 3-4 and Appendix D.
31858	4	baca.andrew@epa.gov	Environmental Protection Agency	In addition, the EPA appreciates that the Co-Lead agencies incorporated our recommendations in the environmental justice analysis. However, within the main report, the finding of no disproportionately high and adverse impacts to tribal populations in the various action alternatives appears inconsistent with other statements throughout the Draft EIS and does not fully explain whether cumulative effects were considered in its conclusions for this population. The EPA recommends that the Co-Lead agencies provide additional discussion to clarify these statements in the Final EIS.	Based on public comments, the co-lead agencies revised the Environmental Justice analysis (Section 3.18.3) to provide additional discussion and support for the characterization of the potential effects to environmental justice populations. Section 3.18.1.2 also acknowledges, "...determinations of effects to environmental justice communities have been organized differently in response to public comments to clarify how the different resource analyses preceding this section are synthesized with consideration of climate, mitigation components, and cumulative effects to holistically discuss effects to people."
31858	5	baca.andrew@epa.gov	Environmental Protection Agency	Consistent with our cooperating agency status and the productive engagement that we have had to date with the Co-Lead Agencies, the EPA would like to engage at your earliest convenience to discuss our review in greater detail and offer specific data and information that could strengthen the EIS. Please contact me at (206) 553-6387 or by email at baca.andrew@epa.gov to arrange that discussion.	The co-lead agencies appreciate EPA's participation as a cooperating agency. The co-lead agencies met with EPA throughout the NEPA process and on June 9, 2020, in response to this comment. We will continue to work with EPA staff throughout the CRSO EIS process and into implementation.
31861	1	rslynch@rslynchaty.com	N/A	Hydropower in the Southwest is not as plentiful as it is in the Northwest but that scarcity makes it even a more operationally valuable asset. However, one thing people have to get over is that hydropower is cheap and all manner costs can be stuck in power rates because of that assumption. Increasing environmental costs being added to hydropower rates plus competition from natural gas-fires generation and other factors have destroyed what was left of any credibility that assumption previously had.	The comment that environmental costs being added to the hydropower system puts upward pressure on electricity rates is consistent with the framework of Bonneville's power rates, as discussed in Section 3.7.2.7, Power Revenue Requirement, at 3-804 in the Draft EIS, and in the rate calculations for the various MOs in Section 3.7.3.2-6. Bonneville buys and sells power on the wholesale power market (see Sections 3.7.2.2 and 3.7.2.5), and public power utilities do the same, which does impact the competitiveness of Bonneville's hydropower. See Competitive Pressure on Bonneville's Power Sales, in Section 3.7.2.5.
31865	1	kutchk46@gmail.com	N/A	Comments to the 2020 CRSO DEIS Alternative MO3 is the only alt that might restore fish. Chapter 2 of the 2019 Comparative Smolt Survival Report contains the operations and configuration required for the Columbia River Power System and should have been the starting point for this Draft EIS (DEIS).	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS and is the current high quality information. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed by the co-lead and cooperating agencies.
31865	2	kutchk46@gmail.com	N/A	ECONOMICS: The DEIS states This EIS will provide for the operating agenciesand the regionto evaluate the costs and benefits of the four lower Snake River dams. Its not clear who the region is, and how it was involved with the co-lead agencies (CLA) evaluation. The majority testimony at all six public hearings stated that the four lower Snake River dams (LSRD) cost more to keep in place than they earn; and, the 2002 Snake River Juvenile Salmon Migration Feasibility Study (SRJSMFS) economic analysis and Tribal Circumstances paper previously and reliably concluded this fact (i.e., the region has known this for two decades); and further, current reputable, and robust economic analyses conclude that the four LSRD have a cost:benefit ratio of <0.2 (they make 20 cents for every dollar that we (rate-payers and tax-payers - the region) spend on them). Therefore it is the federal governments fiduciary responsibility to shut them down to save the hundreds of millions of dollars the waste each year. It is obvious that the CLA did not equitably, accurately, effectively, and efficiently use the region and its expertise to calculate the costs for MO3. The region must be provided the opportunity to evaluate the costs and benefits of the four LSRD - as is promised in the DEIS. The DEIS fails procedurally and substantively if this discrepancy is not resolved. MO3: Appendix Q, Annex A) calculates an additional $75M for hatchery fish during breaching (false, bypassing would occur during Dec-Mar when theres little or no fish migration). Annex B) calculates $203M for bridge and structure maintenance/ upgrading costs; however, these structures were in place before the dams (the pictures in the Executive Summary of the rail bridge near Celilo show the exact same supports then as now) and much needed maintenance costs can not be applied only to MO3. And, Annex B) - calculates sediment deposits at the mouth of the Snake River would cost $108M to dredge, which is false, if true it wouldve been included in the 2002 SRJSMFS; and, because Ice Harbor Dam is seven miles upriver it would take decades to become an issue. Thus, there are hundreds of millions of dollars falsely applied to increase the cost of MO3.	A benefit cost ratio was not calculated for the CRSO EIS. It is not a requirement of NEPA nor is it the basis of alternative selection under NEPA (see 40 C.F.R. 1502.23). Instead, the direct and indirect effects to the natural and human environment were evaluated, including some effects that were evaluated quantitatively and monetized, while others were evaluated qualitatively. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). These dams provide over 1000 MW of carbon-free energy and up to 2000 MW of peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2200 MW of capability in certain months of the year. Regarding costs, the four lower Snake River dams are some of the most reliable and lowest-cost electricity sources of the 31 Federal dams from which Bonneville markets power. Bonneville also has sufficient funds to support these, and all, FCRPS projects. Bonneville sets its power rates to recover its total system costs, including the costs of the four lower Snake River dams, and therefore, does not sell power from these projects at a loss. (See Draft EIS Section 3.7.2.7, Power Rate Determination). Rather, Bonneville recovers its costs and maintains sufficient funds to support the FCRPS consistent with its statutory mandates. Finally, Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are not exclusively sold as surplus, but rather is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. (See Draft EIS Section 3.7.2.5, Bonneville Power and Transmission Customers). As noted in the comment, the cost analysis estimates the capital and O&M costs savings that would occur under MO3 (see Table 4-1 and 5-1 in Appendix Q). The capital costs include additional construction and capital requirements that would be needed in the future to maintain the lower Snake River dams. Tables 4-1 and 5-1 in Appendix Q show the costs and cost savings under MO3. There would be approximately $107 million in annual capital and O&M cost savings under MO3 compared to the No Action Alternative for the four lower Snake River projects over the 50-year period of analysis. Costs for stabilizing bridges and roads was included as mitigation for ensuring that the infrastructure is not harmed by the act of breaching the dams. Sediment loads to the Snake and Columbia rivers that could occur under the MO3 Breach Snake Embankments measure were analyzed using sediment transport models as described in Appendix C, Section 3.4. The sediment impounded behind the four lower Snake River dams is predominately fine grained and readily transported in suspension. Analysis results for the MO3 Breach Snake Embankments measure indicate that increased sediment concentrations could occur during the construction season with impacts to dissolved oxygen as described in Section 3.4.1 of Appendix C. Mitigation actions to address these potential impacts are described in Section 5.4.3, including transport of some listed fish. These short term major adverse impacts can only partially be mitigated. A specific discussion of mitigation for effects to anadromous fish from MO3 is included in Section 5.4.3.2. Sediment transport modeling suggests that impounded sediments within the historical river channel extents would scour back to the historical river bed elevations over the near-term (2-7 years) depending on the magnitude and duration of watershed hydrology. Impounded margin sediments remaining on higher elevation floodplain terraces would be expected to incrementally erode over a longer time (>10 years) as seasonal floods access those surfaces. Regarding fisheries, the EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other areas, including the Upper, Middle, and Lower Columbia rivers, would have minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The Draft EIS acknowledges that with breaching of the Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, other mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer be possible. The rationale for this, as stated in the Draft EIS, is that Bonneville's funding is directly tied to the operation of the LSR dams. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. A summary of this qualitative discussion is provided for the reader for each Snake River species. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described. For the purposes of comparing alternatives, however, a more detailed description is not needed. A complete analysis of all hatchery programs and the status of maintenance/operations of each one is beyond the scope of this EIS.
31865	3	kutchk46@gmail.com	N/A	BARGING VS. ELECTRICITY PRODUCTION, IRRIGATION, RECREATION: The justification that the four LSRD areessential- because of their flexibility in producing electricity for peaking and filling gaps in load demands - contradicts the congressionally-mandated purpose of the dams. Only 5% of their	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				purpose is mandated for electricity production. Conversely, 80% of their purpose is to provide commodities transportation via barging - a heavily skewed unilateral congressional purpose that was rare by the standards of the late 1960s and early-70s. This 80% of the mandated purpose can be converted ecologically, economically, and reliably to truck and rail - and the fact that barges and fish both need water (barges shipped to Lewiston before the dams). Only 20% of the congressional mandate for the four LSRD is for recreation (7%), irrigation (8%),and electricity production (5%). Existing irrigation for 35,000 acres is pumped water that can still be provided by extending the pumps into the restored natural river levels. Bypassing the four FSRD will provide recreation opportunities that would exceed current levels. The combined four LSRD generation capacity is 1.8 to 2.6% of the Columbia River Power System and the ramping and peak load efficiency flexibility can reliably, efficiently, and economically be replaced with conservation and alternative production. The four LSRD generate an average 770 Mw (vs the 2-2,500 Mw claimed in the DEIS as one of the justifications for not choosing MO3). Where is the congressional authority for the CLA to operate outside the congressional mandate? Congress authorized only 5% of the dams mandate is electricity production so how can they operate so far outside that mandate? BYPASSING THE FOUR LSRD ALLOWS STORAGE RESERVOIR ELEVATIONS TO REMAIN RELATIVELY FULL AND STABLE THUS MAXIMIZING IRRIGATION, FLOOD RISK MANAGEMENT, AND ELECTRICITY PRODUCTION OBJECTIVES.	alternatives on fish as detailed in Section 3.5. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. Further, the commenter has misconstrued how the projects are authorized and operated for the congressionally authorized purposes. The purposes are balanced as some operations can be performed at the same time for multiple purposes and are not based on a percentage.
31865	4	kutchk46@gmail.com	N/A	THE EIS IS FATALLY FLAWED UNLESS ALT MO3 INCLUDES THIS ANALYSIS: The impacts to storage reservoir elevations of alternative MO3 is not complete. In the mid 1990s the Watershed Equity Team, under the Columbia Basin Fish And Wildlife Authority, comprised of the Columbia Basin tribes, four state fish and wildlife agencies, and the US Fish and Wildlife Service and National Marine Fisheries Service, including modeling from the Northwest Power and Planning Council (Jim Ruff and James Fodrea) concluded that water velocity travel times met the needs of migrating spring salmon, without needing additional flow augmentation from the storage reservoirs (Grand Coulee, Dowarshak, Hungry Horse, Libby, and Brownlee) - allowing those storage reservoirs to remain relatively full and stable - benefitting other needs such as resident fish and wildlife, lamprey, recreation, irrigation, power production and flood risk management. The DEIS is fatally flawed unless alternative MO3 includes this analysis and modeling. These analyses need to try to meet both the upper river and lower river needs; they must treat the entire Columbia River system as one, combining opportunities in the Snake and the Columbia to find win-win solutions for all.	MO3 does not change flow augmentation as compared to the No Action Alternative.
31865	5	kutchk46@gmail.com	N/A	THE DEIS LOSES SIGHT OF ITS ENVIRONMENTAL MANDATE AND ENDANGERED SPECIES ACT RESPONSIBILITIES: The purpose of and need for is the District Court Opinion and Order, and over twenty-five years of failed ESA Biological Opinions. This EIS needs to FINALLY adopt a Preferred Alternative that first and foremost meets the needs of preventing jeopardy to threatened and endangered fish, and then aims at harvestable surplus as required by the 1980 Pacific Northwest Electric Power Planning and Conservation Act (NPA), tribal rights, and US v Oregon. Then once those needs are met, the objectives should aim to meet the reliable, efficient and economical electricity production, water supply and irrigation needs and navigation. The PA needs to require bypassing the four LSRD (MO3) and provide the spill and other actions and operations called for in the drafted PA that aim for the numeric goals/objectives required by tribal rights, US v Oregon and the NPA.	The co-lead agencies acknowledge there are many factors that affect salmonid populations that are outside the authority of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and the Northwest Power Act. Moreover, Chapter 7 identifies the reasons that MO3 was not identified as the Preferred Alternative. These reasons are summarized in the Executive Summary and described in more detail in Sections 7.2, 7.3, and 7.4 of the CRSO EIS. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Finally, alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal govemments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
31865	6	kutchk46@gmail.com	N/A	Caution is required in setting spill at 120-125% N supersaturation. Theres a reason why state and federal water quality standards are limited to 115%. At 125% we can definitely see significant levels of dissolved gas trauma and gas bubble disease.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
31865	7	kutchk46@gmail.com	N/A	Also, actions to meet fish objectives need to utilize Artificial Production to rebuild naturally-producing (wild) runs. THE OBJECTIVES NEED TO PROVIDE CONDITIONS FOR THE ANADROMOUS FISH, RESIDENT FISH, AND LAMPREY THAT ARE FLOORS THAT WE CANNOT GO BELOW RATHER THAN CEILINGS THAT WE DO NOT HAVE TO EXCEED. Objectives to ... meet existing and assure future water supply while vaguely ... improving ... fish is 180 backwards. Instead the objective (and we are not fooled into thinking there are four separate fish objectives, they should be lumped in into one objective to prevent conflict between species) should be to stated as - ... meet ESA survival criteria to prevent jeopardy and meets juvenile and adult salmon, resident fish, and lamprey numeric goals for harvestable surplus as mandated by the NPA, tribal rights, and US v Oregon	Recovery efforts referenced in this comment and references to the Northwest Power and Conservation Councils (Council's)fish and wildlife program with associated target for broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31865	8	kutchk46@gmail.com	N/A	This is an ENVIRONMENTAL IMPACT STATEMENT under the NATIONAL ENVIRONMENTAL POLICY ACT: it is Not a water supply impact statement; Not an electricity production impact statement; and Not a barging impact statement. The EIS Needs to be aimed at the most good for the environment, Yet those actions receive short-shrift (MO3 is not the PA; and its costs are falsely exagerated). The DEIS admits fish have been adversely impacted, yet the Alternatives are intent on minimizing adverse impacts to project purposes other than fish. The EIS instead should develop a PA that first meets the needs of the fish, then meets the other multiple objectives of the built capacity. THE ONLY ALTERNATIVES SHOULD BE ABOUT BYPASSING THE FOUR LSRD: This EIS should not have evaluated any option other than the various decommissioning alternatives regarding what to do with the concrete spillway, navigation locks, and powerhouse once the earthen portion of the dams are removed. Should the structures be moth-balled and maintained enough so that they can be put back into service if the natural river alternative proves to be a failure after 50 years (the number of years the dams existed). Or, should the concrete portions just be walked away from and left to fall into disrepair. Or, should one or several be maintained as museums.Etc. The objective to Minimize greenhouse gas emissions is admirable; and that type of language is needed for the fish objectives e.g., Minimize fish mortality caused by man-made river operations. Maximize adaptable water management is a great, very much needed objective! Likewise there should be an objective to ... Maximize actions that prevent jeopardy to and recover fish species.	The Draft EIS contains a range of alternatives intended to emphasize trade-offs required to balance competing needs in a complex system. The goal of the EIS is not salmon recovery. That is outside of the authority of any of the co-lead agencies, and falls under the purview of NMFS and USFWS. Rather, the intent of the EIS, as stated in the Purpose and Need Statement, is to provide a plan for operations and configuration of the CRS for the next 25 years, which meets congressionally authorized purposes. An EIS that presented alternatives focused only on breaching the four lower Snake River dams, as you suggest, would not provide a reasonable range of alternatives, as required by NEPA.
31866	1	moiralightmann@gmail.com	N/A	I am writing to strongly support restoring the lower Snake River via breaching the four lower dams. Ecologists, marine biologists, and even former USFW members have concluded that this is the single most vital requirement to feed and support the Pacific Northwest's most iconic wildlife: orcas. The lower four Snake River dams currently serve as a geographical guillotine for wild salmon and steelhead. Thesedams prevent fish from both reaching the ocean	The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				and returning to their spawning ground to propagate--this is evident in low salmon return rate (~1%) and in the dwindling population of the Southern Resident orcas.	Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
31866	2	moiralightmann@gmail.com	N/A	Marine biologists have unquestionably implicated insufficient food as the cause of orca's lack of reproductive success; salmon is the historically staple diet for these orcas. Breaching the lower four would increase the salmon return rate to an estimated 4%, which would support and expand fish populations. A comprehensive review article concerning these orca's chances of survival can be found at: https://damsense.org/wp-content/uploads/2020/02/Feb-2020-Review-paper.pdf	The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Also, see response to Comment 6110-16. The co-lead agencies conclude there could be a minor beneficial effect to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
31866	3	moiralightmann@gmail.com	N/A	Additionally, we have treaty promises to uphold. We must honor commitments made with the Nez Perce, Shoshone-Bannock, Umatilla, Warm Springs, and Yakama Tribes. These Peoples gave up thousands of acres of their land for the right to hunt and fish in their "usual and accustomed places," a promise which has not been kept by our government. This is an injustice. Restoring the vitality of the Snake River by breaching the lower four dams is a first step to bolstering salmon runs and to honor our nation's agreements with native tribes.It is simply a moral action here.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. Congressionally ratified treaties bind all parties and have the force and effect of federal law. The co-lead agencies recognize and respect that fact. Indeed, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are also engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4, and additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
31880	1	Carol.Savonen@oregonstate.edu	N/A	First, the DEIS fails to follow the direction of courts dating back decades for a major overhaul of hydrosystem operations to protect threatened and endangered salmon and steelhead. The Preferred Alternative (PA) represents only minor changes to status quo, which has led to continued declines in the populations of wild salmon and steelhead, and has resulted in loss of critical prey (Chinook salmon) for the southern resident orcas leaving them close to extinction. The approach proposed in the DEIS has already been rejected in federal court five consecutive times. It is time for a new approach that will recover salmon and steelhead populations, provide benefits for the Northwest, particularly in the rural communities of Idaho and Northeast Oregon.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. Finally, the co-lead agencies disagree the Preferred Alternative is a slight deviation from previous operations. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
31880	2	Carol.Savonen@oregonstate.edu	N/A	The PA is built around the concept of flexible spill that was implemented as a temporary measure to stave legal challenges while the DEIS was being developed. Although increased spill can lower mortality for juvenile fish at dams, it is not a long-term strategy to prevent extinction of salmon and steelhead populations, much less to provide for recovery. Because flexible spill allows operations to prioritize hydropower generation, it provided little	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waivers had to be changed to implement the new spill regime. The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				benefit in 2019 because spill was often provided during the day and not in the evening or at night when most of the juvenile fish migrate. In fact, survival for some populations were lower under flexible spill than under the 2018 Biological Opinion.	Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It will likely take years to understand the true effect because adult returns are needed to measure the key effect, SARs, not in-river survival. The Flexible spill operations measure does not prioritize hydropower generation, but rather intends to meet the Fish Benefit, Hydropower Generation, and Operational Feasibility principles with specific performance targets to evaluate whether the principles have been met. Regarding the performance of 2019 flexible spill operations, which was planned for a 120% TDG level: one year of in-river data to assess the benefits of flex spill is not adequate because the primary metrics will be SARs, so the co-lead agencies will have to wait for generations of adult returns to assess the effectiveness of the action. Regarding your comment on recovery: the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on our analysis in the Fish resources section of Chapter 7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31880	3	Carol.Savonen@oregonstate.edu	N/A	Analysis in the DESI shows that implementation of the PA would result in survival (smolt to adult ratio or SAR) at levels that would result in a continued decline in the populations and put them at increased risk of extinction. Additionally, changing flow and water temperature conditions due to climate change will make implementation of the PA difficult and negate any benefits of flexible spill as a long-term strategy. The only action identified in the DEIS with a reasonable chance of success for wild salmon and steelhead is to breach the four lower Snake River dams. This action coupled with increased spill at the lower Columbia River dams would prevent extinction and has a high probability of recovering salmon and steelhead populations. The dam breaching alternative was shown in the DEIS to be the one option with the highest SAR for salmon and steelhead, at levels that would meet the regional goal of an average SAR of 4% (2-6%) to provide for recovery of populations.	The co-lead agencies used the current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
31880	4	Carol.Savonen@oregonstate.edu	N/A	The DEIS failed to take a long-term perspective when analyzing costs and benefits. For example, total costs of operating the four lower Snake River dams did not fully account for the long-term costs of maintenance that should have included the inevitable replacement costs of aging turbines; recent turbine replacement at McNary Dam cost $48 million). The DEIS also overstated the hydropower production of the dams and their relatively small regional contribution to power (4% by some estimates). Because power production of the dams is highest during spring, alternative sources such as wind and solar are available and their costs have steadily declined. Barging traffic has declined over the last 20 years by 45% for grain and by 70% for freight, with shifts to rail transportation. Benefits of restoring the lower Snake River were undervalued in the DEIS. For example, the contribution of restoring salmon and steelhead to the sportfishing economy were not addressed although it generates over $2 billion regionally. In addition, the DEIS did not include intrinsic values of a free-flowing river or recovered salmon and steelhead populations even though those values are widely accepted in economic analysis and were used by U.S Bureau of Reclamation in evaluating the removal of dams on the Klamath River.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A table added to Section 7.4 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. It is true that barge movements on the Snake/Columbia River have declined somewhat over the past 20 years. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. In regards to intrinsic values Section 3.15.2.2 describes the literature considered on this topic (passive use values) for this EIS. As described in the EIS, Section 3.15.2.2, "Best practices for benefit transfer identified in OMB Circular A-4 describe that meeting all criteria is difficult and that professional judgment is required in determining whether a particular transfer is too speculative (OMB 2003, 26). Given the limitations of the existing literature, this EIS does not include a quantitative benefit transfer of passive use values. This analysis acknowledges that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching."
31880	5	Carol.Savonen@oregonstate.edu	N/A	In summary, the PA fails to provide an approach that is needed to protect and recover the federally listed salmon and steelhead populations in the Columbia River Basin. Scientific analyses have shown that restoring the lower Snake River by breaching the four dams will protect these populations from extinction and have a high probability of recovering them to harvestable levels, providing for sport, commercial, and tribal fisheries as well as other ecological benefits such as critical prey for orcas. It is time to change course from the decades of failed strategies that have resulted in continual decline of these iconic species.	There are many factors that effect salmonid populations that are outside the authority of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Section 7(a)(2) does not require the co-lead agencies to recover ESA-listed species. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution to recovery targets. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. Finally, the co-lead agencies disagree the Preferred Alternative is a slight deviation from previous operations. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
31881	1	jayo@uidaho.edu	N/A	The preferred alternative (PA) in the February 28, 2020, Draft Environmental Impact Statement (DEIS) for Columbia River System Operations (CRSO) attempts to balance eight objectives. This approach fails to recognize that because salmon and steelhead species protected by the Endangered Species Act (ESA) are involved, their conservation and survival needs should take precedence over other objectives. In short, passage in the migration corridor from salmon/steelhead spawning and rearing habitat in Idaho to the coastal estuaries and marine habitat needs to be improved to reduce risk to the surviving members of these threatened fish populations. If Idaho salmon and steelhead were given the priority they should receive because of ESA mandates, then the multiple objective alternative MO3 would be the preferred alternative choice in the CRSO. The DEIS (p.24) states that MO3 predicts the highest benefits for several of the ESA-listed juvenile and adult salmon and provides additional riverine type recreational opportunities. It also returns access and opportunities to some of the traditional cultural resources and properties for tribal purposes. This conclusion is based on the smolt-to-adult ratio (SAR), a metric accepted in the DEIS, and elsewhere, as an appropriate benchmark for CRSO conservation. On the same day that the DEIS was	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations and the multiple congressionally authorized purposes of the CRS projects. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Recovery efforts referenced in this comment and references to the Northwest Power and Conservation Council (Council)fish and wildlife program with associated target for broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				released to the public (February 28, 2020) The Fish Passage Center released a memorandum to the Northwest Power and Conservation Council regarding SARs potentially attainable under the six CRSO alternatives in the DEIS: Among the federal alternatives, MO3 (the four dam breach alternative with spill to the 120% tailrace TDG in the Middle Columbia River) resulted in the highest SARs and in-river survivals, followed by MO4 (the spill to the 125% tailrace TDG alternative). These two alternatives, among the federal alternatives, resulted in the highest likelihood of meeting the 4% average SAR regional goal. The lower end of the predicted SAR range for MO3 was also above 1% for both Chinook and steelhead but for MO4, the lower end of the predicted SAR was slightly below 1%, indicating greater risk of further population decline. The other federal alternatives (NAA, MO1, MO2, and the PA) did not meet the regional 4% SAR goal and the lower end of the predicted SAR ranges were well below 1%, indicating greater risk of further population decline under each of these alternatives. For all fish survival metrics, the PA resulted in only slightly better performance than the NAA and MO1, and had lower performance than both MO3 and MO4.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the draft CRSO EIS. Any modeling not presented in the EIS was not developed by the co-lead and cooperating agencies.
31881	2	jayo@uidaho.edu	N/A	Because the modeled datasets provided by the federal agencies used daily averages, the CSS results for the PA are likely overestimates. (Document is available online at https://www.wildsalmon.org/images/factsheets-and-reports/2020.FPC.Report.DEIS.Alternatives.pdf)	In practice, model estimates may not overestimate PITPH due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of night time spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their estimates of effects to fish passage. These examples of adaptive management operations would continue during implementation of the Preferred Alternative. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty from the models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
31883	1	nsarmie2@gmail.com	N/A	The fate of the Southern Resident Killer Whales are at stake and the available scientific evidence is insufficient in the DEIS to make conclusions about the importance of snake river salmon to their diet. It angers me that you have ignored NOAAs own data, or have chosen to omit it, for a reason that I hope is not to make dam breaching not seem as necessary. This is the opportunity to communicate what scientists have been discovering the past few years, Colombia River basin salmon stocks are one of the most important for Southern Resident Killer Whale survival and recovery! The laws of nature say, eat and you will live, do not eat and you will die. This is overwhelmingly clear for the Southern Residents, who, can be helped by other measures but will ultimately perish (SOON) without available food, chinook salmon. Denying this highly intelligent and ancient species their right to eat, and right to live, is power that should make you very, very, uncomfortable. The rhetoric currently used does not show this consideration.	The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Also, see response to Comment 6110-16.
31883	2	nsarmie2@gmail.com	N/A	The DEIS does not weigh economic effects of the Southern Residents going extinct, let alone the social effects. All associated tourism will be lost. Every business, utility company, bank, & individual who uses the Orca as an emblem or name will have to change it, or deal with the fact that they no longer exist thanks to human carelessness. How many millions of dollars will be lost? This is critical information needed to compare alternatives and come to a conclusive decision about CRSO.	The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
31889	1	kfaeustle@gmail.com	N/A	On the DEIS process so far, First of all, I appreciate the extended call time and available times to hear the comments of the public. As for the DEIS itself, I urge you to choose the MO3 alternative to breach the lower snake river dams. It is the alternative that addresses the factors that have no alternatives - salmon spawning and river conditions and cultural sites for the local tribes. There is no other place where these salmon can spawn.	The co-lead agencies appreciate the acknowledgement of the time and energy invested in the process. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31889	2	kfaeustle@gmail.com	N/A	They have spent thousands of years undergoing evolution for a flowing river and these dams inhibit that. As for the cultural sites of the local tribes - they cannot be replaced. There is no other place where they can create cultural sites all of a sudden, at least not like the ones that are culturally significant and culture building. Removing the dams would return the existence and access to these sites. Its says it all in the report.	The co-lead agencies acknowledge that removal of the Lower Snake River dams would likely result in greater access to Traditional Cultural Properties. Please see Section 3.16.3.6 for additional details.
31889	3	kfaeustle@gmail.com	N/A	Transportation can be done by trains and trucks, recreation will increase in the long term, and the dams do not provide a significant amount of power, though they doubtlessly do provide power for the region. This power can be produced others ways, and in itself, is not vital to the region. Salmon are vital to the health of these ecosystems.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As described in Section 3.7.3.5 of the draft EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the FCRPS. Further, the seasonality of the power supply is important. The region often has surplus power in the spring when the weather is mild and flows are high. The LOLP analysis of Multiple Objective Alternative 3 showed that the region would have an annual risk of power shortages of around 14 percent stemming from shortages in the winter and summer. See Appendix J, Hydropower, Section 4.1.2.4 in the draft EIS. As suggested by the comment, the EIS does identify ways of replacing the power from these dams, and the resulting costs impose substantial upward pressure on regional power rates.
31889	4	kfaeustle@gmail.com	N/A	Recreation increases due to the dam removal in MO3 could also provide economic benefit for the region through tourism and recreation.	The Recreation Section 3.11.3.5 describes the potential economic benefits in the long-term under MO3, which includes the dam breach measure.
31889	5	kfaeustle@gmail.com	N/A	The preferred alternative would increase salmon runs by about 75%, but that is with the already greatly reduced runs of salmon that have come since the dams implementation. Up another 75% maybe, still without the natural river conditions surely is worse than the thousands of percent decrease in salmon and steelhead runs that have come since the dams removal. The salmon, once gone, cannot return. Power can still be created, grain can still be transported. Cultural sites are nonexistant and cannot still be created.	The co-lead agencies used the best available science and high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
31892	1	davidsolomonriverman@gmail.com	N/A	Unfortunately, the DEIS is incomplete inadequate and inaccurate in terms of its analysis of the benefits of removing these dams on salmon, steelhead and for the wildlife that depend on the salmon food chain. Furthermore, the negative economic and energy impacts of removing the dams are relatively small given the worsening economic cost of producing power, subsidizing barge transportation and billions of dollars thrown at attempts at fish habitat mitigation. I will elaborate the 6 interconnected issues below that should be addressed by finding new pragmatic solutions, and allow the removal of these four dams: 1. The Cause of Salmon Collapse: Loss of Free Access to and From Spawning Habitat: There is no question in the scientific literature that the plight of the aquatic wildlife in the Snake and Columbia began with the loss of habitat, and that dams have made it difficult for mature migratory fish to swim upstream to spawn and impossible for their fry to return to the sea. Fewer dams will result in higher percentage of successful spawning runs. These dams have the lowest economic benefit and the largest negative impact on fish runs, would open up over 5,000 miles of continuous habitat in the Snake, and therefore are the highest priority to remove. 32 salmon biologists and 6 whale scientists signed letters in 2018 to Washington governor Inslee advocating for removal of these four dams in order to re-establish productive access for Chinook, other salmon and steelhead and to support species that rely on these populations.	Historical review of salmon populations in the Columbia Basin was addressed in the Affected Environment section of Chapter 3 (Section 5). Effects of the Multiple Objective alternatives were also considered in Section 3.5. See also response to this comment under 31892-3 (3rd element of this comment letter).
31892	2	davidsolomonriverman@gmail.com	N/A	2. Salmon Food Chain: The DEIS ignores the critical importance of increasing salmon runs for critically endangered Southern Resident orcas.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the

					whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Also, see response to Comment 6110-16.
31892	3	davidsolomonriverman@gmail.com	N/A	Solar and wind at utility scale are the lowest cost of energy $/MWh on a fully-burdened, non-subsidized basis, as documented in Lazard's Levelized Cost of Energy Report (www.lazard.com/perspective/lcoe2019). The BPA, on the other hand, is producing energy at a higher cost than the market, and the only benefit of hydro from these dams is to solve for intermittency. The grid in Washington has plenty of hydro to use for balancing solar intermittency.	Contrary to the statement that the only benefit of hydropower is to solve for intermittency, the EIS finds that decreasing hydropower generation decreases regional power system reliability and increases costs under three Multiple Objective (MO) alternatives, including MO1, MO3 (which includes breaching the four lower Snake River dams) and MO4. See Table 1-1 in Chapter 1 of Appendix H, Power and Transmission in the draft EIS for the full summary of effects on hydropower generation, reliability, and costs. Wind and solar power are declining in cost; however, to provide the same amount of value in terms of both energy and capacity, 1 MW of hydropower would need to be replaced with more than 1 MW of wind or solar and coupled with batteries or some other storage technology due to the variable nature of these resources. See draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs at pages 3-904-905 and Table 3-160. As for the cost of generation of the Columbia River System projects, many commenters are interested in the cost of generation at the four lower Snake River dams. The average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
31892	4	davidsolomonriverman@gmail.com	N/A	It is time to shift to the future of clean, lower-cost solar instead of forcing rate payers to subsidize above-market electricity from the BPA, by some estimates $5/MWh over the market. Over the life of new solar infrastructure, the cost per megawatt hour would go down.	The comment incorrectly suggests that the wholesale spot-market price for power is equivalent in value to the firm power provided under Bonneville's long-term power sales contracts. The spot market is for wholesale power market purchases of surplus energy. It does not ensure availability nor deliverability, and is not suitable for load service, i.e., service to a load in any amount at all times. It is suitable only for buying and selling around firm load and resource forecast error, and for reducing system and fuel costs where and when more optimal and lower cost dispatch of energy resources is possible. Bonneville's long-term power sales are sold at a rate that is designed for firm load service; it ensures that what is needed is provided regardless of weather, hydrology, load, wind, market depth, or solar variability. For additional details on the Bonneville rate-making procedure, see Section 3.7.2.5, Bonneville Power and Transmission Customers, and Section 3.7.2.7, Power Rate Determination in the draft EIS.
31892	5	davidsolomonriverman@gmail.com	N/A	Agricultural Transport: There are other solutions for grain transport for the 130 miles from Lewiston to the Columbia, including rail (which would admittedly require some capital to upgrade capacity) and truck. In fact, freight volume on the Snake corridor has declined by 70% in the last 20 years as rail and truck are taking share. The transport cost of the existing barge system is currently subsidized (the farmers are not paying the fully-burdened cost of the lock system, dam maintenance, etc), so their higher-cost to use alternatives is a false choice. As part of a grand bargain, the farmers could be protected for several years through a declining subsidy of rail.	Section 3.10 of the EIS recognizes that access to barge transportation is the most cost effective means of accessing export markets for the majority of grain producers in the Northwest currently and removing that option would increase transportation costs for grain producers. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but not by 70% and the decline has stabilized over the past 10 years. That decline is mostly attributed to investments in shuttle rail terminals. The EIS utilizes the most recent 10-year average as a basis for its forecast volume of freight that would transit on the lower Snake River. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted.
31896	1	grussing@nezpercesystems.com	N/A	Given the immense interest in the subject, it is truly unfortunate that the comment period has not been extended, especially with the Coronavirus pandemic raging to the point of forcing cancellation of scheduled public hearings. The teleconference hearings were a complete failure, leaving many potential participants unable to participate in the process.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period. In response to COVID-19 concerns and public health requirements within the comment period, the agencies converted the six planned in-person regional public comment meetings to conference calls that provided an approach consistent with the format of the planned in-person comment meetings. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. These teleconference meetings were structured similarly to the previously scheduled in-person public comment meetings and provided speakers with the same amount of time to submit a verbal comment. Due to the format of these meetings, they were accessible to any public commenter, regardless of location. Participation in these meetings was robust.
31896	2	grussing@nezpercesystems.com	N/A	First of all, throughout the document, the co-agencies speak of theColumbia-Snake System as single unit. In reality, the analyses in the document focus primarily (only?) on actions and impacts that occur on the Snake River.	The specific geographic scope of the CRS Multiple Objective alternatives (MOs) encompasses the 14 Federal projects on the Columbia River and its major tributaries. The 14 Federal projects are operated as a coordinated system within the interior Columbia River Basin in the states of Idaho, Montana, Oregon, and Washington. The 14 CRS projects are: Libby, Hungry Horse, Albeni Falls, Grand Coulee, Chief Joseph, Dworshak, Lower Granite, Little Goose, Lower Monumental, Ice Harbor, McNary, John Day, The Dalles, and Bonneville. The effects analysis is divided into Regions A (Libby, Hungry Horse, and Albeni Falls), B (Grand Coulee, and Chief Joseph), C (Dworshak, Lower Granite, Little Goose, Lower Monumental, and Ice Harbor), and D (McNary, John Day, The Dalles, and Bonneville) and does not focus primarily on the Snake River.
31896	3	grussing@nezpercesystems.com	N/A	Since freight transportation on the Columbia River would be unaffected by any of the proposed actions and alternatives, only the impacts to shipping on the Snake should be considered.	The commenter is generally correct that the findings of the EIS are that the alternatives other than dam breach would not have substantial effects on freight transportation on the Columbia River. Freight volume by mode to the Columbia River ports for export may change under MO3 as more tonnage may arrive via rail as opposed to barge. This area is referred to as Region D in the document. Navigation and transportation-related impacts to Region D are described for each alternative in Section 3.10.
31896	4	grussing@nezpercesystems.com	N/A	Inadequacy of the Preferred Alternative The Preferred Alternative is completely inadequate, and fails to make significant improvements for Snake River salmon and steelhead populations Neither the Preferred Alternative or other operation alternatives include any specific numerical identification of benefit to ESA-listed salmon and steelhead (CRSO-DEIS Executive Summary, p.32). The goal is only generally described as improving juvenile salmon and improving adult salmon. What about steelhead? The Northwest Power and Conservation Council (NWPCC) established regional smolt to adult return ratio goals of 4% (on average) for recovery of listed populations, but none of the DEISs alternatives achieve that goal except for MO3 (dam removal). The Preferred Alternative is worse than adherence and continuation of the status quo because it only mandates flex spill for one year, the last year of the Flex Spill Agreement (CRSO-DEIS p.7-15, Section 7.4 Summary). After the completion of the spill agreement there is only a process. The Preferred Alternative is inadequate because it makes no substantive changes to restore Snake River salmon and steelhead. There are only vague references to adaptive management processes which are a continuation of the failed history to restore Snake River anadromous fish. The Preferred Alternative carries significant risk for ESA-listed salmon and steelhead, not only that they will not recover but that they will go extinct.	The alternatives in the EIS examined a range of spill options identified to benefit ESA-listed fish, including steelhead. The Juvenile Fish Passage Operation measure with adaptive management was determined to provide flexibility in the spill operations for ESA-listed fish, while adaptive management would allow the co-lead agencies, in consultation with regional fisheries managers, to adjust the spill regime as more information is learned about the effects of flex spill. The Juvenile Fish Passage Operation measure provides flexibility to adjust operations to benefit fish, while also limiting impacts to other project purposes such as hydropower generation.
31896	5	grussing@nezpercesystems.com	N/A	Social Welfare Analysis is Imbalanced and Incomplete To develop the PA, the co-lead agencies selected a combination of suites of measuresbased on how well the measures met the Purpose and Need Statement and EIS objectives, with consideration of environmental, economic and social effects. (ES, p..32) Yet, the co-agencies ask the public to favor, even sanction, the needs of fewer than two dozen irrigators all located on just one of the four reservoirs, the Ice Harbor Reservoir. The Executive Summary (p. 28) assumes, that if the dams were breached, that 47,926 acres would no longer be irrigated at a social welfare cost of $458 million. That assumption is false on the face of it, since the river itself would remain available for irrigation. A one-time expense of aid to farmers to upgrade pumps and lengthen water lines could ensure sections of the 47,926 acres could be irrigated post breaching. At the same time that it expresses concern about the social welfare costs for irrigators, the CRSO-DEIS essentially ignores or disregards the needs of fishing communities in Oregon, Washington and north central Idaho which right now are suffering a severe social welfare cost due to the loss of thriving salmon and steelhead runs. The CRSO-DEIS disregards the individuals and businesses that create jobs in those communities and the significant positive impact of fishing on the overall economies of Washington, Oregon and Idaho. In 2019, the Idaho Department of Labors economist for Region 2 (north central Idaho) reported that salmon and steelhead fishing contribute an estimated $8.61 million per month to the region.	Section 3.12.3.4 discusses the assumptions related to the loss of irrigated acreage under the MO3 alternative. This section also discusses the Regional Economic Effects analysis which estimates how the decreased agricultural production will effect employment, labor income and output (sales) in this region. The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
31896	6	grussing@nezpercesystems.com	N/A	Analysis of Cost/Benefit of Shipping Freight and Grain Doesn't Add Up In 2000, the Port of Lewiston barged 17,590 TEUs of containerized freight. In 2017, container-on-barge shipping stood at zero. This steep decline began long before the Port of Portland closed its container operations in 2015 and was driven by the regions producers themselves. In 1995, the Port of Lewiston shipped 952,599 tons of wheat via the lower Snake River. By 2018, wheat volume had decreased by 332,013 tons, a drop of 35%. Today all wheat at the Lewiston port is shipped by the private corporation Lewis-Clark Terminal over its own docks, not by the taxpayer-supported Port of Lewiston. Total lower Snake River freight volume 2015-2018 averaged 2.64 million tons, a 40% decline since 2000. Paper, pulp, petroleum, pulse, logs and lumber are no longer shipped on the lower Snake either by choice of the producers or, in the case of pulse, because containers are no longer shipped out of Port of Lewiston by barge. Grain shipping, too, has dropped as increasing numbers of grain growers shift to rail transport. Of all freight shipped on the lower Snake today, 90% of it is grain, but volume of grain shipped has been in steady decline. All waterborne freight to and from Lewiston, Idaho, passes through the lock at Lower Granite Dam. In 1994, 1,233 loaded barges were locked through Lower Granite. In 2017, just 314 were locked through. The lower Snake River dams and reservoirs transport the next to the lowest freight volume among seventeen rivers in the Inland Waterways System. In 2014-2016, the annual average freight volume on the lower Snake totaled 0.28 billion ton-miles. If that volume tripled, the river would still be classified as a low use river. The truth is that compared to waterways throughout the United States, the lower Snakes importance as a transportation waterway is negligible. The Snake River transportation waterway, to take this reality further, does not compare in any meaningful way to the importance of thriving anadromous fish populations to people, to rural economies, and to natural environments throughout the Snake River Basin. Thus, using lower Snake freight transportation as an excuse for allowing salmon and steelhead to go extinct is a false, unjustifiably expensive conclusion, making no economic sense.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. This is different than container shipping, which we agree is not currently occurring on the Snake River. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but not by 70 percent. While it is true that the Snake River freight volume is certainly smaller than the volume of the Mississippi and Ohio River systems, it is nonetheless an important transportation option for a large volume of freight, particularly for farm products, with the Columbia-Snake River system serving as one of the largest exporters of farm products in the U.S., and the largest exporter of wheat. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investments in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. These effects are considered in the context of the overall objectives of the EIS.
31896	7	grussing@nezpercesystems.com	N/A	Benefits of Snake River Dams Power Production Are Overstated The four lower Snake dams, combined, produce 3.3% of the Pacific Northwest's power supply. If the 4 lower Snake dams were breached, the PNW regional power surplus would still be 13.7%. For 2020, the projected regional load is 23,906 average Megawatts (aMW). Under critical water conditions, the projected generation in 2020 is 28,820 aMW, which leaves a surplus of 3,950 aMW, four times the average lower Snake production. In other words, were all four lower Snake dams breached, the PNW region would still have an energy surplus. Historically, BPAs revenue stream relied in part upon the sale of surplus energy. Today, however, due to fast-paced development of other energy sources in places such as California to which BPA previously sold surplus at a profit, BPAs surplus power is no longer in high demand. BPA now is, in fact, compelled at times to sell the Northwests surplus power at negative prices. There are times today, too, such as during spring run-off, when surplus power significantly increases, and that increase causes BPA to reduce or shut down wind and other power sources as per its Oversupply Management Protocol. Weve taken huge hits in the secondary revenues market, with cheap gas, low load growth, and the oversupply conditions. Its been a bloodbath for folks in the wholesale market. Elliot Mainzer, Administrator, Bonneville Power Admin. I take Mr. Mainzer at his word, and believe its time to eliminate the lower Snake dams from BPAs wholesale market.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville supplies firm load. The comment also appears to be considering the regional power system, not the FCRPS. The comment also suggests that the region could absorb this loss because on average the region has surplus energy. To determine resource replacement amounts, the EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council. See EIS Section 3.7.2.2; Appendix H Power and Transmission, at Section 2.1; Appendix I Hydroregulation, Section 2.4.4 in the draft EIS. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year having one or more blackouts. See Appendix H Power and Transmission at Section 2.1 in the draft EIS. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one year with blackouts every 15 years. The EIS uses this LOLP level as the benchmark from which to compare the other Multiple Objective (MO) Alternatives. As the commenter notes, under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one year with blackouts every seven years. See page 3-903 and Appendix H, Power and Transmission, at Table 2-1 in the draft EIS. The statement that Bonneville's revenues include the sale of surplus energy is accurate; however, Bonneville's surplus power is still in demand and sold regionally and exported beyond the region, when available. If the output of the four lower Snake River dams is removed, then Bonneville would have less firm power (used to serve regional utilities) and less surplus power to sell. The rate pressure impacts of this outcome are described in Section 3.7.3.5, Table 3-166. The comment notes that Bonneville sells surplus power during certain months of the year. However, Bonneville's firm power obligations are determined by the load placed on Bonneville throughout the year. These loads tend to be winter peaking, meaning the extra surplus produced in spring does not assist in meeting these firm obligations. Regarding oversupply management protocol and negative prices, it is Bonneville's policy not to bid on negative market prices.
31896	8	grussing@nezpercesystems.com	N/A	From 2008 to 2017, BPAs cost for fish and wildlife mitigation in the Columbia Basin averaged $727 million per year, or about 24% of BPAs annual budget. Since 2001, the Corps of Engineers has spent at least $1.8 billion on structural improvements to lower Snake and lower Columbia dams in an attempt to increase juvenile fish survival. After 20-plus years and a cost of over $15 billion, no Columbia or Snake River threatened or endangered salmon or steelhead species is on a path to recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. Moreover, the comments suggestion that approximately $15 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
31896	9	grussing@nezpercesystems.com	N/A	Summary The 2020 DEIS Preferred Alternative is, quite simply, unacceptable. The PA fails to ensure an average 4% smolt-to-adult return ratio of threatened and endangered salmon and/or steelhead, which means that the co-agencies have, with the PA, failed to meet the mandate of the court order that precipitated the drafting of the 2020 CRSO-DEIS and failed to establish justification for the courts acceptance of the PA. Conversely, Alternative 3 (MO3) would ensure the needed SARS and would enable the court to accept the results of the CRSO DEIS. The Opinion and Order from the U.S. District Court for the District of Oregon, states that the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species, or result in the destruction or adverse modification of designated critical habitat. The 2020 CRSO DEIS Preferred Alternative is inadequate to the task; whereas the 2020 CRSO DEIS Alternative 3 (MO3), including breach, is adequate to the task and must become the preferred alternative. A TDG level of 125% saturation at the 4 lower Columbia dam tailraces should be added to MO3 as a component of what should become the preferred alternative. Conclusion Scientific analyses in the CRSO-EIS leads to the conclusion that breach of the four lower Snake River Dams is the only option that has potential for recovery of Snake River salmon and steelhead. Based upon the data and analyses used to develop the CRSO-DEIS, I recommend that the Final EIS establish the objective to balance hydropower generation with substantive and meaningful restoration of anadromous fish. This is clearly not the objective of the Preferred Alternative, which places greater emphasis on power production while anadromous fish survival is relegated to tweaks of the existing hydro system. Meaningful restoration of salmon and steelhead must include breaching the four lower Snake River dams (MO3 alternative), with plans and a schedule to accomplish that goal. In the meantime, until the dams are breached, the analyses of alternatives clearly demonstrate that spill to the 125% tailrace gas cap (MO4 alternative) at all of the projects, 24 hours per day, must be implemented as an interim measure. Analyses in the CRSO-DEIS show this is the best available option for salmon and steelhead recovery, while still providing sufficient regional energy.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Improving anadromous fish conditions was included in the EIS objectives. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative for the reasons described below. The agencies also disagree that an interim "Preferred Alternative" should be MO4 given the reasons outlined in Chapter 7. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. It should be noted that the 4% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes.

31905	1	abellaphotography@ymail.com	N/A	Due to the extra weight put on our postal system we did not get this until April 13th. Please allow comments for at least another week as many others may not have gotten their notices in time either. Thank you.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
31907	1	N/A	N/A	During the life span on the dams, we have had some very good Salmon and Steelhead runs which suggests that there are other factors involved in the reduced runs of the past few years. Those other factors may be difficult to measure or control but removing the dams will not change those conditions.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
31910	1	davegoodhart@msn.com	N/A	As a fishing guide on the Grande Ronde River in Washington, I have watched as the steelhead runs have declined to such an extent that it was almost impossible to guide a customer to a steelhead last year, and business is therefore collapsing. Dam removal is the most impactful action to help the salmon and steelhead survive. These dams are not essential. I think preserving salmon and steelhead runs is essential. Does anyone at the agencies care about the future of these fish? Once the fish are gone, they are gone forever. We need to get serious and make sure the fish survive. We can't just keep treading water and let them dwindle away. It is absurd that we value non-essential dams over the future of wild fish. The Snake River Basin has the best salmon and steelhead habitat in the entire Columbia drainage. We need to commit to making sure its native fish survive. It should be our number one priority. Once their future is assured, there are many options to work out the rest. Step one is to remove the dams. The EIS needs that option and it should be not just preferred, it should be compulsory.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the EIS analysis of the fish resources in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Additionally, the EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15).
31910	2	davegoodhart@msn.com	N/A	As a fishing guide on the Grande Ronde River in Washington, I have watched as the steelhead runs have declined to such an extent that it was almost impossible to guide a customer to a steelhead last year, and business is therefore collapsing. Dam removal is the most impactful action to help the salmon and steelhead survive. These dams are not essential. I think preserving salmon and steelhead runs is essential. Does anyone at the agencies care about the future of these fish? Once the fish are gone, they are gone forever. We need to get serious and make sure the fish survive. We can't just keep treading water and let them dwindle away. It is absurd that we value non-essential dams over the future of wild fish. The Snake River Basin has the best salmon and steelhead habitat in the entire Columbia drainage. We need to commit to making sure its native fish survive. It should be our number one priority. Once their future is assured, there are many options to work out the rest. Step one is to remove the dams. The EIS needs that option and it should be not just preferred, it should be compulsory.	The EIS evaluates the performance of the CRSO alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. The Preferred Alternative was chosen to meet the purpose and need to operate the system for the congressionally authorized multiple purposes, including fish, hydropower, and water supply, while minimizing adverse effect to biological and socioeconomic resources. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. Consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. In addition, the EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15).
31916	1	beaman.jeff@gmail.com	N/A	Although I am empathetic to the salmon's plight and believer in the importance of protecting biodiversity, I believe removing the dams at this time is unwise. The bigger, more pervasive environmental, economic and human survival threat we face today is global warming. Taking 1,000 MW of renewable energy with load following capability and baseload serving attributes offline makes no sense in light of this greater threat. The salmon need help and it's clear that we are at best holding the line at this point. However, dam removal has become a matter of orthodoxy easily spread among members of environmental organizations. This was made clear by the effort to ID Snake River runs as critical to the Puget Sound orcas. The NOAA findings show this population contributes only a small percentage to the whales' food supply. The criticality claim makes it clear dam removal advocates will exaggerate greatly to bolster their case. Renewable, emission-free energy takes a higher priority at this time while maintaining current efforts to restore the fish runs.	Thank you for your comment.
31917	1	N/A	N/A	Salmon define us as a region. Obsolete lower Snake dams block fish from ancestral breeding grounds. Wild fish not hatchery clones need those miles of rivers and streams now. Starving orcas need wild chinook.	The lower Snake dams were constructed with fish ladders, and do not block tributary spawning grounds. There are upstream barriers, including the Hells canyon complex in the middle Snake River, Dworshak Dam, and additional barriers in streams that do not have fish ladders and do block a significant amount of historic habitat for spring/summer/fall Chinook and steelhead.
31924	1	loo@ida.net	N/A	The Preferred Alternative should minimize the increases to the wholesale power rates as indicated in the study which is important to me and others live in the region.	In developing a Preferred Alternative, the co-lead agencies considered the need for an adequate, efficient, economical and reliable power supply, combined with the need to meet other authorized CRS purposes. The agencies additionally committed to mitigating for impacts to fish and wildlife impacted by CRS operations. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
31929	1	N/A	N/A	To my understanding, the controversial issues are the salmon and hydropower. Between these two, the salmon is more important. Salmon is a part of the natives culture being included in their traditions. Also, fishers rely on the salmon to become the substances for them and their families and as a resource to sell to others for income. The hydropower surely can be replaced with more environmental-friendly power sources. However, salmon are not replaceable because they are one of the keystone species, which feed various predators, including bears and orcas. If the salmon becomes extinct, few other species that rely on the salmon might become endangered or, worse, extinct.	Tribal partners also provided valuable input and expertise throughout the development of the EIS, and tribal interests and perspectives played an important role in how the co-lead agencies shaped the Preferred Alternative. The importance of healthy salmon and steelhead populations to tribal cultures and economies are a central part of the rationale for selecting juvenile fish passage spill measures that have the potential to provide major improvements in smolt-to-adult returns. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3, the alternative that includes the measure to breach the lower Snake River dams. However, the preferred alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. Multiple Objective 3, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend dam breaching because the preferred alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31931	1	nsarmie2@gmail.com	N/A	My comment below addresses one of the fatal flaws in the DEIS, rendering it unusable, and supporting my demand for immediate breaching of the Lower Snake River dams, if salmon, orca and ratepayers are to be saved. In the draft environmental impact statement, I found the claim of hydroelectric generation to be carbon free incorrect. The scientific community may have believed that decades ago, however it is now clear that all hydroelectric projects produce significant methane emissions from the algal growth in the adjacent reservoirs (depending on factors like temperature, latitude and bathymetry). The DEIS ignored this information, but I have attached a research paper from the Department of Energy to make sure you it is presented to you. Since one of the objectives of the study is to minimize green-house gasses (GHG), it is important to distinguish hydroelectricity from wind and solar, that to date have no methane or other greenhouse gas emitting impacts. In the multiple objective analysis, knowledge of methane emissions from reservoirs would be important to assess the reduction in GHG emissions given a breach alternative. Replacement with wind and solar for MO3 would significantly reduce GHG that is annually emitted from the decaying algal blooms and contributing to global climate change.	Appendix G, Chapter 5 of the Draft EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8 in the Draft EIS. Section 3.8 and Appendix G include references to and discussion of Amtzen et al. (2013), research supported by the U.S. Department of Energy referenced in this comment. In the case of the four lower Snake River dams, recent research concluded that data were insufficient to estimate the reservoir methane emissions specifically for the CRS projects, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The Draft EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams. While the commenter references that using renewable power generation sources would reduce GHGs for MO3, however, the Draft EIS analysis estimates that Multiple Objective alternative 3 would increase greenhouse gas emissions by 3.5% or 1.3 million metric tons if replacement generation resources were solely renewables.
31935	1	kristin@middleforklodge.com	N/A	It is time for a reckoning and recognition that this plan will not save our fish from extinction and additionally serves to insult Idahos outfitter and guiding community by not considering the crushing negative economic impact that eventuality will cause our industry.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
31935	2	kristin@middleforklodge.com	N/A	The plan equally and further disregards and disrespects the unsung heroes living deep inside of Central Idaho along the Lemhi, Pahsimeroi and Salmon Rivers who have been working innovatively and collaboratively for decades on their private lands to improve critical spawning habitat for salmon and steelhead - in an anticipation of salmon and steelhead recovery and abundance. In addition to my recreation background, I have a 12 year history as the founding Executive Director of Lemhi Regional Land Trust that was formed by local ranchers in 2005, in Salmon, Idaho. Our primary and initial challenge was to keep ranching a viable industry in the face of sky rocketing land prices in Central Idaho. During those early years we quickly began to understand that we had a pragmatic nexus consisting of ranchers who wished to stay whole and operating, who valued the namesake fish species of our region, and that financial resources were available to find new, creative ways for ranching and quality fish habitat to co-exist. Despite how the rest of the world viewed the term conservation, this savvy group of ranchers defined it for themselves in an unlikely landscape and embraced unimaginable change. Over time, we made significant strides addressing and solving wildly complex resource issues such as re-connecting de-watered tributaries, re-plumbing irrigation systems and completely re-thinking how to graze cattle in sensitive riparian areas. In most cases, it was the ranchers themselves who came up with the smartest and most innovative ideas. When they recognized there was an authentic desire from partners in the community with both financial and human resources to help, they were willing to do hard things. They gave up water rights and other property rights to do what they could to keep both our fish populations and their own operations viable. Ranchers did this repeatedly in our region with an early and notable effort to add water to re-connect the mouth of Lemhi River to the Salmon River in the 1990s. All of this work has been done to ready ourselves for recovery in Central Idaho. We know what fish need; they need natural river systems and processes to thrive. How is it that your EIS team is not asking themselves how to re-imagine the system in a way that re-establishes salmon and steelhead abundance while also finding ways to keep the folks and industries dependent the Lower Snake River hydro system whole? The Idaho outfitters and guides in our industry who have been shamefully and embarrassingly left out of any such considerations of being kept whole are the very people imploring that such an option is embraced for our downriver neighbors. The ranchers in our community have done their part. Outfitters and guides have endured the economic impacts of declining runs. Our communities struggle to find the words to describe the social and cultural impacts in a place like Salmon, Idaho on the Salmon River. We will not be spectators to this willful demise of our treasured, iconic, and still-mysterious ocean running fish. It is time to find solutions that are not carried on the backs of Central Idahoans, but by our region as a whole.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery.
31942	1	N/A	N/A	This DEIS isn't good enough. It fails us as Idahoans and it fails the salmon and it fails the river system. There is no long-term strategy here. A Lower Snake River restoration plan would come with innumerable benefits, and yet it was given no real attention in this DEIS. Without such a plan, it is increasingly unlikely that our endangered salmon populations will ever recover to healthy and abundant numbers. How good can a DEIS be if it fails to consider the salmon, which are such a huge part of what Idahoans consider part of their river identity?	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31949	1	20aquigley@students.cdaschools.org	N/A	Having salmon and wildlife in rivers is something that a lot of people worry about and are passionate about when they live next to or fish at rivers where this topic is an issue. I think that this growing problem is dealing with the growing population in general. Having enough power for people to have a sustainable amount for homes and businesses, and I think in this growing economy this will take precedence over salmon. After reading all of the information, I see that there is a big need for hydropower and this is a need in the areas provided. Although salmon are a big part of the community, having no power to supply the city can become a problem. Some concerns that may come with the dam will be the cost, the fish loss, the overall water quality, etc. These are all issues that have to be faced if we want to solve the problem at hand.	The EIS recognizes the various concerns mentioned in the comment and the statement that hydropower is important for the regional power system is consistent with the findings of the EIS. Consistent with the comment, the co-lead agencies developed a Preferred Alternative that seeks to balance across the multiple purposes of the federal projects including ensuring reliable and affordable power. See Section 7.7.9.1, Rate Sensitivity Analysis, Table 7-32 of the Draft EIS.
31950	1	bsallinger@audubonportland.org	Portland Audubon Society	Comment is attached (see PDF from Audubon Society of Portland et al	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
31951	1	jnpaglieri@gmail.com	N/A	The removal of the Snake River dams would significantly harm both the economy and the environment. I agree with the conclusions of the consultants report (FCS Group). The EIS needs to address in more depth and detail the number of deaths and injuries that would result from leaving the dams in place compared with their removal. For example, the potential number of injuries (and possible) deaths that would result from industrial accidents in physical removal of the the dams. Also, the number of injuries that would result from manufacture, installation, maintenance, and end of life removal of wind mills (and solar panels). Another very significant concern is the long term energy shortage even with the dams left intact.	The method proposed for breaching the four lower Snake River dams is based on extensive analysis completed for the 2002 Feasibility Study, which also considered dam breaching. The methodology developed is intended to minimize impacts to ESA-listed fish runs, other aquatic organisms and the built environment, while providing maximum protection to human health and safety. The CRSO EIS uses the same assumptions. For the purposes of this EIS, the 2002 cost estimates were inflated to 2019 price levels. The co-lead agencies will continue to adhere to Federal standards for dam and levee safety and human life safety considerations. In the event that breaching of the four lower Snake River dams is implemented, additional analysis will be conducted to refine methods and costs. The commenter's concern with potential long term energy losses is consistent with the EIS, particularly in light of the planned retirement of many regional coal-plants even without loss of generation from the four lower Snake River dams. The EIS did not analyze detail the number of deaths and injuries that would result from leaving the dams in place compared with their removal or industrial injuries associated with wind power. These were outside the scope of addressing effects of changes to system operations. However, any implemented alternative will develop an on-site safety plan for the projects, including construction and maintenance activities. Safety concerns due to increases in truck and rail traffic from MO3 are discussed qualitatively in Section 3.10.
31952	1	pbaigas@yahoo.com	N/A	For decades, salmon recovery efforts in the Columbia river system have unsuccessfully tried to balance fish recovery with Hydro power operation and barge transport, among other competing interests. The preferred alternative clearly, although implicitly, abandons The federally listed wild spring chinook salmon and steelhead as a lost cause. Is therefore illegal and will be subject to costly litigation. The preferred alternative ignores the consensus of fishery scientist Who overwhelmingly agree that breaching the four dams on the lower snake river is the only option to restore wild fish in the lower Snake and Salmon rivers. Wild snake River salmon and steelhead are less than 2% of pre-project numbers and the preferred alternative will drive wild spring chinook and still head towards extinction not recovery.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Recovery efforts referenced in this comment associated with broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Northwest Power and Conservation Council (Council) fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31953	1	N/A	N/A	Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly 1 million adult Chinook salmon returning to the mouth of the Columbia River, providing significant relief for endangered Southern Resident orcas. As you know Chinook salmon are the orcas' primary food source from central California to the Salish Sea. And the Columbia Basin supports salmon runs that the orcas have relied on for centuries. Historically half of all the salmon returning to the Columbia Basin were bound for the Snake River. But after the river was dammed more than half a century ago, the wild salmon runs plummeted and left the orcas with fewer fish to eat. Despite the fish ladders and our current interim spill measures, dams continue to cause serious salmon declines by directly killing and preventing their migration. Breaching these dams will cut dam-caused mortality by at least 50%.	The co-lead agencies evaluated the effects of alternatives to operating, configuring and maintaining the CRS projects, including an alternative that included a measure of breaching the four lower Snake River dams. Consistent with existing caselaw on ongoing actions, the co-lead agencies used the year in which the Notice of Intent to Prepare the EIS was issued (2016) as the No Action Alternative as the basis for comparison against the action alternatives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. Also, see responses to Comment 6110-16 and 6110-25 and updated language of effects on SRKWs in Chapter 3.6 and Chapter 7. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. The results are presented in Section 3.5 tables for each species as a percent change from the No Action Alternative (NAA) in the Draft EIS. Also presented are the median and average values for other metrics modeled, such as in-river system survival, proportion of powerhouse passage, total dissolved gas (TDG) exposure, etc. The co-lead agencies highlighted the more relevant metrics in the Executive Summary: median Smolt-to-Adult return rates (SARs) and their percent change from the NAA. When referencing these Preferred Alternative fish results the co-lead agencies are using language similar to this to help clarify any potential misunderstandings: The Preferred Alternative increases SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. Moreover, the 4% average SARs target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the anadromous fish analysis in Section 7.7.4, the Preferred Alternative would make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
31953	2	N/A	N/A	What's more, these dams have flooded miles of spawning habitat, destroyed healthy riparian forests, and created lethal warm-water reservoirs. With climate change, the number of days where temperatures will reach deadly levels are expected to increase. Independent research has stated that removing these four dams will help cool the river. By removing these dams, we'll also be increasing salmon access to more than 5,500 miles of free-flowing, climate-resilient, federally protected spawning habitat in northwest Oregon, southeast Washington and central Idaho. And doing so will deliver tremendous economic, ecological and cultural benefits to the region and nation.	It is well understood that the CRS dams have an impact on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS document. A system water quality model was developed to look at water temperature and TDG effects throughout the Columbia and Snake River system for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31953	3	N/A	N/A	Removing the dams, of course, will require both state and federal governments to invest in infrastructure that eases the transition for farmers and communities that rely on these dams. But it's an essential endeavor. Investments in rail infrastructure, irrigation pipes and renewable energy will ensure a just transition for the region and help support salmon and orca recovery.	Thank you for your comment. As noted in the EIS, if MO3 were the selected alternative, implementation would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
31953	4	N/A	N/A	Southern Resident orcas are among the most endangered mammals on the planet, and they're starving to death with only 72 individuals left in the wild. While the orcas also face threats from vessel noise and contamination, breaching the four lower Snake River dams is the most significant action the federal government can take right now to restore salmon runs and orcas' most valuable food source.	The co-lead agencies evaluated alternatives to operating, configuring and maintaining the CRS projects, including an alternative that evaluated the effects of breaching the four lower Snake River dams. Consistent with existing caselaw on ongoing actions, the co-lead agencies used the year in which the Notice of Intent to Prepare the EIS was issued (2016) as the No Action Alternative as the basis for comparison against the action alternatives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. Also, see responses to Comment 6110-16 and 6110-25 and updated language of effects on SRKWs in Chapter 3.6 and Chapter 7. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The co-lead agencies conclude there could be a minor effect to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead).
31956	1	kairos42@earthlink.net	N/A	The DEIS formulation of MO3 is fatally flawed because it took the single action breach alternative and without explanation, added costly work on lower Columbia dams along with more spill. Additional spill has shown little evidence to support its biological benefit thus far and also ties additional loss of power to breaching. This effectively creates the poison pill scenario for breaching. Even with additional cost loaded onto breaching to formulate MO3, Table 7-2 of Appendix Q displaying the change in Annual Equivalent Cost from the NAA shows that MO3 saves $93 million over the current conditions and $97 million over the Preferred Alternative. In addition, the PA is stripped of many features found in the other non-breach alternatives without explanation as a means, apparently, to make it look like a lost cost option. Note that none of these comments attempt to address Fish and Wildlife costs that very significantly and as the DEIS states are dependent on further analysis, especially in regards to a breach. In terms of assessing an overall benefit to cost ratio for the MOs, NAA and PA, no single table does this, although such a table may have been briefed to the Public Power Council by Jim Frederick for the Crops NW division. Lacking such a table, it appears that the DEIS provides costs in three different categories: Implementation costs, Hydro power impact costs, and mitigation costs for MOs, the NAA and PA. When costs based on the more detailed analysis for the lower Snake River Dams (LSRDs) in the 2002 EIS are corrected, mostly be correcting faulty assumptions, brought forward and then properly accounted for as implementation, power, and mitigation costs, the cost/economic benefits of a poisoned MO3 become more evident. For a stand alone breaching alternative, even more effective in terms of short term costs and life cycle economic benefit over ALL non breach MOs and alternatives. Specifically, Tables 3-308 and 3-309 in Chapter 3 and Tables 7-1 and 7-2 in Appendix Q are changed by using corrected breaching, mitigation and implementation costs (see attachments) they will show that a poisoned MO3 even after adding in mitigation costs for bridge pier armoring, channel work, hatcheries, RR embankment protection, dredging, gas line protection, cultural resource protection, irrigation modification, $80 million in RR siding, grain conveyance mods at elevators and upgrading the Port of Columbias short line from Prescott to Dayton WA, has an annualized implementation costs of $57 million and $61 million dollars less than the NAA and PA respectively! These same tables would show an annualized savings of $100 and $104 million over the NAA and PA respectively for a breach only alternative! In terms of power impacts among the MOs and PA, the DEIS states unsupported claims totaling, it is hard to tell without a B/C table, something over $1 billion annually in terms of benefits by keeping the dams or conversely a $1 billion cost to ratepayers to replace the capabilities of the LSRDs if breached. However, the DEIS is rather vague about how absolute the estimates are and often notes that further analysis is needed if breaching were implemented. Indeed, given the amount of power surpluses, BPAs most recent resource estimates, and how much money they actually generate from secondary sales, the need for replacing the power is in question and evident in the DEIS. But by using these high benefit claims as another reason to develop a Preferred Alternative, the agencies have not only ignored their own data but have fatally biased the PA and breaching in positive and negative manners, respectively. As such the process will never get to an answer any more than the 2002 EIS did because of the inherent pro dam biases of the the Corps and BPA. These errors in assumptions from the 2002 EIS and expanded upon in the DEIS show the effects of attempting to perjure any form of breach alternative. These fatal flaws are so egregious as to render the DEIS process invalid. As such the Corps and BPA should immediately implement breaching of the LSRDs this year as the only way left to reduce costs to ratepayers, saving BPA, salmon and SRKW.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A table added to Section 7.4 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. The commenter is correct when describing that the EIS provides costs across different categories. There are costs estimated for implementing and operating and maintaining the system under each alternative - these costs also include fish & wildlife program costs along with mitigation measure costs. For example, when compared to the No Action Alternative, MO3 would reduce system costs between $53 and $158 million annually. Compared to the No Action Alternative, the Preferred Alternative would range from a decrease in costs of $40 million to an increase in costs of $7 million annually. However, these figures do not consider the benefits provided by the lower Snake River dams, including hydropower, navigation, water supply, and recreation. As the commenter points out, hydropower impacts can be described as costs or lost generation, as well as benefits or increased generation. When considering hydropower only, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $156 million and $417 million and the benefit-cost ratios are between 2.9 and 6.1. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $57 million and the benefit-cost ratio would fall to 1.7. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020.
31958	1	N/A	N/A	Considering ALL 4 stocks of Idahos precious, native salmon and steelhead are still threatened or endangered, the only legitimate way forward is the option most likely to increase native salmon numbers. Furthermore, other species listed under the Endangered Species Act (ESA) such as critically endangered Southern resident Orca and threatened grizzly bear are dependent on or would benefit from nutrients derived from salmon. Salmon and steelhead are incredibly important keystone species that support ecosystem health in the entire Pacific Northwest. No place more so than the rugged, Salmon -Selway Ecosystem (SSE). Comprised of the Frank Church-River of No Return, Selway-Bitterroot and Gospel Hump wilderness areas and adjacent roadless areas, the SSE is one of the last intact ecosystems in the continental US and it is missing a keystone species that brings nutrients from	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Grizzly bear reintroduction is beyond the scope of this EIS as well as authority. The USFWS has the authority and responsibility for Grizzly Bear recovery program. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the Pacific far into the depths of the inland northwest. I consider the proposed option to be a direct afront to salmon recovery but also reestablishment of Grizzly Bear in the SSE, a critical link in the Yellowstone to Yukon corridor system. It is indeed shortsighted to sacrifice a thriving hotspot of biological diversity, an ecosystem that would support even more diversity, cultural practices and recreational opportunities if nutrients brought inland from the Pacific Ocean via salmon were replenished. These issues were not adequately taken into account in the EIS. While I understand there are competing interests over control of the Snake River, the desire to appease stakeholders such as power brokers and the Port of Lewiston should not take precedence over the primary issue of salmon and steelhead recovery. The proposed option does not provide native salmon with the best chance at survival, therefore, it is inadequate.	
31958	2	N/A	N/A	Page 13 of the report states NMFSs LCM attributes the majority of recent declines to the arrival time of juveniles entering the ocean (e.g., fish that enter the ocean later in their migration run-timing tend to have lower survival), and deteriorating ocean conditions (decadal scale cycles in ocean productivity and warming water in the Northeast Pacific). These issues are not adequately addressed by the unproven Juvenile Fish Passage Spill in the Preferred Alternative. Potential benefits are not enough.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31958	3	N/A	N/A	Clean reliable power should certainly be a national priority, however, there are multiple ways to Provide a Reliable and Economic Power Supply. The Columbia River Gorge has a high capacity for wind power, vast areas of the Columbia Basin are suitable to solar and coastal areas could utilize wave energy. Furthermore, Idaho, Oregon and Washington all have high capacity for geothermal energy due to hydrothermal activity in the Snake River plain in Idaho and the Cascade Range in Oregon and Washington. This reliable, economic source of clean energy was not a focus of the long but deficient EIS. Energy conservation and efficiency are also viable avenues to reduce demand.	The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. Regarding the range of renewable technologies considered, the source of resource information used in the EIS is from the Northwest Power and Conservation Council's (Council) 7th Power Plan and Mid-term update. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. Geothermal energy was not considered a primary technology and thus, was not included as a replacement resource. The replacement resource analysis modeled potential wind power replacement for both the Columbia River Gorge and Montana; however, the analysis did not identify wind energy as cost-effective relative to solar power (see draft EIS, Chapter 2 of Appendix H for additional details). The conventional least-cost and the zero-carbon resource portfolios were intended to provide a range for the cost and emissions impacts of the Multiple Objective Alternatives assuming current technologies could be scaled to replace the four lower Snake River dams' capabilities. See draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs at pages 3-904-909 and Table 3-162. All cost effective conservation identified by the Councils 7th Power Plan is included in the load forecast. See draft EIS, Appendix H, Power and Transmission, Section 2.2 at page H-2-3. Under Washington and Oregon law, all cost effective conservation must be acquired regardless of the status of the Federal Columbia River Power System. Therefore, conservation was not considered as a potential resource replacement.
31958	4	N/A	N/A	Just as there are alternatives for clean energy, there are also several alternatives for transporting wheat for export, rail lines run right next to the Columbia River and the United States has a first-class interstate system.	The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investments in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The EIS finds that average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are much higher, depending on their specific location and other conditions.
31958	5	N/A	N/A	Page 8 of the EIS report states The October 19, 2018 Presidential Memorandum on Promoting the Reliable Supply and Delivery of Water in the West directed the co-lead agencies to shorten the timeline to prepare the EIS a year ahead of the original schedule adopted in the Opinion and Order. Compression of the schedule between the completion of the Draft EIS and signing the records of decision and a predisposition of the current administration against the Endangered Species Act is indeed contrary to the protection of salmon and steelhead. I support a new, regionally-led, scientifically-based approach to salmon and steelhead recovery in the Columbia River Basin.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions on the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on current conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion.
31958	6	N/A	N/A	Lastly, it is unjust that only a 45 days comment period was issued for such a long technical report and that no extension was granted during this time of national emergency dealing with the coronavirus. I would very much have liked to share my comments in person. I did submit comments via a phone conference but, it was not conducive to listening to comments by various stakeholders and in my opinion was ineffective. Also, I think more cities in Idaho should be included in the public comment roster as these issues disproportionately affect Idaho citizens.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period. In response to COVID-19 concerns and public health requirements within the comment period, the agencies converted the six planned in-person regional public comment meetings to conference calls that provided an approach consistent with the format of the planned in-person comment meetings. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. These teleconference meetings were structured similarly to the previously scheduled in-person public comment meetings and provided speakers with the same amount of time to submit a verbal comment. Due to the format of these meetings, they were accessible to any public commenter, regardless of location. Participation in these meetings was robust.
31962	1	MarjyL@charter.net	N/A	The Snake River dams are crucial to the entire state of Washington. The clean energy and low cost of electricity provided by the dams encourages companies to choose Washington when seeking a place to locate. Farms which feed all of Washington and beyond depend on the water for irrigation and for barge transportation of grains and other goods, as well as electricity. Without the barges delivering tons of goods, cargo would be forced to use trucks for transportation, resulting in increased traffic, more damage to roads, greater pollution, more carbon in the air, and greater fuel usage.	The potential economic impacts from breaching of the lower Snake River dams are described throughout the EIS organized by resource area including Power and Transmission (Section 3.7), Navigation and Transportation (Section 3.10) , Water Supply (Section 3.12), and Recreation (Section 3.11). Effects to livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that follow. Please see Section 3.10, Section 3.12, and Appendix N for additional information.
31963	1	finnegd@wwu.edu	N/A	As a young biologist who grew up recreating on nearby Idaho rivers, it is my strong opinion that the 4 lower Snake River (LSR) dams should be breached to comply with the Endangered Species Act, which will enhance migratory habitat for listed salmon and steelhead.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31963	2	finnegd@wwu.edu	N/A	Limited commodity transport and hydro-power potential differentiates the LSR from the mainstem CRSO and continued maintenance and operation of the LSR dams can no longer be economically justified. A free flowing Snake River will provide countless ecological benefits throughout the Northwest, as well as enhance the economy through the creation of new jobs surrounding the recreational and commercial fishing industry.	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
31963	3	finnegd@wwu.edu	N/A	Fish and Wildlife Scientists estimate the Snake River basin holds approximately 70% of the wild salmon and steelhead recovery potential for the entire Columbia River basin due to high habitat quality, but smolt to adult ratios (SAR) and return rates for wild fish remain well below population maintenance thresholds with SARs averaging < 2% for Snake River Sockeye, Snake River Spring/Summer Chinook and Snake River Steelhead (3 of 4 listed stocks). Fish mortality related to migration through the LSR dams is increased by longer migration times, diminished rearing habitat that provides reduced nutrition, slower growth and higher vulnerability to predators.	The co-lead agencies used the best available science and high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The Preferred Alternative will improve fish migration times, which will reduce vulnerability to predators. The Preferred Alternative also includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies. Likewise, continued habitat improvement actions such as those included in the proposed action to NMFS and the U.S. Fish and Wildlife Service will continue to improve rearing habitat.
31963	4	finnegd@wwu.edu	N/A	Mortality is compounded by warming temperatures due to global climate change. Scientists agree that reservoirs impounded by dams absorb and retain more heat than free flowing rivers. Record high temperatures during 2015 diminished adult salmon and steelhead return success and continued warming is expected for years to come.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for use in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. The same is true for projecting changes to TDG. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Regarding water temperatures under dam breach scenarios, a system water quality model was developed to look water temperature and TDG effects throughout the Columbia and Snake River system for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. Further, the models showed minor changes in the Columbia River under this alternative, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River, where much of the mortality took place during the record hot temperatures of 2015.
31963	5	finnegd@wwu.edu	N/A	Science does not indicate increased spill over the LSR dams will recover Snake River salmon and steelhead. Spill increases sufficient to aid salmon and steelhead migration without dam removal would reduce hydropower output while failing to provide cost savings due to the expense of continued dam maintenance and operation. Increased spill could not be implemented during low flow years and the benefits of reduced water temperatures and improved habitat created by a free flowing Snake River would not be realized.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
31963	6	finnegd@wwu.edu	N/A	The economic benefits provided by fishing to river communities in Idaho that depend on salmon and steelhead returns, such as Salmon, Challis, McCall, Riggins, White Bird, Grangeville, Orofino and Kamiah were not sufficiently evaluated in the draft EIS. While fishing is only one of many benefits of a free flowing Snake River, a 2005 study determined that salmon and steelhead fishing could bring Idaho over $544 million dollars annually.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
31963	7	finnegd@wwu.edu	N/A	Other threatened and endangered species affected by the LSR dams include the West Coasts Southern Resident Killer Whales, which feed on Chinook salmon, and bull trout, which feed on salmon eggs. In addition, an estimated 95% of Pacific lamprey have disappeared from the lower Snake River and its tributaries. Also worth considering, the LSR dams flooded approximately 30,000 acres, much of it once highly productive riverine habitat. As written by Idaho Historian Keith Peterson in his book River of Life, Channel of Death, Washington Department of Fish and Game noted that in 1972 this habitat was home to an estimated 22,000 pheasants, 57,000 quail, 20,000 partridge, and 120,000 mourning dovesall game birds. By 1987 the total game bird population supported along the river was just 2,000, a 99% decline. Furbearing animals dropped from 13,000 to 500. Songbirds that wintered in the area dropped from 95,000 to 3,000.	Effects from the alternatives to Southern Resident killer whale, other threatened and endangered species, and wildlife are included in Section 3.6 and additional information is included in Chapters 4, 5, 6, and 7. Effects to habitat and wildlife populations due to the construction of the CRS projects and inundation are not included in this analysis, although the co-lead agencies do have mitigation agreements across the basin due to losses from construction and those are discussed in the CRSO EIS in the No Action Alternative and Chapter 5.
31963	8	finnegd@wwu.edu	N/A	Power Generation The four LSR dams provide just 4-5% of the Northwests power supply. By 2013, wind energy in the Pacific Northwest produced 3.4 times as much electricity as all four LSR dams. Wind energy alone has thus already replaced the power generated by all four LSR dams more than three times over. The Pacific Northwest presently enjoys a 16% surplus of electricity. If the 4 LSR dams were removed today we would still enjoy an 11% electricity surplus. By relying on available hydropower from other dams in the Columbia River basin, grid stability at any point in time can readily be achieved. Analysis by the NW Energy Coalition and the RAND Corp. found that power from the LSR dams can be affordably replaced with proven carbon-free energy sources and efficiency upgrades. Like wind, hydropower output varies greatly. These two energy sources share similar efficiency ratings (production vs. nameplate capacity) on an annual basis. Further, hydropower produces its greatest volume of power during the spring, when the demand and price for that power are at their lowest levels.	The comment makes multiple claims comparing regional wind power and the hydropower generation of four lower Snake River dams. The EIS analysis considers both the increase in wind power generation in the region (see Figure 3-160 and Table 3-108 in the draft EIS) and the balancing potential of other hydropower dams, and, contrary to the comment, still finds that Multiple Objective (MO) Alternative 3 (which includes breaching the four lower Snake River dams) substantially reduces the power system reliability. To determine resource replacement amounts, the EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council. See draft EIS, Section 3.7.2.2; Appendix H Power and Transmission, Section 2.1; Appendix I Hydroregulation, Section 2.4.4. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year with one or more blackouts. See Appendix H Power and Transmission at Section 2.1 in the draft EIS. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one year with blackouts in every 15 years. The EIS uses this LOLP level as the benchmark from which to gauge the other MOs. Under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams, there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one year with blackouts every seven years. See draft EIS, Section 3.7.5.3, at page 3-903 and Appendix H, Power and Transmission, Table 2-1. Regarding surplus, while the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are not exclusively sold as surplus as implied by the comment, but rather is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. See Section 3.7.2.5, Bonneville Power and Transmission Customers in the draft EIS. The comment notes that Bonneville sells surplus power during certain months of the year. However, Bonneville's firm power obligations are determined by the load placed on Bonneville throughout the year. These loads tend to be winter peaking, meaning the extra surplus produced in spring does not assist in meeting these firm obligations. The EIS acknowledges previous analyses of breaching the four lower Snake River dams. Regarding the Northwest Energy Coalition (NWEC) study, as described in the draft EIS in Appendix H, Power and Transmission, and Section 3.7.3.5, the EIS considered the NWEC study cited in the comment, but it is not directly comparable with the EIS. This is for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. Regarding the RAND study, the EIS relies on current information to evaluate the tradeoffs associated with dam breach under MO3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago.
31963	9	finnegd@wwu.edu	N/A	According to an analysis published by the NW Energy Coalition during 2015, power costs to Northwest ratepayers would increase by about $1 dollar per month if the LSR dams are breached.	The EIS considered the NW Energy Coalition study cited by the commenter, but that study is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. See Section 3.7.3.1, Step 3, at page 3-820 in the Draft EIS; Section 3.7.3.5, Related Study, at page 3-913 in the Draft EIS; Appendix H, Power and Transmission, Section 2.4. To maintain regional reliability at the No Action Alternative levels, replacement resources would be needed under MO3, which includes breaching the four lower Snake River dams. The cost of replacing the capability of the four lower Snake River dams is described in detail in the Draft EIS in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. The Draft EIS takes into account the cost savings from the breaching of the four lower Snake River dams. Even with these savings, base rates paid by customers of Bonneville (local public and community owned utilities) would likely increase. Using natural gas as the replacement resource (the least-cost resource portfolio) Bonneville's wholesale power rates could increase 4 percent to 10 percent. See Table 3-166 in the Draft EIS. Using zero-carbon resources to replace lost capability from the four lower Snake River dams capability, Bonneville's wholesale power rate could increase 13 percent to 50 percent. See Table 3-166 in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
31963	10	finnegd@wwu.edu	N/A	Irrigation Of the 4 LSR dams, only the Ice Harbor dam provides irrigation for farms. The relatively small amount of irrigated farmland along the LSR could be maintained by extending intake pipes to the free flowing river. Removal or breaching of the 4 LSR dams may actually take pressure off irrigators who otherwise would have to leave more water in the river to mitigate the effects of the dams.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
31963	11	finnegd@wwu.edu	N/A	Commercial Freight Transportation The LSR is no longer necessary or viable for commercial freight. During the past fifteen years freight transport on the LSR has declined 69%, from a peak of 9.14 million tons in 1998 to 2.83 million tons in 2014. Freight volume in 2015 trended downward and has averaged over the past seven years 2.6 million tons per year. Of the twenty-one largest employers in the quad-cities of Lewiston, Clarkston, Moscow and Pullman, only one ships anything by water. That company is located about two miles from the Port of Lewiston (POL), produced 50% more tonnage of product than all the grain shipped through the POL, and yet in 2014 transported 99.5% of its product by truck and rail. A 2015 study conducted by Anthony M. Jones of the Boise economic consulting firm Rocky Mountain Econometrics found that farmers who use the river instead of rail save about 2.4 cents per ton, or about $7.6 million annually. But he said the Army Corps of Engineers spends $17.8 million per year to maintain the river transportation system and hundreds of millions each year to mitigate the harm dams cause to fish. He calculated that the dams provide a benefit of 21 cents for every dollar the Corps spends. Container shipping on the LSR has ceased, and the waterway has been all but abandoned by the lumber industry, along with paper, pulp, and petroleum. The LSR waterway is categorized by the Corps of Engineers as a waterway of negligible use. Removal of the LSR dams will reduce the river barge corridor by only 140 miles. Freight transportation can be accommodated by rail and truck. Investments in a modern rail system and improved highways is not only affordable, it will provide more benefits to the regions farmers, businesses and communities than the LSR barge system does.	Section 3.10 of the EIS recognizes that access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently and removing that option would increase transportation costs for grain producers. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but not by 70% and the decline has stabilized over the past 10 years. That decline is mostly attributed to investments in shuttle rail terminals. The EIS utilizes the most recent 10-year average as a basis for its forecast volume of freight that would transit on the lower Snake River. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted.
31963	12	finnegd@wwu.edu	N/A	Flood Control The LSR dams do not provide flood control. Instead, they create a flood risk. They are run-of-river dams, that dont store significant water volume. A growing flood threat exists to the cities of Clarkston and Lewiston because naturally occurring sediment accumulating at the confluence of the Clearwater and Snake Rivers is raising respective river levels. Proposed remedies, such as raising levees, dredging, and other measures will cost millions of dollars over the long term and pose threats to fish, wildlife and recreation opportunities. Lewiston community leaders are opposed to raising levees, which will cut the town off further from its rivers and disrupt popular biking and walking paths. The Corps admits that the volume of sediment is too vast for dredging to solve the problem.	The commenter is correct that the breaching measure in MO3 would eliminate sediment buildup and reduce flood risk at the confluence area of the Snake and Clearwater rivers (clarifying information has been added to Appendix K.1.7.3.). Furthermore, the Walla Walla District constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. The lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Chapter 1, Section 1.2. As indicated in Section 3.9 and Chapter 7, and as shown in Table 7-1, there is no elevated risk to flooding in the lower Snake River reach for any of the EIS alternatives. Unlike freely flowing channels, in Lower Granite Reservoir, the forebay elevation at the dam controls the energy grade-line of the water surface. Under current operations or as modeled under the No Action Alternative, during high flows Lower Granite Reservoir is operated at a lower stage to increase conveyance and manage water surface elevations within the Lewiston vicinity. The most recent dredging in the Lewiston area was to maintain a 14-foot depth in the Federal navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (PSMP). Dredging outside of the navigation channel limits to maintain conveyance capacity has not been conducted since 1992.
31963	13	finnegd@wwu.edu	N/A	Operating Cost The 2015 study by Rocky Mountain Econometrics determined that the cost of maintaining the LSR dams and mitigating their impacts has been soaring while benefits are in steep decline. The economic benefit of shipping by barge out of the LSR Basin has plummeted from about $19.4 million per year to about $7.6 million in 2014. Meanwhile, direct costs for LSR dam operation and maintenance are at about $227 million per year and increasing about 4.5% annually. In addition to direct costs, fish related mitigation significantly increases the expense of LSR dam and navigation system operation and maintenance. In 2014 the Bonneville Power Administration (BPA) reported $782 million in mitigation costs for Columbia River Salmon and Steelhead. After subtracting hatchery operation costs of $35 million, if even one-fourth of annual mitigation costs are spent on the LSR dams, mitigation expenditures related to the lower Snake River total $187 million per year. Despite spending more than $1 billion for fish passage improvements on the LSR dams, survival of threatened and endangered salmon and steelhead has not improved since the 2002 LSR EIS was implemented.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework (see 40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Regarding the comment related to barge shipments, navigation benefits are estimated to range from $14 to $48 million annually (see Table 3-244 & Table 3-246). These benefits are estimated as increased transportation costs (decreased social welfare benefits) under MO3, based on barge traffic going away on the four lower Snake River dams and shifting to truck or rail transportation. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1); these costs include costs to maintain the navigation channel. Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. As described in Chapter 6 of Appendix Q, Bonneville currently pays USFWS approximately $34 million annually to operate fish facilities associated with the Lower Snake River Compensation Plan (LSRCP). Bonneville's funding authority for the LSRCP is directly tied to the operation of the lower Snake River dams. In addition, approximately, $1 million annually is expended on the Columbia River Fish Mitigation associated with the four lower Snake River projects. Under MO3, Bonneville would no longer have an obligation to fund USFWS for O&M of the LSRCP facilities because Bonneville's funding authority is directly tied to the operation of these dams. Bonneville's Fish and Wildlife Program is estimated to cost $282 million annually, and includes fish mitigation projects and studies across the Basin. To assess the potential costs associated with the four lower Snake River projects only, the potential costs savings associated with MO3 are considered. As stated in the CRSO EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made through the CRSO EIS process. Future Fish and Wildlife funding decisions would be made in consultation with the region, through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Based on the inherent uncertainty of Bonneville's F&W Program funding requirements, with lower Snake River dam breaching, Bonneville's Fish and Wildlife costs were provided as a range, from current levels ($282 million annually) to $177 million annually, a reduction of $105 million. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
31963	14	finnegd@wwu.edu	N/A	The economic benefits of dam breaching have been illustrated. In developing the 2002 LSR EIS, the Corps hired noted recreational economist John Loomis. Loomis pegged the economic gain via dam breaching at over $300 million. Temporary job growth to facilitate dam breaching, infrastructure modifications and restoration ecology would be significant. Improved commercial fisheries and recreation opportunities would generate long term economic growth. Improved aesthetics and quality of life associated with the enjoyment of a free flowing LSR would attract business and industry to the region. In spite of over $1 billion spent on fish passage improvements on the LSR dams, survival rates of endangered salmon and steelhead have not improved since the 2002 EIS was implemented.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11); commercial fisheries (Section 3.15); and visual resource (3.13). The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The evaluations generally include social welfare effects, regional economic effects, and other social effects The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. Moreover, the comments suggestion that approximately $1 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
31963	15	finnegd@wwu.edu	N/A	The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. Recovery of abundant, healthy and harvestable levels of Snake River salmon and steelhead is not achievable with the dams in place, as several decades of failed recovery efforts and billions of dollars	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				have revealed. The agencies should call on Congress to make the necessary investments to replace the dams benefits so we can both recover the fish and maintain a vibrant regional economy.	fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Recovery efforts referenced in this comment associated with broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Northwest Power and Conservation Council (Council) fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31963	16	finnegd@wwu.edu	N/A	Cultural Importance to Indigenous Tribes Lastly, the recovery of salmon and steelhead runs is of the utmost importance to indigenous tribes who sustainably fished the Northwest rivers for hundreds of years. They reserve the right to fish for sustenance and preservation of culture, and restoring a free flowing Snake River will help to ensure this for years to come.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are also engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study.Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
31968	1	kairos42@earthlink.net	N/A	14 Fatal Flaws that render the DEIS pointless, necessitating immediate breach in 2020. 1. Peaking, Ramping, Balancing, & Reserve hydropower benefits of the Lower Snake River Dams (LSRDs). - Claimed over 2,000 MW with a value of $966 million for replacement cost. - Inconsistent with claimed 15 MW in 2002 EIS, Waddell et al. 2020 Claims of Sustained Peaking, Ramping, Reserve, Flexibility and Balancing Power from the lower Snake River Dams, What Is Feasible?	The EIS power analysis relies on historical data on the ramping and flexibility of the four lower Snake River dams. Table 3-160 (in the draft EIS) in Section 3.7.3.5 presents the historical sustained ramping capability of the four lower Snake River dams. Contrary to the statement in the comment, the 2002 FREIS identified the lower Snake River dams as 15 percent, rather than 15 MW, of the Federal Columbia River Power System ramping capacity, which is higher than the amount discussed in the EIS.
31968	2	kairos42@earthlink.net	N/A	2. Recreation Visitation Estimated at 2.4 million non-local visitors/year for LSRDs. - 2.4 million visitors is more than those going to Mt Rainier, 6,575 visitors every day. - Data from 2002 EIS since corrected to 53,000 visitors/year by Earth Economics 2016 National Economic Analysis of Four LSRDs. - Used to extrapolate Multiple Objective 3 (MO3) losses of 1,420 jobs, $59 million in labor income, and $189 million in annual sales. No benefits quantified, though 3-4,000 jobs would be created (Earth Economics 2016).	As described in Table 3-256, visitation at Lower Granite accounts for over 60 percent of visitation at the four lower Snake River projects. The Corps counts visits as recreation visitor days for all non-campers. For example, 2 people boating on a reservoir for 2 days would count as 4 visits. For campers, consistent with NPS visits, campers are counted per night. That is a party of two stay for two nights is counted as 4 visits. This may account for relatively higher number of visits as each day that a person visits is counted as a "visit." The visitation data comes from Corps sources, including traffic counters and visitor use surveys and includes the most up to date visitation data available at the time of the analysis. It should be noted that project visitation data (at each reservoir) includes recreation areas on the reservoirs as well as recreation areas located above the lake or below the dam in the river reaches. Section 3.11.3.5 describes the impacts under MO3 in the long term when the transition to river conditions is complete. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. This visitation in the long-term is predicated on the need to developed access to the river resource. However, a specific estimate of river-based visitation was not provided because of the uncertainty and the large range in potential visitation. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
31968	3	kairos42@earthlink.net	N/A	3. MO3 anadromous fish mitigation with additional hatchery salmon, cost of 78.1 million. - Absent in the 2002 EIS breach alternative because appropriate timing is in winter, when almost no fish are in the river. Breaching is the mitigation, preventing the death of ~8 million chinook smolts per year.	The breaching would be timed as well as can be controlled to take place outside of the migration period. However, the hatchery fish mitigation is to provide fish during the short-term to address impacts associated not with the demolition, but the flushing of stagnant water and sediments as the reservoir elevation drops substantially. This is anticipated to drop dissolved oxygen levels in the water column significantly, and potentially cause 2-7 years of no biological productivity and aquatic losses. Description of these impacts are in the Multiple Objective alternative 3 analysis for water quality and fish in Chapter 3.
31968	4	kairos42@earthlink.net	N/A	4. Salmon survival/mortality data insufficient. - Does not assess latent and reservoir mortality, SAR values, and recovery standards for each multiple objective even though the Biological Opinion says the PA adversely affects all stocks.	Latent mortality, reservoir mortality and SAR values are assessed extensively throughout Section 3.5 and Chapter 7. Recovery efforts referenced in this comment and references to the Northwest Power and Conservation Council (Council) fish and wildlife program with associated target for broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31968	5	kairos42@earthlink.net	N/A	5. Snake Chinook deemed insignificant prey source for Southern Resident Killer Whales (SRKW). - Ignores NOAA data on SRKW diet.	The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident Killer Whale (SRKW), along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the SRKW depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The MO3 analysis for SRKW will be revised in the FEIS to reflect this clarifying information on the overall importance of Snake River Chinook to SRKW.
31968	6	kairos42@earthlink.net	N/A	6. Irrigation mitigation of MO3 based on devaluing irrigated land, 47,840 acres at cost of $313.7 million. - Mitigation method justifies loss of 4,800 jobs, $232 million in labor income and 460.5 million in sales. - Pipe extension and pump installation mitigation overlooked, estimated at $20 million from Sampson, Rob 2018 A brief review of the impacts to irrigated farmland from breaching the four dams on Lower Snake River.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks. This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
31968	7	kairos42@earthlink.net	N/A	7. MO3 navigation rate increase based solely on opinion of some stakeholders. - 25 to 50% increase in rail shipment costs cannot be justified without cost estimate modeling and supporting data. - Use of recently upgraded rail line along the snake that can move all grain to market is not mentioned.	How rail rates would change without lower Snake River shallow draft barging can not be known with certainty. Therefore, in order to evaluate the impacts of potential rate increases, a range of rail rate increases were evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased, freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID to Ayer Junction, WA. Our research suggests that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers.
31968	8	kairos42@earthlink.net	N/A	8. Navigation dredging of Lake Wallula/Lower Snake in MO3 with cost of $76 million. - 2002 EIS did not include this cost because no dredging is required in this location, breaching sediment drops out above Ice Harbor. 9. Flood conveyance dredging at Lewiston absent in multiple objective costs. - Should increase cost by approx. $12 million/year for NA, MO1, MO2, MO4 & PA.	Updated estimates of dredging costs were done for Lake Wallula / Lower Snake. In regards to conveyance dredging near Lewiston, dredging costs were developed based upon historic dredging quantities and costs. Although these costs may generally be referred to as simply dredging costs or navigation dredging costs, dredging outside of the federal navigation channel could still occur in the future if needed and are captured within the historic quantities. Dredging costs were included for all alternatives, and it is recognized that dredging would no longer be needed on the lower Snake near Lewiston, ID under MO3.
31968	9	kairos42@earthlink.net	N/A	10. LSRD breach cost from 2002 EIS without mitigation uncorrected and escalated to $994 million. - Error of approx. $600 million, from Waddell et al. 2016 Reevaluation of The Lower Snake River Juvenile Salmon Migration Feasibility Report And Supplemental Environmental Impact Statement Appendix D Natural River Drawdown Engineering. - Stated as $994 million in chapter 3, inconsistent with appendix Q that says it is $955 million.	Engineers and cost estimators at the USACE reached out to dam-breaching experts at the Bureau of Reclamation and considered techniques used at other facilities. Approaches and constraints associated with those techniques were compared to those used in the 2002 EIS and determined that the approach used in the 2002 EIS was still appropriate. The USACE engineering and cost estimators then double checked engineering requirements, quantities, and reestablished cost estimates based on current prices. Breaching costs are estimated to be $994 million in project first costs (no discounting), $953 million discounted and presented in 2019 dollars, or $36 million in annual-equivalent costs over the 50-year period (using a discount rate of 2.875%).
31968	10	kairos42@earthlink.net	N/A	11. Congressional authorization assumption for MO3 incorrect.	Breaching the earthen embankment of the lower Snake River dams is a major Federal action that conflicts with the authority granted by Congress under which these projects were constructed and are operated. Therefore, de-authorization of the projects by Congress would be required prior to breaching. Breaching would require expenditures from the Federal government to implement the action which have not been appropriated. The co-lead agencies do not have the authority to override Federal decisions of Congress, remove congressionally-approved purposes, or appropriate Federal monies outside of the decisions outlined in annual Congressional Federal appropriation bills. De-authorization and appropriation for the breaching of the earthen embankments are a requirement to implement MO3. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
31968	11	kairos42@earthlink.net	N/A	12. Breach alternative MO3 conflated with construction and mitigation costs on other dams.	The EIS considers the costs to implement the structural and operational measures under each of the alternatives across the CRS of 14 dams. As a result, costs are assessed across the CRS. In Appendix Q, the costs are identified by project, including capital (Table 4-1), and operations and maintenance costs (Table 5-1). Mitigation costs include fish and wildlife mitigation as well as addition mitigation to reduce the adverse effects of the alternatives. These costs are described in Chapter 6 of Appendix Q.
31968	12	kairos42@earthlink.net	N/A	13. Power Replacement Costs & Loss of Load Probability overstated for 1,000 MW. - Least-cost power resource acquisition strategy not modeled, most up-to-date costs of wind and solar not used for cost replacement, if needed.	The EIS presents a range of replacement resource costs that would be needed to maintain regional reliability at the No Action Alternative levels based on two resource portfolios: one that is based on renewable resources and another that is based on natural gas resources, which are generally the least-cost means to maintain reliability (see draft EIS at Section 3.7.3.5, Potential Replacement Resources and Associated Costs). The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources available at the time of the analysis, the 7th Power Plan and Mid-term updates. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, at Section 2.2 in the draft EIS. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for MO3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the Final EIS. The Final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan.
31968	13	kairos42@earthlink.net	N/A	14. Greenhouse gas emissions from LSRDs ignored in MO3. - From US Department of Energy 2013 Evaluating greenhouse gas emissions from hydropower complexes on large rivers in Eastern Washington.	Appendix G, Chapter 5 of the Draft EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8 in the Draft EIS. Section 3.8 and Appendix G include references to and discussion of Amtzen et al. (2013), research supported by the U.S. Department of Energy referenced in this comment. In the case of the four lower Snake River dams, recent research concluded that data were insufficient to estimate the reservoir methane emissions specifically for the CRS projects, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The Draft EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
31971	1	arlynnh@hotmail.com	N/A	I am against this document. A significant percentage of Idaho's economy is based on tourism. Recreation & fishing on Idaho's waterways are essential to Idaho's economy & heritage. This document does not provide for improving our native fish to recover to numbers that will allow the healthy harvest necessary for our economy	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
31973	1	rmerriman4600@gmail.com	N/A	I am very concerned that "Breaching 'the 4 Dams would result in a major economic economic impact to the Northwest. Any change ;to an area (people-highways-dams-etc.) has positive and negative values; the existing dams positive values far outweigh the negative. Fish survival numbers are negatively impacted by many issues - not just dams; compare fish survival changes to the non-dam rives in the NW. Does "Breaching" dams include all dam structures and foundations, back to pre-dam conditions; ? Is this included in the cost estimates?	The co-lead agencies acknowledge there are many factors that affect salmonid populations that are outside the authority of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Additionally, the co-lead agencies did not evaluate an alternative that would breach all dams because of the unreasonable impacts to public health and safety from reduced reliability and flood risk management. Finally, there are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. MO3, includes removal of the earthen embankments and adjacent structures also known as Breach Snake Embankments throughout the EIS. The demolition would remove the earthen embankments, abutments, and portions of existing structures at the dams to eliminate the reservoirs behind the Lower Granite, Little Goose, Lower Monumental, and Ice Harbor Projects. In addition, equipment and infrastructure would be modified to adjust to drawdown conditions at each lower Snake River dam, known as Lower Snake Infrastructure Drawdown throughout the EIS. In order to implement breaching, the reservoirs would be drawn down to spillway elevations. In order to evacuate the reservoirs below this level, three turbines at each of the four lower Snake River dams would be modified so that they could be used as low-level water outlets to support a controlled drawdown of the reservoirs. The post-breaching condition would not be established to "pre-dam conditions" as some of the infrastructure would remain in place. The cost analysis in Section 3.19 and Appendix Q describes the CRSO EIS implementation and system costs. The costs associated with the breaching the Snake embankments and infrastructure drawdown are included as part of the "construction costs of the structural measures" (see Chapter 3 and Annex A of Appendix Q), with a construction first cost of $994 million or an annual equivalent cost of $36.2 million.
31979	1	cberven@moscow.com	N/A	I am writing to express my strong displeasure with the Preferred Alternative for the Draft EIS. I have two major issues with it. First it does not sufficiently ensure a return rate for 4% or more for the smolt-to-adult return rate. A sufficiently high return rate is of absolute necessity if the native wild salmon and steelhead stocks are to be self-sustaining. No amount of mitigation using hatcheries will sufficient to help the wild stocks.	The 4% average SAR target referenced in this comment and references to the Northwest Power and Conservation Council (Council) fish and wildlife program with associated targets for broad-sense recovery are separate and distinct from the obligations of any single entity or, in this case, a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
31979	2	cberven@moscow.com	N/A	Second, the Preferred Alternative Draft EIS ignored the positive economic impact of having healthy salmon and steelhead stocks for the communities that rely on them; specifically sport-fishing. These communities are much more than just the local ones as healthy populations of salmon and steelhead have an impact up and down the coast of the the Pacific Northwest. It is amazing to me that information that was available that could have been use to show the very positive economic impact of sport-fishing and other benefits to have healthy salmon and steelhead populations was ignored in favor of only qualitative analysis when all other economic impacts were quantified.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
31981	1	tmyrum@wswra.org	Washington State Water Resources Association	See attached letter	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
31995	1	N/A	N/A	Thank you for the opportunity to comment on the 2020 CRS Draft EIS. While the DEIS is extremely long and detailed, I find the report and the preferred alternative along with the cancelled public meetings exceedingly insufficient and completely unsatisfactory. In fact, Im shocked that such a minor effort would even be suggested as a solution to such a major disaster. It is primarily due to the extensive system of dams on the CRS that two iconic NW species salmon and resident orcas - are on the brink of extinction, while salmon-dependent Native American Tribes on the rivers experience extreme poverty and the solution is to allow a little more spill over a handful of dams? The minor improvement of allowing more spill is an operational tweak that should have happened decades ago in response to the growing emergency, and it should have been accomplished with an internal memo. All evidence points to the removal of the four lower dams on the Snake River as the salmon and orcas best chance of survival, and the only way to restore Native American fishing treaty rights. While this solution is accompanied by some expense and requires certain sacrifices, the financial costs can be recovered by decreased dam maintenance and salmon management expenses, while the devastating prior sacrifices of the few would be more equitably shared by the many.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Additionally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia Basin. The EIS analysis in Section 3.6 (Wildlife section) found only a potential for negligible to minor beneficial effect to the Southern Resident killer whale (SRKW) would result from implementing MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3, with long-term increases in wild prey. The co-lead agencies do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation and trap and haul facilities described in Chapter 5 and the fact that these additional hatchery fish should mitigate short-term construction effects to Snake River populations.
31995	2	N/A	N/A	The DEIS Preferred Alternative does very little to improve the outlook for salmon and the orcas who depend on them. It does almost nothing for the Tribes who have been promised access to salmon by treaty, and whose traditional lands and fishing sites necessary for the continuance of culture have been flooded. It will do very little for recreational fishermen and women, as well as guides upstream and down; and it does nothing to address climate change and the warming waters behind the dams that are killing young fish heading to sea. The preferred solution clearly privileges and props-up the status-quo at all costs. But the status-quo is a crime against nature: the CRS has a near-death strangle-hold on the Columbia River and its tributaries with dozens of dams: not satisfied with more than sufficient hydropower and water, the powers-that-be (especially and historically non-Indians) had to have it all and want to keep it all. I would argue the next CRS Management Plan must be measured against the status-quo of the majestic Columbia River System that once was not the strangled and subdued current version. I offer the following specific observations about the report to support my conclusions: 1.The lead agencies essentially ignored what the US District Court ordered, and the preferred solution comes nowhere near preserving - much less restoring - native salmon and steelhead. This DEIS is the result of the Opinion and Order from the U.S. District Court of Oregon, which as quoted in the report, states the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species, or result in the destruction or adverse modification of designated critical habitat. The Preferred Alternative of increased spill is, thankfully, already in-place, but according to reliable independent science will not reverse the decline of endangered species. The report suggests increased spill could improve juvenile fish survival by, at most, about 30%. According to the DEIS, up to 16 million fish migrated up the Columbia River before the late 1800s, but now the numbers are reduced to about 1.5 million, 40% of which are hatchery-born and managed at great expense - including being literally vacuumed up and trucked around dams! This approach has been a great failure at great expense, yet it remains a part of the Preferred Alternative. Quoting again from the report: Tremendous effort and billions of dollars have been invested in infrastructure, hatcheries, and other projects to improve passage and habitat for fish in the basin over the last 50 years. So, in conclusion, the Preferred Alternative appears to be to 1) continue spending billions of dollars to maintain current, artificially propped-up and dangerously low fish populations, and then 2) supplement those extremely expensive and insufficient populations with a 30% increased spill at most - of currently depleted juvenile fish populations over the dams, and 3) asserting that this modest improvement solved the problem and averted extinction! The world watched in horror as a mother resident killer whale pushed her dead newborn along the surface of the Salish Sea for 18 days, desperately willing the baby to survive: the whales are starving to death. What happens to the CRS impacts Puget Sound, and the public will no longer tolerate these half-hearted, dis-ingenuine solutions.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The co-lead agencies used the best available science and current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The Preferred Alternative will improve fish migration times which reduce vulnerability to predators. Likewise, continued habitat improvement actions such as those submitted in the proposed action to NMFS and the U.S. Fish and Wildlife Service will continue to improve rearing habitat. Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation. Both Biological Opinions concluded that the proposed action will not jeopardize the continued existence of or destroy or adversely modify the designated critical habitat of ESA-listed species. The comment incorrectly implies that hatchery fish are not relevant to the CRSO EIS. However, hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have a legal requirement to produce hatchery fish as mitigation for components of the CRS. The co-lead agencies do not agree that all statistics claimed in this comment are accurate (e.g., hatchery percentages, percent spill increase associated with Preferred Alternative, associated salmon/steelhead response to Preferred Alternative spill, and characterizations of the transportation program) and refer the commenter to Chapter 3, Section 5, and Chapter 7 for a more precise representation of those topic areas. The population dynamics of the SRKW are complicated, and there is no one factor that contributes to overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to SRKW would be minor. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
31995	3	N/A	N/A	2. Even though the report goes to great lengths to include extensive description of the pain and suffering the dams have caused Native Americans, there is NO MENTION of even attempting to right some of these wrongs in the Preferred Alternative. Quoting from different sections of the report, It is difficult to overstate the effects the CRS has had on tribal culture, way of life, and traditions Many of the tribes have not only lost access to traditional places, but have lost access to the one thing that all these places on the river had in common, which bound them together - the salmon Present tribal suffering stems, in large part, from the cumulative stripping away of tribal Treaty-protected resources to create wealth for non-Indians of the region; bureaucrats [at the time dams were built] asserted that uncertainty regarding impacts on salmon could be managed. And yet, nothing in the Preferred Alternative addresses these historic wrongs, when this would have been the perfect opportunity. Removing the 4 lower Snake River dams restores the salmon and treaty-guaranteed tribal fishing rights. But according to the report, Many of the facilities and much of the infrastructure that make up the CRS were put in place before legislation or enactment of executive orders that required the U.S. government to consider the effects these actions would have on the natural and cultural environment, and tribes. When the tribes did raise their concerns, they were often ignored or minimized: The report appears to conclude that since there were no laws preventing these abuses in the past, the co-lead agencies are not responsible for fixing or even addressing them in the present. This was a golden opportunity lost.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. The scope of the EIS focuses on the area affected by the alternatives presented for operation, maintenance, and configuration of Columbia River System Projects. The alternatives are evaluated in terms of change from the No Action Alternative, which is the baseline condition of 2016 when the development of the EIS began. The co-lead agencies defined the No Action Alternative consistent with NEPA and implementing regulations. In the case of an ongoing action, such as operation of the CRS, the no action alternative represents no change in current management direction or level of management intensity. The no action alternative thus assumes the existence of the CRS projects and does not attempt to hypothesize the direct and indirect costs of each of Congress's decisions to construct CRS projects. Under NEPA, the co-lead agencies are required to analyze a range of alternatives, including the No Action Alternative, to meet the purpose and need of the Project. The EIS analyzing the effects of the No Action Alternative on resources, environmental and socioeconomic, at present and into the future. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
31995	4	N/A	N/A	3. The Preferred Alternative clearly prioritizes all other Congressionally-authorized purposes of the CRS including flood risk management, navigation, hydropower generation, irrigation and water supply over fish and wildlife conservation. This is especially true since the four lower Snake River dams are not needed for flood control; they currently produce surplus power (which could be replaced with efficiencies in other dams and renewable energy); irrigation/water supply is possible without dams; and rail transportation could replace barges. This is not to discount or minimize the impact removing barge transport would have on farmers it would require careful, joint planning and likely compensation in the process, but the barges are government-subsidized transportation inasmuch as their costs are absorbed in dam maintenance. Farming and fishing communities both deserve opportunities thrive. While the above congressionally-authorized purposes are essentially the agencies missions, the mission is fundamentally flawed as it completely overlooks sustainability of the river ecosystem for future generations.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investments in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS finds that under MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.).
31995	5	N/A	N/A	4) Loss of hydropower by removal of the 4 lower dams on the Snake River could be readily replaced by a combination of increased efficiencies for the many remaining dams plus new, renewable energy sources, and would pay for itself in the long run. The cost of the new, renewable energy sources would be offset by significant savings realized when decommissioned dams no longer require upgrades and maintenance and increasing fish populations require decreasing amounts of expensive human intervention.	The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Northwest Power and Conservation Councils (Council) 7th Power Plan. The EIS analysis considered that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as under Multiple Objective Alternative 3. The EIS power analysis included all cost-effective conservation identified by the Council in the load forecasts analyzed in the power analysis (See Section 3.7.3.1 Methodology in the draft EIS). All cost effective conservation in the region is assumed to be acquired consistent with existing law and mandates regardless of the status of the four lower Snake River dams. The EIS did look at potential carbon-free resource replacements. Contrary to the claim in the comment, the EIS considered the avoided operations and maintenance (expense) and capital costs associated with dam breaching in the cost analysis and included these cost savings in the power rates analysis finding that costs increase, and there is upward power rate pressure under Multiple Objective Alternative 3. See Section 3.7.3.5, Bonneville's Fish and Wildlife Program and Lower Snake River Compensation Plan Costs, at page 3-913 and Section 3.7.3.5, Table 3-166 in the draft EIS.
31995	6	N/A	N/A	5) The warm water accumulating behind the dams is killing young fish before they can out-migrate, and the Preferred Alternative (as well as the No Action Alternative) would have no impact on water temperature, so it is simply unacceptable. The Preferred Alternative does not address climate change, whereas dam removal would.	The co-lead agencies' analysis of MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than conditions in the No Action Alternative in the lower Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during high air temperature events. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3. However, the Preferred Alternative also meets all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The dam breaching alternative, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding climate change, the climate science community is still developing models at the resolution necessary to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature to the Multiple Objective alternatives (Section 4.2.3) and the Preferred Alternative (Section 7.8.4).
31995	7	N/A	N/A	6) The DEIS erroneously suggests anything but the No Action Alternative would degrade air quality. Air quality can be maintained or improved with increased efficiencies and clean energy, whether were talking about replacing hydroelectricity or transportation.	The EIS considers renewable energy resources for replacing losses from breaching the four lower Snake River dams. As described in Section 3.8.3.5 of the Draft EIS, the analysis finds that, especially in the short-term, some level of fossil fuel generation would be required to maintain reliability in the electric system, and as described in Section 3.7.3.5 in the Draft EIS, the reliance on renewable resources would result in some tradeoffs due to the relatively high financial costs.
31995	8	N/A	N/A	7) The DEIS fails to acknowledge that, of all the alternatives considered, Snake River dam removal provides the greatest potential benefit for orcas and their survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives and only minor effects to SRKW. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
31995	9	N/A	N/A	8) Because numerous public meetings for public comment on the DEIS were canceled due to the Covid-19 pandemic, the public comment period needs to be extended. There is a great deal of public interest in this subject, but the teleconferences replacing the public meetings were not well-advertised, and teleconferences are far less appealing and democratic than meeting in person.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
32000	1	jameswarren58@hotmail.com	N/A	The life cycle of the Salmon is complex and fraught with problems. Some are man made and others occur as part of life in the natural world. I believe these very beneficial dams be left in place and operated as they were originally intended. That is, for example, no drastic drawdowns, minimize spilling, etc. With the dams in place we study and emphasize the following: * Expand barging of juvenile fish. If problems are found that can be mitigated reasonably we should move to support needed change. * The upstream bound adults must: 1. Return in numbers after completing the major part of their life cycle at sea. Man can monitor and somewhat control harvest. Most of the survival criteria at sea is at the mercy of nature. 2. Once the adults are in the system the main predator, the sea lion, must be controlled. 3. Access to spawning grounds must be available and as appealing to the spawning fish as possible. 4. If access to spawning grounds is not available it should be considered based on the estimated success of such efforts. This includes employing new techniques such as the pneumatic tube whoosh approach. All of these possible positive contributing factors are known to positively affect the Salmon. They should be given a chance to demonstrate their efficacy. In any case, removal of the subject dams and the possible inclusion of the removal of others, should be eliminated as an impediment to the cooperation of all involved for developing acceptable solution(s).	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The co-lead agencies received additional comments related to use of water cannons, or similar proprietary adult fish passage devices. The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. Many of the considerations for structural changes proposed in the EIS would be to address downstream juvenile passage and survival, as well as habitat concerns. The technology of fish cannons or similar devices will continue to be evaluated for future applications. Varying levels of transportation were included in all MOs with the exception of MO3 (dam breach). MO2 considered much higher levels of transportation that are currently implemented under the NAA. Transportation effects were also analyzed in the Preferred Alternative. The juvenile salmon transportation program is managed by expected fish benefits as well as cost efficiency. SAR estimate for each week of the outmigrations, combined with other environmental and biological data, drive the decisions. Prior to these data being available, transportation began at the beginning of April; however, we learned that fish transported in early April performed very poorly. Transporting too early is not effective and does not justify the expense.
32002	1	N/A	N/A	I am concerned about the ecological impact, cultural heritage, and state tourism associated with the health of the Southern Resident Killer Whales. I am writing to strongly support restoring the lower Snake River via breaching the four lower dams. Ecologists, marine biologists, and even former USFW members have concluded that this is the single most vital requirement to feed and support the Pacific Northwest's most iconic wildlife: orcas. The lower four Snake River dams currently serve as a geographical guillotine for wild salmon and steelhead. These dams prevent fish from both reaching the ocean and returning to their spawning ground to propagate--this is evident in low salmon return rate (~1%) and in the dwindling population of the Southern	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Resident orcas. Marine biologists have unquestionably implicated insufficient food as the cause of orca's lack of reproductive success; salmon is the historically staple diet for these orcas. Breaching the lower four would increase the salmon return rate to an estimated 4%, which would support and expand fish populations. A comprehensive review article concerning these orca's chances of survival can be found at: https://damsense.org/wp-content/uploads/2020/02/Feb-2020-Review-paper.pdf Additionally, we have treaty promises to uphold.	fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies conclude there could be a minor beneficial effect to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Also, see response to Comment 6110-16.
32002	2	N/A	N/A	We must honor commitments made with the Nez Perce, Shoshone-Bannock, Umatilla, Warm Springs, and Yakama Tribes. These Peoples gave up thousands of acres of their land for the right to hunt and fish in their "usual and accustomed places," a promise which has not been kept by our government. This is an injustice. Restoring the vitality of the Snake River by breaching the lower four dams is a first step to bolstering salmon runs and to honor our nation's agreements with native tribes. It is simply a moral action here.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study.Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
32007	1	N/A	N/A	Salmon need one thing, they need a river and after reviewing the EIS and comparing MO3 to the preferred alternative, Im definitely on the side of the MO3 plan. For just a moment, put all these figures aside and look at the basic needs for survival, food and water. There are alternatives to hydro-power and we need to lead the charge in clean and sustainable energyfor all, not just humans. Salmon is a huge food source for human consumption along with food sources for land and aquatic animals. Those animals are suffering due to human interference's and we will suffer when another food source of our own disappears. The preferred alternative is just a band-aid, the river needs to be restored to its original structure if we are going to see any massive increases to the population of salmon and steel-head fish. There are alternatives to hydro-power that do not rely on coal or other natural gases and the burning of fossil fuels as energy resources that would add CO 2 into the atmosphere i.e. solar, wind. I came across this article while researching alternatives to the use of dams for hydro-power, https://www.businessinsider.com/wastewater-sewage-heat-recovery-energy-2016-6 . I understand that for a quick fix that returning to a resource that is already known to work like the use of natural gases would be the easy solution, but easy doesnt mean that it is the best decision. The dams produce about 3k megawatts of power, that is not an astronomical amount that couldnt be replaced. Energy isnt going to feed you like salmon would.	To maintain regional power reliability at the No Action Alternative level, the EIS found that additional replacement resources would be necessary. The EIS considered a range of resource portfolios to replace the power output of the four lower Snake River dams. That range is reflected in two portfolios used to outline the potential resource options: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See draft EIS, Section 3.7.3.5 at pages 3-904-910. These portfolios represent a range of potential portfolios that could be used to return the regional power system to the reliability level of the No Action Alternative. Under both of these replacement portfolios, however, regional power rate pressure increases considerably. The rate impacts of these replacement resources, which includes cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166 and pages 3-920-924. As described in the EIS, even with the cost savings associated with reductions in dam maintenance and other costs, the net impact on power rates is in the range of between 13-50 percent (for zero carbon resources replacements) and 4-10 percent (for natural gas/least cost replacements). The region has also announced plans to retire most of the existing coal-fired power plants, and the combination of replacing the lost hydropower and the coal plants would require a very large investment in new zero-carbon resources. See e.g., draft EIS, Section 3.7.3.5, Coal Retirement Considerations at page 3-911 and Table 3-166. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options; however, to avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest.
32007	2	N/A	N/A	Restoring the fish will also honor the federal treaties with the local tribal communities that entered into these treaties with the understanding that their food and water sources would not be diminished or destroyed and unfortunately that is exactly what the dams are doing.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
32013	1	N/A	N/A	Hydropower is one of the most reliable forms of energy and Idaho's rivers provide immense amounts of power. Hydropower can alter environments along with the species around it. Since all species work together, if we lost Salmon, it obviously could alter the environment greatly. Salmon sort nutrients throughout the rivers when they migrate, which helps the trees live and grow. This can also alter the food chain and other species in that environment.	The Corps considered several actions that could balance power and ecological needs: Flexible spill. One major change that the Preferred Alternative represents is a new spill operation (flexible spill), which would test an innovative approach to balancing fish benefits and energy goals by spilling more water in the spring for juvenile fish passage. The intent of flexible spill is to increase spill when the projected value of power is relatively low, pass higher proportions of fish through the spillway, and spill less water for limited durations when the projected value of power is relatively higher (e.g., during peak power demand). The flexible spill operation creates an opportunity for a major potential benefit to salmon and steelhead through increased spill, as indicated by the CSS model, while avoiding many of the adverse effects to power generation and reliability associated with juvenile spill operations analyzed in MO4. The flexible spill operation in the Preferred Alternative would be implemented through an adaptive framework that allows the co-lead agencies to adjust operations as new information emerges. While the flexible spill operation was originally initiated under the flexible spill agreement, this type of operation is a major change from the No Action Alternative and how the co-lead agencies have operated the system historically.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Increased spill. As part of the flexible spill operation, we would increase planned spill up to 125 percent total dissolved gas levels at some projects, which is the new state water quality standard for maximum allowable total dissolved gas. Previous state water quality standards limited juvenile fish passage spill to lower amounts of spill. The goal of higher spill is to increase the number of juvenile fish passing through the spillways, in lieu of the powerhouse bypass systems and turbines, which is predicted to result in increased adult fish returns. Extensive regional collaboration. The flexible spill operation included as part of the Preferred Alternative is a result of extensive regional collaboration. Negotiations for the 2019-2021 Spill Operation Agreement began in the summer of 2018. The parties to the original agreement included Bonneville, the Corps, Reclamation, the states of Oregon and Washington, and the Nez Perce Tribe. The Preferred Alternative intended to build off of the collaboration fostered through the agreement and apply that to the existing regional coordination processes (Regional Forum). Other changes. The Preferred Alternative also contains measures to benefit resident fish, as well as lamprey, while providing reliable flood risk management, water supply for irrigation, and flexibility in hydropower generation that would be valuable for integrating wind and solar energy.
32016	1	N/A	N/A	This document was, as I read it, written to convey the agencies objectives and considerations. It is not apparent how the relative weighting of the various objectives compare. Overall, I am disappointed that greater seriousness isnt attached to the long term viability of anadromous fish. The agencies preferred alternative relies on tweaking the operational parameters, more than anything else, to satisfy all the competing objectives, perhaps better, perhaps only marginally, and perhaps no better. I write perhaps no better because in an era of climate change and increasing frequency of extreme events, such as warm ocean waters, hot water in the Snake or Columbia, or drought or anomalously high precipitation could further degrade the salmon and steelhead stocks, and their gene pool. And flexibly and adaptably tweaking operational parameters will probably not be adequate to improve Smolt to Adult Ratios enough to overcome the impacts of such climate change heterogeneity in ocean and weather events.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. The carbon-free attributes of the Federal hydropower system are described in the Air Quality Section of the Draft EIS (Section 3.8). The analysis includes the effects to GHG emissions resulting from changes in hydropower generation for each alternative, including breaching the Lower Snake River dams in MO3.
32016	2	N/A	N/A	Furthermore, there is to me another large concern that is entirely unaddressed in the draft EIS, based on all Ive been able to read. Forest health in the Pacific and Inland Northwest is linked to the nutrient pump that the anadromous fish runs provide. Fish go to sea, collect nutrients and climb up the rivers to spawn. Via predation and scavenging by myriad creatures of the forest ecosystem, these fish distribute these nutrients widely in the terrestrial ecosystem, and release their nutrients in the streams themselves, where the also and die and rot, nurturing both stream life and trees. In this era, with forests threatened by climate change, drought, bark beetles and other pests, it would seem important to reestablish the only significant nutrient import mechanism available to forests, anadromous fish runs. But the vision these agencies bring to these fish runs is pretty much business as usual, with little tweaks, to muddle by. It is a bad business to run an administrative process that has the potential, perhaps, to secure a future for these one magnificent fish runs, but that through balancing too many competing claims, fails.	The Draft EIS analyzes the effects of the alternative approaches to the operation, maintenance, and configuration of the CRS on anadromous fish abundance, which is the driving mechanism of oceanic derived nutrient cycling. The commenter is correct, there are broad ecological effects. However, the actual mechanisms, effects, magnitudes, and process are very complex and that uncertainty is reflected in the EIS. The co-lead agencies disagree that the Draft EIS preferred alternative is "business as usual." The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waivers and standards had to be changed to implement the new spill regime. The CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the NPCC recovery targets for the region) as a result of the Preferred Alternative.
32016	3	N/A	N/A	It seems that in the agencies analysis, a great weight is attached to the economic aspects of power production, associated power rates, and river transportation as primarily benefits the agricultural sector. There is already a significant well established subsidy of agriculture through federal price support for major commodity crops. Maintaining navigability for barges seems like another major federal subsidy. Cheap electricity for irrigation seems like a subsidy as well. In the current context of a federal US trade war driving off buyers for US grain, and damaging trade relationships for a indeterminate future, it seems imprudent to base decisions on a model of maximizing agricultural exports of previous years. It is also ecologically foolish to trade the future of anadromous fish for s few more years of agricultural earnings, which may indeed not eventuate, as grain is a global commodity and the profit margins are frequently marginal, and the full impacts of climate change are still to be experienced by our farmers. In summary, I cannot help but suspect that this process was constructed to arrive at conclusions acceptable to the agencies concerned. I think too little weight has been given to the value of restored runs of anadromous fish species, to the cultural importance of these runs to native American tribes, to the importance of these runs to forest health. I think the agencies ought to start over again, and think more deeply about this matter.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
32031	1	N/A	N/A	The dams are destroying our ecosystem. We need the rivers to flow freely in order for salmon to spawn and orcas to survive. It is all interconnected and our lives depend on it because this plays into our water filtration system we benefit from as humans.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
32032	1	mattrudolf@hotmail.com	N/A	I believe the time has come to eliminate the Snake River Dams and open up the habitat for enhanced spawning grounds. I disagree with my local wheat association that these dams are imperative for transportation and power production. Both of these have alternatives that will be cost effective for farmers and helpful to our environment for the future. The time is now. Remove the dams. Change is hard on people, but we farmers can adjust to rail and truck and downstream barging. The facts are that the Snake River dams help a small percentage of the wheat that moves on the Columbia. Most of the Columbia wheat is loaded downstream of the lower 4 dams on the Snake River.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investments in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS finds that under MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest).
32033	1	willowrose2@gmail.com	N/A	I strongly favor removal of the four Lower Snake River dams. Abundant research and documentation show that their removal will produce negligible, if any, economic losses to any parties. Barging of grain and other commodities can be transferred to train; energy production, already losing money, is being replaced by other more sustainable sources such as solar and wind. Cities such as Lewiston in the upper reaches of the river at risk of flooding, and subject to extremely costly remediation, will no longer be under threat, and while they may see some loss in sectors such as boating and lakeside businesses, other economic impacts will be positive. Above all, the dams' removal will restore one of the great inland waterways of the world and enhance the prospects for a return of salmon, whose numbers have fallen precipitously since the dams were built – almost to the point of no return. Renewed salmon runs up the Columbia and Snake rivers and their tributaries are a linchpin in a wider, long-term restoration and preservation of the inland waters, coastal salmon runs, orca and other predators in the food chain, and biospheres from the Oregon coast all the way to Alaska and back. Sports fishers, tourism entrepreneurs, riverside home and property owners will all benefit from a free-flowing Snake River. It's a no-brainer.	The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). An evaluation of flood risk management is provided in Section 3.9. It should be noted that the lower Snake dams are not authorized for flood risk management and this is clearly stated in the EIS in Chapter 1, Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the lower Snake River reach for any of the EIS Alternatives, although flood risk would be reduced with breaching of the lower Snake River projects. The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. AThe EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
32036	1	jon123ochi@gmail.com	N/A	Objectives #1 and #2: To Improve Juvenile Salmon (Objective #1) and to Improve Adult Salmon (Objective #2) could be thought of as a single objective. Intuitively, all else being equal, one can say the more adults returning to spawn, the more eggs, the more smelts, the more adults returning to repeat the cycle. Removal of the Lower Snake Hydroelectric Dams would benefit Juvenile and Adult Salmon. If we assume figure 5-4 Overall Dam Passage Survival	Regarding your comment on objectives 1 and 2, the commenter is correct that Smolt-to-Adult returns (SAR) and adult abundance changes reflect improvements to both juvenile and adult fish survival. Both in-river system survival estimates and SAR estimates modeled by the CSS and NMFS Life Cycle models include the cumulative effect of passing the four lower Snake River and four lower Columbia River dams. Additionally, the CSS model incorporates predictions of reductions in latent mortality effects of passing the dams.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				survival rates accurately portray the rate of fish survival in passing through the four Lower Snake River Dams (LSRDs) followed by fish survival rates in passing through the four Lower Columbia River Dams (LCRDs), the cumulative effects are noteworthy. By the data given in figure ES-4 one can see a loss of about one to seven percent of the fish at each dam. The uppermost dam, Lower Granite Dam, could result in losses of one to seven percent, followed by losses of one to seven percent repeated seven more times. Furthermore, the general weakening of the fish with prolonged stretches of flatwater at each of the eight dams degrades the health of the fish more both in downstream travel for smelts and for upstream travel of adults. The action of channeling the smelts to go around dams or through dams in certain locations means even the fish that survive the dam still are in weakened condition to survive the avaian, other fish, or mammal predators that await near the fish channels that spew out the smelts or the fish ladders that more precisely locate the adults salmonids, allowing predator attacks. And when the smelts reach the mouth of the Columbia the totality of damage comes from longer travel time, physical trauma at the dams from spill, trauma from predators, and combined with the warming effects of slackwater behind dams means the smelts must transition to salt water in a much weaker condition than had there been fewer cumulative effects.	
32036	2	jon123ochi@gmail.com	N/A	Objective #3: Restoring a free flowing Lower Snake River would Improve Resident Fish (Objective #3) by bringing the Lower Snake River to the status that resident fish evolved to fit into.	The commenter is correct. Increasing riverine habitat and reducing reservoir area would probably increase carrying capacity for some species of resident fish such as white sturgeon. There would likely be less habitat area for native and nonnative resident species that favor lakes and reservoirs including smallmouth bass, northern pikeminnow, and walleye. However, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The Preferred Alternative also meets the other objectives for the EIS, for juvenile and adult salmon and steelhead, hydropower generation, water management, and water supply, while also minimizing adverse impacts to communities and the economy.
32036	3	jon123ochi@gmail.com	N/A	Objective #4: Removal of the four Lower Snake River Dams while keeping the Lower Columbia River Dams would allow the majority of hydropower generation to continue to occur since the Lower Columbia Dams produce much more power and more reliable power (Objective #4) than the Lower Snake River dams. One economic benefit of the using only the Lower Columbia River Dams would be that the large and increasing cost of salmonid mitigation measures measured in the billions of dollars, would make the cost of the power generated at the Lower Columbia River Dams more economical (Objective #4). Simply put, lowered costs for salmon mitigation would lower hydropower costs for the entire Columbia River System of hydropower. The lower Columbia River Dams were built earlier than the lower Snake River Dams. One can correlate the dramatic salmonid declines in Snake River populations to the installation of Ice Harbor, lower Monumental, little Goose, and lower Granite Dams. So we already know that removing the Lower Snake River Dams would further enhance Objective #1 and #2. The power from loss of the four Lower Snake River dams could be generated from a source as reliable as the lower Snake River Dams. The potential for alternative energy sources will be noted later in this paper.	The Preferred Alternative meets Objectives 1, 2 and 4, as documented in Chapter 7 of the EIS, including Table 7-1 in the Draft EIS. While there would likely be some long-term reduction in mitigation expenditures if the four lower Snake River dams were breached; those savings would be exceeded by the costs associated with development of replacement resources needed to bring the region back to current reliability levels. The reduced dam operating and fish and wildlife mitigation costs are discussed for MO3 in Section 3.19 and Appendix Q. For MO3, Bonneville's Fish and Wildlife (F&W) Program is estimated to cost $282 million annually and includes mitigation projects and studies across the Columbia River Basin. As stated in the CRSO Draft EIS, funding decisions for Bonneville's F&W Program are not being made through the CRSO EIS process. Future F&W Program funding decisions would be made in consultation with the region, through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Based on the inherent uncertainty of Bonneville's F&W Program funding requirements, with breaching the four lower Snake River dams, a range was provided for MO3, from current levels ($282 million annually) to $177 million annually, a reduction of $105 million. Bonneville currently pays US Fish & Wildlife Service approximately $34 million annually to operate fish facilities associated with the Lower Snake River Compensation Plan (LSRCP). Bonneville's funding authority for the LSRCP is directly tied to the operation of the four lower Snake River dams. In addition to LSRCP, approximately, $1 million annually is expended on the Columbia River Fish Mitigation associated with the four lower Snake River projects. Total F&W Program costs for the four lower Snake River projects could range from a low of $35 million ($34 million for LSRCP plus $1 million for Columbia River Fish Mitigation) to $140 million ($35 million plus $105 million in F&W Program funding). The range in potential reductions in these costs under MO3 is captured in the Power Rate Pressure Analysis, Appendix H Section 4.1. Appendix H, Section 4.1.1.3 describes the F&W Program costs and reduction in these costs under MO3. Annual equivalent capital, operations and maintenance costs would also be reduced by $107 million per year under MO3. Table 4-3 for capital and Table 5-4 for operations and maintenance. These savings, ranging from $142 million to $212 million per year are offset by the cost to replace the power of the four lower Snake River dams ranging from $270 million to $540 million as shown in Table 3-171, Table 3-171. Average Annual Social Welfare Effect of Multiple Objective 3 Based on the Increased Cost of Producing Power to Meet Demand (2019 U.S. Dollars) in the Draft EIS. Therefore, it is not expected that breaching the four lower Snake River dams would result in lower hydropower costs for the entire Federal Columbia River Power System.
32036	4	jon123ochi@gmail.com	N/A	Objective #5: The salmonid have no option other than to move through the Columbia and Snake River systems as part of their life cycle. But as human beings we do have some alternative sources of energy that could minimize greenhouse gases (Objective #5). On need only look at the world class wind surfing at Hood River to know there is tremendous potential for wind energy in the Columbia River system that could generate reliable and increasingly economical energy. Wind energy needs greater exploration. like it or not, the development of new, smaller, modular nuclear energy reactors is being developed. Nuclear energy technology has stagnated since it was first developed in the 1950s. The issues of waste recycling and safe shutdown would and should be addressed. Modular designs could be repeated in different locations without having to go through the entire National Environmental Policy Act (NEPA) process each time, a process that was necessary when every reactor was different. Nuclear energy also offers the benefit to minimize greenhouse gases (Objective #5).	In the zero-carbon replacement portfolio of the power analysis, the EIS considered wind energy as a potential replacement resource, but did not find wind cost-effective at improving power system reliability compared to solar for Multiple Objective (MO) Alternative 1, MO3, and MO4. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. Small modular nuclear reactors (SMRs) are not considered primary technologies by the Council and were not included in this step. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, Section 2.2 in the draft EIS. For MO3, under the full replacement sensitivity, consistent with the suggestion in the comment, the EIS did consider SMRs as a potential replacement for some of the attributes of the four lower Snake River dams and costs estimates are provided in Section 3.7.3.5. See draft EIS at page 3-909. However, as noted in the EIS, the ramping capability of SMRs is unknown. Thus it is unknown if an SMR would be able to provide ramping capability similar to the four lower Snake River projects at this time. See Section 3.7.3.5, at page 3-910 in the draft EIS. Appendix H, Section 2.2 in the Final EIS provides further discussion on the selection of replacement power resources.
32036	5	jon123ochi@gmail.com	N/A	Objective #6: Removing the four lower Snake River Dams would reduce some adaptable water management possibilities. Obviously, one could not have the same degree of flood control without the four lower Snake River Dams. But is flood control really a major issue in the lower Snake River? Moving water more quickly through the reaches of the lower Snake River would have some water management (Objective #6) benefits. Specifically, without the miles of slackwater pools behind the dams, water would have less heating as the world warms.	The lower Snake River dams are not authorized for flood risk management; see Chapter 1, Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the lower Snake River reach for any of the EIS Alternatives. Regarding water temperatures in the lower Snake River, it is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact.
32036	6	jon123ochi@gmail.com	N/A	Objective #7: Use of wind energy or nuclear energy could provide a source of electricity for irrigators who do pump water should the irrigators' pumps need to be altered in order to pump water from the Lower Snake River so that contractual obligations to provide water supply (Objective #7) could be met. It can also be argued there are contractual obligations to provide water supply (Objective #7) so that Tribes can continue to hunt and fish "in their normal manner." If our federal government fails to protect anadromous fish by letting them die off, it could well be considered a breach of treaty obligations that the Tribes would always be able to hunt and fish in their normal places.	To replace lost power generation in the alternatives such as MO3, the EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1 Methodology and Chapter 2 of Appendix H for additional details. Wind generation is a primary resource, but wind was less cost-effective for this alternative than the combination of solar, demand response, and storage technologies. See Section 3.7.3.5, at 3-904-910. Nuclear energy was not considered primary technologies and thus were not included as a replacement resource. The specific resources that would be acquired will be determined through formal resource acquisition processes, and any appropriate technology would likely be considered. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
32036	7	jon123ochi@gmail.com	N/A	Objective #8: The benefits of dam removal on the Lower Snake River would improve lamprey (Objective #8). Without Lower Snake Dam removal the lamprey, like the sockeye salmon are headed towards extinction. In sum, all eight objectives are enhanced by removal of the Lower Snake River dams. Why is not dam removal the Preferred Alternative or even given serious consideration as a reasonable alternative?	The substantial benefits to lamprey under MO3 are recognized and described starting on page 3-572, and benefits to sockeye salmon and other Snake River salmonids are also described in those respective Sections. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), as well as Pacific lamprey, but not as much as MO3, the alternative that includes the measure to breach the lower Snake River dams. However, the Preferred Alternative also meets the objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. MO3, the alternative that includes the measure to breach the lower Snake River dams, by contrast, has significant regional economic impacts and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy the multiple, complex and, at times, conflicting legal requirements that apply to the CRS.
32042	1	jpaul7@q.com	N/A	Since the first Columbia River EIS in 2002, there has been little change in the structure the US Army Corps of Engineers (COE) uses to evaluate projects. Unlike other government agencies, the COE cost benefits analysis does not include consideration of non-use values such as improving the economy of small rural communities due to the increase of tourism, recreation and supporting businesses. Economic increases in small towns along the river corridor would help keep and/or increase the local populations. If non-use values and resulting environmental benefits are ignored, then removal of the dams is not justified. The non-use values are the key to measuring the true benefits of dam removal. Granted, some sectors of the regional economy will experience a shift, however dam removal is fundamentally a massive public works project that will increase regional net jobs and income. Non-use values are valid and must be considered because of the overwhelming rationalization they provide for removing the lower Snake River dams. The EIS makes clear that not removing the lower Snake River dams is the best option for Snake River salmon and steelhead, but substantially underestimates the level of benefit. The final EIS should include a preferred alternative that addresses the removal of the lower Snake River dams. Agencies should call on Congress to make the necessary investments to replace the dams current benefits so we can both recover the fish and maintain a vibrant regional economy.	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. As described in the EIS, Section 3.15.2.2, "Best practices for benefit transfer identified in OMB Circular A-4 describe that meeting all criteria is difficult and that professional judgment is required in determining whether a particular transfer is too speculative (OMB 2003, 26). Given the limitations of the existing literature, this EIS does not include a quantitative benefit transfer of passive use values. This analysis acknowledges that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching."
32043	1	tomh@fhsupply.com	N/A	The thought of REMOVING THE FOUR LOWER SNAKE RIVER DAMS is A HUGH STEP BACK IN TIME. There is MORE FISHING AND RECREATION GOING ON NOW, THEN THERE EVER WAS WHEN THERE WERE NO DAMS. Have lived here all my LIFE, 75 years and have seen a lot happen on the River system. It is at a Record setting time for Fishing & recreational Activities, Beside the HYDRO DAMS AND THE SHIPPING, WHICH IS HUGH... Have lots of water for Recreation, and Irrigation.. Many Jobs would be lost if the Dams were removed, in all sectors of life.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The social welfare and regional economic effects to navigation and recreation under MO3 are described in Sections 3.10.3.5 and 3.11.3.4, respectively.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32045	1	oebuisness@yahoo.com	N/A	Until a source of power which equals hydro, the dams have to stay. To remove is to remove human lives due to hardship financially, lack of energy for food production and heat would not be affordable for many.	Multiple Objective 3, which includes breaching the four lower Snake River dams, was not identified as the Preferred Alternative in the EIS. The EIS acknowledges the importance of ensuring affordable electricity costs. Consistent with the comment, the EIS finds that replacing lost hydropower generation from the four lower Snake River dams increases electricity costs. See Section 3.7.3.5 Electricity Rate Pressure; see also Table 3-166 in the Draft EIS.
32052	1	fchorst1@gmail.com	N/A	This change requires that we consider not only our triumphs but our shortcomings and adapt accordingly. The chain of dams on the Columbia and lower Snake have created something impressive as a human feat, we have an inland seaport in Lewiston, Idaho, a landlocked state. That said, barging has decreasing economic benefit and farmers in the Palouse increasingly use road and rail transportation as its costs appear more competitive and attractive compared to barging	The EIS includes extensive analysis of the impacts of changes in navigation and transportation in Section 3.10. Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently, and removing that option would increase transportation costs for grain producers, as the EIS shows. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted.
32052	2	fchorst1@gmail.com	N/A	The other side of the economic equation that must be considered is not what are we gaining, but what are we losing by maintaining the status quo with this system of dams and reservoirs. Anyone who lives in the Pacific Northwest can attest to the fact the outdoor recreation in an essential part of not only our lifestyle but also our culture in this region. In addition to recreational sports like skiing, kayaking, biking, and hiking there are many outdoorsmen and women who are avid hunters and fisherman and tourism is a big industry for many of our communities. As our runs of steelhead and salmon diminish to nearing extinction these individuals, as well as the dollars that they would pump into the local, regional and state economies through the pursuit of these outdoor activities must be considered. Take the town of Riggins, Idaho for example. In good fish return years in the early 2000's their local economy benefited from an increase of dollars spent in the community of near $10 million. These fishermen and women not only buy licenses and supplies, but also shop at local businesses, eat at local restaurants and bars, and stay at local hotels. It is clear that the dams on the lower Snake river have served a positive roll economically for local communities in this area. Job creation of course is a big one, as well as the opening of supply channels through barging and power generation, but lets be real with ourselves and our community members.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The social welfare effects under MO3 on commercial fisheries are described as major and beneficial in the long-term in this reach, with increases in regional economic effects if commercial fish catch rates increase. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses.
32052	3	fchorst1@gmail.com	N/A	Barging, as noted earlier, is losing its edge economically in the northwest as farmers are finding it more affordable to ship via road and rail. Those in these local communities who are employed through the operation of these dams are important people and members of their communities. They should not fall through the cracks, and it is our responsibility locally and as a region to support these people. That said, supporting them does not mean maintaining the status quo if it does not otherwise make sense. As with any issue, is it right to put a special interest group, any special interest group over the greater good? I would argue it is not, but that does not mean we leave that group behind. Dam breach does not mean we forget these people. It means we value the service they've provided and we train and educate them to occupy new positions moving forward and enable them to continue to provide for their families and be positive and contributing members of their communities.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. As to the commenter's suggestion that employees be trained and educated in other positions, the co-lead agencies do not have the authority to provide this type of mitigation due to the effects of MO3. For Federal employees affected by MO3, if MO3 were the selected alternative, further discussion and planning would occur within the Corps to determine needs and placement of current employees.
32052	4	fchorst1@gmail.com	N/A	In the end what we have now, on the 900 plus mile journey from the upper reaches of the Salmon river to the Pacific through the Columbia River drainage is over 300 miles of what was once river now classified as reservoir. As we know the major killer of salmon is the fact that these reservoirs aren't salmons habitat and an overwhelming majority of smolts never even make it to the pacific.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32066	2	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Snohomish POD supports the Draft EIS Preferred Alternative as the favored outcome of the NEPA process and recommends it adopted in the Final EIS. Snohomish PUD recognizes the great difficulty facing the Co-Lead Agencies in balancing and managing a set of objectives for the system that are not only diverse, but in many cases compete with one another. The Preferred Alternative satisfies the Co-Lead Agencies' obligations under the Endangered Species Act and represents a blend and balance of operational and structural measures that satisfies both the multiple objectives and the authorized purposes of the CRS. The Preferred Alternative also recognizes the importance of mitigating any adverse impacts to the delivery of electric service and stability of the region's power grid.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation.
32066	3	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Support for the Preferred Alternative in the Draft EIS Snohomish PUD developed a set of guiding principles that served as the basis and lens through which staff considered, reviewed and interpreted findings of the CRS Draft EIS. At the conclusion of its own review, Snohomish PUD supports adoption of the Preferred Alternative in the Final EIS. The CRS Draft EIS represents an extraordinary challenge given the fact that the Co-Lead Agencies have such a variety of, and sometimes competing purposes to be balanced. The Preferred Alternative satisfies the Co-Lead Agencies obligations under the Endangered Species Act, while continuing to provide a reliable, cost-effective, and renewable source of power for the Northwest region. The Draft EIS scope and analyses have resulted in an informed alternative required by the EIS and the National Environmental Policy Act (NEPA) process.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation.
32066	4	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Snohomish PUD advocates that the Preferred Alternative be adopted in the Final EIS. The Preferred Alternative, as drafted, demonstrates that it is the more favored approach in aggregate for CRS operations in the near term. It also recognizes the importance of mitigating any adverse impacts to the delivery of electric service and to the stability of the regions power grid; critical elements for Snohomish PUD and the customers its serves. Adoption of the Preferred Alternative in the Final EIS will not preclude discussions among regional stakeholder forums and groups outside this EIS process. Snohomish PUD is committed to working with other regional stakeholders to explore what would be needed to arrive at a long-term, enduring solution that could benefit salmon and other endangered species while meeting the authorized purposes and needs of other users of the Columbia and Snake river systems whether inside or outside of this EIS process.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation.
32066	5	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Socioeconomic Considerations Socioeconomic outcomes associated with the alternatives studied in the Draft EIS vary in both the type of and the location of the impacts. The types of socioeconomic impacts described in the Draft EIS were principally noted as: Power and Transmission changes, Fisheries changes, Navigation and Transportation changes, Water Supply changes, Recreation changes, and Flood Risk Management changes. There was limited analysis of the distribution of such impacts across communities in the Draft EIS. As such, there should be recognition given that the distribution of socioeconomic impacts associated with the alternatives both positive and negative would likely not be equally distributed across sub-regions, communities, and customers. From Snohomish PUDs review of the Draft EIS, it appears many of the above listed socio-economic impact types will be borne by communities located closest to the CRS. For Snohomish PUDs customers, who are not as closely located to the CRS as other communities, the primary socioeconomic impacts come from Power and Transmission changes. While Snohomish PUDs comments focus on impacts most direct and relevant to its own customer-owners, it is important to acknowledge that in order to be an acceptable alternative for all communities, any identified alternative must also be generally equitable in its distribution of anticipated socioeconomic costs and benefits across sub-regions, communities, and customers served by CRS operations. The Preferred Alternative appears to represent the most equitable distribution of costs and benefits in that it balances regional Power and Transmission and Fisheries outcomes with more localized Water Supply, Navigation & Transportation, Recreation and Flood Risk Management impacts.	The statement in the comment that the analysis of socioeconomic effects differed across resources based on the location and magnitude of effects is consistent with findings in the EIS. For each resource, there is a discussion of the scope and scale of the respective socioeconomic analysis. For some resources, these effects are likely limited to the direct vicinity of the Columbia River Basin or even more narrowly to the region around the Columbia River System projects (e.g. the four lower Snake River dams for certain effects in MO3.Consistent with the comment, however, other effects like the power analysis have the potential to affect areas outside the Columbia River Basin and thus, had a larger area of analysis. Regarding the comment about distribution of effects from power outside the basin, the EIS power analysis considers effects at the county level and acknowledges that socio-economic effects are not evenly distributed across the region. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as maps for the distribution of effects by county for each alternative. As suggested in the comment, the Preferred Alternative includes a combination of measures from the alternatives, and seeks to balance across environmental, economic, and social objectives, one of which is ensuring reliable and affordable power. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
32066	6	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Impacts to Snohomish PUD Associated with BPA Rates Increases As BPAs largest customer who receives over 85% of its carbon free energy from the Federal System, Snohomish PUD and its customers are profoundly impacted by Power and Transmission Rate changes expressed in the Draft EIS. Table 1-1 provides estimates of the forecast BPA rate pressure associated with MO1, MO3, MO4, and the Preferred Alternative when compared to the No Action Alternative.1 The pressure on BPAs average Priority Firm (PF) power rate for the alternatives ranges from .4% to 2.7% for the Preferred Alternative, to highs of 40.8% and 50.3% for MO4 and MO3 respectively.2 Any rate increase can have detrimental effects on households and businesses within Snohomish PUDs service territory, but increases of the magnitude at the larger end of the spectrum could prove disastrous for communities. It is Snohomish PUDs perspective that the analysis likely underestimates the financial impacts of MO3 and MO4, and that the actual costs are likely to be both higher in total, and could also be proportionally higher for Snohomish PUD specifically.3 The anticipated increased cost, and increased cost share that could be potentially borne by Snohomish PUDs customers raises concerns about MO3 and MO4, and increases confidence that the Preferred Alternative is a more favored outcome for Snohomish PUD and for the region. Increases to retail electric rates create economic hardships not only for low-income residents, but also for fixed-income residents, housing-cost burdened residents, and businesses that may not be eligible for income-based	The statements in the comment that the Preferred Alternative would result in an increase of wholesale power rates (up to 2.7% including rate sensitivities) and that costs in the region would increase under Multiple Objective (MO) Alternative 3 (which includes breaching the four lower Snake River dams) and MO4 are consistent with EIS findings. See draft EIS, Section 7.7.9.1, Rate Sensitivity Analysis, Table 7-32; Section 3.7.3.5 at pages 3-918-924;and Table 3-166 and page 3-182. Consistent with the concerns voiced in the comment, MO3 and MO4 did not meet the EIS objective of providing an adequate, economical, efficient and reliable power supply, among others, and were thus, not selected as the Preferred Alternative. See Draft EIS, Section 7.3.4, Multiple Objective 3 and 7.3.5, Multiple Objective Alternative 4 at pages 7-8 to 7-15. The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 and Section 7.7.20 of the EIS) provides further detail on this as well as the potential disproportionate effects to tribal, low-income and minority populations. The EIS also discusses that Bonneville customers, such as public utility districts, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				rate relief. The following reflectperspectives on the diversity of Snohomish PUD customers who would be particularly hard hit by large increases in BPAs rates: Snohomish PUD works to aid its lower-income households by offering year-round, income-qualified rate discounts for electric service customers based on their total household income. In 2019, an average of 12,000 customers per month or ~5% of its residential customers were enrolled in this rate discount program. This percentage reflects enrollment during favorable economic times and no overall Snohomish PUD rate increases the past three years. County information and demographics suggest many more customers may be eligible for Snohomish PUDs discount program but are not enrolled today. Increases in electric service rates, with or without challenging economic cycles, would greatly increase the percentage of customers needing this income-qualified rate assistance. Communities with lower median incomes are more impacted by rate pressures, and in Snohomish County, these communities tend to be more rural and agricultural. The rate impacts of MO3 and MO4 would increase household costs, and increase costs for local schools, hospitals, and public amenities in these communities. For example, utility expenditures currently account for around $220,000 annually for the Darrington School District located in rural Snohomish County. This amount exceeds what is available annually for vocational training.4 A 50% increase in BPA power rates indicated as a high range estimate under MO3 would nearly double this rural school districts utility costs compared to what is budgeted annually for vocational training. Working households across Snohomish County face affordable housing challenges as median housing costs in Snohomish County continue to outpace wage growth. Between 2013 and 2016 housing costs increased by 30% in Snohomish County, while wages stagnated. By 2018 a family needed to make $26 an hour in wages in order to afford the average two-bedroom apartment in the county. In total, it is estimated that Snohomish County is currently short roughly 50,000 affordable housing units to meet residents needs.5 Snohomish County working families simply do not have the financial resources to absorb new utility rate pressures, especially if reasonable alternatives can be considered. Lastly, Snohomish County is home to over 18,000 business of various sizes that provide the economic fabric of the community, and account for a large share of the jobs for more than 800,000 residents. While these businesses are eligible for targeted energy efficiency incentives, they are not eligible for income-based rate-relief. As such, these businesses are also vulnerable to rate increases associated with some of the Draft EIS alternatives. About 20.8% of Snohomish Countys non-farm employment is in the energy-intensive manufacturing sector, the highest in the State of Washington, and higher than the national average. Snohomish County relies on its skilled labor force, aerospace niche, proximity to trade transportation AND relatively low energy costs to maintain its economic viability.	
32066	7	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	The Draft EIS Underestimates the Financial Impacts of New Energy Policies As noted above, Snohomish PUD respectfully posits that the vintage of the Draft EIS analysis likely underestimates the financial impacts, particularly of MO3 and MO4. This underestimation stems from the vintage of the alternatives analysis in that it underappreciates the impact of recent state policy changes and omits functions provided by the CRS in the form of non-power benefits to the region. In May 2019, Washington State adopted the Clean Energy Transformation Act (CETA), eliminating coal-fired electricity from utility portfolios by 2025, 100% greenhouse gas neutral portfolios by 2030, and serving retail customers with 100% clean power by 2045. This transformation has expedited removal of a significant amount of baseload, firm capacity from the regions portfolios, with an influx of new renewable resources and demand-side measures from utilities expected in order to meet the 100% clean power goals. While the Draft EIS evaluated the expedited removal of coal from the region, it did not simultaneously consider the availability of replacement resources to make up that capacity. One reasonable expectation is that regional renewable supply will increase along with demand-side measures including demand response. While the lowest cost replacement resource option in MO3 references 600 MW of demand response. Given recent energy regulatory policy changes, it is likely that only a portion of this demand response would be available. Much of the potential will have already been used or identified by utilities as a future resource to meet their own replacement and policy compliance needs. Another important cost consideration is the value of the CRS in providing reserves and renewable integration services. Assumptions for MO3 and MO4 note that other regional resources would be available to meet the peaking, storage, and dispatchable capacity attributes of the CRS lost under these alternatives. This assumption is not reasonable given the adoption of state energy policies like CETA and the forecast of regional capacity deficits in the near and mid-term. These recent regulatory changes underestimates the value of the CRS providing these services, and therefore significantly under represents the loss of value noted under the MO3 and MO4 alternatives.	The comment discusses changes in the regional power system and state energy policy and that these changes result in underestimated power system costs. Since the start of the CRSO EIS process in 2016, additional coal retirements have been announced as well as new energy policy such as Clean Energy Transformation Act in Washington. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See draft EIS, Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842 and Section 3.7.3.2, Table 3-123. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017, and the EIS presents base case analysis first before discussions of information resulting from additional sensitivities and potential cost pressures. These rate sensitivities are largely consistent with the concerns voiced in the comment. Specifically, the sensitivities estimate the costs of potential carbon compliance, and the effect of coal retirements on the replacement resources needed for each alternative. Table 4-10 in Appendix I of the draft EIS acknowledges specifically the 600 MW of demand response, as well as wind from Montana over transmission made available by the coal retirements, would likely be used to replace generation from retiring coal plants and may not be available to replace lost generation from reductions in Columbia River System hydropower. (For a description of all sensitivities see Section 3.7.3.1 Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis). In addition, Appendix H, Section 2.2 in the Final EIS includes a more comprehensive discussion of the steps involved in acquiring new resources. The EIS acknowledges that there would be more demand for generation flexibility and the ability to carry reserves in the power system as coal plants retire and flexible resources are needed to integrate new variable renewable resources. As a consequence of the increase in demand for flexibility to provide reserves, the value of this capability is likely to increase. The EIS partially reflects the costs of acquiring this additional flexibility in the rate sensitivity analysis. Please see the Integration Services sensitivity (reflecting the cost of additional balancing reserves needed to integrate replacement renewable resources) and the Ramping and Flexibility sensitivity (reflecting the cost of additional ramping and sustained peaking capacity needed in Multiple Objective Alternative 3). See EIS, Section 3.7.3.1.
32066	8	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Replacement Resource Costs are Likely Larger The Draft EIS states that replacement power resources identified under MO3 or MO4 could be replaced either by BPA or its customers. Snohomish PUDs estimate of its share of replacement resource attributable under MO3 to its BPA Slice product ranges from 50 average megawatts (aMW) of energy each year, to a total of 90 aMW of on peak capability which Snohomish PUD regularly uses to help meet its customers peak winter needs, and to balance the renewable generation in its portfolio. The estimated annual cost for this portion of Snohomish PUDs long-term BPA power contract could result in as much as approximately $40 million dollars of new costs annually. This equates to approximately an 8% rate increase per year for just half of Snohomish PUDs long-term BPA power contract. Any BPA replacement resource costs or rate increases would be additive to these new costs.	The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 and Section 7.7.20 of the EIS) provides further detail on this as well as the potential disproportionate effects to tribal, low-income and minority populations. The EIS also discusses that Bonneville customers, such as public utility districts, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. See draft EIS, Section 3.7.3.5, Residential Effects at page 3-929. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment. The EIS does consider two financing options, Bonneville or Region Financed, consistent with the statement in the comment. The comment is also consistent with the EIS that these replacement costs in the Region Financed scenario are additive with any Bonneville rate increases. It should be noted that even under the Region Finances scenario, there would still be an increase in Bonneville's rates resulting from the loss of firm power and the resulting redistribution of Bonneville's fixed costs over a smaller amount Tier-1 power sales. However, in contrast to the comment, the analysis assumed that Bonneville or the region would replace resources, not both, so any replacement opted for by regional utilities would not be in addition to Bonneville replacement resources.
32066	9	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Costs and Benefits of the Lower Snake River Dams Should be Further Explained Snohomish PUD recommends that the Co-Lead Agencies include within the Final EIS a clear, easy-to-follow summary that illustrates the relative costs and benefits of the lower Snake River dams, with a specific focus on electricity generation and transportation. Comments at the virtual public meetings brought to light a common misinterpretation of the economic value of the lower Snake River dams to the Co-Lead Agencies. This misinterpretation primarily involves the value of the electricity generated by these projects and the navigable waters and transportation services they provide. While these costs are already contained in the Draft EIS, they are not collected in a single location. A clear summary of these costs and benefits would assist in the evaluation of the alternatives in the Draft EIS and aid with future conversations around these issues. With respect to transportation services and navigation, this summary should show the costs involved in operating and maintaining the locks and other transportation facilities and services, and any revenues associated with lock operations and associated transportation facilities. The summary should also detail local and regional costs and benefits associated with providing irrigation and transportation access. It also would be helpful for the Co-Lead agencies to clarify for all categories whether such costs are inclusive, or exclusive, of fish and wildlife mitigation expenses.	Regarding the presentation of all the effects of the alternatives, Table 3-1 and Table 7-55 in the Draft EIS provide a summary of the effects for all the alternatives and resources, which includes many of the recommendations from the comment. Chapters 3, 4, 6 and 7 detail this effects analysis, and denote adverse and beneficial impacts, where appropriate. Moreover, Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. Note that a benefit cost analysis is not a requirement of NEPA or the basis of alternative selection under NEPA (40 C.F.R. 1502.23). Instead the direct and indirect effects to the natural and human environment were evaluated, including some effects that were evaluated quantitatively and monetized, while others were evaluated qualitatively. The comment noting the economic benefits and adverse effects of losing hydropower are consistent with the findings of the EIS. In response to this and other public comments, Chapter 7 of the Final EIS includes a table summarizing all socioeconomic effects at the end of the chapter (see Table 7-56).
32066	10	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	NEPA Process is Sufficient Snohomish PUD is confident that the Co-Lead Agencies approach and analysis meets the requirements of NEPA in that an EIS [r]igorously explore and objectively evaluate all reasonable alternatives to the proposed action, including alternatives not within the jurisdiction of the lead agency.6 The touchstone for courts reviewing challenges to an EIS under NEPA is whether an EIS's selection and discussion of alternatives fosters informed decision-making and informed public participation.7 The choice of alternatives is bounded by some notion of feasibility and an agency is not required to consider remote and speculative alternatives.8 The courts review an agency's range of alternatives under a rule of reason standard that requires an agency to set forth only those alternatives necessary to permit a reasoned choice.9 An agency need not consider alternatives that extend beyond those reasonably related to the purposes of the project.10 Finally, an EIS only needs to briefly discuss the reasons for eliminating an alternative not selected for detailed examination. The Draft EIS includes and analyzes six alternativesthe four multi-objective action alternatives, the Preferred Alternative, and a No Action Alternative. The scope of measures included in these six alternatives ensures informed consideration of a broad range of CRS operational actions, including: those that benefit ESA-listed fish species; increase hydropower generation; provide water management flexibility and water supply; and breach the four lower Snake River dams.12 Therefore, the NEPA process conducted by the Co-Lead Agencies is sufficient.	The co-lead agencies presented a range of alternatives for the continued operation and management of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. The co-lead agencies agree that the EIS followed the required NEPA process, fulfills the intent of NEPA in terms of sufficiency, and that the Preferred Alternative meets the Purpose and Need Statement. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32066	11	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Clarify the Purpose and Need Statement Snohomish PUD recommends that the Co-Lead Agencies clarify the statement of the purpose and need for the proposed action. Under NEPA, this statement, shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action.13 Accordingly, the statement should focus on the purpose and need for the continued operation of the CRS, and not simply the purpose and need of the environmental review being undertaken in the Draft EIS. In specifying the need to which they are responding, the Co-Lead Agencies state that it is to review and update the management of the CRS, including evaluating measures to avoid, offset, or minimize impacts to resources affected by managing the CRS in the context of new information and changed conditions in the Columbia River Basin since the SOR EIS was released, and to respond to the decision from the U.S. District Court for the District of Oregon regarding the evaluation of certain measure to address impacts to ESA-listed species and their critical habitat.14 While we recognize that these needs are focused on, and are the motivation for, the scope of the updated environmental review, Snohomish PUD encourages the Co-Lead Agencies to revise the statement further to explain the need for the continued operation of the CRS, which is the action that is being evaluated in the Draft EIS. The Co-Lead Agencies also identify a suite of resource, legal, and institutional purposes of the action.15 In part, the Co-Lead Agencies state that they must act within the authorities granted to the agencies under existing statutes and comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements.16 While these purposes relate to the general legal framework under which the Co-Lead Agencies operate, the Co-Lead Agencies should	The co-lead agencies drafted the Purpose and Need Statement to focus the analysis of the EIS, to frame the alternatives, and to convey to the public the overarching reasons for undertaking the EIS. The Purpose and Need Statement conveys the need for a long-term coordinated operation and management of the CRS projects for the multiple purposes for which the projects are authorized. The congressionally authorized purposes for the projects are briefly described in section 1.1 Background and more fully described in Chapter 3 under the specific resources. The co-lead agencies responded to the Order of Remand from the U.S. District Court for the District of Oregon and public comments to analyze breaching the four lower Snake River dams.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				revise these general statements to better correspond to the specific purposes for the action being reviewed in the Draft EIS. For example, this should include specifying the Congressional authorizations for the construction and continued operation of the 14 Federal projects.	
32066	12	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Ensure Objectives are Aligned with the Corresponding Purposes and Needs Snohomish PUD recommends that the Co-Lead Agencies provide additional explanation regarding the linkage between the identified objectives and the statement of the purpose and need for the proposed action, to ensure they are consistent. Under NEPA, the purpose and need statement establishes the range of alternatives that are considered.17 The Co-Lead Agencies explain that they first identified eight objectives for future management of the CRS in order to develop the alternatives. The objectives are described as statements of the desired outcome of various resource conditions that are expected to result by taking Federal action(s).18 In turn, the Co-Lead Agencies state that the alternatives reflect a combination of one or more measures that, together, would address one or more of the objectives.19 However, it is not clear that the scope of the identified objectives is consistent or aligned with all of the stated purposes and needs for the proposed action. Because the purpose and need statement dictates the range of alternatives considered, the Co-Lead Agencies should further explain the relationship between the stated purpose and need, their identified objectives, and the proposed alternatives. When specific statutes drive a proposed action, the Courts have explained that the statutory objectives of the project serve as a guide by which to determine the reasonableness of objectives outlined in an EIS.20 The Co-Lead Agencies should broaden and provide additional elaboration regarding how the identified objectives meet the corresponding purpose and need.21 By further describing the relevant objectives, and clarifying the relationship between the objectives and the purposes and needs for the proposed action, the Co-Lead Agencies would provide additional support for the scope of the identified alternatives and the selection of the Preferred Alternative.	The co-lead agencies provide an overview of objectives, the role of objectives in the study, and how they relate to the alternatives, in section 2.2 and in the Executive Summary of the EIS. Objectives are simply what the co-leads want to accomplish - the "why". They are the stated desired outcomes for operations and management of the CRS. Chapter 7 includes an evaluation of how well the alternatives, including the Preferred Alternative, meet not only the Purpose and Need Statement, but also the eight EIS objectives. At this time, the information and explanation of the objectives are sufficient to inform the public about the desired outcomes and to inform the decision makers.
32066	13	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Clarify Authority to Modify Congressionally Authorized Projects Snohomish PUD recommends that the Co-Lead Agencies clarify and further explain the scope of their authority to remove the lower Snake River dams (MO3). During the public comment period, there appeared to be confusion regarding the ability of the Army Corps to place the dams in non-operational status and breach the embankments without first obtaining Congressional approval. To address this uncertainty, the Final EIS should clearly describe the Congressional authorization for the construction and continued operation of the lower Snake River dams for their specified purposes.22 In addition, the Final EIS should explain the scope of the Army Corps existing authority to make modifications to completed projects.23 Finally, the Final EIS should explain whether, and to what extent, additional Congressional authorization and appropriations would be necessary in order to bypass one or more lower Snake River dam, and if authorization is required, the process by which the Army Corps would recommend and receive this authorization before potential action of this nature could be implemented.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
32066	14	jkallstrom@snopud.com	Snohomish County Public Utility District No. 1	Conclusion Snohomish PUD and its customers are profoundly impacted by the Power and Transmission Rate changes and any change in CRS coordinated operations that may adversely impact the reliability of electric service for the region. It is Snohomish PUDs view that: The cost impacts and rate pressures identified specifically for MO3 and MO4 have been underestimated; The severe impacts to reliability and increased likelihood of blackouts under MO3 and MO4 are wholly unacceptable for the region and for Snohomish PUD given its reliance on BPA; The actual availability of identified replacement resources is likely overestimated; and The value of the non-power benefits for the region from CRS operations is likely under-estimated given recent changes in state energy policy to shift away from fossil-fueled resources, specifically in Washington State. For these reasons, Snohomish PUD supports the Draft EISs Preferred Alternative as the more favored outcome for its customer-owners, businesses and communities.	The EIS recognizes the concern voiced in the comment regarding the impacts of increasing power rates and decreases in regional power reliability. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017 and that the energy sector is undergoing transformation. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See Draft EIS, Section 3.7.3.1, Availability of Coal Resources pages 3-841-842 and Section 3.7.3.2, Table 3-123. The EIS presents the base case analysis first before discussions of information resulting from additional sensitivities and potential cost pressures. These rate sensitivities are largely consistent with the concerns voiced in the comment. Specifically, the sensitivities estimate the costs of potential carbon policy compliance and coal retirements (for a description of all sensitivities see Section 3.7.3.1 Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis). Although the focus of the EIS is not on replacing coal generation, these scenarios highlighted the large regional need for replacement resources that would be competing with the need to replace any lost hydropower generation. While the EIS finds that MO3 and Multiple Objective alternative 4 (MO4) would lead to large increases in the risk of blackouts above the No Action Alternative, the potential replacement resources identified in the EIS are designed to return regional reliability to the level of the No Action Alternative once these resources are built and in service. As suggested by the comment, the Preferred Alternative includes a combination of measures from all the alternatives with consideration of environmental, economic, and social effects. Under the Preferred Alternative regional power reliability is the same as the No Action Alternative. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
32073	1	d_cbaldwin@msn.com	N/A	The prefered way to handle this problem is to have fish bypass options.	In terms of bypassing fish upstream: The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. The 4 lower Snake and 4 lower Columbia River dams also have systems for bypassing fish around turbines and powerhouses. Additional surface passage systems were considered but not carried into the Preferred Alternative. The Preferred Alternative uses increased spill to bypass more juvenile fish away from powerhouses.
32075	1	melissahallas@gmail.com	N/A	One of the ways the analysis could have addressed costs is by looking at the so-called savings that cheap hydroelectricity has provided for all these years and subtracted those from realistic energy sources that reflect limited hydropower (I'm acknowledging that a limited number of dams could be justified). Frankly, the cheap hydropower can be considered a form of blood money. Rampant greed and with it, the drive for development, caused a tiny segment of the population to make damaging decisions decades ago. The report states that two coal-powered plants would be used to make up for the loss to the electric grid should the lower Snake River dams be breached. But Bonneville already lost a major customer in California (https://www.eenews.net/stories/1061110823), so why is so much power needed? And if it truly is, why can't natural gas be used until renewables and batteries are more cost-effective?	There is nothing in the EIS that suggest that two coal-powered plants would be used to make up for the loss to the electric grid should the four lower Snake River dams be breached. All of the alternatives in the Draft EIS included two potential replacement portfolios: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Section 3.7.3.5, at pages 3-904-910 in the Draft EIS. In the zero-carbon replacement portfolio of the power analysis, the EIS considered wind energy as a potential replacement resource, but did not find wind cost-effective at improving power system reliability compared to solar. Until replacement resources are constructed, existing natural gas plants would likely increase generation to help meet demand in the Northwest. However, the region would have roughly double the risk of power shortages until new resources are on-line. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements would likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their 7th Power Plan (page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS; see also Appendix H, Power and Transmission, at Section 2.2. While it is true that California is developing large amounts of wind and solar power, sales to California on the wholesale spot market are only a small fraction of Bonneville's sales, and California continues to purchase power from Bonneville and other Northwest utilities on the wholesale spot market.
32080	1	N/A	N/A	The proposals are limited and have great bearing to the preservation of salmon and steelhead for future generations. We are in agreement with the former commissioners statement: Recommended Alternative Approach Although a regional solution will be required to recover Idaho's salmon and steelhead, these fish are first and foremost the heritage of the citizens and tribes within Idaho.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
32080	2	N/A	N/A	In order to move toward achieving the mandates of the Endangered Species Act regarding listed salmon and steelhead, a much more aggressive approach will be required than the DEIS Preferred Alternative. Efforts should strive to recreate, as closely as possible, the natural migration conditions under which salmon and steelhead evolved. With the prospect of challenging ocean conditions becoming the norm while climate change is addressed, aggressive actions must be taken now and not delayed by waiting for yet another biological opinion cycle.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The Co-Lead Agencies recognize that there are many effects to salmon and steelhead populations outside those associated with the maintenance and operation of the dams, including ocean conditions. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such all of the models used in these analyses use metrics of ocean productivity to predict adult returns. An example of the important ocean metrics can be seen at: https://www.nwfsc.noaa.gov/research/divisions/fe/estuarine/oeip/g-forecast.cfm.
32080	3	N/A	N/A	Multiple Objective Alternative 3 calls for breaching the four Lower Snake River (LSR) dams, this alternative clearly provides the best choice to attain the objectives for the salmon and steelhead. The breaching of the four LSR dams must be approved as the final objective. Both the CSS and the LCM models show that this is what is best for the fish. It is recognized that the approval of MOA 3 will require time to implement as congressional approval and appropriations are required for both dam removal and the many programs that will be necessary to make whole those adversely effected by this action. It is imperative that we recognize the fish may not have the time to wait for implementation of this MOA. There are alternatives to power and transportation issues, however, once extinct, the wild fish cannot be brought back. Any continuation of the status quo in any form, including the tinkering with the status quo represented by the Preferred Alternative, is essentially a decision leading to eventual extinction of wild anadromous fish in Idaho. Therefore, it is recommended that commencing in 2021, Multiple Objective Alternative 4 be implemented in the interim while Multiple Objective Alternative 3 is authorized, funded, commenced and completed. CSS modeling clearly shows positive results from a program of 24 hour/7 day per week spills over all eight Columbia River system dams. The LCM is less definitive but shows that improvements in SARs are likely. Please consider MOA 4 as our recommendation for immediate implementation, with study and consideration for MOA3 in the future.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The alternative that includes a measure to breach the lower Snake River dams (MO3), by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend dam breaching because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Based on the analysis in Fish section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative will provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
32084	1	N/A	N/A	To make up for the loss of barge traffic, plenty of land exists in between the Tri-Cities and Idaho on which additional railroad tracks could be built.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. The co-lead agencies' analysis finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
32091	1	heatherfold@yahoo.com	N/A	A better option that must be considered is to breach the four LSRDs and implement 125% TDG spill at Columbia River dams.	Combining the dam breach measures from MO3 and 125% spill contemplated for the lower Columbia River projects under MO4 would not be a reasonable alternative to meet the multiple and complex objectives of the EIS and the multiple purposes of the CRS projects. From a power perspective, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g., increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts.
32091	2	heatherfold@yahoo.com	N/A	Inadequate consideration for SRKW, they are not even mentioned in the 36 page executive summary. Inadequate representation of how important Columbia basin salmon are for SRKW survival. Salmon in other rivers cannot substitue for salmon in the Columbia basin. Like humans, SRKW must have ample food all year long, not just sometimes. Over half SRKW diet when theyre at the outer coast are from Columbia basin with spring Chinook particularly important. SRKW co-evolved with massive wild Chinook from Snake. They need wild salmon back. NOAAs long standing 2000 BiOp shows breacing the LSRD is the best option for these species recovery.	The Executive Summary is a high level summary of the CRSO EIS and is not intended to represent the importance of species and issues related to the CRS. SRKW analysis has been done and described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The 2000 NMFS BiOp does not currently meet this standard because it is over 20 years old and does not consider current operations and configuration. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies conclude there could be a minor beneficial effect to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32091	3	heatherfold@yahoo.com	N/A	Temperate reservoirs emit, even long after built. The 2012 PNNL study found methane in a Snake River reservoir. Findings are even very conservative. USACE cannot claim Snake River reservoirs dont emit.	Appendix G, Chapter 5 of the Draft EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8 in the Draft EIS. Section 3.8 and Appendix G include references to and discussion of Arntzen et al. (2013), research supported by the U.S. Department of Energy referenced in this comment. In the case of the four lower Snake River dams, recent research concluded that data were insufficient to estimate the reservoir methane emissions specifically for the CRS projects, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The Draft EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
32108	1	suesander1@gmail.com	N/A	Did you look at those studies and assess if fish passage options would be possible at each of the Dams? Also, I prepared several studies for those Districts to access the possiblity of revegetating both rivers and determine what types of vegetation could be planted and could survive even during drought conditions and if the water levels in the rivers were lower than average. This should be reassessed, since vegetation helped to create habitat for birds, mammals, fish, etc. It was amazing at the number of faunal species that started to move and live in those areas. The key sites were on the Hanford Reach.	The dams within the CRS project area were assessed for structural and operational measures that would improve existing fish passage. Impacts on vegetation as a result of operations, maintenance, and configuration of the dam were analyzed in the EIS, specifically in Sections 3.6 and 7.7.7. Those analyses utilized current high quality information. Measures to address vegetation for areas that would be replanted are discussed in Chapter 5, Mitigation.
32108	2	suesander1@gmail.com	N/A	Another issues, that my Team worked on was an Integrated Water Resource study for the Yakima/Columbia River Region. It was apparent that the water levels in all of the rivers and streams in Eastern Washington are dramatically reduced during the late spring, summer, and early fall time periods due to irrigation requirements in the region. These water levels reduce fish passage and in addition, the temperature of the water increases dramatically as the water levels are reduced.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle, including depletions from irrigation requirements, in the Affected Environment description. This EIS analyzes the effects of the operation, maintenance, and configuration of the CRS projects as described in Chapter 3.4. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. To the extent that alternatives included additional depletions for irrigation, these would come from the mainstem Columbia River diversion point and were included in the hydrology analyses, which were then used to evaluate the effects on fish resources.
32108	3	suesander1@gmail.com	N/A	According to numerous Washington State Departments, the water levels in all of the rivers and the water temperatures were monitored in the past to ensure that the rivers and all fauna/flora were protected. This process ensured that the fish were able to migrate from Canada and Eastern Washington would be able to eventually get to the Pacific Ocean. We repeatedly evaluated this issue and currently, this is not an issue that is addressed, the fsh number in the rivers are reducing due to the increased water temperature and lack of fish passage systems at each dams, which then prevent the fish from migrating to the Pacific Ocean.	Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence from Dworshak Dam operations. The co-lead agencies' analysis shows that under a dam breaching scenario, nighttime summer water temperatures, as well as fall water temperatures, would be cooler than the conditions in the No Action Alternative in the lower Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under MO3, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The co-lead agencies refer the commenter to chapter 3, section 5 for a discussion of fish passage improvements and current survival levels at each CRS dam as well as cumulative survival through the CRS system. Latent mortality associated with passage at CRS dams will remain a focus of the Preferred Alternative, but the co-lead agencies do not agree that there is a lack of fish passage facilities at the CRS dams.
32108	4	suesander1@gmail.com	N/A	In addition another environmental issue, King County and other jurisdiction in the region transport their untreated sewage sludge to eastern washington, as well as manuer from cow and other animals that is used as "clean fertilizer". This hazardous and toxic substance is used throughout Washington State and across the US/World to fertilize our vegetable and fruit. Unfortunately, although it is "free" to use, it contributes to significant diseases. Currently, the Coronavirus is contained in the sewage sludge and it is contributing to the spread of this disease. In addition, if you evaluated key cities/regions in Eastern, it will be discovered that this is contributing to MLS, CANCER, ALS, etc in the region. My Team would be pleased to provide you with information on these issues, etc., to support you with the preparation of this EIS ,and ways to increase environmental protection and prevention. Please contact me if you would like to discuss this and obtain additional information.	Thank you for your comment. Although important, these issues are well outside of the scope of this EIS that is evaluating the operations and maintenance of the Columbia River System.
32123	1	pass2sue@yahoo.com	N/A	There is no evidence that the removal of the dams will increase fish populations, so rather than destroy the economics of our region, how about we figure a way to improve the fish ladders and bypass systems.	Currently, fish ladders are proven effective at moving adult fish upstream at the dams that have them. In terms of bypassing fish upstream, the current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. The 4 lower Snake and 4 lower Columbia River dams also have systems for bypassing fish around turbines and powerhouses. Additional surface passage systems were considered but not carried into the Preferred Alternative. The Preferred Alternative uses increased spill to bypass more juvenile fish away from powerhouses.
32128	1	kathystangl@gmail.com	N/A	A TDG level of 125% saturation at the 4 lower Columbia dam tailraces must be added to MO3 as a component of what must become the preferred alternative".	The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The agencies disagree that an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is reasonable, and thus was not proposed as an alternative given the unacceptable risks to public safety from such an alternative.
32128	2	kathystangl@gmail.com	N/A	Until the dams are breached, the EIS analyses clearly demonstrate that spill to the 125% tailrace gas cap (MO4 alternative) at all of the projects, 24 hours per day, must be implemented as an interim measure. Analyses in the CRSO-DEIS show this is the only available alternative for salmon and steelhead recovery, while still providing sufficient regional energy and irrigation potential.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32137	1	carlbevis@yahoo.com	N/A	elative to the improvement of salmon and steelhead habitat, I believe that the realistic evaluation should include "removal" or breaching of the snake river dams. By this I mean inclusion of equivalent alternatives for current economic contributions of the dams (i.e. power production, irrigation, transportation, recreation, etc.) to the state and local communities should be detailed. Another aspect that should be included is that of the recreation attractiveness of a "free flowing river" with specific reference to the river prior to the installation of the dams	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. For MO3, hydropower effects are described in Section 3.7.3.5; water supply and irrigation in Section 3.12.3.4; and recreation in Section 3.11.3.5. Section 3.11.3.5 describes the potential for increased fishing and river-based recreation in the long-term under MO3, as compared to the No Action Alternative.
32160	1	N/A	N/A	Do not remove the dams. Instead increase the spillage when the salmon are traveling or improve the fish ladders.	The co-lead agencies analyzed a reasonable range of alternatives in the EIS to address current and anticipated operations, maintenance and configuration including different levels of fish passage spill. For example, the Preferred Alternative includes the following measures: Increased spill. As part of the juvenile fish passage spill measure, the co-lead agencies would increase planned spill up to 125 percent total dissolved gas levels at some projects, which is the maximum allowable total dissolved gas limit in Oregon and Washington. Previous state water quality standards limited juvenile fish passage spill to lower amounts of spill. The goal of higher spill is to increase the number of juvenile fish passing through the spillways, in lieu of the powerhouse bypass systems and turbines, which is predicted to result in increased adult fish returns. Extensive regional collaboration. The juvenile fish passage spill operation included as part of the Preferred Alternative is a result of extensive regional collaboration. Negotiations for the 2019-2021 Spill Operation Agreement began in the summer of 2018. Other changes. The Preferred Alternative also contains measures to improve fish ladders, however the fish ladders at the 4 lower Snake and Columbia river dams have been improved over time, and already perform well in terms of passing adult salmon and steelhead upstream.
32169	1	N/A	N/A	Now, this is were we reach the true culprits of the salmon's measly survival rates to adulthood. Birds love to eat those young and more vulnerable salmon just cruising the river, ocean-bound. Seals can be seen gorging at the base of river outlets as salmon jump into their mouths unknowingly in their quest to land in the ocean. Killer whales require 200 to 390 pounds of Chinook salmon in their 20-80 diet, 20% other, 80% salmon, to eat well and remain healthy. Successful fishers and tribal ceremonies often enough whittle the survival numbers lower. But when the buffet is chipped away and there are slim pickings left, you still can fill your plate and stomach. However, all the high numbers that successfully bypass the dams are eroded by the birds, fat seals, fishers, tribes and killer whales. Then, the fish ladders see little traffic and the dams become the scapegoat. So, lets focus on whittling down predators, especially the seals and birds and then turn to the dams.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
32174	1	okeefe@americanwhitewater.org	American Whitewater	See attached PDF for comments of American Whitewater.	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
32179	1	billbstallion@yahoo.com	N/A	I have also seen the immense fisheries potential the Salmon River provides. With my educational background in fisheries and my knowledge of the economy of the area I firmly believe that all impediments to the Salmon and Steelhead recovery should be removed. Dam removal is one of the primary impediments and remains one of main impediments to the fish recovery while any new mining will threaten their survival	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
32179	2	billbstallion@yahoo.com	N/A	The technology exists that will allow the grains to be shipped and the power to be produced that will alleviate any problems that result from the dam removal. Federal government subsidies should be used to implement said technology in future infrastructure.	As described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures described. But, rather it provides a list of potential mitigation needs which could potentially include some infrastructure items, some of which could be implemented by other agencies, officials or the public who would potentially benefit from the mitigation measure.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32180	1	redfish@bluefish.org	N/A	Most people in the Pacific Northwest don't think a lot about the rivers flowing through the hearts of our communities and states, but farmers certainly do. The Columbia and Snake rivers in particular are an incredibly generous waterway system. Hydropower from their dams is one of the most reliable and environmentally friendly sources of power available, and contributes 90% of the renewable energy produced in the Pacific Northwest. This low-carbon energy heats our homes, powers our equipment, and never quits. Its the major factor in achieving our goal of being carbon-neutral by 2040. (Kristin Meira, Pacific Northwest Waterways Association) - Conservation - (Appendix H 2-6) According to the Seventh Power Plan, by 2022 there is 1,871 aMW of conservation available to the region at $80 per MWh or below. [Text includes figure that does not transfer to database.] My best guess is that this "Conservation below $80 per MWh" refers to Year 7 in the NW Council's graphic above. The full 20-year curve of increasing conservation should be incorporated in all CRSO analysis of the power system. By Year 7 the region has acquired 900 aMW of Conservation below $20 per MWh, which is surprisingly similar to the "Average Market Price" (Appendix H Table 4-8) of Bonneville's surplus power. (Appendix H page 4-9) 1937 was a relatively dry year with a very early runoff of winter snowpack. This year is used to compute what is considered "firm" generation. Average water years produce more – and a better shape of – generation, such that if loads are met with 1937 water conditions, more generation will be available to sell. This excess (is) then sold into the market producing secondary revenue credits, which are credited to the PF rate, reducing the net revenue requirement collected from Bonneville's long-term firm power customers. In some periods, under certain weather or water conditions, Bonneville makes balancing purchases to meet load (bluefish: while taking a sizable credit from the US Treasury called 4(h)(10)(A)). These (purchases) are netted from total secondary sales before the secondary credit is applied against the cost base collected in rates.	This comment is consistent with the findings of this EIS. Conservation expectations are included in the load forecast used to establish Loss of Load Probability (LOLP) under the No Action Alternative and are included similarly in all of the other alternatives. See Appendix H, Power and Transmission, Section 2.2, H-2-3 in the Draft EIS. Therefore, the full curve of expected conservation acquisitions is considered before accounting for additional resource acquisitions necessary to meet regional reliability metrics. The EIS analysis assumed that all energy efficiency assumed in the Northwest Power and Conservation Councils (Council) Seventh Plan is appropriate and, likely aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Seventh Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3.
32180	2	redfish@bluefish.org	N/A	The choice of an economically preferable alternative hinges on the "loss of exports". That was the case in the 2002 EIS in overruling Alternative 4-LSR Dam Breach for its loss of $250 million worth of power, and it continues to be the case in this CRSO Draft. This fact of the matter needs to be clearly stated, and the analysis must be transparent and repeatable. Importantly, Bonneville has yet to share the appropriate data that has been requested by NW Council to provide informed comment on this Draft. (Appendix H, 2-6) The CRSO Draft draws on the NW Council for expertise in determining the amount of "conservation available in the region", "energy storage costs", and the cost of the Battery Storage Reference Plants for 2021 Power Plan. The NW Council is charged by statute, with exactly the task of balancing the needs of fish with the objective of maintaining an "adequate, efficient, economical, and reliable power supply". The NW Council staff are the most respected experts on this very subject. Looking at details of the CRSO power analysis, one sees that Bonneville is seeking to usurp that authority, leaving the NW Council completely out of the process.	The load forecast included in the reliability modeling only includes regional loads netted for all cost effective conservation. The model runs all generating resources to meet that net load. This comment mischaracterizes the Northwest Power and Conservation Councils (Council) involvement in the development of this EIS. The Council is directed by the Northwest Power Act to establish and amend a regional fish and wildlife program and a power plan every five years. The power plan takes into account the fish and wildlife program and forecasts, based on the Administrators long term firm power supply contracts to meet demand, and the type and amount of resources (conservation, renewables, high fuel efficient generation, etc.) available for acquisition by the Administrator if they determine a need to acquire. The CRSO EIS is conducted pursuant to different Federal statutes and regulations including, but not limited to the National Environmental Policy Act (NEPA) and the Endangered Species Act. This is not a usurpation of the Councils authority to review and amend either the fish and wildlife program or the power plan. Since the Council is not a Federal, Tribal, state or local agency, it could not serve as a cooperating agency under NEPA. The Council received the Draft EIS when it was available for public review. The Council received periodic updates on the CRSO EIS NEPA process similar to the general public. While the Council does not play a formal role in the EIS, the Councils 7th Power Plan was foundational to the resource cost and resource availability data provided by the plan. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS; see also Appendix H, Power and Transmission, at Section 2.2. Bonneville is the Federal agency charged with marketing the power from the Columbia River System. It is Bonneville's duty under NEPA to analyze the effects of its power marketing actions on affected resources. Bonneville must also ensure it is complying with other laws, including the Northwest Power Act. The EIS discusses this in more detail in Chapter 8.
32180	3	redfish@bluefish.org	N/A	Coal - Executive Summary The second issue concerning the base case zero-carbon replacement portfolio is that the composition of the regional power system is undergoing rapid change, and will continue to do so over the coming years with increased coal plant retirements and restrictions on the use of natural gas generation. The base case portfolio implicitly assumes that other regional resources would be used to make up for any deficiencies in the power system's sustained peaking, storage, and dispatchable capability caused by the loss of generation from the lower Snake River dams. As a result, given the expected coal plant retirements and restrictions on natural gas generation, replacing the full flexibility and capability of the lower Snake River dams with zero-carbon resources would require substantially more resources, such as additional dispatchable battery technology, than estimate in the base case analysis. To reflect these additional costs, a rate sensitivity analysis was performed for MO3 to estimate the rate pressure effect of an expanded zero-carbon resource portfolio on Bonneville's wholesale power rate. This expanded zero-carbon resource portfolio would include power capabilities similar to those lost with the breaching of the lower Snake River projects. (Appendix J page 4-18) The CRSO is concerned more with a decision on selection of the future preferred operation of the CRS and not directly with the retirement of coalfired plants owned by investor-owned utilities in the region. However, regional reliability depends on all utilities, and the loss of baseload generation in the region affects the value of the hydropower produced by the CRS. A legitimate NEPA document does not move away from the baseline established after the Scope is set. Doing otherwise would make the NEPA analysis intractable. Looking at "future coal retirements" at a late stage in the game, after most all of the analysis is completed (as frequently stated in the Appendices) is disingenuous.	As described in the comment, the focus of the EIS is to evaluate the impacts of the alternatives on resources affected by Columbia River System operations, maintenance and configuration. The co-lead agencies developed a reasonable range of alternatives, including Multiple Objective (MO) Alternative 3, which identifies the impacts of breaching the four lower Snake River dams. The co-lead agencies also agree with the statement [h]owever, regional reliability depends on all utilities, and the loss of baseload generation in the region affects the value of the hydropower produced by the CRS. Thus, the CRSO EIS analyzed the value of the lost power generation associated with MO3 in the context of the regional power system. The comment takes issue with the EISs discussion of future coal retirements and its impact on the scope of the EIS analysis. The Base Case analysis which was started in 2017 included high-quality information on the availability of resources. Coal generation that was online or expected to remain online was presumed to continue to operate in the Base Case. See Section 3.7.3.1, Base Case Methodology in the draft EIS. Since 2017, additional coal retirements were announced, along with other changes in the energy industry. The comment suggests that the co-lead agencies should have ignored these changes and limited the EIS to the information available in the Base Case. The co-lead agencies, however, are not permitted under NEPA to ignore reasonably foreseeable future actions (e.g., coal retirements). More importantly, based on current information, the agencies could not legally ignore these coal retirements because this information squarely falls under significant information relevant to environmental concerns and bearing on the proposed action or its impacts. This language is the test for whether an agency would need to supplement an EIS. 40 C.F.R. 1502.9. Thus, consistent with NEPA, the agencies decided to acknowledge significant changes in the energy landscape in the EIS to avoid the need to supplement the EIS at a later date. To account for these changes, the EIS included a Rates Sensitivity Analysis and Regional Cost Pressure Analysis. See Section 3.7.3.1, Rate Sensitivity Analysis in the draft EIS. The Rate Sensitivity Analysis and Regional Cost Pressure Analysis capture the effects of new or updated information on regional reliability. Specifically, the Regional Cost Pressure Analysis, described in the draft EIS in Section 3.7.3.1, addresses the impacts on regional reliability and regional resource costs if coal retirements were to accelerate. See Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842 in the draft EIS. This analysis is presented as a sensitivity above the Base Case because the full extent of future coal remains uncertain. To reflect this uncertainty, the EIS developed two coal availability scenarios: limited coal and no coal. See Appendix H, Power and Transmission, Section 2.3 at pages H-2-8 15. The effect of the limited coal and no coal scenarios on regional reliability under each MO is described in the EIS. See Section 3.7.3.2, No Action Alternative at pages 3-845-84, Table 3-123 in the draft EIS. Describing the MOs in light of known or likely additional coal retirements provides a more complete picture of the regional impacts of the MOs on regional reliability and costs.
32180	4	redfish@bluefish.org	N/A	- Carbon Sequestration - CRSO Objective: Minimize GHG Emissions Minimize greenhouse gas (GHG) emissions from power production in the Pacific Northwest by generating carbon-free power through a combination of hydropower and integration of other renewable energy sources. (Chapter 7, p.12) MO3 would result in shipping activities shifting from barge to road and rail transport as described below. As barge transportation is a relatively low source of GHG emissions per ton-mile of freight, compared with truck or train transportation, MO3 would also increase transportation-related emissions for what is currently transported along the lower Snake River by up to 53 percent (an increase of 0.056 MMT of CO2). By mentioning the transportation sector GHG emissions, the CRSO Draft is expanding the Scope of the Objective beyond "emissions from power production in the Pacific Northwest... I agree that this expansion of that Objective's scope is appropriate. GHG emissions are worldwide, and to limit the conversation to merely the Northwest Power System is to look at a small part of a much bigger picture. An ever growing (pun intended) amount of carbon sequestration will arrive, if we let Idaho's salmonids bring marine-derived nutrients to Idaho's forests, as Mother Nature intended.	With respect to the influence of salmon on carbon sequestration, Section 3.5 identifies that fish migration through the lower Snake River corridor would improve under MO3. Section 3.5.2.3 recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. This indicates that, in some areas, MO3 would likely improve landscape carbon sequestration. However, in other areas, MO3 may reduce landscape carbon sequestration. As described in Section 3.6.3.5, lower water levels in the spring and early summer in some areas under MO3 would reduce productivity in some existing emergent herbaceous and forested and scrub-shrub wetlands. The overall effect of MO3 on landscape level carbon sequestration across the Basin is uncertain.
32180	5	redfish@bluefish.org	N/A	The mathematics is straightforward (see Question17). The CRSO Draft documented this benefit of salmon; therefore, the accounting should, too. There are a several well respected groups tallying and verifying carbon credits. They should be employed now, to establish a baseline, and then monitor the sequestration, soon to accrue in Idaho's forest. The CRSO accounting should estimate the ecological benefits financially. (Chapter 3, page 299) Aquatic Habitat Connectivity Migratory salmonids are important vectors of energy and nutrients between marine and freshwater ecosystems. For example, anadromous fish carry nutrients across habitat boundaries, and they influence community and food web structure in aquatic as well as terrestrial ecosystems. Spawning salmon contribute an estimate 5 to 95% of the nitrogen and phosphorous in salmon-bearing streams. Anadromous fish deliver resources that affect food web productivity and influence a diverse array of flora and fauna across vast landscapes in the Columbia River Basin.	Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes. In addition, as described in Section 3.5, fish migration through the lower Snake River corridor would improve. As highlighted in this comment, Section 3.5.2.3 does describe that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. However, the extent to which the fish benefits described under MO3 affects productivity in Idaho forests is uncertain and, as described in Section 3.6.3.5, lower water levels in the spring and early summer in some areas under MO3 would reduce productivity in some existing emergent herbaceous and forested and scrub-shrub wetlands.
32180	6	redfish@bluefish.org	N/A	Irrigation - Executive Summary MO3 would meet the objective to Maximize Adaptable Water Management and Provide Water Supply, but there would be adverse impacts to irrigation in the lower Snake River borne by other public and private entities, due to dam breaching. Assuming 47,926 acres were no longer irrigated, the present value of the lost social welfare benefit, under the MO3 alternative is $458 million (annual equivalent value is $17 million). (Appendix N, 4-1) The Corps 2002 report analyzed dam removal and the impact on water supply. Several system modifications were considered that would allow for the continuation of water deliveries to existing farmlands. The report concluded that modifying the existing pump system was cost prohibitive. For the regional analysis the report assumed that most of the irrigate acres receiving water form the current pumps would no longer be irrigated. The report assumed that 21% of the irrigated land might support the development of alternative water supplies to replace lost irrigation water and the replacement water would be used to irrigate some of the fruit orchards and vineyards. The development cost for replacement water would need to be included as part of the alternative to assess the net benefits of irrigation under this scenario. ... This analysis assumed that all irrigated acres receiving water from the current pumps would no longer be irrigated. This assumption was based on "conversations with several extension agents in Washington and Oregon" and on this basis, "the analysis assumed that "there isn't a suitable substitute water source". To a great fault, the CRSO Draft takes for certain that the 2002 Corps report was correct in concluding that the cost prohibitive modifications to existing pumps, necessarily precludes consideration of other, more economic, mitigation solutions. Importantly, NEPA requires that "all relevant, reasonable mitigations" be considered and "identified in the document" regardless of who might eventually pay for it.	The comment is correct that, in Region C under the MO3 alternative, the analysis concludes that pumps are unable to deliver water to an estimated 48,000 acres. This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences, specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. This report remains the most current information on these impacts. There is a physical limitation to delivering water to these lands in the absence of the dams. Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms. Please see Section 3.12 and Appendix N for additional information. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in this chapter is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in this chapter serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks.
32180	7	redfish@bluefish.org	N/A	CRSO Draft Chapter 5 - Mitigation (page 5-2) NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. Included in my previous comment to the CRSO process, a 30-mile pipeline upon an abandoned railway grade – now owned by Washington State Parks' Columbia Plateau Trail State Park – could gravity feed irrigation to the existing pumps. It is odd that the CRSO Draft ignored this affordable mitigation, the CRSO Final Report should include. There are many miles of large diameter irrigation pipes in Central Washington and Southern Idaho. This web page calculator tool is a useful way to determine the various dimensions worth considering. Failing to consider and "identify" this mitigation is a fatal flaw of the Draft document. The abandoned railway is sitting there, scattered with 2-4 inch basalt rocks, waiting for better use. Could things be much easier?	With exception of MO3, the alternatives including the Preferred Alternative are not expected to have an effect on water delivery in the Columbia River Basin. MO3 could affect delivery of current water supply in Region C, and is expected to result in major effects to the Ice Harbor private, municipal, and industrial pumps located near Ice Harbor dam. As mentioned in Section 5.4.3.7, Water Supply, private and public entities could extend intake pumps, ground water wells, or other infrastructure to offset any potential effect as a result of MO3. The co-lead agencies would not prescribe how those entities would implement their actions.
32180	8	redfish@bluefish.org	N/A	Barging Wheat - Executive Summary MO3 would result in shipping activities shifting from barge to road and rail transport as described below. As barge transportation is a relatively low source of GHG emissions per ton-mile of freight compared with truck or train transportation, MO3 would also increase transportation-related emissions for wheat that is currently transported along the lower Snake River by up to 53% (an increase of 0.056 MMT of CO2).	The statement in the comment that emissions from shipping would increase under MO3 by up to 53 percent is consistent with the findings of the EIS (see Section 3.8.3.5 in the Draft EIS). The EIS finds that barge freight transportation is more efficient (i.e., has a lower energy intensity) per ton-mile than trucks or rail (see Section 3.8.2.2, Transportation Sector Greenhouse Gas Emissions in the Draft EIS). The most recent version of the Transportation Energy Data Book, cited by the comment, is consistent with this finding and with respect to the emissions factors used in the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Contrary to what PNWA & NWRP would have us believe (and the CRSO Draft Executive Summary as well), shipping by Rail has been more efficient than by Barge for over a quarter century (see 29th ed. Transportation Energy Data Book below). After I brought this important and relevant fact (see bluefish.org/freight0.htm) to the attention of BPA Administrator Stephen Wright during a meeting in his executive suite, the Department of Energy (DOE) worked to rewrite the facts. Strange as it may seem, the 30th Edition Transportation Energy Data Book excluded Waterborne Commerce from Table 2.16. Then in their 31st Edition, the Waterborne Commerce reappeared but with a different methodology in its computation. No explanation was given for this new methodology. Moreover, the newly tabulated data was only available for a third as many years that were previously available, in the 29th edition. Could BPA's Stephen Wright really be that dishonest? One only needs to ask the current Administrator about his findings and his concerted efforts to rebuild trust at Bonneville following the Veteran's Hiring Scandal that took place under Wright's leadership. The facts in this case are straightforward. The Transportation Energy Data Book methodology for Waterborne Commerce changed in the years shortly following my bringing it to the attention of Mr. Wright. This fraudulence is appalling and Orwellian. Is Mainzer's Bonneville to be considered as being more trustworthy? Time will tell. 29th Edition Transportation Energy Data Book Department of Energy, Center for Transportation Analysis [Text contains figure that doe not transfer to database.] In 2011, the Columbia-Snake Waterways experienced an extended closure. To boost the economy, President Obama's America Recovery Act provided funding to anything shovel ready: Previously shelved, uneconomic projects were given go ahead funding. Following this closure, Ken Casavant, Director Freight Policy Transportation Institute, Professor Economics Washington State University, concluded in his "Economic and Environmental Impacts of the Columbia-Snake River Extended Lock Outage": The overall result in energy intensity during the year of the lock outage was an increase of 10 percent more Btu's consumed. This increase in energy use is logical as more tonnage was shipped from August 2010 to July 2011 than during a typical year and truck was mostly used to replace barge during the lock outage, which is more energy intense. However, energy consumed per ton decreased 4.8 percent due to heavy use of rail, which is more energy efficient than barge or truck, and the increased use of barge prior to and after the lock outage. The CRSO Final Report must consider more than PNWA documents. It must consider "all relevant, publicly available documents". Casavant's report is certainly relevant. Executive Summary: Areas of Controversy, Lower Snake River Dam Breach: Breaching the four lower Snake River dams has been a topic of public discourse for decades. This EIS provides an updated analysis of the many biological and sociological variables and the costs and benefits of retaining or breaching the lower Snake River dams. In combination with other sources of information and analysis available in the public domain, this document can help inform the regional conversation on this complex and often polarizing issue. A NEPA process must be honest, if decision makers are to make well-informed decisions. Asking the public and decision makers to believe that shipping by Barge is more efficient than by Rail is preposterous, unfounded and deceitful. BPA Administrator Elliot Mainzer should know better, especially because he led the development of the Northwest Wind Integration Action. Harnessing energy from wind is much the same as powering a boat: the fluid medium slips away from the propeller or turbine and a great amount of energy is lost. Compare that to a steel wheel on a steel rail with no slipping whatsoever. The physics is simple, so lets be honest	Dr. Casavant of Washington State University, referenced in this comment, was an advisor and analyst for the navigation and transportation analysis in the CRSO EIS. Thus, this Section is consistent with Dr. Casavant's research and models. The EIS considers all relevant literature on the topic of the efficiency of shipping modes, as opposed to relying solely on information from the PNWA as stated in this comment. The EIS relies on current, high quality information and applies current models and data rather than relying on findings from previous studies.
32180	9	redfish@bluefish.org	N/A	Barging Salmon and Steelhead - While on the topic of barging, did you know that salmon are barged downstream? Decades ago, when the federal hydrosystem was very deadly for Idaho's salmon and steelhead heading downstream to the grow strong in the ocean, their full life-cycle survival was a little better for juveniles that took a boat ride -- transported by barge -- to the estuary. They thereby avoided the more injurious and hazardous hydrosystem. With billions of dollars spent to improve that migration, and with further improvements difficult to imagine, it is now close to a tie as to which is a safer route to the ocean. (Chapter 3, page 383) Overall, transported Snake River spring/summer-run Chinook salmon tend to have relatively low rates of straying. Wild yearling Chinook salmon tend to have the lowest transport benefit, and hatchery yearling Chinook salmon and hatchery steelhead tend to have higher benefits from transport. In addition, fish transported later in the year generally show greater benefits from being transported late. ... For example, in most years, beginning in May, adult returns are higher for transported spring summer Chinook than for in river fish. Under Northwest Fish Science Center's Life-Cycle Module (NWFSC LCM) in the Draft Preferred Alternative, barging is oftentimes safer than leaving the juveniles in the river. Barging Salmon and Steelhead - While on the topic of barging, did you know that salmon are barged downstream? Decades ago, when the federal hydrosystem was very deadly for Idaho's salmon and steelhead heading downstream to the grow strong in the ocean, their full life-cycle survival was a little better for juveniles that took a boat ride -- transported by barge -- to the estuary. They thereby avoided the more injurious and hazardous hydrosystem. With billions of dollars spent to improve that migration, and with further improvements difficult to imagine, it is now close to a tie as to which is a safer route to the ocean. (Chapter 3, page 383) Overall, transported Snake River spring/summer-run Chinook salmon tend to have relatively low rates of straying. Wild yearling Chinook salmon tend to have the lowest transport benefit, and hatchery yearling Chinook salmon and hatchery steelhead tend to have higher benefits from transport. In addition, fish transported later in the year generally show greater benefits from being transported late. ... For example, in most years, beginning in May, adult returns are higher for transported spring summer Chinook than for in river fish. Under Northwest Fish Science Center's Life-Cycle Module (NWFSC LCM) in the Draft Preferred Alternative, barging is oftentimes safer than leaving the juveniles in the river.	Varying levels of transportation were included in all MOs with the exception of MO3 (dam breach). MO2 considered much higher levels of transportation that are currently implemented under the NAA. In the Preferred Alternative, the co-lead agencies have proposed to continue the use of barge and truck transportation, albeit at lower rates than under previous spill operations. However, the majority of juvenile fish will migrate in-river. As the comment notes, transportation by barge or truck has been shown to provide a benefit that varies by species, by time of year, and by water condition. The juvenile salmon transportation program is managed by expected fish benefits as well as cost efficiency. SAR estimate for each week of the outmigrations, combined with other environmental and biological data, drive the decisions. Prior to these data being available, transportation began at the beginning of April; however, we learned that fish transported in early April performed very poorly. Transporting too early is not effective and does not justify the expense.
32180	10	redfish@bluefish.org	N/A	(Chapter 7, page 104) Snake River Steelhead: While a Preferred Alternative Transport to In-River Survival Ratio (TIR) of 1.1 represents a reduction in TIR relative to the No Action Alternative, the TIR still represents a season-wide benefit to transport relative to in-river migration, measured in terms of relative SARs (Smolt-to-Adult ratio). In contrast to the Preferred Alternative, restoring the Lower Snake River to a riverine system would completely end barging of juveniles, and SARs triple! Both of the CRSO models unequivocally show that MO3 is the "environmentally preferred" MO. Importantly, MO3 is the only MO alternative that leads to the recovery of ESA-listed salmonids (see graphic next page). With that in hand, the CRSO process should now consider MO3 without increasing spill to 120%TDG. The science remains undecided as to whether or not spill is beneficial. CRSO models agree with the 2002 Juvenile Migration FS/EIS: MO3's essential part is Breach Lower Snake River Embankments.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 states the Preferred Alternative would have substantial benefits to salmon and steelhead. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery goals.
32180	11	redfish@bluefish.org	N/A	CRSO Caveat: Difficulty Calibrating NWFSC LCM Model (Chapter 3 page 560) The NWFSC LCM results generally indicate high variability in potential fish response to dam breach depending on the breach scenario input dataset used for calibration. The CSS LCM results generally indicate that MO3 adult abundance over time would show substantial increases from the No Action Alternative.	For the 2000 Biological Opinion, NOAA proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap to the Lower Granite bypass and from the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from these differences between these two trap-to-dam estimates (Ferguson et al (2004). For the CRSO Draft EIS, NMFS used a similar method of estimating free-flowing survivals and travel times with their COMPASS model. PIT-based monitoring efforts have been added at a variety of additional hatchery and wild trap locations in the Snake and upper Columbia since the 2000 BiOp. The Salmon trap to Lower Granite reservoir free-flowing survival rate is used as representative of yearling Chinook populations for the main text of the MO3 analysis. In the appendix, NMFS carries out a sensitivity analysis for the choice of upstream trap location by comparing free-flowing survival rate estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent dam breach conditions under MO3. There is a wide variance in per-kilometer travel times and survival rates to Lower Granite Dam among all the hatchery and wild trap locations. The three locations were selected by NMFS to represent spatial variation in stream conditions such as natural predation rates. Most juveniles at these sites are tagged as outgoing smolts and few display signs of continued tributary rearing. Ferguson J. (2004) Memorandum to FCRPS Biological Opinion Remand Administrative Record RE: Updated estimates of free-flowing river survival. NW Fisheries Science Center.
32180	12	redfish@bluefish.org	N/A	(Appendix E 1-11) The dam breach in alternative MO3 will change the river environment to conditions well outside the range of the calibration dataset with water velocities 5-8 times faster under MO3 than in the calibration data. The model responds to this change in water velocity and there are no numerical issues with using the model in MO3. However, it is unknown if the behavioral patterns fitted by the model will hold or if they will change at higher velocities. ... It appears that both assumptions for the MO3-GRNIMN calibration are being violated to some extent. However, after detailed examination of the calibration process, no errors were found in calibration. While it seems unlikely that the Grande Ronde and Imnaha dataset is representative of the Snake River as a whole, it is an important component of the basin-wide population, and it is valuable to include this calibration for comparison to the other models and as a measure of the uncertainty associated with the MO3 alternative.	For the 2000 Biological Opinion, NMFS proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap, and from the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from the difference between these two trap-to-dam estimates (Ferguson et al (2004). For the CRSO EIS, NMFS used a similar method of estimating free-flowing survivals and travel times with their COMPASS model. PIT-based monitoring efforts have occurred at 20-plus additional hatchery and wild trap locations in the Snake and upper Columbia since the 2000 BiOp. In Appendix E, NMFS carried out a sensitivity analysis for the choice of upstream trap location by comparing free-flowing survival rates estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent dam breach conditions under alternative MO3. There is a wide variance in per-kilometer travel times and survival rates to Lower Granite Dam among all of the possible hatchery release sites and screw trap locations upstream of Lower Granite Dam. The river conditions and migration behavior of fish in tributaries to the Snake River is much less representative of river conditions we expect in the lower Snake River following dam breaching than are the river conditions in the free-flowing Snake River between the confluence of the Clearwater River and the confluence of the Salmon River. NMFS selected the three locations because each trap location was low in the tributary and are very close to the mainstem Snake River; we expect that reach of the free-flowing Snake to be very similar to what the breached lower Snake would look like in MO3. Traps further up in the tributaries are likely to tag more parr while these three traps tend to intercept mostly smolt-aged fish that arrive at Lower Granite without further rearing behavior. Yet it does appear that some fish in the Lower Granite and Imnaha (GRN-IMN) data exhibit parr-like behavior, especially in early April. This is a major contributor to why the GRN-IMN model predicts slower migration and lower survival in MO3 than the other calibrations, and the reason for why it was placed into the appendix. The Salmon trap-to-Lower Granite reservoir free-flowing survival rate is used as a representative yearling Chinook population for the main text of the MO3 analysis. In response to the comment "outside the range of the data so the model is useless," this criticism can only apply to the SNK calibration. Yes, MO3 is outside the range of the calibration data for the SNK calibration, as is noted in the CRSO EIS text. The calibration between the Snake River Trap and Lower Granite Dam was just a calibration used to get at the GRN-IMN and SAL calibrations, and was not used in any prospective model runs for the Draft EIS. However, the SAL and GRN-IMN calibrations

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					are NOT outside the range of the calibration data when used for MO3. Flow, water velocity and temperature are all comparable between the free-flowing reaches of the Snake River used for calibration and the breached Lower Snake in MO3. Ferguson J. (2004) Memorandum to FCRPS Biological Opinion Remand Administrative Record RE: Updated estimates of free-flowing river survival. NW Fisheries Science Center.
32180	13	redfish@bluefish.org	N/A	Upward of $80M has been spent on this CRSO and the model from Bonneville (i.e. Department of Energy) doesnt work out quite right. It is likely due to NOAA Fisheries refusal to accept that latent mortality runs around 75% of Direct Mortality (see graphic above). The survey of science literature (Table 6 of Schaller et al.) Evaluating river management during seaward migration to recover Columbia River stream-type Chinook salmon considering the variation of marine conditions has been available to the region for half dozen years, and pointed to regularly by bluefish.org.	The model results presented in Section 3.5 and Chapter 7 address latent mortality and reservoir mortality. Latent mortality is captured directly in the CSS model for SARs and abundance levels, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results because the level of latent mortality is uncertain. In fact, the ISAB in their 2007 report stated, "The ISAB concludes that the hydrosystem causes some fish to experience latent mortality, but strongly advises against continuing to try to measure absolute latent mortality. Latent mortality relative to a damless reference is not measurable. Instead, the focus should be on the total mortality of in-river migrants and transported fish, which is the critical issue for recovery of listed salmonids. Efforts would be better expended on estimation of processes, such as in-river versus transport mortality that can be measured directly." There are additional scientific uncertainties regarding mechanisms and magnitude of delayed mortality or carryover effects resulting from migration through the CRS. Several studies using acoustic or active tags have monitored the survival of smolts through the estuary and coastal ocean below Bonneville Dam after barging vs. migrating in river (Eder et al. 2009, Dietrich et al. 2016, Rechisky et al. 2012), and following passage through eight dams vs. four dams (Rechisky et al. 2013). While there were short-term indications showing effects of barging, there was little evidence for delayed survival effects of multiple dam passage in the estuary below Bonneville. This remains an active area of research. Eder, K., Thompson, D., Buchanan, R., Hublein, J., Groff, J., Dietrich, J., ... & Loge, F. J. (2009). Survival and travel times of in-river and transported yearling Chinook salmon in the lower Columbia River and estuary with investigation into causes of differential mortality. Final Report submitted to the USACE, Walla Walla District, Walla Walla, Washington. Dietrich, J., Eder, K., Thompson, D., Buchanan, R., Skalski, J., McMichael, G., ... & Loge, F. (2016). Survival and transit of in-river and transported yearling Chinook salmon in the lower Columbia River and estuary. Fisheries Research, 183, 435-446. Rechisky, E. L., Welch, D. W., Porter, A. D., Jacobs-Scott, M. C., & Winchell, P. M. (2013). Influence of multiple dam passage on survival of juvenile Chinook salmon in the Columbia River estuary and coastal ocean. Proceedings of the National Academy of Sciences, 110(17), 6883-6888. The Preferred Alternative includes an adaptive management process that would consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
32180	14	redfish@bluefish.org	N/A	Chapter 7 Preferred Alternative - 7.7.4.1 Salmon and Steelhead The CSS model predicts the Preferred Alternative would result in a relative increase of 35 percent for Snake River Spring/Summer Chinook compared to the No Action Alternative. In contrast, NMFS' Life Cycle Model (LCM) shows a reduction in SARs of -7.5 percent for Snake River Spring/Summer Chinook relative to the No Action Alternative. This predicted reduction in SARs by NMFS LCM is primarily a function of reduced (barge) transportation rates. (Appendix E, 3-189) Lower Snake River Juvenile Migration Feasibility Report estimates that spawning substrate for Chinook salmon (gravel and cobble similar to NPM needs) would increase from 226 to 3,521 acres under a breach scenario.	Thank you for your comment, the co-lead agencies concur with this comment.
32180	15	redfish@bluefish.org	N/A	That 2002 EIS found that LSR dam breaching was the "environmentally preferred alternative", easily providing the most benefit to Idaho's salmon and steelhead of all measures that were imaginable at the time. In the twenty years since, billions of dollars have been spent to no avail, with populations now worse than before that EIS. Idaho's steelhead recently triggered the Early Warning Indicator, to which the Regional Implementation Oversight Group (RIOG) has yet to respond. This lapse is in spite of the Adaptive Management Implementation Plan having set a 120-day deadline for decisions as to what actions to take now. Much to the RIOG's trepidation, the only action to now prudently recommend is to Breach Lower Snake River Embankments. This is why they have failed to act. The forces within this CRSO process are the same forces within the 2002 EIS process, within that RIOG process, and within NOAA Fisheries. With five remanded Biological Opinions regarding Idaho's salmonids, the so-called Action Agencies have fought long and hard to maintain the status quo. They shudder at the realization that Idaho's salmon populations cannot recover with the Lower Snake River dams in place. Quis custodiet ipsos custodes? The 2002 EIS found economics to be the deciding factor in maintaining the status quo. "Additional annual power costs of $271 million per year" were deemed too important and the (Alternative 4) Breaching Lower Snake River Embankments was set aside, yet to be proven as "necessary at this time". That time has come. It is time to get it done. As the keystone species now dwindles, the ecosystem shows more signs of cracks. The CRSO should ask again, if this time Breaching Lower Snake River Embankments is now necessary? Avoiding that all-important question, set in stone by the 2002 EIS, would be a fatal mistake. A legitimate NEPA document must consider the ecosystem collapse that is now taking place: Salish Sea Orcas need more of Idaho's Chinook. The very few humans that benefit from the status quo, the subsidized wheat shippers and Bonneville's subsidized ratepayers, have infiltrated every imaginable government position that will give them the necessary force to protect their status quo benefits. Please ask yourself, "How did Dan James, former lobbyist for Kristin Meira's Pacific Northwest Waterways Association, come to be a primary author of this CRSO Draft?" To get to that position, Dan James was somehow appointed to become the Deputy Administrator of Bonneville Power Administration. How did a lobbyist from a waterway association, qualify for that position? Many highly qualified personnel from the energy industry were passed over so that a lobbyist could take this powerful post. Is this reminiscent of Bonneville's former hiring scandal under the leadership of Stephen Wright? Yes, there has been corruption at the DOE for a long time now. Former Administrator Bill Drummond attested to that when he was asked to come back to Bonneville's helm, "No, I would not work with a deputy secretary that I do not trust or respect."	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative meets the objectives of the EIS for ESA-listed juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Regarding the Preferred Alternative, this alternative is not simply a minor change to operations and maintenance of the CRS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and the Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall run (Upriver Brights), Lower Columbia River spring run, Middle Columbia River fall run, and Snake River spring/summer run. SRKW also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). NMFS CSS and Lifecycle models predict that lower Snake River Chinook salmon Smolt-to-Adult return rates (SARs) would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long-term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short-term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the CRS directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NMFS BiOp 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short-term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
32180	16	redfish@bluefish.org	N/A	MO3: the Environmentally Preferred Alternative Breach LSR Embankments, Spill to 120%TDG (Chapter 3, p.560) Snake River Spring/Summer-run Chinook Salmon Several structural measures in MO3 are anticipated to benefit adult Snake River spring/summer-run Chinook passage upstream and these include modifying the upper ladder serpentine sections at Bonneville dam. Overall, as with the other MOs, neither CSS nor the LCM indicates that powerhouse surface passage structures in MO3 would have a substantial effect on adult abundance over a 30-year period. Fallback rates of Snake River spring/summer-run Chinook at the lower Columbia dams may increase under MO3 since fallback for this ESU has been associated with higher flow and higher spill levels at many dams. In those studies, fish that fell back were less likely to reach their spawning areas compared to fish that never fell back. For example, of the 11% of Snake River spring-summer Chinook that fell back at Bonneville dam nearly 14% failed to re-ascend. Thus, the MO3 higher spill operation may result in a small increase in the fallback of Snake River spring/summer-run Chinook salmon adults as they migrate upstream. ...	The commenter is correct regarding projected effects on adult upstream migrants under MO3. Fallback may increase under conditions of higher flow and spill. Powerhouse surface passage structures were not anticipated to have a large effect on juvenile passage or adult fallback in the CSS and NMFS COMPASS models but were primarily discussed qualitatively. As real world operations are implemented, increased evidence of fallback would be managed through in-season adaptive management as part of the Regional Forum teams like TMT.
32180	17	redfish@bluefish.org	N/A	Snake River Steelhead For Snake River steelhead, the COMPASS and CSS models estimate that MO3 would increase juvenile survival and reduce travel time (-45%, -32%), elevated TDG (-5%), and powerhouse encounters (-76%, -77%). ... The COMPASS and CSS modeling results indicate that survival rates would increase between 23 and 46% relative to the No Action Alternative. ... For Snake River steelhead, the CSS cohort model estimates that MO3 would produce a substantial increase (178%) in SAR relative to the No Action Alternative. The CSS model estimated an absolute SAR of 5.0%. There are no LCM model estimates available for this DPS. ...	The NMFS COMPASS model forecasted a 23% improvement in in-river survival, and 45% decrease in travel time, and the CSS model predicted a 46% increase in survival and 32% decrease in travel time for Snake River steelhead. The substantial (178%) increase in SAR under MO3 relative to the No Action Alternative in the CSS model results both from the improvement in in-river survival and a decline in delayed mortality.
32180	18	redfish@bluefish.org	N/A	Snake River Sockeye Key long-term effects of MO3 would improve downstream and upstream migration survival through the lower Snake River due to breaching the four dams. Benefits would accrue through faster downstream travel time, fewer powerhouse encounters, lower predation, and reduced TDG effects.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32180	19	redfish@bluefish.org	N/A	Snake River Fall-run Chinook Salmon Key long-term effects of MO3 for fall-run Chinook would be the major increase in available spawning habitat. Other major improvements would include the downstream migration survival through the lower Snake River due to breaching the four dams. Benefits would accrue through faster downstream travel time, fewer powerhouse encounters, substantially less predation, and reduced TDG. ... Breaching the	Thank you for the summary of the environmental consequences analysis of the Draft EIS for Snake River fall-run Chinook, under MO3.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				four lower Snake River dams is estimated to increase the available spawning habitat for fall-run Chinook from 226 acres to 3,521 acres, an increase of 15 times the area available today. ... MO3 would lead to large increase in spawning habitat and improved conditions for spawning. Under MO3, juvenile fall-run Chinook may move downstream to use McNary and John Day reservoirs for rearing. One of the long-term effects is that the portion of the fish that overwinter in reservoirs for their first year is expected to be smaller in MO3 compared to the No Action Alternative. ... Temperatures at Ice Harbor would experience a moderate decrease with only 29.2% of all adult migration days over 20C compared to 54.3% in the No Action Alternative. Straying and migration delays, as well as susceptibility to disease, would be reduced in MO3. All of these effects would improve survival and spawning success.	
32180	20	redfish@bluefish.org	N/A	Draft PA: Flex Spill to 125%TDG, Protect the Status Quo (Chapter 7, p.99) No Breach of Lower Snake River Embankments, Flex Spill increases to 125% TDG, Snake River Spring/Summer-Run Chinook Salmon Depending on the model used and assumptions regarding latent mortality, CSS and LCM modeling indicate that the Preferred Alternative would result in lower (-7%) to substantially higher (35%) SARs for Snake River spring/summer Chinook salmon. Juvenile survival would be very similar to the No Action Alternative (about 0.6% higher). ... Snake River Steelhead For Snake River steelhead, the CSS cohort model estimates that SARs would increase from 1.8% under the No Action Alternative to 2.3% under the Preferred Alternative which is a 28% increase from the No Action Alternative. ... There is no NMFS LCM model for Snake River steelhead. Snake River Sockeye Salmon Juvenile survival would be very similar to the No Action Alternative (about 0.6% higher). Travel time would be faster and powerhouse encounters substantially fewer. Fewer juvenile Snake River sockeye would be transported. Adults could see benefits to upriver migration with some structural measures, but may experience potentially higher fallback. Both adults and juveniles would be exposed to higher levels of TDG.	Thank you for your comment, the co-lead agencies concur with this comment.
32180	21	redfish@bluefish.org	N/A	Understatements (Appendix Q, 2-3) Over the last decade, the Co-lead Agencies have spent tens of millions of dollars to improve the quantity and quality of fish habitat in the estuary and tributaries as "off-site mitigation" for the residual adverse effects of system water management on migrating salmon and steelheads. ("Bonneville budget specialists" should know better). "Tens of millions of dollars... is an understatement, and needs to be updated.	Current and anticipated future fish and wildlife mitigation measures and operations are described under the No Action Alternative, Section 2.4.2.Many of the structural and operation measures are carried forward and proposed to be implemented or expanded under the Preferred Alternative (See Section 7.6). Funding of fish and wildlife mitigation actions and programs is described in Appendix Q, Section 6.1 and Table 6-1. Additionally, Section 5.2.1 describes the existing mitigation programs under the No Action Alternative and provides a high-level summary of some of the accomplishments stemming from the significant Federal investment to date. Since the 1990s, the Federal agencies have overhauled system operations and infrastructure, achieving juvenile dam passage survival that meets or exceeds performance standards of 96% and 93% for spring and summer migrants respectively, a marked improvement as compared to when Congress passed the Act and the estimated average juvenile mortality at each mainstem dam and reservoir project was 15%20% with losses recorded as high as 30%. Travel time improved for yearling Chinook and juvenile steelhead through the system, even in low flow years such as 2015, and total In-River survival has improved for migrating juvenile salmon and steelhead. Comparing two time periods reported in NOAAs reach study (19972007 and 20082016), there has been a 10% survival increase for hatchery and wild sockeye salmon, a 2% increase in hatchery and wild Chinook (4% for wild), and a 25% survival increase for hatchery and wild steelhead (13% for wild). Regarding the statement in the Cost Appendix Q, the phrase " tens of millions of dollars" has been removed and replaced with updated language in the final EIS.
32180	22	redfish@bluefish.org	N/A	Inconsistencies (Chapter 7 page 10) Model estimates for MO3 showed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead amongst the alternatives. ... 140 percent relative to the No Action Alternative. ... (Chapter 3 page 560) For Snake River spring/summer Chinook salmon, the NMFS LCMs and CSS LCM indicate that MO3 may result in a wide range of predicted increases to SAR rates. CSS predicts SARs from Lower Granite to Lower Granite would increase by about 170% relative to the No Action Alternative. The NMFS Life Cycle Model predicts relative increase in Lower Granite to Bonneville SARs that range from 14% to 70% depending on the magnitude of reductions in latent mortality. Which comparison to the No Action Alternative will the Final CRSO document choose to use? The best choice would be to make MO comparisons when Latent Mortality is assumed to be 75% of Direct Mortality. This would conform to the best available science, documented in detail in Table 6 of Schaller's survey of literature. [Text contains figure that does not transfer to database.]	For MO3, Chapter 3 incorrectly presented CSS SAR results as "LGR-LGR". These should be LGR-BON, and will be corrected in the final. As such, they are comparable across all the multiple objective alternatives and the No Action Alternative. The model results presented in Sections 3.5 and 7.7.4 address latent mortality and reservoir mortality. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results. Moreover, the value of latent mortality is uncertain. In fact, the Independent Scientific Advisory Board (ISAB) in their 2007 report stated, "The ISAB concludes that the hydrosystem causes some fish to experience latent mortality, but strongly advices against continuing to try to measure absolute latent mortality. Latent mortality relative to a damless reference is not measurable. Instead, the focus should be on the total mortality of in-river migrants and transported fish, which is the critical issue for recovery of listed salmonids. Efforts would be better expended on estimation of processes, such as in-river versus transport mortality that can be measured directly." Under the Preferred Alternative, the inclusion of the adaptive management process would provide additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
32180	23	redfish@bluefish.org	N/A	There are many factors that contribute to the survival of fish, and most would not be improved by a free-flowing Lower Snake River. Juvenile fish survival rates currently range from 95% to 98% past each of the eight federal dams on the Columbia and Snake rivers, with continued investment in additional fish passage improvements. (Kristin Meira, Executive Director Pacific Northwest Waterways Association) - Juvenile Survival through the Hydrosystem- [Text contains figure that does not transfer to database.] (Chapter 5, 5-6) Since the 1990s, the federal agencies have overhauled system operations and infrastructure, achieving juvenile dam passage survival that meets or exceeds performance standards of 96% and 93% for spring and summer migrants respectively, a marked improvement as compared to when Congress passed the Act and the estimated average juvenile mortality at each mainstem dam and reservoir project was 15%20% with losses recorded as high as 30%. Travel time improved for yearling Chinook and juvenile steelhead through the system, even in low flow years such as 2015, and total In-River survival has improved for migrating juvenile salmon and steelhead. Comparing two time periods reported in NOAAs reach study, (1997 2007 and 20082016), there has been a 10% survival increase for hatchery and wild sockeye salmon, a 2% increase in hatchery and wild Chinook (4% for wild), and a 25% survival increase for hatchery and wild steelhead (13% for wild).	Thank you for your comment.
32180	24	redfish@bluefish.org	N/A	Water Temperature - Executive Summary There is regional controversy over the role the federal projects may play in contributing to higher water temperatures. The only "controversy" to speak of is that the federal agencies are steadfastly refusing to listen to the science: The LSR dams impound a slow-moving thermal reservoir. We should acknowledge that under MO3 there would be fewer high water temperature days than under any of the other MOs. It is troubling to find the CRSO Draft being so reticent to state the benefits of Breach Lower Snake River Embankments. Data is scattered in various tables, but nary a word is said about cooling the Columbia River.	The EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives effects on salmon and steelhead, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Water temperatures under MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the lower Snake River dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative.
32180	25	redfish@bluefish.org	N/A	(Chapter 4, p.34) Warming Water Temperatures Projected changes in stream and river temperatures may cause direct mortality due to heat stress and greater disease susceptibility, if the range of physiological tolerance is exceeded. For example, in the Columbia Basin, Snake River sockeye salmon are at high risk from heat waves during their mid-summer adult migration. Historical water temperatures have already approached lethal limits for adult steelhead in the upper Snake and middle Columbia Rivers. Thus, even minor increases in thermal exposure put some of these populations above lethal limits. In MO3, consideration could be given to ending the current management of "the available storage to augment summer (July and August) flows in the lower Columbia River and lower Snake River in an attempt to meet flow objectives and minimize increases in water temperatures." Some of these measures' "attempt to" cool has seen no biological benefit whatsoever. For instance, the cool water releases from Dworshak Dam slip underneath the warm Snake River (see map two pages below).	The co-lead agencies agree with the commenter's concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used current high quality information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence from Dworshak Dam operations. The study results indicate that the operations of the CRS do impact water temperature, but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. The co-lead agencies agree life history patterns are driven significantly by the high air temperature in the summer. However, although the cooler water slips beneath the warm Snake River water, it does provide benefits. Telemetry studies with depth sensitive transmitters show that migrating adult salmon indeed migrated deeper in the Lower Granite reservoirs than the same fish has in the downstream reservoirs, and juvenile condition and health improved since temperature management began. The warm and cold waters mix going through Lower Granite Dam, although the surface waters do warm due to air temperatures and solar input.
32180	26	redfish@bluefish.org	N/A	Strikingly, the CRSO authors completely avoided a well-document warm water tragedy when 99% of Idaho's Sockeye Salmon perished in warm reservoir waters of July 2015. But the CRSO Draft was unable to hide this tragic event entirely from the readers' view: The region's sturgeon die-off was also noteworthy. But to say the death of engorged sturgeon was due to "temperatures interacting" with the large sockeye run, is a deceptive understatement: "Interacting" is a very poor choice of words.	The effects of the No Action Alternative (Page 3-389) discusses the recent survival rates of Snake River sockeye salmon that range from 0%-70% to Redfish Lake, the Sawtooth hatchery weir, or other locations. The conditions affecting survival are also discussed, with water temperatures receiving the most attention. This range of survivals in differing conditions under the No Action Alternative is the baseline to which the multiple objective alternatives are compared. In years such as 2015, with low flows and high air temperatures, survival would continue to be compromised under all alternatives. The models showed minor changes in the Columbia River even under MO3 (the alternative with the dam breaching measure), indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Regarding white sturgeon, this language came from our workshop with fish managers to describe the interaction between high temperatures limiting metabolism coinciding with the abundance of salmon carcasses.
32180	27	redfish@bluefish.org	N/A	(Chapter 3 page 493) White Sturgeon: Mass mortality events and increased single mortalities are observed more frequently during high temperature events, often coupled with sockeye mortality events. Elevated water temperatures can have adverse effects on white sturgeon. Temperatures over 20C can limit egg survival, and in some years, a combination of low flows, elevated summer temperatures, and low DO levels have led to white sturgeon mortality (IDFG 2008). During 2015, elevated water temperatures interacted with large sockeye runs to increase white sturgeon mortality. Sturgeon gorged on decomposing sockeye while water temperatures were near 22C and were unable to metabolize these fish. Under current conditions, mean high temperatures greater than 21C would occur nearly 10 percent of the year at McNary Dam and only about 1 percent of the year at Priest Rapids Dam.Under the No Action Alternative, extreme low-flow or high-temperature years would continue to result in white sturgeon mortality events. [Text contains figure that does not transfer to database.]	Thank you for your comment; this entire comment is a direct quote from Chapter 3, page 430 (No Action Alternative) of the Draft EIS, although the commenter references page 493 (MO1). The co-lead agencies continue to support the material referenced in this comment.
32180	28	redfish@bluefish.org	N/A	Under MO3, cooler un-impounded water will contribute to cooling the Columbia River, but by how much? The CRSO should "attempt to minimize increase in water temperature" with Breach Lower Snake River Embankments and notice the heat exchange differences that would lower Columbia River water temperatures. Recreating riverine conditions on the Lower Snake River greatly improves water temperature on those 140 miles, impounded and heated by warm air temperatures and the near-daily summertime sun. A free-flowing river will be much cooler.	Reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact.
32180	29	redfish@bluefish.org	N/A	Additionally, Dworshak flows that "attempt to cool" the impounded Lower Snake River, (currently without effect, see map above) may provide benefit on the Columbia River where thermal blockages regularly occur. Potential survival benefit of adults should be thoroughly studied by analysts familiar with heat transfers thermostatics. Additionally, the adequacy of the power system under MO3 without Dworshak flows should be given full consideration: An updated GENESYS run will likely show a reduced LOLP. Adult Migration/Survival The percent of days over 18C between June 21 and July 31 would be 87.3 percent, which is three additional days over 18C compared to the No Action Alternative. This means Snake River sockeye might	Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures in show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence of Dworshak Dam operations. The co-lead agencies' analysis of MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than conditions in the No Action Alternative in the lower Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during high air temperature events. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				have slightly greater thermal stress than under the No Action Alternative. However, breaching of the four lower Snake River dams is expected to reduce delays in upstream migration and decrease the time fish are exposed to the slightly warmer water temperatures. Additionally, sockeye would not have the transportation effects that can increase straying and fallback and prolong their exposure to thermal stress.	Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3. However, the Preferred Alternative also meets all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The dam breaching alternative, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The models showed minor changes in the Columbia River under this alternative, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Summer water temperatures exiting the Snake River are typically 1 to 3 degrees Fahrenheit warmer than the receiving Columbia River temperatures. Even though the cold water released from Dworshak during the summer is less than 50 degrees Fahrenheit, the volume of water released is less than one tenth of the flow in the Columbia River. Since the distance between the confluence of the Snake and Columbia Rivers is about 180 miles downstream from Dworshak, the impact on water temperatures is negligible. Regionally high air and water temperatures result in water quality standard exceedances that are beyond the ability of the CRS to cool.
32180	30	redfish@bluefish.org	N/A	(Appendix I, Chapter 4-14) During the spring snowmelt runoff (April-May or June) Dworshak is operated to maximize the probability of re-filling the reservoir for summer flow augmentation while providing flows to meet spring objectives in the lower Snake River during the downstream migration of juvenile salmon and steelhead. Summer flow augmentation (July-September) is provided from Dworshak to increase survival of ESA-listed adult fish by moderating river temperature and increasing water velocities in the lower Snake River. (Appendix R, Annex A 1-4) April Mitigation Toolbox - Water Quality: Operate run-ofriver projects that stratify (e.g. LSR projects) to pass cooler water from deeper in the forebay to cool downstream temperatures during warm/flow conditions. [Text contains figure that does not transfer to database.]	The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally, high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Drier and warmer years such as 2015, as summarized in NOAAs 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the EIS. In addition, the co-lead agencies are actively working on implementing the recommendations identified in NMFS's 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision making and reduce, to the extent practicable, the negative impacts of high summer temperatures on migrating salmon, including adult sockeye salmon. Future analysis, particularly for real-time water temperature management, should focus on optimizing spill versus passing the water through the turbine units to maximize benefits to migrating salmonids.
32180	31	redfish@bluefish.org	N/A	Predation by Birds - Removing flow and pool elevation restrictions at John Day alongside Breach Lower Snake River Embankments, could provide the twin benefits--economic and ecologic-- of reducing nesting habitat on Blalock Island while increasing the reliability of the grid. Hydropower efficiency is improved by higher pool elevations (Energy = mass x gravity x height), and being able to ramp at a wider variety of rates for greater amounts of time will improve the GENESYS modeled adequacy of the hydropower system. The CRSO process should seriously consider these benefits of both MO2 and MO3.	Predator disruption and breaching the lower Snake River Dams were analyzed as part of MO2 and MO3. The Preferred Alternative includes the predator disruption measure at the John Day reservoir. A version of the John Day pool operation was carried into the Preferred Alternative, however, the breaching measure was not included in the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32180	32	redfish@bluefish.org	N/A	Salmon populations around the world are struggling due to climate change, rising carbon levels, pollution and more. Eliminating the clean power and efficient transportation provided by the Lower Snake River dams would add to climate change and pollution by increasing carbon from truck traffic and other sources of power, such as natural gas. This would lead to a cumulative increase in carbon emissions equivalent to building a coal-fired power plant like the one in Boardman, Ore., every 5 or 6 years. (Kristin Meira, Pacific Northwest Waterways Association) - Greenhouse Gases - (Chapter 3, 3-977) Based on various GHG inventories, emissions in the Pacific Northwest are generally low compared to other states and national averages. This is in large part because of the abundance of hydropower in the region, which does not create GHG emissions when generating power. As such, electric power generation is not the largest GHG-emitting sector in the region as it is nationally. [Text contains figure that does not transfer to database.] Notably, the 3MMT of GHG emissions that is estimated to result from MO3 is tiny by comparison with the Total U.S. Emissions from Power Generation (graphic above) where 3MMT is less than the thickness of the black line depicting Total Emissions.	The findings of the EIS emissions analysis for Multiple Objective Alternative 3 are consistent with this comment. The EIS does compare regional emissions to national levels in the Affected Environment discussion, finding relatively low levels of power sector emissions in the Northwest compared to national averages (see Draft EIS 3.8.2.2 pages 3-945 to 3-978). However, despite being small on a national scale, the increase in CO2 emissions that are anticipated under MO3, (even assuming reliance on renewable resources to replace power from the four lower Snake River Dams) makes regional emissions policies and goals more difficult to achieve.
32180	33	redfish@bluefish.org	N/A	Executive Summary MO3 would not meet the objective to Minimize GHG Emissions. GHG emissions were analyzed for the base case hydropower impacts without the effect of the additional coal-plant retirements. GHG emissions would increase the most if the hydropower were replaced with natural gas. This would lead to an additional 3.3 million metric tons (MMT) of CO2, a 10 percent increase in power-related emissions across the Northwest (needs correction). ... This increased reliance on fossil-fuel-based resources is estimated to increase power-related emissions by 2.7 percent (1MMT of CO2) across the region even assuming the new replacement resources are other renewables. In the future, technical advances in storage and other low-carbon options may become increasingly viable to help integrate variable renewable generation.	The findings of the emissions analysis for MO3 are consistent with this comment. The EIS acknowledges that the renewable power resource portfolio may better reflect future trends (see EIS Section 3.8.3.1 page 3-987 in the Draft EIS). In addition, regarding the potential benefits of future clean energy technology, the EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their Seventh Power Plan (page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. The basis for developing the power portfolios may be found in Section 3.7.3.1, Methodology, and Section 3.7.3.5, Potential Replacement Resources and Associated Costs for MO3 specifically in the Draft EIS.
32180	34	redfish@bluefish.org	N/A	A large part of the Executive Summary was dedicated to Coal Plant closures that were announced after the CRSO process began. The Base Case is all that is pertinent, otherwise a NEPA analysis would become unnecessarily complex and intractable by adding ever changing future conditions: trends in solar plus battery and wind plus battery installations, 15-minute Energy Imbalance Markets, changes in load and conservation forecasts due to Covid-19, a newly announced loss of a Tier 1 customer from Bonneville's ever shortening list of Direct Service Industries, construction of a 1,150 mile Gateway West transmission line connecting Wyoming's burgeoning fleet of wind farms to the Pacific Northwest, development of flow batteries, and on and on. Under MO3, the CRSO considers that ensuring "an adequate, efficient, economical and reliable power supply" would necessarily require a natural gas backup, promoting a need for "Conventional Replacement Portfolio" alongside Breach Lower Snake River Dam Embankments. Notably, the Seventh Power Plan, which the CRSO Draft frequently references, found that NW Council's "Least Cost Replacement Portfolio" would simply reduce the export of the Bonneville's omnipresent surplus of electricity. Consequently, under the Seventh Power Plan's analysis, natural gas backup would be provided almost entirely by existing natural gas power plants (Figure 3-13 next page).	The comment suggests the EIS should have ignored information relevant to environmental concerns and bearing on the proposed action or its impacts, which is inconsistent with the co-lead agencies obligations under NEPA. See 40 C.F.R. 1502.9. As described in a previous response, the analytical approach used in this EIS which included more recent information - provides a more complete picture of the Multiple Objective (MO) Alternatives impacts on regional reliability and costs and is consistent with what NEPA requires. The comment incorrectly suggests that MO3 only considered a natural gas resource replacement portfolio. The EIS considered a range of resource portfolios to replace the power output of the four lower Snake River dams. That range is reflected in two portfolios used to outline the potential resource options: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Section 3.7.3.5, at pages 3-904-910 in the draft EIS. These portfolios represent a range of potential portfolios that could be used to return the regional power system to the reliability level of the No Action Alternative. The commenter is presumably referring to the Councils removal study in mentioning the Councils Least-Cost Conventional Portfolio. That analysis is not comparable to the analysis performed in the EIS. The Councils study removed a generic 1000 aMW carbon-free resource in the 7th Power Plan, rather than removing the four lower Snake River dams, with their particular generation, shape, and characteristics. Further, it is not clear if this study was modeled using the GENESYS model, which is the model relied upon in the EIS. See Section 3.7.3.1, Step 2: Analyze Effects on Power System Reliability at page 3-819 in the draft EIS. Further, the Councils study had an approximately 2,000 aMW lower load forecast than the forecast used in the EIS, which is more current. The comment suggests that the lost capability from the four lower Snake River dams could be supplied through reduced exports of electricity from Bonneville. This is incorrect. The four lower Snake River dams are not used exclusively to support power sales out of the region. Rather, Bonneville sells power from the Federal projects on a coordinated, system basis. Loss of the capability from the four lower Snake River dams would increase the regions risk of a blackout. Under average water conditions and 80-year water data, the four lower Snake River dams produce between 460 aMW to upwards of 1400 aMW of power during the winter months of December through February, which are typically the most energy intensive months for Bonneville. See Section 3.7.3.5, Changes in Power Generation, Table 3-159 in the draft EIS. Without replacing the power from the four lower Snake River dams, the Loss of Load Probability (i.e., risk of blackouts) for the region would more than double to 14 percent, which is equivalent to one blackout every seven years. See draft EIS, Section 3.7, page 3-903 and Appendix H-Power and Transmission at Table 2-1.
32180	35	redfish@bluefish.org	N/A	The NW Council staff specifically designed Seventh Power Plan's "Planned Loss of a Major non-GHG Emitting Resource" to be very similar to the removal of Lower Snake River dams, one removal every other year over eight years. Oddly, NW Council's extensive computer modeling results are completely absent from the CRSO Draft. [Text contains figures that do not transfer to database.] The CRSO process did not include the NW Council "reasonable mitigation" of simply reducing exports, and pressed forward with an unfound need for "Replacement Portfolios" alongside Breach of Lower Snake River Embankments. Importantly, the NW Council found that under the "Planned Loss" scenario, reducing exports is not cost prohibitive (Figure 3-20, previous page). Undeterred, the CRSO repeatedly insists that Replacement Portfolios are needed for an "adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System." As an aside, shouldn't that sentence structure be reversed? Is it not the Columbia River Power System that is providing that support? After all, the CRSO Draft highlights the benefit of hydropower as a means to balance intermittent renewables.	There are notable differences between the Northwest Power and Conservation Councils (Council) analysis of Planned Loss of a Major non-GHG Emitting Resource and the Multiple Objective Alternative 3 analysis in the EIS that included breaching of the four lower Snake River dams. The Council modeled the loss of generic non-GHG emitting resources. If the Council had analyzed the timed removal of the four lower Snake River dams, resource strategies would have had to also account for the 1,700 to 2,000 megawatts of sustained peaking loss and not just the loss of 1,000 average megawatts of energy generating capability. This would have likely increased the magnitude of the requirement for replacement resources. (Council 7th Power Plan, page 3-13). Specifically, In the Planned Loss of a Major Resource scenario, it was assumed that a total of 1,000 megawatts nameplate capacity producing 855 average megawatts of energy resources that do not emit carbon dioxide were retired by 2030. (Council 7th Power Plan, page 15-37). This is a resource that is not only slightly smaller in energy, but significantly smaller in capacity than the combination of the four lower Snake River dams. In the EIS LOLP analysis, surplus/export loads are not included. Even without this load, the LOLP for MO3 at 14 percent was more than double that of the No Action Alternative at 6.6 percent and nearly three times the Councils target of 5 percent. The Council used their Resource Portfolio Model for the 7th Power Plan analysis of this study. The EIS used the Councils GENESYS model, Council data (including that of the 2022 Resource Adequacy Assessment), and the Councils resource adequacy metric and standard and only proposed replacement resource portfolios if that standard was not met.
32180	36	redfish@bluefish.org	N/A	The CRSO Draft suggests that MO3 requires a need for more natural gas combustion; apparently Bonneville needs to sell surplus power for Secondary Revenue Credits (see Table 4-9, next page). Consider that even if all of the Lower Snake hydropower output were replaced (half of which is surplus, see Table 3-111, next page), only 3.2 MMT of CO2 would be added to the entire West Coast. With that in mind, recall that the recovery of Idaho's Salmon and Steelhead would provide ever growing amounts of carbon sequestration in Idaho's forests, with marine-derived nutrients arriving for free. The result of MO3 would surely be a net benefit for sequestering Greenhouse Gases. (Chapter 3, p.1015) Across the wider Western Interconnection, excluding regions outside of the United States, average emissions from AURORA in MO3 with the conventional least-cost replacement portfolio would be 166 MMT CO2, approximately 2% greater than No Action Alternative.	The findings of the emissions analysis for Multiple Objective Alternative 3 (MO3) are consistent with this comment. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, one that included natural gas and one that included all renewable resources, both of which maintain regional power system reliability. The EIS does find an increase in fossil fuel generation even assuming all renewable replacement resources are built to meet demand. This increase results when renewables are not generating power because some level of fossil fuel generation would be required to maintain reliability in the electric system. Given that policy and legislative decisions in Oregon and Washington are targeting large reductions in greenhouse gas emissions, even a 2.7 percent increase in CO2 emissions, even with the renewable replacement resources, makes these goals more difficult to achieve. The basis for developing both of these power portfolios may be found in Section 3.7.3.1, Methodology, and Section 3.7.3.5, Potential Replacement Resources and Associated Costs for MO3 specifically of the Draft EIS. With respect to the influence of salmon on carbon sequestration, Section 3.5 identifies that fish migration through the lower Snake River corridor would improve under MO3. Section 3.5.2.3 recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. This indicates that, in some areas, MO3 would likely improve landscape carbon sequestration. However, in other areas, MO3 may reduce landscape carbon sequestration. As described in Section 3.6.3.5, lower water levels in the spring and early summer in some areas under MO3 would reduce productivity in some existing emergent herbaceous and forested and scrub-shrub wetlands. The overall effect of MO3 on landscape level carbon sequestration across the Basin is uncertain.
32180	37	redfish@bluefish.org	N/A	Lastly, while referencing NW Council's "Achievable Conservation Potentials" (Figure 12-6, next page), consider that Climate Change projections see a decrease in electricity demands in warmer winters, but an increase in demand during warmer summers. These forecasted changes will change the LOLP modeled for MO3. (Appendix J 6-15 Climate Change) The power shortages in December through February under the NAA and MO alternatives could be reduced into the 2030s as loads in those months decrease. Conversely, the summer shortages that increase in MO1, MO3, and MO4 as compared to the NAA are likely to be further exacerbated as temperatures and load in those months increase. [Text contains figures that do not transfer to database.]	The comments in this statement regarding changes in power generation due to climate change are consistent with discussions in Section 4.2.5, Power Generation and Transmissions, and Appendix J, Hydropower in the Draft EIS. Specifically, the EIS examined four future climate scenarios to assess potential changes in hydrology, and thus, how climate change may impact generation. Section 4.2.5.2 in the Draft EIS discusses the change in loads and impacts to reliability in relation to climate change.
32180	38	redfish@bluefish.org	N/A	An Adequate Power Supply - . (Appendix H, 2-4) The specific resources that would be developed to maintain a sufficient and reliable supply of power are uncertain. Costs, technical feasibility, and regional greenhouse gas emissions policies and targets, among other factors, all influence resource availability in the future. ... This analysis considers two potential replacement portfolios. ... To maintain power system reliability in the Northwest with MO3, additional generation resources would be needed. For the previous analysis, Bonneville considered two scenarios for replacement portfolios. The first scenario adds resources to restore the LOLP to the same level as the No Action Alternative for the base scenario without additional coal-plant	This comment identifies a complexity in the EIS analysis that is described in the body of the EIS and in the Appendix H. Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS. The language in Appendix H is attempting to describe the Base Case assumptions of including sufficient zero-carbon resources to return regional reliability to the No Action Alternative, while also replacing a portion of the lost capability of the four lower Snake River dams. See Appendix H, Power and Transmission, Section 2.2.1, at H-2-5 in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				retirements. This approach replaces only the generation produced in dry water conditions (in the water years when power shortages are most likely), but does not replace the full capability that would be lost in MO3. It also relies more on generation from non-CRSO projects (i.e. leans on the rest of the regional power system) to meet load in the region, primarily by operating thermal resources. In the future condition with additional coal-plant retirements, this option would not be sufficient to return the LOLP to the No Action level, because without coal, more of the capability or replacement capability of the Lower Snake River (LSR) projects would be needed for power system reliability. The third scenario developed (bluefish: before mention of a second) designed a portfolio of replacement resources that replaces all of the generation capabilities currently supplied by the LSR projects. In the short-term, this portfolio may replace some of the generation capability that may be considered surplus. However, as more coal plants retire, replacing the full capability of the LSR projects becomes more essential to maintain the reliability of the power system. For example, the ability of the projects to ramp generation up and down quickly is very valuable to integrating new renewable generation. It is in this third scenario that employs the newly created energy metric the CRSO refers to as "Historical Sustained Ramping" which in February amounts to over 2,000 MW of something or another. I asked NW Power & Conservation Council staff about this metric, I learned that they too had never heard of it before, and were unable able to parse "Historical Sustained Ramping" into anything meaningfully or useful. Notice second paragraph H-2-5 Bonneville considers two scenarios then discusses a first scenario adds resources The next paragraph then introduces us to a third scenario. which "replace some of the generation capability that may be considered surplus. The reader is told to expect only two scenarios, but suddenly there are three. That is curious. It seems that someone late in the game added a third to look at the power system needs when future coal plants are retired. What happened to the second? Continuing further, we learn that for the cost analysis, scenario 2 is used. For the rate analysis (scenario 2), Bonneville chose to design a portfolio that is inbetween the two scenarios described above, in other words, more than replacing the minimum generation needed just for power system reliability under the current system before coal plants retire but less than a full replacement of all capabilities. Finally the mystery is solved. This is why Bonneville did not ask NW Council to run the GENESYS model. This is why Bonneville did not share their input data with the NW Council. The CRSO generates inflated costs that are far more than are necessary for "replacing the minimum generation needed just for power system reliability". Thank goodness this sleight of hand was documented in Appendix H. In order to show an increase in rates under Breach Lower Snake River Embankments, the CRSO added LOLP in MO3 by including an increase in spill to 120% TDG. Not only did the CRSO ignore the Seventh Power Plan's findings of a Least Cost Resource Portfolio under a "Planned Loss" scenario, Bonneville sought to inflate the needs of its two replacement portfolios beyond what is necessary. This is shocking and underhanded. [Text contains table that does not transfer to database.] In addition to more carbon emissions, losing the Snake River dams puts us at risk for higher electricity prices and doubles the risk of blackouts from lack of power during peak demand periods. (Kristin Meira, Pacific Northwest Waterways Association)	For the Base Case, the EIS assumed that half of the installed solar (2,550 MW in the Draft EIS) in MO3 would need to be accompanied by battery storage to provide sustained power during longer events without sufficient solar generation without leaning on or overloading existing regional capacity to integrate these renewables. The value was used as a proxy for the estimated amount of capacity needed to support new renewable integration in light of the loss of the four lower Snake River dams and potential future restrictions of available capacity due to increased retirement of coal capacity. The commenter appears to question the need for this additional capacity in MO3 if the objective is to only return regional reliability to the No Action Alternative level. The need for resource capacity to integrate renewable resources is well established and discussed at length in the EIS. In the Draft EIS please see Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at pages 3-904-905; Table 3-160; and, Section 3.7.3.1, Integration Services, page 3-832. Solar resources are not dispatchable, and demand response resources hold promise, but are arguably not mature enough within the Northwest to replace the lost flexibility of the Federal Columbia River Power System (FCRPS) under a dam breach scenario. Therefore, additional resource costs associated with additional storage which might be necessary to meet load and resource variability at time steps smaller than monthly-diurnal increments, was included as a proxy for the value of lost flexibility, such as sustained peaking and ramping capability. While the EIS use of this proxy is an accurate reflection of true missing costs under this scenario, the co-lead agencies, in response to public comments, updated the amount of the solar plus batteries replacement under the MO3 scenario framework in the analysis in the Final EIS in Section 3.7.3.5. Additional spill to 120% Total Dissolved Gas at the lower Columbia projects was included in MO3 in response to the desire expressed by cooperating agencies to increase spill to aid migrating anadromous fish.
32180	39	redfish@bluefish.org	N/A	An Economic Power Supply - Executive Summary MO3 would not meet the objective to Provide a Reliable and Economic Power Supply. Under MO3, hydropower generation would decrease by 1,100 aMW under average water conditions, and 730 aMW under low water conditions compared to the No Action Alternative. A surprise to those that have only read the Executive Summary and missed the hidden details of the Draft CRSO, BPA is NOT forecasting an increase in rates under MO3, but foresees a decrease in electricity rates across the region (see Figure 5-4 below). [Text contains figures that donot transfer to database.] In stark contrast to rates under MO3, the Draft Preferred Alternative sees an increase in regional electrical rates throughout the region (see Chapter 7 Figure 7-22 above). In the previous section, we learned that "Bonneville chose to design" a rate effect analysis employing two portfolios that exceed the Loss of Load Probability (LOLP) needs. Following that, Bonneville then considered how the region might replace the many purported hydropower benefits of the LSR dams and designed two Replacement Portfolios that might be beneficial when coal-plant retirements someday occurs. Both of these portfolios, by design, bring about an increase in power rates across the region. But no such replacement portfolio is needed, nor will it every actually occur. Note that the Draft CRSO adds a caveat to their "conventional" and "zero-carbon" portfolios: (SOMEWHERE in CRSO Draft) Before making such an investment, Bonneville and its regional partners would need to collaborate on identifying other viable options that could maintain reliability and meet regional carbon objectives, while also ensuring federal power remains competitively priced for Bonneville's power customers. The graphic below is derived from Bonnevilles similar graphic, which Bonneville presents to erroneously suggest that LSR Dams are among their low cost producers. In actuality, as the CRSO Draft has also shown (see Figure 5-4 above), Bonneville's "Total Cost" of Lower Snake River hydropower and Compensation Plan Hatcheries is above the Secondary Energy price of $16.10/MWh (or $19.10 by AURORA, below). [Text contains figures that do not transfer to database.] Figure 5-4 at the end of Appendix H, aligns with and confirms what I have been saying for years now: Removing the four LSR Dams, (with half their power being surplus, Table 3-111 above) and shuttering LSR Compensation Plan hatcheries, is not only the best biologic choice, it is the most economic choice as well. [Text contains figures that do not transfer to database.]	The average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Finally, the reduced dam operating and fish and wildlife mitigation costs are discussed for MO3 in Section 3.19 and Appendix Q. For MO3, Bonneville's Fish and Wildlife (F&W) Program is estimated to cost $282 million annually and includes fish mitigation projects and studies across the Basin. As stated in the CRSO Draft EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made through the CRSO EIS process. Future Fish and Wildlife funding decisions would be made in consultation with the region, through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Based on the inherent uncertainty of Bonneville's F&W Program funding requirements, with lower Snake River dam breaching, Bonneville's Fish and Wildlife costs were provided as a range for MO3, from current levels ($282 million annually) to $177 million annually, a reduction of $105 million. Bonneville currently pays USFWS approximately $34 million annually to operate fish facilities associated with the Lower Snake River Compensation Plan (LSRCP). Bonneville's funding authority for the LSRCP is directly tied to the operation of the four lower Snake River dams. In addition, approximately, $1 million annually is expended on the Columbia River Fish Mitigation associated with the four lower Snake River projects. Therefore, total fish and wildlife funding (or costs) for the four lower Snake River projects could range from a low of $35 million ($34 million for LSRCP plus $1 million for Columbia River Fish Mitigation) to $140 million ($35 million plus $105 million in F&W Program funding). The range in potential reductions in salmonid mitigation costs under MO3 is captured in the Power Rate Pressure Analysis, Appendix H Section 4.1. Section 4.1.1.3 describes the Fish and Wildlife program costs and reduction in these costs under MO3. Annual equivalent capital, operations and maintenance costs would also be reduced by $107 million per year under MO3 (Table 4-3 for capital and Table 5-4 for operations and maintenance). These savings, ranging from $142 million to $212 million per year are offset by the cost to replace the power of the four lower Snake River dams ranging from $270 million to $540 million (Table 3-171). Therefore, it is not expected that breaching the four lower Snake River dams would result in lower hydropower costs for the entire Federal Columbia River Power System.
32180	40	redfish@bluefish.org	N/A	- A Reliable Power Supply - (Chapter 7, p.10) - MO3 would only partially meet the objective for an adequate, efficient, economical, and reliable power supply due to the loss of hydropower generation, system flexibility and peaking capabilities at the four lower Snake River projects. As discussed in more detail below, without adequate and timely resource replacement, including battery storage (at utility level scales), MO3 would not meet the objective for hydropower due to the loss of 1,100 average megawatts (aMW) of hydropower generation, more than 2,000 megawatts (MW) of sustained peaking capabilities during the winter, and a quarter of Bonneville's current reserves holding capability provided by the four lower Snake River projects. (Appendix I page 4-6 footnote 13) There is little capacity to hold reserves at the Lower Snake River dams when the forebays are maintained within a narrow operating range at MOP. This operating range restriction constrains reservoir storage capability and therefore limits the ability to hold many reserves. Which of the above excerpts concerning Bonneville reserves are you going to believe? (Appendix I, 4-6 footnote) Hydropower is dispatchable as long as there is flexibility to increase or decrease generation, which sometimes means having ability to increase or decrease flow coming from an upstream reservoir. For example, there is little capacity to hold reserves at the Lower Snake River dams when the forebays are maintained within a narrow operating range at MOP. This operating range restriction constrains reservoir storage capability and therefore limits the ability to hold many reserves. [Text contains figures that do not transfer to database.] (Appendix J. 2-8, and see flowchart of previous page) For the CRSO DEIS alternatives, the GENESYS model was run by Bonneville staff. Datasets containing hydropower generation plant parameters and constraints (inputs similar to HYDSIM and ResSim) thermal generation plant parameters and constraints, and other generation sources and constraints were input into the model. Not only did Bonneville design replacement portfolios in excess of LOLP needs, but inputs to the GENESYS model were input by Bonneville staff. Why were the experts at the NW Council not asked to oversee, or at least validate, this CRSO process? Why has the NW Council not been involved in all of this analysis? They are the region's experts. Statute dictates that it is for the NW Council to "assure a reliable, economic, adequate power supply". The CRSO has used disinformation to yield calibration difficulties, caveats, and incomplete results. Instead, why not seek out the NW Council expertise, critiques and reviews vetted by an Independent Science Advisory Board. The best way that I see for the CRSO to proceed, is to run NW Council's Redeveloped GENESYS with Bonneville "first scenario" which "adds resources to restore the LOLP to the same level as the No Action Alternative for the base scenario without additional coal-plant retirements. This approach replaces only the generation produced in dry water conditions (in the water years when power shortages are most likely)". (Appendix H) Regional Power Supply Loss of Load Probability (LOLP) Under the No Action Alternative, regional LOLP is currently 6.6 percent. Without replacement resources, regional LOLP would increase under MO1 (+4.6 percentage points), MO3 (+7.3 percentage points) and MO4 (+23 percentage points). LOLP would decrease under MO2 (-1.6 percentage points) and the Preferred Alternative (-0.1	The four lower Snake River projects provide over 2,000 MW of sustained peaking capacity when there is sufficient flexibility in the forebay operating range. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907, Table 3-160 in the Draft EIS. Outside the fish passage season, the projects have 3-5 feet of operating range. The dams provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. Within the fish-passage season, the four lower Snake River projects are restricted in their operating range. (1-foot range in the No Action Alternative expanded to 1.5 feet under the Preferred Alternative.) The projects can increase generation for a brief period (1 to a few hours if flows are not so low that the project is restricted to minimum generation). The travel time for flows to reach the next project is about an hour. So if Lower Granite increases generation and outflow in one hour, then Little Goose would have higher inflows the next hour. Consequently, the projects are typically able to provide some reserves even with a restricted forebay range, but not the full amount they provide in the fall and winter. Bonneville staff have the expertise to run the GENESYS model and describe its outputs for the CRSO EIS. Bonneville has worked with the Northwest Power and Conservation Council (Council) on developing the model for many years. For areas of the CRSO EIS power analysis where Bonneville staff did not have expertise, Bonneville hired consultants; however for the GENESYS model, this expertise is housed within Bonneville. The Council received periodic updates on the CRSO EIS process similar to the general public. Since it is not a Federal, Tribal, state or local agency, the Council could not serve as a cooperating agency under NEPA. The Council received the Draft EIS when it was available for public review. The Councils redeveloped GENESYS is still in the testing phase, and was not available for use in the CRSO EIS. The comment accurately cites to the EIS, which describes the need for additional resources to maintain regional reliability at the No Action Alternative level. While the EIS use of this proxy is an accurate reflection of true missing costs under this scenario, the co-lead agencies, in response to public comments, updated the amount of the solar plus batteries replacement under the MO3 scenario framework in the analysis in the Final EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				percent) relative to the No Action Alternative. If Bonneville and/or its power customers did not acquire additional resources to replace the reduction in hydropower generation under MO1, MO3, MO4, then there would be an increased risk of power shortages. Replacement resources would be required not only to replace the energy lost but also to replace some peaking capability of the hydropower system. ... Replacing lost peaking capability would result in a need for replacement resources. Under MO3, 1,120 MW of natural gas or 3,150 MW of zero-carbon resources would be required. Our decision makers need an honest report if they are to make well-informed decisions regarding the plight of Idaho's salmon and critically endangered Orcas. Let's get it right in the Final CRSO EIS. A collapsing ecosystem depends on it	
32180	41	redfish@bluefish.org	N/A	- An Efficient Power Supply - Oversupply - Transmission Congestion (Appendix H, 3-4) In this analysis, transmission interfaces experiencing flows within 0.1% of its current transfer limit are said to be "congested." The change in the number of congested hours is one measure of the impact that the alternatives and their resource replacement portfolios have on the regional transmission system. Transmission interfaces that are congested can, therefore, restrict the dispatch of lower cost generating plants and instead require the dispatch of higher cost generating plants, which increase the overall cost of serving customer loads. Appendix H 3.1.1 Transmission Interface Utilization Results Given the hydropower generation levels under each CRSO alternative, the gas-fueled replacement generation resources added for the conventional least-cost resource replacement portfolio were regularly called on as part of GridView's hourly least-cost generation dispatch process. .... The changes in the patterns of generation under the MO alternatives and their resource replacement portfolios would have measurable impacts on loading and congestion for many regional transmission interfaces. Results show that MO3 with "Conventional" Replacement Portfolio increases oversupply in many cases, whereas congestion decreases under MO3 during median and high runoff conditions. This is further evidence that Bonneville's "scenario 2" Replacement Portfolios are an overbuild beyond what is necessary for the system. Oregon-California: with multiple interties increases 47 congestion hours (Table 3-14), "For the three run-off scenarios, all lines in this interface would experience the greatest number of congested hours under MO3 in higher run-off conditions." Congestion also Increases: PO8 Northwest to Montana: increases by 44 congestion hours (Table 3-8) P14 Northwest to Idaho: increases by 125 congestion hours (Table 3-9) P65 Pacific DC Intertie: increases by 100 to 365 congestion hours (Table 3-10) South of Custer: increases by 87 congestion hours under High run off (Table 3-13) Notably, these increases in transmission line congestion hours are in flows out of the region. The market has been in surplus for many decades now, with Bonneville reporting on their ever-present surplus in their annual reports going back to the 1980s. Congestion Decreases on the transmission path to Idaho: P75 Hemingway-Summer Lake: decreases by 159 to 528 congestion hours (Table 3- 11) "Relative to the No Action Alternative, the number of congestion hours in the west to east direction decrease under MO4 and MO3 for median and high run-off when there would be less hydropower generation to send in an easterly direction under those alternatives." Under high run-off conditions, in which Canada is also exporting excess hydropower: MO3 under High run-off power from Canada adds congestion. Raver-Paul: decreases by 10 to 57 congestion hours (Table 3-12) "Congestion would decrease under the median and high run-off scenarios under MO3 and MO4, particularly under high run off conditions." Powerflow (Appendix H)	A change in transmission congestion does not inherently reflect an overbuild of resources when these resources are needed to meet resource adequacy or power system reliability objectives. The power system reliability analysis described under Step 2 of Section 3.7.3.1, Methods, estimated the effect of the alternatives on power system reliability (i.e., Loss of Load Probability) and Step 3 describes the identification of replacement resource portfolios, including the use of zero-carbon resources (e.g. solar) with lower capacity factors and variable output. As discussed under Step 4 of Section 3.7.3.1, Methods, the transmission congestion modeling evaluated the dispatch of resources and transmission use on an hourly-basis for a year under different hydro runoff conditions. Transmission flows with each alternatives resource replacement portfolios were compared against flows for the No Action Alternative. While there may be an increase in transmission congestion hours or exports under certain flow regimes with replacement resource portfolios, the power reliability attributes of those portfolios and the ability to meet unserved load should be considered as well. Resources may be needed to meet power system reliability adequacy during a certain portion of the year. Transmission congestion modeling may reflect some congestion hours during other portions of the year when the resources may not be needed for power reliability purposes, but are available to displace resources with higher variable costs in different locations. Increases in transmission congestion hours reflect a potential increased cost to serve customer loads relative to an uncongested system.
32180	42	redfish@bluefish.org	N/A	The Powerflow analysis focused on the lower CRS hydropower generation variation by alternative (note to editors, a repeat of this sentence then follows in Draft): 1) The transmission system generally evolved with high generation output from the various Columbia River System resources. Operation of the transmission system with reduced generation at the CRS projects generally results in reduced stress to the transmission system. 2) Since reduced peak output from the CRS resources was central to all of the MO alternatives, result would be a system that has less capacity or ability to reliably serve peak load typical in July and August (see graphic of conservation before "An Adequate Power Supply") when there is a reduced availability of hydropower generation. 3) The third consideration was the location of the replacement resources. For the conventional least-cost and zero-carbon portfolios, it was important to see how the reduced output from the CRS hydropower projects would interact with the addition of the replacement resources. Again, it is the times when the CRS resources are at their lowest output that are critical to determining whether the transmission system, in concert with the replacement resources, will still be able to reliably serve load within the Region. While the CRS resources would be at a reduced output, the replacement resources would be at or near their expected full output to serve the required load. For each of the MOs and the Preferred Alternative, the No Action Alternative was adjusted by modifying the generation at the Lower Snake and Lower Columbia River projects to the minimum levels specified in each of the alternatives. The replacement resources were then added to preserve service to loads within the region and to support exports on the Southern Interties.	The co-lead agencies evaluated a range of spill levels to determine the various impacts across resources affected by CRS operations, maintenance and configuration. This included spill levels near 110% Total Dissolved Gas (TDG) up to 125% TDG. It is true that spill is typically lower in July and August than earlier in the juvenile fish passage season (April June). In MO3, spill for juvenile salmon passage reduces to surface passage (significantly lower spill levels) in August. In the Draft EIS, please see Exhibit 3 of Appendix J, Hydropower, top figure on page J-E3-3, which shows that generation at most lower Columbia River projects is slightly lower in MO3 than in the No Action Alternative (-90 to +40 aMW) in July; but, is 300-400 aMW higher in August.
32180	43	redfish@bluefish.org	N/A	Table 3-15 (Appendix H) is interesting, as it seems to show the effect of increased spill, while at their lowest outputs, typically July and August. Notably, the interface Flows change very little from NAA under MO3 without replacement portfolios (HydSim). The only exception is for Interface Flows West of Lower Monumental: 1,659 down to 1,504. This is yet another reason for running a complete analysis of MO3 without increased spill for the CRSO Final Report, changes due to Spill to 120% TDG are significant. [Text contains figures that do not transfer to database]	The co-lead agencies evaluated a range of spill levels to determine the various impacts across resources affected by CRS operations, maintenance and configuration. This included spill levels near 110% Total Dissolved Gas (TDG) up to 125% TDG. It is true that spill is typically lower in July and August than earlier in the juvenile fish passage season (April June). In MO3, spill for juvenile salmon passage reduces to surface passage (significantly lower spill levels) in August. In the Draft EIS, please see Exhibit 3 of Appendix J, Hydropower, top figure on page J-E3-3, which shows that generation at most lower Columbia River projects is slightly lower in MO3 than in the No Action Alternative (-90 to +40 aMW) in July; but, is 300-400 aMW higher in August. Finally, the agencies that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), and also meets most of all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions. It minimizing adverse impacts to communities and the economy. The Preferred Alternative is likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32180	44	redfish@bluefish.org	N/A	(Appendix J-iv) NW-US and CRS MO3 generation is reduced year-round from the loss of CRS generation at the four lower Snake River dams, although this reduction from NAA generation is offset in August by lower Columbia River projects' generation increases. The greatest reductions from the NAA occur in spring and summer due to increase fish passage spill at the lower Columbia projects. The August NW-US and CRS generation increase results from terminating CRS fish passage spill earlier than the NAA. Small changes were observed for the Mid-Columbia and Canadian systems. Critical Year graphic (Figure 3-5) reveals that it is MO3 increased spill that increases LOLP in January, and May and June LOLP is half due to the increase in spill. [Text contains figures that do not transfer to database]	Appendix J, Figure 3-5 in the Draft EIS, shows the critical-year generation for MO1. The comparable graph showing monthly generation changes under critical water conditions (1937 water) for MO3 is Figure 3-9. In Figure 3-9, there is a slight net increase in generation in January as the increase in generation at Grand Coulee, the lower Columbia River, and other projects exceeds the lost generation from the four lower Snake River dams. However, the generation change for all three winter months on average is a loss. The commenter is correct that the generation loss in May and June from losing generation at the four lower Snake River dams is roughly comparable to the loss in generation due to increased spill and small changes in flows at the four lower Columbia River projects.
32180	45	redfish@bluefish.org	N/A	3.2.1 Powerflow Results (Appendix H) Given seasonal demand for power in the Pacific Northwest and seasonal differences in transmission system capacity, winter and spring/fall demand scenarios were determined not to produce conditions that were limiting. During the summer, however, many areas experience substantial peak loads at the same time that the capability of the transmission system is reduced. The capability of the transmission system is reduced in the summer because higher ambient temperatures limit the ability of the system to transmit energy. Additionally, due to low streamflow conditions and spill requirements generation and flexibility allowed under the various alternatives for the Columbia and Lower Snake hydropower projects is at the lowest levels, which results in a higher reliance on the replacement resources. Reduction in allowed generation also limits the flexibility of the CRS projects during the limiting summer season. ... MO3, which includes the breach of LSR dams, would be the only alternative where the studies indicated a need for system reinforcement. Generation at Ice Harbor provides load service to the Tri-Cities during peak summer load conditions and during emergencies (e.g., loss of the main grid connection at Sacajawea). An outage of one of the transmission lines connecting the Tri-Cities area to the main transmission grid limits the amount of power that can be delivered to the Tri-Cities load. During such outages, having generation from the Ice Harbor project supports reliable service to the Tri-Cities load. The generation at Ice Harbor also provides support for transmission operations and maintenance in the Tri-Cities area. In MO3, the inability to take lines out of service for maintenance and to respond to operational constraints, such as the loss of a transmission line, could result in loss of load within the Tri-Cities area. Prior to evaluating the impacts of potential breach of Ice Harbor Dam, Bonneville had identified the need for a transmission reinforcement project just beyond the 10- year planning horizon to maintain	As discussed in the Bonneville Transmission System Reliability and Operations subsection in Section 3.7.3.5 of the Draft EIS and Section 3.2.2 of Appendix H, prior to evaluating the impacts of potential breach of Ice Harbor Dam, Bonneville had identified the need for a transmission reinforcement project just beyond the 10-year planning horizon (2018-2028) to maintain reliable load service to accommodate load growth, to the Tri-Cities area and to support transmission operations and maintenance. From a transmission rates perspective, this means that Bonneville would not expect to see the impact of such a project within the 10-year planning horizon. The base need for the project would arise independent of removal of the generation at Ice Harbor. However, the timing of the reinforcement is very dependent on when Ice Harbor might be breached and would be needed immediately. As such, the transmission analysis considered the speed up of the timing for the need for the reinforcement project as a result of breaching the four lower Snake River dams evaluated under MO3, by including the costs of the project starting at the time the generation from Ice Harbor would be removed from the system. This would allow time for environmental compliance, permitting and construction to occur. The EIS analyzed the cumulative transmission rate pressure changes relative to the No Action Alternative through 2028 for all of the alternatives. Under the No Action Alternative, the Tri-Cities area reinforcement would not be needed within this 10-year time frame and was, therefore, not reflected in the baseline for this time period. The transmission rate pressure relative to the No Action Alternative for MO3 did reflect these reinforcement costs as MO3 would require the reinforcement project under both resource replacement portfolios during the 10-year transmission rate pressure analysis timeframe. Section 4.2.1.1, Revenue Requirement, of Appendix H contains a discussion of the transmission capital cost assumptions, including the timing and direct costs. As discussed in Section 3.7.3.5, Potential Replacement Resources and Associated Costs, under the least-cost replacement generation portfolio, returning Loss of Load Probability to the No Action Alternative level could be accomplished with approximately 1,120 MW of combined cycle natural gas turbines located in northeastern Oregon in a base case without additional coal closures. As a result, the transmission analysis identified interconnection costs associated with the identified resource replacement, which was assumed to be located in northeastern Oregon near McNary due to the location of existing infrastructure.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				reliable load service to the Tri-cities area and to support transmission operations and maintenance. The base need for the project would arise independent of removal of the generation at Ice Harbor. The timing of the reinforcement, however, is very dependent upon when Ice Harbor generation might be removed.	The Northwest Power and Conservation Council (Council) ran a study of the loss of a major non-carbon producing resource, but this study did not look at breaching the four lower Snake River dams, in the Seventh Power Plan using their resource portfolio model. The lost-resource in the Councils study had a smaller energy and much smaller capacity attribute compared to the four lower Snake River dams. Further, the Councils load forecast at the time of the Seventh Power Plan was lower than the more recent load forecast used in the EIS. The EIS did not use the Councils resource portfolio model. The EIS instead used the Councils GENESYS model, Council data including that of the 2022 Resource Adequacy Assessment, and the Councils resource adequacy metric and standard and only proposed replacement resource portfolios if that standard was not met. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821; and Appendix H, Power and Transmission, at Section 2.2 in the Draft EIS.
32180	46	redfish@bluefish.org	N/A	(Appendix H, 3-26) The system study identified the need for network reinforcement sooner than currently planned to maintain reliable load service to the Tri-Cities area under MO3. The cost associated with implementing this project on an accelerated timeline would be about $94.5 million under both the conventional least-cost and the zero-carbon resource replacement portfolios. The system study did not identify additional network reinforcements under any of the MO alternatives based on the assumed replacement resource portfolios. The CRSO accounting should consider that this "approximately $94 million in capital costs to construct" is needed regardless, only the timing of implementation is changed. Accounting should also consider that the $72 million to interconnect more Gas Generation at McNary assumes that this new gas is actually needed. The Seventh Power Plan analysis of LSR Breaching found that existing turbine facilities would provide sufficient power to "assure a reliable, economic and adequate power system". Only when looking far out in time, did the 7th Power Plan foresee a need for more natural gas power plants, and this need arose to a large degree, whether or not LSR Breaching were to occur (Fig 3-12 next page, purple bar between orange and pink). (Appendix H 3.2.5)	As discussed in the Bonneville Transmission System Reliability and Operations subsection in Section 3.7.3.5 of the Draft EIS and Section 3.2.2 of Appendix H, prior to evaluating the impacts of potential breach of Ice Harbor Dam, Bonneville had identified the need for a transmission reinforcement project just beyond the 10-year planning horizon (2018-2028) to maintain reliable load service to accommodate load growth to the Tri-Cities area and to support transmission operations and maintenance. From a transmission rates perspective, this means that Bonneville would not expect to see the impact of such a project within the 10-year planning horizon. The base need for the project would arise independent of removal of the generation at Ice Harbor. However, the timing of the reinforcement is very dependent on when Ice Harbor might be breached and would be needed immediately. As such, the transmission analysis considered the speed up of the timing for the need for the reinforcement project as a result of breaching the four lower Snake River dams evaluated under MO3, by including the costs of the project starting at the time the generation from Ice Harbor would be removed from the system. This would allow time for environmental compliance, permitting and construction to occur. The EIS analyzed the cumulative transmission rate pressure changes relative to the No Action Alternative through 2028 for all of the alternatives. Under the No Action Alternative, the Tri-Cities area reinforcement would not be needed within this 10-year time frame and was, therefore, not reflected in the baseline for this time period. The transmission rate pressure relative to the No Action Alternative for MO3 did reflect these reinforcement costs as MO3 would require the reinforcement project under both resource replacement portfolios during the 10-year transmission rate pressure analysis timeframe. Section 4.2.1.1, Revenue Requirement, of Appendix H contains a discussion of the transmission capital cost assumptions, including the timing and direct costs. As discussed in Section 3.7.3.5, Potential Replacement Resources and Associated Costs, under the least-cost replacement generation portfolio, returning Loss of Load Probability to the No Action Alternative level could be accomplished with approximately 1,120 MW of combined cycle natural gas turbines located in northeastern Oregon in a base case without additional coal closures. As a result, the transmission analysis identified interconnection costs associated with the identified resource replacement, which was assumed to be located in northeastern Oregon near McNary due to the location of existing infrastructure. The Northwest Power and Conservation Council (Council) ran a study of the loss of a major non-carbon producing resource, but this study did not look at breaching the four lower Snake River dams, in the Seventh Power Plan using their resource portfolio model. The lost-resource in the Councils study had a smaller energy and much smaller capacity attribute compared to the four lower Snake River dams. Further, the Councils load forecast at the time of the Seventh Power Plan was lower than the more recent load forecast used in the EIS. The EIS did not use the Councils resource portfolio model. The EIS instead used the Councils GENESYS model, Council data including that of the 2022 Resource Adequacy Assessment, and the Councils resource adequacy metric and standard and only proposed replacement resource portfolios if that standard was not met. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821; and Appendix H, Power and Transmission, at Section 2.2 in the Draft EIS.
32180	47	redfish@bluefish.org	N/A	Summary of Transmission Infrastructure Costs Under MO3, replacement costs under the conventional least-cost resource replacement scenario would be about $166.9 million. [Trxt contains figure that does not transfer to database.] (Appendix H 3.2.4) Lost hydropower generation under MO1, MO3, and MO4 may affect voltage and dynamic stability on the transmission system due to a reduction of generators that are online during certain times of the year. Without sufficient voltage support, inertia, and frequency response capability, the power system will not be stable. This, in turn, can lead to equipment damage and potentially widespread uncontrolled loss of load. ... The "conventional" least-cost replacement portfolios assume the location of replacement resources would be in close proximity to the CRS projects where hydropower generation is being displaced and would provide similar voltage and dynamic support for the transmission system.	The statements in this comment regarding transmission system reliability and operations and the location of natural gas resources is consistent with the Bonneville Transmission System Reliability and Operations subsections of Section 3.7.3.3, Section 3.7.3.5, and Section 3.7.3.6 of the Draft EIS and Section 3.2.4 of Appendix H.
32180	48	redfish@bluefish.org	N/A	If no replacement resources were added, as bluefish is suggesting in this comment, synchronous condensers could be added to several substations to improve system reliability via voltage control. This additional cost should be added into the accounting. Regardless of that consideration, my previous comment to the CRSO pointed out that LSR turbine bays could be converted into synchronous condensers, as was suggested by electrical engineers at Idaho Power. This mitigation is missing from the NEPA document, which is yet another fatal flaw.	As explained in the draft EIS, Section 3.7.3.1, Base Case Methodology and Cost Sensitivities Analysis, the analysis evaluates the power impacts of the Multiple Objective (MO) Alternatives on regional power system reliability, as measured through loss of load probability (LOLP). The ensuing assessment of the transmission system evaluated the feasibility of whether the identified portfolio of replacement resources might reasonably be able to reliably integrate into the transmission system. As such, the impacts to the transmission system and any associated mitigation was based on the preceding power system reliability steps. MO3 includes the removal of generation from the four lower Snake River projects. Bonneville is aware of the suggestions that the existing stations that currently integrate the output from the four lower Snake River projects could be used to accommodate synchronous condensers. The EIS analysis and modeling considered that additional static devices, such as reactors or capacitors, might be added or be used to modify the existing reactive equipment at these sites. The assessment found that removal of generation from these points on the transmission system would negate the need for supplemental voltage support from devices such as synchronous condensers at these locations. The analysis concluded that such modification would not be needed at these sites in the event of complete removal of the generation from the four lower Snake River projects.
32180	49	redfish@bluefish.org	N/A	(A footnote somewhere in CRSO) Examples of requirements could include: increased synchronous condensing capability (i.e., free-spinning motor that adjusts to conditions on the power grid to provide voltage support) at the Lower Columbia projects; Addition of static reactive power devices (electrical devices that provide quick response to maintain voltage stability) at strategic points of the transmission system (voltage support only); An increased requirement for generating units at the Lower Columbia projects to be online in order to provide voltage and dynamic support for requirements of the transmission system. In other words, voltage support needs are best when placed near the export to California lines, where the big congestion is, and near loads. Far away from that, Ice Harbor doesn't really do much by comparison. But admitting this frankly, would diminish the importance of Ice Harbor as being important for the electricity grid.	The commenter suggests that the EIS inappropriately cites Ice Harbor as being critical to main grid stability and voltage support. The EIS did not assert that the transmission system need for the Ice Harbor resource was to support the transmission system in general for the export to California lines. Rather the EIS cites that Ice Harbor is uniquely situated in the transmission network to provide active load support to loads within the Tri-Cities area, in Washington (see Draft EIS Section 3.7.3.5, Bonneville Transmission System Reliability and Operations). As such Ice Harbor is a critical resource to the transmission system. The EIS also considers that if Ice Harbor is breached and generation is completely removed under MO3 there would be an additional need to provide another transmission source to serve Tri-Cities load immediately.
32180	50	redfish@bluefish.org	N/A	(Appendix H) Chapter 4-Wholesale Power and Transmission Rates Interesting that both Tier 1 and Public Utility Loads drop under MO3 (Table 4-1). It would be informative if this drop was explained in the Final CRSO document. Also worth noting is that the reduction in surplus decreases the cost of Power Division using the Transmission System (Table 4-6). This is yet another indication as to how Breach Lower Snake River Embankments reduces exports. Following this substantial critique, the CRSO process should run this same analysis without replacement portfolio, aligning itself with the Seventh Power Plan finding that reducing exports is the Least Cost Resource Portfolio. This is done in (Figure 5-4).	The draft EIS describes, in the referenced table in Section 4.1.1.1 of Appendix H, that customer loads were calculated after updating Tier 1 resource generation under each alternative. If the amount of firm generation available from the Federal Columbia River Power System decreases, then the amount of Tier 1 power that customers are entitled to purchase from Bonneville must decrease. Customers then have the choice of either purchasing Tier 2 power from Bonneville or acquiring power elsewhere. Thus, the level of loads presented in the table are driven by the changes in hydropower generation and generation from replacement resources. If the replacement resources are not financed by Bonneville (i.e., the region finances scenarios) then no replacement resource generation was included, reducing the loads relative to the No Action Alternative. When Bonneville finances the portfolio, the power analysis finds that the zero-carbon portfolio does not replace all of the hydropower generation lost under Multiple Objective (MO) Alternative 3 (which includes breaching of the four lower Snake River dams); therefore, Tier 1 loads decrease relative to the No Action Alternative. However, with a least-cost portfolio of natural gas, public customer loads increased relative to the No Action Alternative due to the increase in natural gas generation needed to maintain power system reliability. Comment 32180-34 (by the same commenter) discusses the Northwest Power and Conservation Councils (Council) study of the Planned Loss of a Major non-GHG Emitting Resource. This study is different in that the attributes of the Councils generic lost resource are not comparable to those of the four lower Snake River dams. For more discussion on this topic, please refer to that comment and response. The comment suggests that Bonneville run an analysis of whether loads can be met by reducing exports and not purchasing replacement resources. The LOLP modeling does not include export loads, and all regional resources are used to meet regional loads. In the EIS, the LOLP was first assessed without replacement resources. The results are presented in Section 3.7.3.5,Effects on Power System Reliability at page 3-905 in the draft EIS. Without replacement resources, the LOLP level more than doubles to 14%. See Section 3.7.3.5, Effects on Power System Reliability, at 3-903 and Appendix H, Table 2-1 in the draft EIS. The Councils 7th Power Plan had an older load forecast and other differences from the EIS. The findings of the EIS regarding surplus sales under MO3 are consistent with the statement in the comment. Due to the reduction in hydropower, secondary sales decrease, this in turn decreases revenue (Table 4-9 of Appendix H in the draft EIS).
32180	51	redfish@bluefish.org	N/A	Corrections: The graphics at end of Appendix H, Table 6-1 (why the MO2/1 and not just MO2?). Based on tables at end of the appendix, Figure 5-2 is MO1 (and notice that the zero-carbon is better in many counties, than is "conventional") Figure 5-3 seems to be MO3 with Replacement Portfolios, Figure 5-4 is MO3 w/o Replacement Portfolios, [Text contains figures that do not transfer to database.]	The figure that the commenter cites, Appendix H Figure 5-4, displays the data for Multiple Objective (MO) Alternative 2, but was inadvertently mislabeled in the draft EIS. Figure 5-2 is MO1 and Figure 5-3 is MO3 and Figure 5-4 is MO2, not MO3 without replacement resources as suggested in the comment. Figure 3-186 in Section 3.7 of the draft EIS, shows the correct figure for MO3. The Tables in Appendix H, Chapter 5 correctly show rate increases for MO3 as noted in the comment. The error in the graphs in Appendix H will be corrected in the final EIS. Regarding Table 6-1, "/1" is a table note and should be superscript. This is corrected in the Final EIS where it is Exhibit 1.
32180	52	redfish@bluefish.org	N/A	Potatoes, Apples & Grapes- [Text contains figures that do not transfer to database.] Errors in moving data from Table 4-14 to 4-15: Alfalfa 175.20/ton to $201.20/ton, and Corn $4.56/bushel to $4.65/bushel = $0.09 /bushel, which seems small at first glance. Notably, CRSO Draft differs from 2002 Report by not removing 21% in calculations. Revising Table 4-15 w/o Apples & Grapes because they will continue to be irrigated. $315.6 - $230 (apples) - $16.2 (grapes) = $69 million Gross Value of Irrigated Crops.	The price of hay was an all-hay price rather than the alfalfa price. This was corrected and the regional economic effects analysis was corrected in the final EIS. The corn price was also corrected in the table. This change did not effect the analysis.
32180	53	redfish@bluefish.org	N/A	Accounting MO3 has an increase in diversions for irrigation, Hungry Horse, Lake Roosevelt, Chief Joseph Additional Water Supply. Being that this new irrigated acreage is not included in the No Action Alternative, the accounting should include that new acreage of irrigation benefit in the MOs that receive this new irrigated acreage. Hungry Horse: 90,000 acre-feet of water for (~20,000 acres). Lake Roosevelt: 1,154,000 acre-feet of water for 255,000 acres Chief Joseph: ~9,600 acre-feet of water for 2,800 acres	You are correct that as part of MO3 there are operations to provide additional water supply at Hungry Horse, Grand Coulee, and for the Chief Joseph Dam project. Socioeconomic effects resulting from the use of this water after withdrawal were not evaluated, because the details of how and where this water would be used is subject to as-yet undefined future Federal and other actions. As a result, additional NEPA analysis would be needed prior to implementing any such action. The MO3 analysis on existing water supply concludes that in Region C that pumps are unable to deliver water to estimated at 48,000 acres. Please see Section 3.12 and Appendix N for additional information.
32180	54	redfish@bluefish.org	N/A	Petroleum to Pasco - It is misleading to include petroleum as a major commodity shipped on the Lower Snake River (LSR). It may be somewhat true, but it confuses the issue as to what is shipped through the LSR dams. Suggesting that petroleum shipments may end due to sediment released in MO3 further disorients the reader. After all, dredging costs in McNary pool are included in MO3. The CRSO should be straightforward and honest. (Appendix L, page 3-1) Primarily an upriver movement that ends above McNary Dam, petroleum products travel via barge in the shallow system and comprise the primary upbound commodity on the lower Snake River segment (100 million tons in 2018). Because these shipments terminate below Ice Harbor Dam and do not utilize the river channel, they would not be directly affected by dam removal. However, barge companies report that these shippers are very sensitive to increased risk and are concerned that potential needs for dredging facilities in McNary pool would discourage those shippers from utilizing the system even if it continues to be made available by periodic dredging (Personal communication Shaver Transportation, January 2020). (Appendix L, page 3-12) Fuel comprises the majority of upbound tonnage on the lower Snake River (91% in 2018), most of which terminated river passage above Pasco, WA. ... However, given the safety concerns associated with fuel movements it is unclear if fuel companies would continue movements in the McNary Pool to Pasco. Surprisingly, the CRSO transportation analysis determined that the existing unit train terminals could handle the 2.4 million tons of wheat now shipped on the Lower Snake River. I was expecting that one more well-located rail terminal would have been recommended at Lewiston,	In 2018, 72 percent of overall freight volume on the Lower Snake system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the Lower Snake River was petroleum products that terminated below Ice Harbor Dam. These shipments do not utilize the Snake River locks and would not be directly affected by dam removal under MO3. This was unclear in some instances in the Draft EIS, and has been corrected and clarified in Section 3.10 and Appendix L. Other commodities that utilized the Snake River system included pulp and paper products (4 percent) as well as chemicals and iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under MO3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Wilma or Central Ferry. Additionally, Costs to improve condition of shortline rail should include rehabilitation of the short line to Grangeville. It would also be interesting to see how the economics of the "Grangeville farmer" would be affected with one more, well-located train terminal. A few more runs of the transportation analysis could help us select one more train terminal that could minimize the price disparity between the "Colfax farmer" and "Grangeville Farmer".	
32180	55	redfish@bluefish.org	N/A	(Appendix L, page 3-16) Assuming constant rail rates, railroad ton-miles would ... increase in volume at each of the four shuttle rail facilities, particularly for the Lacrosse facility given its close proximity to the river and the fact that it would be the most likely alternative for production impacted by river closure. This increase would represent an increase in the number of unit trains (with ~110 cars per train) from approximately 4 trains to approximately 8 trains per month at each shuttle rail facility. Washington State's Grain Train is a "relevant and reasonable mitigation" that should be included within the NEPA document. Continuing to add cars, under the current capital building program, assures cars are available to meet inconsistent demand. Appendix L, page 3-14) Commenters have further stated it is difficult to secure a unit train on short notice to take advantages of season demand (comments of Idaho Cooperating Agencies, December 2019).	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, low air emissions relative to other transportation modes, potential regional economic, and other social effects that could occur under MO3. Section 3.10 of the EIS recognizes that access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option would increase transportation costs for grain producers. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in this Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide payments or provide infrastructure for rail lines.
32180	56	redfish@bluefish.org	N/A	Moreover, it is inappropriate for the transportation optimization model to disallow "shipments on river terminals along the lower Snake River". (Appendix L, page 3-13) It is likely that the facilities with rail access would continue to be used to some extent for storage and transport via rail or truck; however, these facilities are assumed to be closed for purposes of this analysis. To the extent that some terminals on the lower Snake River could continue to be used, the effects to shippers would be lower than model results suggest.	The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID to Ayer Junction, WA. Research completed for the EIS suggests that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The commenter is correct that the effect of including this assumption and allowing movements on these short lines during a dam breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. A statement has been added to Section 3.10.3.5 to this effect, along with a reference to Appendix L that provides additional discussion of the impacts of modifying this assumption on quantified costs to shippers.
32180	57	redfish@bluefish.org	N/A	If the final CRSO document wishes to include "Shipments of Oversized Objects" then mention should also be made to the Nez Perce opposition and strong resistance to those shipments. (e.g. "Megaload Decision a Blow to Business at Port of Lewiston", "Nez Perce Tribe Stands Up for Treaty Rights in Megaload Case", "Nez Perce Arrested Protesting Megaloads", "Nez Perce Leaders Stand Firm on Frontlines of Mega-Load Transport", "U.S. Forest Service Shuts Down Highway 12 to Megaloads"). (Appendix L, page 3-1) Shipments of Oversized Objects The Columbia-Snake Navigation System provides a unique water route to transport oversized cargo into the interior of the U.S. Cargo transported upriver to the Port of Lewiston can then be transported on U.S. Highway 12, which has no cargo height restrictions. ... While the system transports shipment of this type infrequently, it is a unique service that could not be replaced by road or rail alone. (Oh, really?)	A clarification has been added to the EIS that describes oversized loads in Section 3.10.3.5 to address the settlement agreement in that litigation.
32180	58	redfish@bluefish.org	N/A	Orca and Idaho's Chinook - Executive Summary In addition, the co-lead agencies are responding to the Opinion and Order issued by the U.S. District Court for the District of Oregon such that this EIS will evaluate how to insure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species. Chapter 7, Table 7-28 Sensitive Species Effects for Preferred Alternative Southern Resident killer whale (SRKW) - Orcinus orca Prey Availability: Negligible effect. Smolt-to-Adult survivorship varies between the two fish models. These models predict a negligible decrease to major increase in Chinook salmon returns. This would result in a minor change in prey availability in comparison from No Action Alternative conditions. Conclusion: Negligible effect. The southern resident killer whale population would remain similar to the No Action Alternative based on the fact that the Columbia and Snake River Chinook salmon are a small percentage of the overall diet for the SRKW populations. Some prey may be more available or there may be a slight decrease in available fish. The fish hatchery production will continue at similar rates into the future. The Preferred Alternative is not likely to adversely affect the southern resident killer whale population. The CRSO Draft inexplicably selected a preferred alternative that admittedly has negligible effect on a critically endangered species. Somehow, the CRSO authors found untold reason to set aside MO3, which they see as having a minor effect on the Southern Resident populations, whose diet is 90% comprised by Chinook Salmon.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed anadromous fish species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NOAA and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The final EIS in Vegetation, Wetlands, Wildlife,and Floodplains (Section 3..6.2.6 and Table 3-102), and Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and the potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
32180	59	redfish@bluefish.org	N/A	Collaboratively, NOAA Fisheries and Washington Department of Fish & Wildlife (WDFW) developed a list of Priority Chinook Stock List to feed the starving Southern Resident Orcas (see next page). From that list, Guy Norman, NW Council's Fish and Wildlife Chairman and former Regional Director at WDFW, emphatically highlighted that seven of the top fifteen Priority Stocks are from the Columbia and Snake Rivers. He further argued that Snake River stocks should rank higher on the Priority List. Other task force members (including Washington Farm Bureau's Tom Davis and Association of Washington Businesses' Gary Chandler) minimized the importance of the Columbia and Snake River Chinook stocks. Coincidentally, the CRSO Draft also shuns respected biologists expertise by agreeing with these latter voices, suggesting that MO3 has only a minor effect on the critically endangered ESA-listed Orcas. (Chapter 3, Table 3-106) Sensitive Species Analysis for MO3 Common Name: Southern Resident Killer Whale (SRKW), Orcinus orca Prey Availability: Minor effect. The Snake River spring/summer Chinook salmon is a negligible portion of their overall diet. Fish models do predict that lower Snake River Chinook salmon smolt-to-adult returns would increase under MO3. There may be short-term negative effects to the SRKW population as the lower Snake River fish population recovers from effects associated with dam breaching. Overall, prey should increase beyond NAA over the long term. This overall effect could change behavior over the short and long term as whales react to the changes in prey availability. Conclusion: Minor effect. The food available to the SRKW from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whale's foraging behavior patterns slightly but will not change their overall conditions or population dynamics. MO3 is not likely to adversely affect the SRKW distinct population segment. How is it possible that the greatly diminished Chinook runs, from the Snake River, cause a "negative effect" following dam breaching, but only a "minor effect" once these runs are recovered? Snake River runs once comprised half of Columbia River Chinook runs. Restoring these runs to that former level is most certainly a Major Effect that should not be so quickly dismissed by the CRSO analysts, especially since they have presented no argument to the contrary. Expert opinion is greatly needed. The world's leading expert on these Orca,	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies conclude there could be a minor beneficial effect to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32180	60	redfish@bluefish.org	N/A	Ken Balcomb strongly criticized the Priority Chinook Stock List for placing Snake River Chinook far too low on the priority list. This he says, even though Idaho's Chinook were placed fairly high in the ranking: Snake River Fall Chinook at fifth position and Snake River Spring/Summer Chinook at ninth. (Appendix F, 3-12) In the Columbia River basin, different stocks vary in overall importance for the diet of SRKW. For example, Snake River spring-summer Chinook salmon are mainly available to SRKW when the fish gather off the mouth of the Columbia, whereas Snake River fall Chinook remain closer to the coast and would be available for a longer period. Center for Whale Research Balcomb notes that samples behind the Priority Chinook Stock List were all taken long after the Snake River Chinook runs became greatly diminished. Historic levels would show these Chinook to be of far greater importance. Balcomb adds that very few samples have been obtained from the rough seas at the Columbia Rivers mouth. By contrast, most all samples being collected were from the relatively tranquil waters of the Salish Sea. Statistical significance is paramount [Text contains figures that do not transfer to database.]	The co-lead agencies recognize that data is being developed and refined in an ongoing manner. The agencies believe that the Priority Stock List is current high quality information and best available science as utilized in the CRSO EIS analysis, recognizing the caveats and assumptions made in the compilation of that list. NMFS and other regional experts are collaborating with scientists to answer the unknowns, fill in the gaps in data, and lowering the assumptions regarding SRKW diet. Currently, current high quality information and best available science indicates that the diet of the SRKWs includes a variety of food sources based on the most available runs. The co-lead agencies agree that the quantity, quality and timing of prey availability is important in health of SRKWs. Also, see response to Comment 6110-16 and updated language of effects on SRKWs in Chapter 3.6 and Chapter 7. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
32180	61	redfish@bluefish.org	N/A	Flex Spill to 125% TDG - Executive Summary: Co-lead agencies developed a Preferred Alternative designed to achieve a reasonable balance of competing river resource needs and co-lead agency mission requirements. Executive Summary Through the EIS, the co-lead agencies are creating an additional opportunity to test the assumptions about the potential for significantly increased salmon survival embedded in the CSS model through the adaptive implementation of a flexible spill operation. This adaptive implementation framework includes careful monitoring and evaluation to ensure there are not adverse impacts on aquatic species or other unintended consequences. (Appendix R, 7-1) By following this adaptive implementation and monitoring framework, the Action Agencies will be able to collaborate with the regional experts, while maintaining the ability to adapt to new information and respond to unanticipated outcomes or challenges that may arise as a result of testing the magnitude of latent mortality. (Chapter 4 p.39) Adult upstream migrations would be challenged by MO4 flow and spill conditions and may be further complicated by the effects of climate change. The additional flow augmentation (McNary Flow Target measure) delivery would increase flows in spring but then reduce them later in summer, resulting in increased water temperature in the Columbia River from Chief Joseph downstream. These temperatures could be further elevated with climate change and could increase delays and fallback. Temperatures would be elevated in MO4, which could make Upper Columbia River sockeye more frequently encounter conditions in the lower Columbia River where it is too warm to migrate, and where there is a thermal block downstream of spawning habitat in the Wenatchee or Okanogan Rivers. Similarly, Pacific lamprey could experience even more days over their thermal stress threshold (temperature above which the fish experience stress) in the Columbia River from Chief Joseph Dam to McNary Dam, where temperatures would be elevated in MO4. The "thermal block" is at the Columbia's confluence with the Snake River. Why is that? [TExt contains figure that does not transfer to database.] CRSO Objective: Provide an adequate, efficient, economical and reliable power supply that supports the integrated Columbia River Power system. MO3 does all of the above, as demonstrated above. The Columbia River Power System is completely adequate under Breach Lower Snake River Embankments (the environmentally preferred ingredient of MO3) while spill and flex spill are speculative and awaiting further testing in the Draft PA. Breach Lower Snake River Embankments is efficient and economic (see Draft Figure 7-22 and Appendix H Figure 5-4, above). The only regional controversy is whether or not MO3 provides a reliable power system. To prove this one way or another, Bonnevilles "first scenario" needs to be modeled, rather than the inflated Replacement Portfolios that were detailed herein. Importantly, last year's Flex Spill Experiment was a disaster for Idaho's juvenile migrants. In mid-September 2019, Rich Zabel reported to Ritchie Graves the official estimates of Juvenile Survival by Reach. The fish kill was unprecedented and tragic. (Appendix R, 5-1) To build off the success of and momentum achieved through the 2019-2021 Spill Operations Agreement, the Action Agencies plan to formally continue the efforts of Flexible Spill Work Group (FSWG). This group would be complementary with the existing Regional Forum. ... Evaluating the effectiveness of these operations will require multiple years of data given the lifecycle of salmon and the potential changes in regional energy markets. ... Spill levels implemented would be adapted or modified based on the framework in this document to account for unanticipated outcomes that affect the ability of the Action Agencies to maintain their individual federal mandates. ... * Ensure the implementation of CRS spill operations is responsive to dynamic conditions experienced during implementation of this novel operation, new scientific information and regional input... * Conduct a transparent adaptive implementation process that keeps stakeholders informed of and involved in annual operation decisions on timing, design, and monitoring... * Conduct monitoring activities, interpret and share results, adapt implementation practices to improve results and better meet project objectives; and * Evaluate the value of flex spill for fish and power over a range of environmental and economic conditions. (Appendix R, 3-3) The Flex Spill Fish Principle: Provide fish benefits, with the understanding that (i) in 2019,	Regarding MO4 and summer temperatures: Under MO4 and as with the No Action Alternative, the four lower Columbia River reservoirs (McNary, John Day, The Dalles, and Bonneville) would continue to show weak to no stratification during the summer months, largely due to the short residence time, wind and flow-induced turbulent diffusion, and convective mixing that occurs in the reservoirs. Maximum tailwater water temperatures and the frequency of water temperature standard exceedances would be similar for MO4 and the No Action Alternative over a range of river and weather conditions. Minor effects to water temperature are anticipated downstream of McNary Dam, while negligible effects are expected downstream of John Day, The Dalles, and Bonneville Dams. Regarding the Preferred Alternative vs. MO3: The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding the FSWG comment: the co-lead agencies are currently in discussions with federal agencies, states, and Tribes on the structure of this forum. While the intent is to keep the spirit of the FSWG, there will be some modifications to the Draft EIS in this area based on our current discussions.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				overall juvenile fish benefits associated with dam and reservoir passage through the lower Snake and Columbia rivers during the spring fish passage season must be at least equal to 2018 spring fish passage spill operations ordered by the court, and (ii) in 2020 and 2021, these fish benefits are improved further (as estimated through indices of improved smolt-to-adult returns, e.g., PITPH, reservoir reach survival, fish travel time); is directly related to Objectives 1, and 2 of the CRSO EIS: * Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival... The Action Agencies are planning to add a fourth principle to the flex spill decision framework: Principle 4: Evaluate the Effectiveness of the Spill Operation by: * Evaluate the extent to which further increase in spill lead to improved adult returns by reducing latent mortality * Monitoring other interim metrics to evaluate progress and avoid unintended consequences. * Evaluating the impacts to power revenues and rates. (NW Fishletter recent F&W costs at $781 million) For Principle 4 to be achieved, the operation will need to be accompanied by a robust study design that can provide statistically meaningful results within a reasonable management timeframe. The analysis of future scenarios and the adaptive implementation of future operations will need to consider and achieve all four principles to provide an optimized outcome that supports improved SARs for fish, affordable and reliable power, feasible implementation, and the ability to discern if the operation is having a measurable benefit. ... Power, fish, and operation metrics will be evaluated to ensure that spill operations are meeting the four principles and that operations are not resulting in negative impacts. The last decade of monitoring the effects of operations under the current configuration of the projects (since approximately 2010) will provide a reference point for evaluation. ... Biological performance metrics will be managed for annual targets (e.g., survival, travel time and gas bubble trauma) of migrating salmonids through the CRS... (Appendix R, 3-1) Lessons Learned from the 2019-2021 Spill Operation Agreement ... After the 2019 spring spill operation concluded, the FSWG met again to discuss whether or not the three pillars of the Agreement were satisfied under the first and only year of flex spill operation, and to finalize details of the 2020 operation based on the lessons learned from 2019. ... (Appendix R, 5-1) The RIOG is a forum for interagency coordination and does not supplant existing federal, state or tribal decision making authorities. All decisions under the authority of the federal government continue to be made by the appropriate federal agency with the statutory authority to make such decisions. As it applies to the flexible spill operations contemplated in this framework, the federal Action Agencies retain final decision making authority related to operations of the dams while taking into account the perspectives of members of the FSWG. The FSWG shall, at a minimum, include a representative from each signatory to the agreement. If carried forward for implementation beyond the terms of the Agreement, other regional sovereigns would also be invited to participate in efforts to resolve an objection. If the FSWG cannot resolve the issue without objection, the issue shall be elevated to RIOG for resolution. Given that this framework will be applied after the expiration of the Agreement, the FSWG would be open to any interested CRS sovereign that requests to be included. The RIOG has failed to meet their deadline of 120 days to determine what actions to take following the triggering of the Early Warning Indicator by Snake River Steelhead population declines to 1990 levels. Should they be trusted? The FSWG and RIOG should be aware of the failure to live up to "three pillars" in the 2019 Flex Spill Agreement. Bonneville and USACE have been informed of the tragedy, by bluefish. -	
32180	62	redfish@bluefish.org	N/A	- Environmental Justice - Executive Summary - Tribal Coordination and Perspective Since time immemorial, the Columbia River Basin has been inhabited by Native American peoples, who successfully subsisted on the abundant natural resources of the region. They built thriving communities that relied on the lands to sustain their way of life. Through treaties, executive orders, judicial decisions, and legislation, the tribes ceded most of their territory to the United States while retaining smaller portions of land for their reservations. Some tribes, through treaties, retained the right to hunt, fish, and gather in their usual and accustomed locations, including areas outside of their reservations. The potentially affected area of the CRS includes portions of tribal reservations, trust lands, and ceded lands of 19 federally recognized tribes. ... In its relations with tribes, the United States has charged itself with moral obligations of the highest responsibility and trust (Seminole Nation v. United States, 1942). These trust responsibilities derive from the historical relationship between the federal government and tribes as expressed in Treaties, Statutes, Executive Orders, and Federal Indian case law. ... The tribes of the Columbia River basin represent diverse and distinct cultures, each different from the next. There is one theme, however, that the tribes all have in common: Their association with the natural resources of the region permeates every aspect of their cultures. This association results in a strong sense of stewardship for the land. It is difficult to overstate the effects the CRS has had on tribal culture, way of life, and traditions. ... The losses of these areas have adversely affected how tribal communities define themselves, interact with each other, and live full spiritual lives; and in the process has undermined the processes through which living cultures are nourished, maintained, and perpetuated. Then immediately following is Tribal Coordination and Perspective	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Section 3.18, Environmental Justice, describes the unique conditions of minority populations, low-income populations, and tribes that may heighten their vulnerability to effects from the alternatives.
32180	63	redfish@bluefish.org	N/A	Where did the HYDSIM and ResSim results go? A legitimate NEPA document would either describe why those outputs were insufficient, or just plain use them. It is very odd to me that Bonneville staff intervened to provide "inputs similar to HYDSIM and ResSim" into the model. What was the point of discussing the AURORA feedback loop "in a second pass of HYDSIM"? No reason is given for Bonneville staff to enter into GENESYS "inputs similar to HYDSIM and ResSim". If there is some legitimate reason, the NEPA document should clearly explain that justification.	Hydroregulation (regulating water) is the process planners and operators use to make decisions about routing water through a series of dams in a river system. Computer hydroregulation modeling is used to simulate operations for the system of dams that operate for multiple purposes, including flood risk management, hydropower, irrigation, navigation, recreation, water supply, and fish and wildlife purposes. Two hydroregulation models were used to simulate operations in the basin in support of the Hydraulics and Hydrology (H&H) analysis: Hydro System Simulator (HYDSIM) and Hydrologic Engineering Center Reservoir System Simulation (ResSim) software. The models mesh together through multiple steps to simulate operations in the Columbia River Basin. More information on these models is available in Section 3.2 and in Appendix B of the Draft EIS. AURORA is a production cost model that uses loads and resource projections to calculate wholesale markets for the West. The model estimates how much power can be sold into the wholesale market and estimates the related prices. Appendix I, Hydroregulation, and Appendix J, Hydropower, provide detailed information on this model. This analysis relies on the hydroregulation modeling. To analyze the power system reliability Bonneville uses the GENeration Evaluation SYStem (GENESYS) model, which simulates regional power generation and demand.
32180	64	redfish@bluefish.org	N/A	Moreover, NW Power & Conservation Council staff have been denied access to this "inputs similar to" data. You will note that The Council is not providing any comments to the Draft. The staff desired to do the work, but Bonneville did not share information for them to review. In light of this absence of cooperation, explicitly dictated by the Northwest Power Act, NW Council staff provided me access to GENESYS and some training so that I might see what the GENESYS, with current data, finds for a LOLP with and without the four LSR dams. Markedly, the politically appointed members from four states could not arrive at a consensus vote to run this simple analysis. Therefore, staff allowed me to run GENESYS in their absence from the process.	Bonneville staff have the expertise to run the GENESYS model and describe its outputs for the CRSO EIS. Bonneville has worked with the Northwest Power and Conservation Council (Council) on developing the model for many years. For areas of the CRSO EIS power analysis where Bonneville staff did not have expertise, Bonneville hired consultants; however, for the GENESYS model, this expertise is housed within Bonneville. The Council received periodic updates on the CRSO EIS NEPA process similar to the general public. Since the Council is not a Federal, Tribal, state or local agency, it could not serve as a cooperating agency under NEPA. The Council received the Draft EIS when it was available for public review.
32181	1	ejkimber@gmail.com	N/A	I also feel the need to point out that the importance of the Columbia salmon as it pertains to the diet of the SRKW Orcas is severely underrepresented. This is not mentioned in the entire 36 pages of the DEIS. This is unacceptable and does not provide a complete picture of the impact. It's also naive and incorrect to label Puget Sound Chinook salmon as "more important" to the diet of the SRKW due to their NEED for a continuous supply throughout ALL seasons in order to maintain healthy body weight, survive longer or harder winters, and lower their already extremely high miscarriage and infant mortality rate.	The co-lead agencies agree that the quantity, quality and timing of prey availability is important in health of SRKWs. Also, see response to Comment 6110-16 and updated language of effects on SRKWs in Chapter 3.6 and Chapter 7. The Draft EIS is much longer than 36 pages and we invite you to read the rest of the Draft EIS in order to acquire the information for which you are looking. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
32181	2	ejkimber@gmail.com	N/A	Due to the COVID-19 issues, I also ask that you please consider extending the comment period.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
32184	1	hlbrb88@gmail.com	N/A	During my career as an electrical engineer for power companies, I bought Dump Power from BPA during spring runoff. At that time utilities on the west Coast had more water than they could use for the generation required to carry their loads. They would be spilling water from dams that did not have storage, like the run-of-the-river dams on the Lower Snake River. BPA would run the generators in those dams so that some of the water would not be "wasted" and sell the energy at extremely low prices to companies, like mine, that did not have generation. Now, in the Northwest, hydro generation that can follow the load is valuable . The run-of-the-river Lower Snake River dams do not have this capability. All dams were not created equal. The Lower Snake River dams are almost 50 years old and generating equipment has a limited life.	The statement that hydropower can follow load and that spill reduces generation is consistent with the EIS. Regarding the four lower Snake River dams, the EIS describes the operational characteristics of these dams in Section 3.7.3.5 - Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). As described in that section, while the four lower Snake River dams are indeed run-of-river projects, there is flow in the lower Snake River year-round. These are not strictly run-of-river projects in the narrowest sense; they have pondage (some flexibility in the forebay elevation) and can provide sustained peaking capability. Upstream storage is used to increase their firm capacity, and they provide up to 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. Upstream storage projects (Dworshak and Brownlee), regulate some of the water flowing into the lower Snake River. In particular, the four lower Snake River dams produce a substantial amount of power in the winter, which is currently the region's highest demand period. See EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159 in the Draft EIS.
32184	2	hlbrb88@gmail.com	N/A	The Lower Snake River dams are almost 50 years old and generating equipment has a limited life. The company I worked for before retiring has a continuing program to replace turbines and generators of this vintage. Often the gates that control the water to the turbines also have to be replaced. It is very expensive and difficult engineering. Picture replacing an engine on an airplane while it is flying. These costs should be considered in the DEIS.	Bonneville, the Corps and Reclamation develop long-term strategies and plans that identify the optimal time to replace equipment based on equipment condition, criticality and risk. Age, although a factor in equipment condition, is not the determining factor when equipment is replaced or rehabbed. Existing strategies place the earliest optimal turbine replacement date in the 2030s, with the majority of the remaining 21 turbines falling in the 2040s and 2050s.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				When they are, this expense and the low value of the dams' power compared to other resources, it does not appear to be cost effective to replace the worn out turbine generators.	Additionally, it has not been determined if all six units at each plant will be replaced at those times. Replacement costs for turbine runners and components are expected to be closer to $600 million in 2020 dollars, if all turbines are replaced. Generator windings would likely be replaced at the same time, which would add another $200 million. The EIS analyzed the avoided capital, operations and maintenance (O&M) costs of breaching the four lower Snake River dams under MO3 in Section 3.19 and Appendix Q of the Draft EIS. The costs for replacement resources, integration costs and transmission reinforcement were greater than the savings realized from the avoided capital, operations and maintenance costs if the dams were breached. Contrary to the implications of the comment, this means breaching the four lower Snake River dams is less cost effective than reinvesting in the equipment at the optimal time based on equipment condition, criticality and risk. For MO3, the costs of replacing the lost generating capability of the four lower Snake River dams is discussed in Section 3.7.3.5, Lower Snake River Replacement, on page 3-905 in the Draft EIS. The rate impacts of these replacement resources, which includes O&M cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, and pages 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operating and fish and wildlife mitigation costs, the net impact on power rates could be substantial. The EIS estimates the costs to operate the CRS dams, as well as the costs to the power system that would occur if the four lower Snake River dams are breached under MO3. Section 3.19, Table 3-307 in the Draft EIS describes the cost components that the EIS considered and analyzed including non-routine maintenance and operations and maintenance, among others. See EIS Section 3.19 for additional detail. Regarding the cost effectiveness of maintenance, the EIS considered the avoided O&M and capital costs associated with dam breaching in the cost analysis and included these reduced costs in power rates analysis. See Section 3.7.3.5, Bonneville's Fish And Wildlife Program And Lower Snake River Compensation Plan Costs, page 3-913 in the Draft EIS. See also Section 3.7.3.5, Table 3-166 in the Draft EIS.
32185	1	ggoodstefani@nrdc.org	Natural Resources Defense Council	The Natural Resources Defense Council joins the Nez Perce Tribe, Shoshone Bannock Tribe, the Upper Snake River Tribes, State of Oregon, and the thousands of people and organizations from across the Pacific Northwest and the United States in calling for the restoration of the lower Snake River. The Fish Passage Centers modeling of Snake River steelhead and spring Chinook survival shows that the action agencies preferred alternative would not meet the criteria for salmon recoverybut dam removal will.1 NOAA Fisheries own survival model also shows that dam removal and replacement with clean energy resources would have the most significant benefit to Snake River salmon and steelhead.2 The only demonstrated path to salmon and steelhead recovery, a climate-change resilient river, continued survival of the Southern Resident killer whales, and abundant salmon and steelhead for tribal sovereigns, fishing businesses, river communities, and all fish and wildlife beneficiaries and appreciators includes breaching the earthen portions of the lower Snake River dams and replacing their energy with clean alternatives.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on the analysis in Fish section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative may provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes breaching the lower Snake River dams (MO3). However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend dam breaching because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32185	2	ggoodstefani@nrdc.org	Natural Resources Defense Council	I. THE NEPA PROCESS IS RUSHED, INADEQUATE, AND PRECLUDES PUBLIC PARTICIPATION The CRSO DEIS public comment period of just 45 days, which ends today, April 13, 2020, is arbitrary and inadequate to allow the public, interested individuals, institutions and governments an adequate opportunity to review, analyze, consider and comment on a document that runs to almost 3,000 pages plus another nearly 5,000 pages of technical appendices. The failure to extend the comment period without explanation in light of numerous requests from elected leaders, sovereigns, organizations, businesses, and individuals during a global health pandemic was arbitrary and capricious. We wrote and requested that you allow at least as much time for comment on the DEIS as you allowed for the much simpler preliminary step of scoping for the CRSO EIS, i.e., 120 days or more. The failure to extend the comment deadline materially impacted individuals review of the document, hindered public engagement and exchange of information, diminished scientific oversight, and limited the impacted publics ability to inform the decisionmaking process. 1 See Fish Passage Center, Comparative Survival Study of PIT-tagged Spring/Summer/Fall Chinook, Summer Steelhead, and Sockeye: 2019 Annual Report, Chapter 2 (December 2019). 2 DEIS, Executive Summary, p. 25. The requested 120 day or more comment timeline would have been consistent with sworn statements from the Action Agencies to the Court in NWF v. NMFS, No. 01-640-SI (D. Or.), when the Court was setting a schedule for preparation of this EIS and a new management plan. At that time, agency managers told the Court that a minimum of five years would be needed to prepare the CRSO EIS. In support of this schedule, the Corps of Engineers explained that for a prior EIS that focused only on the lower Snake River, the agencies provided a five-month comment period on the Draft EIS and then explained that the CRSO EIS would be more complicated and draw greater public interest and therefore would require more time than the earlier lower Snake River study. The Corps also explained that it would take at least a year to analyze the number and depth of comments it expected to receive on the CRSO Draft EIS. Likewise, the Bureau of Reclamation pointed the Court to an EIS in the Klamath Basin where it provided a 100-day comment period on the Draft EIS and again indicated that the CRSO EIS was more complex and would require even more time. To truncate public participation under current conditions without a pressing reason is an act of politics and not solid policy, and it defeats the stated purpose of NEPA.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9 that they should plan to submit comments by the close of the comment period.
32185	3	ggoodstefani@nrdc.org	Natural Resources Defense Council	II. THE DEIS FAILS TO ANALYZE REASONABLE ALTERNATIVES The CRSO DEIS failed to analyze all available and reasonable alternatives. In particular, the CRSO DEIS failed to consider the alternative of breaching the lower Snake Dams and spilling to 125% at the lower Columbia Projects. The alternative of combining the breaching of the lower Snake River Dams with spill to the 125% gas cap was also presented to the CRSO-EIS Fish Technical Team on September 21, 2017. Although initial CSS analyses indicated that the combination of breach and spill at the lower Columbia River projects to 125% produced the highest Smolt-to-Adult Returns (SARs), the federal agencies did not consider in the CRSO DEIS an alternative that incorporated this operation. Consequently, the range of alternatives considered in the DEIS does not examine a reasonable and available alternative for dam operations that would actually produce the highest survival rates for Snake River salmon and steelhead (and other species given the higher spill levels at the lower Columbia River dams).	The co-lead agencies presented a range of alternatives for the continued operation and maintenance of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. Improving anadromous fish conditions was part of the EIS objectives. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
32185	4	ggoodstefani@nrdc.org	Natural Resources Defense Council	The CSS 2019 Annual Report analyzed an alternative they termed MO34. The MO34 option included breach of the four lower Snake River dams with spring spill operation at all four lower Columbia River dams was spill to the 125% TDG levels. The MO34 option also includes the addition of fish friendly turbines at John Day Dam and the installation of Powerhouse Surface Passage routes (PSPs) at McNary and John Day dams. The MO34 alternative demonstrated the greatest expected improvements across all biological response metrics, compared to all of the federal CRSO DEIS alternatives. On average, the MO34 alternative exceeded the 4% average SAR regional goal. The predicted SARs for MO34 were above 1% for both Chinook (SAR>1% for 85% of simulations) and steelhead (SAR>1% for 92% of simulations) indicating that MO34 had the highest likelihood of avoiding further population declines and supporting population rebuilding. The CSS alternative MO34 performed better than any of the alternatives analyzed in the DEIS and is built from actions considered in these alternatives and so would be reasonable to consider but, was not developed or considered by the federal agencies in the CRSO DEIS. The MO34 alternative had the lowest probability of producing SARs less than 1% and the greatest probability of SARs greater than 2%. Therefore, MO34 had the best probability of successful restoration of healthy salmon populations and recovery with the lowest risk to extinction of all the alternatives.	The co-lead agencies presented a range of alternatives for the continued operation and management of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. Improving anadromous fish conditions was part of the objectives of the CRSO EIS. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32185	5	ggoodstefani@nrdc.org	Natural Resources Defense Council	The CRSO DEIS also should have investigated how to optimize Dworshak releases to regulate water temperature and improve fish survival in a free-flowing lower Snake. For instance, MO1 proposes releasing more Dworshak water in June/July, less in August, and more again in September/October. This schedule would release cold water during the peak of the sockeye and S/S Chinook migrations in June/July and again during the peak of fall Chinook and steelhead migrations in September and October. Because MO1 does not include lower Snake dam removal, temperature modeling showed (unsurprisingly) that this early summer/early fall Dworshak release schedule would have little to no impact on water temperatures or fish survival in the lower Snake River. A much more informative inquiry, one that would assist the public and decision-makers alike, would be to model how the Dworshak release schedule influence temperature and fish migration success in a free-flowing Snake River. The CRSO DEIS should have investigated how the combination of Snake River dam removal and different Dworshak dam release patterns could provide the most benefit for fish survival.	Each Multiple Objective alternative (MO) was evaluated against the No Action Alternative. The Preferred Alternative includes a combination of measures that meet the Purpose and Need Statement and objectives of the CRSO EIS, while balancing the authorized purposes of the 14 Federal dam and reservoir projects that make up the CRS. In some instances, measures were modified to improve their ability to meet the Purpose and Need Statement or objectives, as well as to avoid, reduce, or minimize environmental, economic, and social effects. It is expected that the Preferred Alternative would allow the co-lead agencies to meet the Purpose and Need Statement and objectives of the EIS, including those to benefit ESA-listed species. As part of the development process for the Preferred Alternative, the co-lead agencies met with and considered input from cooperating agencies, members of the congressional delegation, state governors and other officials, Tribes, the National Marine Fisheries Service (NMFS), the U.S. Fish and Wildlife Service (USFWS), and other groups with a vested interest in system operations, including utility customers, irrigators, environmental organizations, and representatives from the navigation sector. During the formulation of the Preferred Alternative, Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams, was not selected due to the inability to meet other objectives (e.g., irrigation, recreation, transportation), and therefore was not evaluated in combination with the Dworshak releases. Finally, as described in Section 3.4, adjusting the timing of Dworshak releases did not provide water temperature benefits, and thus, was not included in the Preferred Alternative.
32185	6	ggoodstefani@nrdc.org	Natural Resources Defense Council	II. THE DEIS FAILS TO TAKE A HARD LOOK AT WATER QUALITY (TEMPERATURE) High summer water temperatures already limit the survival of some salmon runs and significantly threaten the future of many Columbia and Snake river salmon fisheries. In 2015, for instance, more than 250,000 adult sockeye died in the Columbia and Snake Rivers because warm water prevented them from successfully migrating upstream. In response to temperature-driven fish kills, the Environmental Protection Agency noted that [t]he need to lower water temperatures becomes more critical as the Pacific Northwest Region continues to address and mitigate climate change.3 The Fish Passage Center similarly concluded that under a climate change scenario, the long-recognized and largely unaddressed problem of high water temperatures in the [Columbia and Snake rivers] becomes an ever-increasing threat to the survival of salmon . . . .4 Unfortunately, the CRSO DEIS consideration of water temperature, dams and dam removal, and climate change is incomplete, occasionally misleading, and lacks consideration in the context of salmon migration, survival, and recovery. Overall, the CRSO DEIS gives the incorrect impression that dam removal would cause the lower Snake River to warm earlier in the spring, have no effect on temperature in the summer, and cool earlier in the falland that the spring and fall effects are equivalent in magnitude and counterbalance each other in terms of benefits to fish. 5 This is misleading and incorrect. 3 EPA, Comments on NOAA Fisheries 2015 Adult Sockeye Salmon Passage Draft Report (May, 2016). 4 Fish Passage Center, Review of Draft of NOAA Fisheries2015 Sockeye Salmon Passage Report (May, 2016). 5 DEIS, p. 4-32; see also DEIS at pp. 1-45, 3-551, 6-42, 7-19, D-6-25, D-6-71.	Reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. The EIS uses CE-QUAL W2 and HEC-RAS to model temperatures in the CRS. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
32185	7	ggoodstefani@nrdc.org	Natural Resources Defense Council	The CRSO DEIS data show that the free-flowing lower Snake would not be meaningfully warmer in the spring (e.g. March, April, and May) than the dammed river. When ranges of uncertainty are incorporated into the models results, springtime temperatures in the free-flowing river almost never exceed the dammed river.6 And in May, the DEIS actually predicts that snowmelt runoff would cause the free-flowing Lower Snake to be colder than the dammed river.7 The CRSO DEIS repeated claim that water temperatures in June, July, and August would be similar8 with or without the dams is also misleading and incorrect. This claim appears to be based exclusively on the Corps projections of daily maximum temperatures in the dammed and free-flowing lower Snake River. Daily maximum temperature is just one of several water temperature parameters that influence how well adult salmon and steelhead migrate and survive. Other temperature parameters and metricsincluding average temperature, diel cooling, and inter-day variabilitywould all be different, and more favorable to salmon and steelhead, in the free-flowing river.9 Accordingly, dam removal would meaningfully improve the temperature profile of the lower Snake in the summertime in ways that benefit salmon and steelhead, even if daily maximum temperatures were sometimes similar to those in the reservoirs. The DEIS blanket assertion that summer temperatures in the Lower Snake would be similar after dam removal is therefore misleading and incorrect.	The reviewer has not provided evidence that our analysis of predicted water temperature under the MO3 alternative is misleading or incorrect. The co-lead agencies chose to use the daily maximum water temperature metric in our analysis because most state water quality standards for water temperature are based on this metric. Fish appropriate water quality metrics were provided for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. The fish team also used water quality outputs to qualitatively examine effects to fish species based upon known relationships between water temperatures and fish responses where quantitative models were not available. In this way, the team was able to discuss effects on time and locality scales that may not be detected by the models. The EIS uses CE-QUAL W2 and HEC-RAS to model temperatures in the CRS. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
32185	8	ggoodstefani@nrdc.org	Natural Resources Defense Council	The DEIS narrative incorrectly implies that predicted fall cooling in the free-flowing Snake River would roughly mirror, and offset, spring warming. The magnitude, duration, and ecological impact of predicted cooling in September, October, and November is far greater than for any warming that might occur in March or April. In contrast to the spring months, when ranges of uncertainty are incorporated into the models results, fall temperatures in the freeflowing river are almost always lower than the dammed river.10 Furthermore, in contrast to the minor differences between the dammed and free-flowing lower Snake predicted for March and 6 DEIS, D-A-2-5 7 DEIS, p. D-6-25 (Explaining that During [May], total river flows are highest due to snowmelt (i.e. spring freshet), resulting in overall cooler water temperatures throughout the [free-flowing] lower Snake River as compared to the No Action Alternative.); see also Id. at D-6-31. 8 DEIS, p. 4-32; see also DEIS at pp. 1-45, 3-551, 6-42, 7-19, D-6-25, D-6-71. 9 See Comments from Columbia Riverkeeper, section V. 10 DEIS, D-A-2-5 April, the significant differences in water temperature predicted in September and October would occur when the dammed river would be warm enough to cause migrating salmon and steelhead thermal stress. Steelhead and fall Chinook attempt to migrate through the lower Snake mostly in September and October. According to EPA migration temperatures for adult steelhead and fall Chinook are 1013 C and 10.619.4 C, respectively.11 Temperatures in the dammed Lower Snake are often above, or at the high end, of these ranges in September and October. Therefore, significant temperature reductions in September and October provided by dam removal would meaningfully improve migration conditions for steelhead and fall Chinook. Dam removal would also improve spawning temperatures, and success, for fall Chinook in the lower Snake, especially in October and early November when the dammed river is often significantly warmer than the 10 degree C optimum spawning temperature or even the 15 C level considered stressful for spawning.12 In sum, the fall cooling predicted in a free-flowing lower Snake River significantly exceeds the magnitude, and benefit to salmonids, of any spring warming that might occur due to dam removal.	It is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. The co-lead agencies agree that reductions in fall water temperatures under MO3 would be beneficial and more significant than any early spring warming that would occur. Water temperature reductions in September and October would meaningfully improve migration conditions for steelhead and fall Chinook in the lower Snake River. These considerations are reflected in the modeling results for steelhead and are discussed qualitatively for Snake River fall Chinook salmon. The CRSO EIS (page 3-567) concludes that the temperature differences under MO3 would reduce straying and migration delays and disease susceptibility that would improve survival and spawning success of fall Chinook and coho salmon. Likewise, the analysis for sockeye salmon (page 3-565) discusses the trade-offs between increased stress potential with warmer spring/summer daytime temperatures and the potential benefits from reduced delays, decreased thermal exposure, reduced straying and fallback due to not being transported as adults, and reduced fallback due to fish ladder temperature differentials. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32185	9	ggoodstefani@nrdc.org	Natural Resources Defense Council	IV. THE DEIS FAILS TO TAKE A HARD LOOK AT ENERGY IMPACTS As explained more completely in comments on the CRSO DEIS submitted by the Northwest Energy Coalition, the CRSO DEIS fails to describe and disclose the effects of the alternatives, especially MO3, on energy generation and system reliability, among other energy related issues, and hence presents an incomplete and misleading picture of the effects of MO3 both energy generation and ratepayers. In particular, the CRSO DEIS overstates the cost of lower Snake River dam removal and replacement with clean energy resources and alternatives. NRDC joined in these comments and refers the agencies to them for a more complete description of the failures of the CRSO DEIS with respect to energy issues. 11 EPA, Summary of Temperature Preference Ranges and Effects for Life Stages of Seven Species of Salmon and Trout, pp. A-3, A-4 (1998). 12 EPA, Issue Paper 1: Salmonid Behavior and Water Temperature, p. 17 (2001).	The EIS presents the effects of the alternatives, including on power generation and system reliability, in Section 3.7.3.5 Environmental Consequences under MO3 in the draft EIS. As a result, the EIS does not fail to describe or disclose this information, as claimed in the comment. Regarding the costs of lower Snake River dam breach, the EIS presents a range of replacement resource costs that would be needed to maintain regional reliability at the No Action Alternative levels based on two resource portfolios: one that is based on renewable resources and another that is based on natural gas resources, which are generally the least cost means to maintain reliability (see Section 3.7.3.5 - Potential Replacement Resources and Associated Costs in the Draft EIS). The EIS uses the best available resource cost information from the Northwest Power and Conservation Council (Council) to estimate the potential range in costs of these replacement resources. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821; and also Appendix H, Power and Transmission, at Section 2.2 in the Draft EIS. The EIS does not suggest fossil fuels should be used to replace the power; the purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for MO3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS.
32185	10	ggoodstefani@nrdc.org	Natural Resources Defense Council	V. THE DEIS FAILS TO TAKE A HARD LOOK AT CULTURAL AND SOCIOECONOMIC IMPACTS Pursuant to NEPAs hard look requirement, the agency must ensure that the adverse environmental effects of the proposed action are adequately identified and evaluated.13 The EIS must contain sufficient discussion of the relevant issues and opposing viewpoints to ensure the agencys decision is fully informed and wellconsidered. The EIS must also contain a reasonably complete discussion of possible mitigation measures, and these measures must be discussed in sufficient detail to ensure that environmental consequences have been fairly evaluated. The DEIS lacks a rigorous assessment and opportunity to comment on the public health, economic, and environmental justice implications of the Columbia Basin Operating System on tribes. Columbia Basin Native communities fishing and hunting lifestyle and diet are critical to their health, wellbeing, and livelihood. The Preferred Alternative fails to ensure the restoration of salmon, and other threatened or endangered fish and wildlife and does not provide an environmentally just result for tribes. The failure of the Preferred Alternative to restore salmon, lamprey, steelhead, sturgeon and other fish and wildlifeor even ensure survival of the several of these speciesdisrespects and directly impacts the Columbia River tribes culture, food, economies, and ways of life.	The CRSO EIS evaluates alternatives to the operations, maintenance and configuration of the CRS. The EIS includes a discussion on mitigation in Section 3.18 (Environmental Justice), Chapter 5 (Mitigation), Chapter 6 (Cumulative Effects) and Chapter 7 (Preferred Alternative), but is not a species restoration document. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), as well as meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is most likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.

32185	11	ggoodstefani@nrdc.org	Natural Resources Defense Council	As the Shoshone Bannock explain in their letter to the Action Agencies, based on a review of an early version of the DEIS: Historically, the Shoshone and Bannock peoples harvested salmon and trout throughout the Basin for subsistence across an almost year-round timeline. Annual salmon and steelhead runs in what are now Oregon, Washington, Idaho and Nevada provided harvest 13 Robertson v. Methow Valley Citizens Council, 490 U.S. at 350. opportunities throughout the year for our people. Anthropogenic impacts to the Basin severely constrained runs of anadromous fish over the next century, in particular System development and operations. Current salmon abundance in the Upper Salmon River subbasin is estimated at about 0.5% of historical runs and the Hells Canyon Complex completely eliminated upstream migration into the Middle Snake Province in Idaho, Nevada, and Oregon. Recent harvest opportunities for Tribal members have only provided 1.2 pounds of salmon per Tribal member compared to historical use of about 700 pounds per person annually. The Columbia River Treaty Tribes (i.e. Nez Perce Tribe, Confederated Tribes of the Umatilla Indian Reservation, Confederated Tribes of the Warm Springs Reservation of Oregon, and the Confederated Tribes and Bands of the Yakama Nation) also submitted comments on an early version of the DEIS. These comments incorporate their assessment, largely based on the Meyer Report, of the linkage between the availability of traditional foods, including especially salmon, and tribal health. The Meyer Report described the importance of salmon to the cultural wellbeing of tribal people as well as their selfesteem as members of their tribes. The Report used tribal poverty, tribal unemployment, tribal per capita income, tribal health and tribal assets as well as more traditional indicators of tribal wellbeing. The Columbia River Treaty Tribe letter explains that the Meyer Report concluded that the impacts of the Snake River dams to the productivity of the Snake River Basins salmon and steelhead had severely impacted the tribes wellbeing.	Thank you for your comment. Appendix P of the EIS includes Tribal Perspectives that were provided to the co-lead agencies. We appreciate the Shoshone Bannock Tribes providing a tribal perspective for inclusion.
32185	12	ggoodstefani@nrdc.org	Natural Resources Defense Council	The DEIS fails to address or take a hard look at the impacts of the Snake River dams and loss of salmon, sturgeon, lamprey, and other fish and wildlife on impacted tribal communities. Adult salmon, sturgeon and lamprey abundance, and tribal harvest, are still far less than historical levels. The DEIS also fails to address inequities in mitigation. Columbia River Treaty Tribes members often prefer fishingrelated economic means of support, which preserve their cultural ties to prior generations, the tribes traditions and the fisheries resources themselves. The proposed mitigation under the Preferred Alternative fails to secure a return of abundant fish populations, and it also discriminates between tribes by failing to employ an in place, inkind practice for loss of traditional tribal natural resources. The DEIS fails to take a hard look at the intertribal justice implications of its mitigation and to match mitigation and harm, so that mitigation benefits the communities most harmed.	Chapter 3 of the EIS provides the analysis of effects to resources from each of the Multiple Objective alternatives (MO), including MO3. MO3 includes the measure to breach the four lower Snake River dams. Chapter 4 considers the effects of climate; Chapter 5 identified mitigation for each MO, while Chapter 6 discusses cumulative effects. Tribal input, concerns, interests, and treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse effects of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. Mitigation for Multiple Objective alternatives 1, 2, 3 and 4 is included in Chapter 5, while Chapter 7 includes mitigation for the Preferred Alternative. Based on the EIS analysis the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs. Broad-sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
32185	13	ggoodstefani@nrdc.org	Natural Resources Defense Council	VI. THE DEIS FAILS TO TAKE A HARD LOOK AT THE IMPACT ON SOUTHERN RESIDENT ORCAS AND CONTRADICTS NOAA FISHERIES OWN FINDINGS The Southern Residents are some of the most well-studied killer whales on the planet.14 Despite the wealth of scientific literature available on Southern Residents, and the numerous studies that were submitted to the Action Agencies by these authors and others during scoping of the DEIS, the DEIS only includes three referenced sources of information on the Southern Residents.15 The DEIS does not address or consider any peer-reviewed studies from independent scientists about the Southern Residents or the most recent NOAA Fisheries conclusions, including scientific analysis and review of the Southern Residents presence in coastal habitat and the importance of Columbia River Basin salmon in particular to SRKW survival.	The co-lead agencies agree that the quantity, quality and timing of prey availability is important in health of SRKWs. Despite statements in this comment, information on SRKW diet is still evolving and being gathered. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. Also, see response to Comment 6110-16 and updated language of effects on SRKWs in Chapter 3.6 and Chapter 7. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
32185	14	ggoodstefani@nrdc.org	Natural Resources Defense Council	By NOAA Fisheries own assessment, the Southern Resident orca population must increase by an average 2.3 percent per year for 28 years in order to be removed from the 14 NOAA Fisheries, Species Directive: Killer Whales, available at: https://www.fisheries.noaa.gov/species/killerwhale. 15 The three sources are the Center for Whale Researchs website (last accessed in 2018); a 2016 5-year review of the SRKWs by the National Marine Fisheries Service; and a list of priority salmon stocks developed by the National Marine Fisheries Service and the Washington Department of Fish and Wildlife. See Columbia River System Operations DEIS at 11-9, 11-48, and 11-50. Endangered Species list,16 yet under current conditions NOAA projects a continued downward trend over the next 50 years.17 NOAA has also recognized that inbreeding in this now very small population of only 73 whales means that the population trajectory may be more negative.18 NOAA Fisheries has recognized the Southern Residents as one of eight marine species most at risk of extinction and considers them a recovery priority number one: a species whose extinction is almost certain in the immediate future because of a rapid population decline . . . .19 NOAA Fisheries itself has concluded in a different recent biological review that the loss of a single [Southern resident orca] individual, or the decrease in reproductive capacity of a single individual, is likely to reduce the likelihood of survival and recovery of the species.20	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Also, see response to Comment 6110-16. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
32185	15	ggoodstefani@nrdc.org	Natural Resources Defense Council	hroughout their range, the Southern Residents face significant threats to their survival, including prey depletion, high toxicant loads, anthropogenic noise, and vessel impacts. A lack of their preferred prey, Chinook salmon, is widely recognized as the primary limiting factor to their immediate survival and future recovery, with increased mortality and decreased fecundity shown to be correlated with coastwide indices of Chinook salmon abundance.21 16 NMFS (2008) Recovery Plan for Southern Resident Killer Whales (Orcinus orca), p. II-82, available at, http://www.nwr.noaa.gov/Marine-Mammals/Whales-Dolphins-Porpoise/Killer-Whales/ESA-Status/Orca-Recovery- Plan.cfm] 17 84 Fed. Reg. at 49,215; National Marine Fisheries Service, West Coast Region (2019) Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales, Draft Biological Report at 7-8 (hereafter NOAA Biological Report). 18 NMFS (2016). Southern Resident Killer Whale (Orcinus orca) 5-Year Review: Summary and Evaluation. National Marine Fisheries Service, West Coast Region. 17 pp., available at: https://www.westcoast.fisheries.noaa.gov/publications/status_reviews/marine_mammals/ kw-review-2016.pdf 19 NOAA Fisheries (2016) Species in the Spotlight: Southern Resident Killer Whale DPS 20 NMFS (2009) Biological Opinion and Conference Opinion on the Long-Term Operations of the Central Valley Project and State Water Project, at 573. 21 Ford, J.K.B, G.M. Ellis, and P.F. Olesiuk (2005) Linking prey and population dynamics: Did food limitation cause recent declines of 'resident' killer whales (Orcinus orca) in British Columbia. Fisheries and Oceans; Ford J.K.B et al. (2010) Linking killer whale survival and prey abundance: food limitation in the oceans apex predator? Biology Letters, 6:139142; Robert C. Lacy, et al. (2017) Evaluating Anthropogenic Threats to Endangered Killer Whales to Inform Effective Recovery Plans, 7 Sci. Reports 14119; Ward E.J, E.E. Holmes, and K.C. Balcomb. (2009) Quantifying the effects of prey abundance on killer whale reproduction. Journal of Applied Ecology, 46: 632640; National Marine Fisheries Service (2008) Recovery Plan for Southern Resident Killer Whales (Orcinus orca). One recent population viability analysis considered how Southern Resident population growth would respond to reductions in current threat levels for each of the three threats, singly or in combination.22 They found that only by addressing prey abundance could the NOAA Fisheries recovery goal of 2.3 percent growth for the SRKW population be achieved.23 The authors concluded that reaching the recovery target without increasing Chinook salmon numbers is likely impossible.24 NOAA Fisheries itself has recognized	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill

				that the principle impediment to orca recovery is a severe shortage of preyparticularly Chinook salmon.25 For their immediate survival and future recovery, the Southern Residents need abundant, diverse, and accessible Chinook salmon prey throughout their range and across seasons.26 Salmon are the mainstay of the Southern Residents diet. This diet must support daily life activities (e.g., foraging, traveling, socializing, resting), in addition to gestation, lactation, and growth.27 To maintain this high energy balance, Southern 22 Robert C. Lacy, et al. (2017) Evaluating Anthropogenic Threats to Endangered Killer Whales to Inform Effective Recovery Plans, 7 Sci. Reports 14119. 23 Id. 24 Id. at 4-5. 25 NOAA Biological Report at 28. 26 Washington State Southern Resident Orca Task Force (2019) Final Report and Recommendations, available at: https://www.governor.wa.gov/sites/default/files/OrcaTaskForce_FinalReportandRecommendations_11.07.19.pdf 27 NOAA Biological Report at 27. Residents preferentially consume Chinook salmon, particularly older (>3 years), larger Chinook age classes.28 Larger salmon offer the additional benefit that fewer are needed to provide a given amount of nutritional value, so larger individuals require fewer prey capture events, and less foraging effort	years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32185	16	ggoodstefani@nrdc.org	Natural Resources Defense Council	Underscoring the importance of Chinook to the Southern Residents, scientists have found a strong correlation between Chinook abundance and SRKW impaired body condition (peanut head), reduced growth rate, reduced overall length,29 reduced social cohesion,30 reduced fecundity,31 and reduced survival.32 Reproductive-age females seem to be particularly vulnerable to nutritional stress. One recent study found that up to 69 percent of all detectable Southern Resident pregnancies were unsuccessful; of these, up to 33 percent failed relatively late in gestation or immediately postpartum, when the energetic cost and risk is especially high (to the mother whale). The authors concluded that [l]ow availability of Chinook salmon appears to be a . . . significant cause of late pregnancy failure, and that point[s] to the importance of promoting Chinook salmon recovery 28 Id. at 10, 27. 29 Durban, J. et al. Biology Letters 6: 139142; Ward, E.J. et al. (2013) Estimating the impacts of Chinook salmon abundance and prey removal by ocean fishing on Southern Resident killer whale, NOAA Technical Memorandum NMFS-NWFSC-123. to enhance population growth of Southern Resident killer whales.33 In particular, the authors concluded that the results of the study strongly suggest that recovering Columbia River Chinook (CRC) runs should be among the highest priorities for managers aiming to recover this endangered population of killer whales.34	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32185	17	ggoodstefani@nrdc.org	Natural Resources Defense Council	The Southern Residents spend more than half the year inhabiting the coastal waters of Washington, Oregon, and northern California. In particular, NOAA Fisheries data compiled from tagged whales, dedicated surveys, and passive acoustic monitoring indicates the Southern Residents spend significant time in the winter and spring (November through May) off the mouth of the Columbia River and have been present there thirty-five times more often than would be expected by chance.35 Although the vast majority of research on Southern Residents is conducted in the Salish Sea, the majority of the population spends the majority of their time in the Pacific, and the majority of their time there is likely within the range of Columbia Basin Chinook. NOAA Fisheries itself has noted this area to be a high use foraging area, and approximately 50 percent of the time spent by the Southern Residents in coastal waters is between Grays Harbor and the Columbia River.36 33 Wasser S.K. et al. (2017) Population growth is limited by nutritional impacts on pregnancy success in endangered Southern Resident killer whales (Orcinus orca). 				N0007017MP4C419. 8 January 2018; Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries Service, September 2019. Available: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killer-whale NOAA Fisheries recently proposed designation of the mouth of the Columbia River, along with other coastal habitat, as critical habitat for the Southern Residents.37 In its Draft Biological Report in support of the proposed revision of critical habitat designation for Southern Residents, NOAA Fisheries highlighted the critical importance of the prey found in the Southern Residents coastal habitat, especially the Columbia River, to SRKW survival and recovery.38 Analysis of fish scale and Southern Resident fecal samples collected on the outer coast indicate that Chinook are the primary species consumed on the outer coast and that over half the Chinook consumed by the Southern Residents are from the Columbia River Basin.39 Elevated triiodothyronine hormone concentrations in early spring indicate that Southern Resident orcas particularly forage on the early spring Columbia River runs.40	According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32185	18	ggoodstefani@nrdc.org	Natural Resources Defense Council	The Columbia Basin early spring interior race Chinook runs likely serve to replenish energetic reserves expended during the previous winter as well as help sustain the whales until . . . late summer Chinook runs peak and therefore should be among the highest priorities to recover the SRKW.41 While it may be correct that Puget Sound Chinook salmon stocks are one of the most important salmon stocks for Southern Residents,42 it is equally true that Columbia River Basin salmon stocks are one of the most important stocks for SRKW survival and recoveryin particular, the fat rich spring Chinook. The Southern Residents need to maintain a balance of 37 National Marine Fisheries Service: Proposed Rulemaking to Revise Critical Habitat for Southern Resident Killer Whale Distinct Population Segment. 84 FR 49214 38 See e.g. NOAA Biological Report at 33. 39 Ward, E. et al (May 2019) NWFSC Science to Inform SRKW Distribution and Diet, Presentation to Pacific Fisheries Management Council SRKW Working Group: available at https://www.fisheries.noaa.gov/webdam/download/92840008 ; NOAA Biological Report at 11. 40 Wasser S.K. et al. (2014) Energy content of Pacific salmon as prey of northern and Southern Resident Killer Whales. Endangered Species Research. 25: 265 281.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32185	19	ggoodstefani@nrdc.org	Natural Resources Defense Council	The DEIS concludes that the Multiple Objective Alternative 3 (MO3), i.e. lower Snake River dam breaching alternative, would result in a moderate to major increase in smolt-to adult returns and overall abundances of adult salmon and steelhead over the long term, and that would increase the prey base available to . . . killer whale[s]. 49 However, the Action Agencies conclude without citation or analysis that the effect for the prey-limited Southern Residents would be only minor. 50 The Columbia River Basin is a critical source of salmon for this prey limited species, and an increase in overall abundance of salmon from the largest river system in the whales range would have a major impact on Southern Residents. NOAAs own recovery plan for Southern Residents states, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin.51 49 Columbia River System Operations DEIS at 3-758. 50 Columbia River System Operations DEIS at 3-758. 51 National Marine Fisheries Service (2008) Recovery Plan for Southern Resident Killer Whales (Orcinus orca).	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The determination for SRKW in regards to MO3 was based on the following facts: The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early

					spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32190	1	N/A	N/A	Rather, the resources should be managed where the tribes also have an economic interest in the benefits from the projects. That could be in the form of hiring preferences for the lower Snake River Dams, derived value from sale of irrigation waters from the dam or value from the lock operations. The tribes need an interest in the continued operations of the projects.	Thank you for your comment.
32190	2	N/A	N/A	Operations also need to be more targeted to benefit fish, more spill is not better. In fact, the best survival path is transport. To protect juvenal fish, maximum transport should be utilized to help increase their survival. While considered, this has never be utilized (as it improves fish survival).	The co-lead agencies have proposed to continue the use of barge and truck transportation, albeit at lower rates than under previous spill operations. However, the majority of juvenile fish will migrate in-river. As the comment notes, transportation by barge or truck has been shown to provide a benefit that varies by species, by time of year, and by water condition. The juvenile salmon transportation program is managed by expected fish benefits as well as cost efficiency. SAR estimate for each week of the outmigrations, combined with other environmental and biological data, drive the decisions. Prior to these data being available, transportation began at the beginning of April; however, we learned that fish transported in early April performed very poorly. Transporting too early is not effective and does not justify the expense. Maximum transportation levels are not part of the Preferred Alternative, but higher transportation levels were analyzed under MO2.
32190	3	N/A	N/A	In addition, power and reduced spill from current high spill levels could then be managed to improve the migration of adults moving upstream.	Regarding improving adult migration: the survival rates for upstream passage through the 8 dams on the lower Columbia River and lower Snake rivers are generally considered to be good. High levels of spill can delay adults and result in higher rates of adults falling back over the dams. There are measures to address known adult delay issues in the Preferred Alternative, but, additionally, operations will be monitored and adaptively managed in coordination with the Regional Forum as needed.
32190	4	N/A	N/A	I believe that the current goal is not to improve the survivability of fish (which is why no transport), but to marginalize the value of the hydroprojects.	The Preferred Alternative is expected to increase fish survival. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% as a result of the Preferred Alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. Varying levels of transportation were included in all MOs with the exception of MO3 (dam breach). MO2 considered much higher levels of transportation that are currently implemented under the NAA. Transportation effects were also analyzed in the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32198	1	brad@lrecoop.com	N/A	Key Points I. Continued need to provide for adequate, efficient, economical, reliable power through the FCRPS. Power generated through the FCRPS supplies SRPA member utilities with their primary source of electric energy. Our member utilities have invested, through rates, in the FCRPS for decades. Should actions proposed in Multiple Objective Alternatives 3 (MO3) and Multiple Objective Alternative 4 (MO4) be implemented, this investment would largely be forgone and our utilities would be left scrambling to acquire alternative power supply. Inadequate power supply and tremendous upward wholesale rate pressure would likely result from such action. These additional expenses would create an unacceptable detrimental impact to our consumers, and the region as a whole. Further, the SRPA asks the co-lead agencies developing the 2020 CRSO-EIS preferred alternative, to limit spill amounts to those maximum levels proposed in Multiple Objective 1 (MO1)3. The SRPA is opposed to breaching of any of the FCRPS dam facilities and or any other actions that would lead to a significant curtailment of power production outside of levels proposed in MO1 and MO2 of the 2020 DEIS.	Neither MO3, which includes the measure to breach the four lower Snake River dams, nor Multiple Objective alternative 4 (MO4) were identified in the Draft EIS as the Preferred Alternative (PA). The statements in the comment regarding potential decreases in power system reliability and rate effects under MO3 and MO4 are consistent with the findings of the EIS. See Section 3.7.3.5, at pages 3-918-924; Table 3-166; Section 3.7.3.6, Electricity Rate Pressure, at pages 3-945-950, and Table 3-182 in the Draft EIS. The Preferred Alternative includes a combination of measures from the MOs, that seek to balance environmental, economic, and social objectives. Under the Preferred Alternative, regional power reliability is the same as under the No Action Alternative. The Preferred Alternative carries forward certain operations in the 2019-2021 Spill Operation Agreement resulting in no loss of reliability compared the No Action Alternative. In contrast, MO1 increased the Loss of Load Probability and had higher Total Dissolved Gas than the Preferred Alternative.
32198	2	brad@lrecoop.com	N/A	II. Necessity of the CRSO to maintain adequate capacity to provide BPA balancing authority response capability. The Bonneville Power Administration (BPA) has regional responsibilities to provide energy balancing services for the Pacific Northwest4. Adequate generation capacity and flexibility are necessary for the BPA to fulfill these obligations. There simply are not base-load dispatchable generation resources of the capacity necessary to replace the lower Snake River Dams on the FCRPS5.	The comment is consistent with discussions in the EIS regarding the dispatchability of renewables and the importance of hydropower for the regional power system. See Section 3.7.2.2 at 3-794 in the draft EIS.
32198	3	brad@lrecoop.com	N/A	III. Environmental benefits of utilizing this carbon-free energy source to mitigate the impacts of carbon-based fuel alternatives We acknowledge that the FCRPS dams, reservoirs and associated infrastructure impact the natural ecosystems of the Columbia River Basin. SRPA member utilities have through member energy rates, paid substantially, for the mitigation of these impacts for decades. The FCRPS 2 (Columbia River System Operations Draft Environemental Impact Statement-Executive Summary, 2020) 3 (Columbia River System Operations Draft Environemental Impact Statement-Executive Summary, 2020) 4 (Bonneville Power Administration (DB/BP-4171), January 2009) 5 (Energy and Environmental Economies, Inc., 2018) environmental impact is often addressed in detrimental terms. One aspect of the power produced from the system, that is often omitted, is its carbon-free attribute. The FCRPS hydro system produces carbon-free 12,000 megawatts of carbon-free power generation annually. Replacing this generation with currently available carbon-based generation would add an additional 50 million metric tons of carbon to the atmosphere6. The lower Snake River Dams produce approximately 12% of the total FCRPS generation. Breaching the lower Snake River Dams or using extreme spill regimes would equate to 6 million tons of additional atmospheric carbon emissions. The environmental cost of replacing these carbon-free generation resources with carbon-based resources would prove costly from an economic and environmental perspective7.	The statements in the comment regarding the importance of regional hydropower for maintaining low regional greenhouse gas emissions is consistent with the findings and discussion in the EIS. The EIS finds that Multiple Objective (MO) Alternative 3 (which includes breaching the four lower Snake River dams) would increase regional greenhouse gas emissions, consistent with the statement in the comment. Contrary to the statistic cited by the comment, the EIS finds that under MO3 and MO4, replacing hydropower with fossil fuel generation would increase emissions by 3.3 and 3.1 million metric tons of CO2, not 6 million tons. The EIS also did not evaluate the greenhouse gas implications of replacing all hydropower generation of the Federal Columbia River Power System as described in the comment. See Section 3.8.3.5, Greenhouse Gas Emissions under Multiple Objective Alternative 3, at 3-1014 in the draft EIS.
32198	4	brad@lrecoop.com	N/A	IV. Preferred alternative must not drastically impact consumer rates The 2020 DEIS addresses customer wholesale power rates in each of the 5 Multiple Objective Alternatives. The viability of any preferred alternative terms must include serious consideration for impact on consumer rates. Rate increases associated with MO3 and MO48 are without question, outside the scope of meeting the providing adequate or economical power supply. Modest rate increases, such as the lower end of estimates provided in the DEIS MO1 of 4.5- 8.6%9 could be acceptable, if there would be significant reduction of fish mortality. Provided that these mortality reduction objectives were met, a potential offset in litigation expenses should be sought to recover these additional costs.	In developing the Preferred Alternative, one of the objectives was to ensure an adequate, efficient, economical and reliable power supply. The MO1 power rate increases quoted in the comment are consistent with the findings of the EIS, and the Preferred Alternative rate pressure is below that of MO1 at 2.7 percent relative to the No Action Alternative. See Section 7.7.9.1, Rate Sensitivity Analysis, Table 7-32 in the Draft EIS. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
32198	5	brad@lrecoop.com	N/A	V. Willingness to Invest in an Ecologically Sound Solution Fish Passage SRPA member utilities have invested heavily to mitigation for the impacts of the FCRPS to fish migration. From 2007-2018, BPA customers spent an average of over $216 million dollars annually in direct funds relative to fish and wildlife programs10. This is a necessary expense, as the presence of the FCRPS does have an impact on wildlife, particularly fish migrations. The many successes of these mitigation measures ought not to be overlooked. While SRPA members realize that there will continue to be mitigation costs	Thank you for your comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				associated with the operation of the FCRPS, we encourage the co-lead agencies to consider the most efficient and effective use of these funds in the preferred alternative determination.	
32217	1	N/A	N/A	While I share the concern for the survival of the salmon and orcas, there is not enough conclusive evidence that breaching the dams would improve their survival rates significantly, and in fact may do more harm than good.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The determination for SRKW in regards to MO3 was based on the following facts: The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32217	2	N/A	N/A	I believe focusing resources and efforts on cleaning the Puget Sound and reducing carbon output would have a more significant impact on the survival of salmon and orcas.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. Reducing carbon output, as a general matter, is outside the scope of this EIS, but the EIS analyzes effects of the range of alternatives on greenhouse gas emissions and climate change in Section 3.8 and Chapters 4 and 7.
32217	3	N/A	N/A	I believe it would be unwise to pursue breaching the dams without having immediately available better, clean, low-cost power alternatives in place. Considering the current economic downturn, such a spike in energy costs without better alternatives in place, and the potential for power black-outs, could have far-reaching and long-lasting impact on the entire area.	The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. In the Draft EIS, please see Section 3.7.3.5, at pages 3-904-910. Under these replacement portfolios, regional power rate pressure increases. In the Draft EIS, please see Section 3.7.3.5, at pages 3-918-924; and Table 3-166. The findings of the Draft EIS are consistent with the comment with regard to the effects on regional power reliability of breaching the four lower Snake River dams, without resource replacement. In the Draft EIS, see Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1. The EIS also acknowledges the risk that replacement resources are not constructed in time to address decreased power system reliability. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS.
32217	4	N/A	N/A	More research is needed to ascertain the broader influences on the salmon and orcas that are threatening their survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. The co-lead agencies agree more information is needed concerning the most crucial prey stocks for SRKW. Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
32218	1	Greg Haller	Pacific Rivers	Due to time constraints imposed by the federal Action Agencies for public comment and the ongoing Covid-19 emergency, we are providing the following bulleted comments for your consideration	Thank you for your comment.
32218	2	Greg Haller	Pacific Rivers	1. DEIS Conflates Purpose of NEPA The National Environmental Policy Act (NEPA) makes it the policy of the federal government to administer federal programs in the most environmentally sound manner. Agencies are to take a hard look at the environmental impacts of a proposed action using the best available information Federal agencies are to evaluate the In the CSRO DEIS, it appears that analysis of the effects of each alternative on authorized project purposes takes precedent over analysis of the ecological impacts of the alternatives, as required by NEPA	NEPA requires Federal agencies to consider the environmental effects before making decisions, but it does not require Federal agencies to administer programs or projects in the most environmentally sound manner or implement an environmentally preferred alternative. The co-lead agencies in the CRSO draft and final EIS have taken a hard look at the effects to the natural and human environments anticipated to arise from the alternatives as described in Chapters 3, 4, 6, and 7. These chapters demonstrate the co-lead agencies evaluated effects to varied resources beyond the authorized purposes for the CRS projects.
32218	3	Greg Haller	Pacific Rivers	2. The Public Comment Process Was Inadequate The agencies failed to provide adequate or meaningful opportunities for the public to comment on the DEIS. It is unconscionable that that the public was given only 45 days to provide comments on a document of this size and complexity during the Covid-19 crisis facing the nation. Members of Congress, tribes, and organizations requested that the Action Agencies extend the public comment period to its original 120-day timeline but were denied. Public hearings were cancelled due to state and federal orders to shelter in place to lessen the spread of Covid-19, and in their place a system of phone-in public comment sessions was implemented. These proved to be lightly attended, disorganized, and inadequate for conveying meaning feedback to the Action Agencies.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
32218	4	Greg Haller	Pacific Rivers	3. Climate Change Analysis Not Complete Current and future water temperatures in the Columbia and Snake Rivers are a major source of concern. Water temperatures often exceed state water quality standards during key lifecycle stages of salmon and steelhead. The Environmental Protection Agency, and others, have shown that federal dams are the primary source of anthropocentric warming in the river. However, and likely due to the truncated timeline for completing the NEPA process, the Action Agencies failed to fully assess the effects of climate change on reservoir temperatures. The climate analysis, which was done by BPA and not supported by the Army Corps or Bureau of Reclamation, only applied to estimates of power production and revenue under four climate scenarios. No other water needs were quantified in the DEIS (i.e fish, water supply, flood risk, navigation, recreation). Additionally, the Action Agencies could have utilized temperature modeling of the Snake and Columbia by the Environmental Protection Agency, which has clearly demonstrated the temperature impacts of the dams, and the benefits of breaching the dams on the lower Snake River to maintain climate resilient conditions, but chose not to include this analysis. Dworshak Dam provides flood risk management for Portland, power to the region, and cooling and flow augmentation water for the lower Snake. It does so at enormous cost to the local environment, to the Nez Perce Tribe and to other communities. Coldwater releases, while beneficial to fish in the Snake, create economic and cultural impacts locally that are not fully assessed in the DEIS. These include impacts such as the inability to swim in the Clearwater River due to dangerously cold water.	The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with USACE climate change policy and guidance. The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. Water temperature modeling for each alternative is described in Chapter 3, however, as you note it was not conducted for conditions of future climate change. Information to develop, drive, and analyze specific projections of future water temperature and fish characteristics were not available on the timeline of this report.
32218	5	Greg Haller	Pacific Rivers	4. DEIS Fails to Account for the Expiration of Coordinated Flood Risk Management Operations with Canada Coordinated flood risk management operations with the Canada are set to expire in 2024 under the U.S.-Canada Columbia River Treaty. At that time, the United States will be required to use all effective storage in the U.S. side of the basin before it can request storage space in Canada to control high flows. Such an operation would upend current authorized project purposes at U.S. reservoirs throughout the Columbia and Snake, impacting operations designed to benefit irrigation, energy, flood control and salmon. There is no evidence that the DEIS evaluates how a major change in flood risk operations will effect salmon and other resources. While treaty negotiations are ongoing, there is not evidence that a deal that includes continued joint flood risk operations will be achieved by 2024. Further, the renegotiation of the Columbia River Treaty is addressing the issue of Ecosystem-based Function in the operation of treaty dams, which contemplates additional flows in low and average flow years to aid juvenile salmon migration. There is no evidence that the DEIS includes consideration of these important changes in the Treaty and its impact on the operation of the Columbia River System.	The Range of Alternatives Section (Section 2.4 of the CRSO EIS), provides a brief discussion of the Columbia River Treaty, why it is not included in the CRSO EIS, and when it would be added to this NEPA effort. As stated in the CRSO Draft EIS, the information about CRT-related operations available in 2016 is applied in the Draft EIS analysis as the best-available information. The CRSO Draft EIS evaluated the implications of the CRS alternatives using the Treaty coordinated operations, including their relationship to hydropower, ecosystem, and flood risk management, with the best available information. As is also noted in the Draft EIS, if CRT-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary.
32218	6	Greg Haller	Pacific Rivers	5. The DEIS Fails in Analyze Fish Passage Fish passage and reintroduction of salmon into areas currently blocked by dams is an important regional issue being explored by tribes and First Nations. Unfortunately, the DEIS fails to include an assessment of fish passage and reintroduction at areas currently blocked by federal dams, including, Grand Coulee, Chief Joseph, and Dworshak. In fact, the discussion of Dworshak fails to mention that it lacks passage (or that it is built on the Nez Perce Reservation for that matter).	Measures to reintroduce salmon above Chief Joseph Dam and Grand Coulee Dam were evaluated early in the process to develop alternatives but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. Section 1.9.7.2 p. 1-41 states that "Dworshak Dam blocks upsteam migration on the North Fork of the Clearwater River." Table 1.2 indicates Dworshak does not include fish passage.
32218	7	Greg Haller	Pacific Rivers	6. Unacceptable Preferred Alternative Given the status of salmon, steelhead, and Pacific Lamprey, the preferred alternative put forward by the Action Agencies is unacceptable. Judge Simon said the system is crying out for a new approach and new thinking if salmon and steelhead are to persist, yet the Action Agencies have delivered more of the same failed policies in attempt to maintain authorized project purposes. The 2020-2021 flexible spill agreement was not intended to serve as a long term operation. However, the DEIS does not evaluate actual spill operations past 2021, leaving uncertainty to how the river will be operated, other than adaptively. Further, adaptive management doesnt preclude reducing spill operations, which is troubling. Clearly, breaching the lower Snake River dams in the alternative likely to have the most success in restoring population of salmon, steelhead and lamprey, as the Action Agencies have concluded. Breaching should be the preferred alternative	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
32231	1	N/A	N/A	Here are a few suggestions: #1 Reduce the number of seals, sea lions etc to the level before the dams were built.	As described in the Preferred Alternative, the co-lead agencies propose several measures to reduce avian and marine mammal predation to mitigate adverse effects to listed species from CRS operations. Ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam.
32231	2	N/A	N/A	#2 Reduce the number of predator birds that gobble up millions of smolt per year.	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. This includes continued implementation of (1) dissuasion measures at the Corps facilities as described in the annual Fish Passage Plan and coordinated with the FPOM, (2) the Inland Avian Predation Management Plan (IAPMP), (3) CATE management plan for reduction in habitat at East Sand Island, and (4) the Double-crested cormorant (DCCO) management plan at East Sand Island. In addition to the ongoing actions, the preferred alternative includes a new measure to dissuade nesting by terns on the Blalock Island colony in the lower Columbia River.
32231	3	N/A	N/A	#3 Decrease the number of pike minnow, walleye etc. in the rivers.	The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies.
32231	4	N/A	N/A	#6 Native Americans and sport fishermen should probably have some limitations or quotas during low number years.	The co-lead agencies developed this EIS to reconsider the operation, maintenance, and configuration of the 14 dams operated as the Columbia River System. Fish harvest management is not within the scope and the co-lead agencies have no role or authority over fishing limitations or quotas. Fishing and harvest are subject to separate actions by federal, state, and tribal agencies outside the scope of this EIS.
32237	1	wildlife.wwu@gmail.com	N/A	(1) The 25-year temporal scope is too brief. Twenty five years is equivalent to just five Chinook salmon generations. Due to long-term consequences of salmonid declines and population extinctions, a much longer analysis window is required to assess risk and impacts accurately.	The temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives (with the exception of the socioeconomic-related resource analysis - 50 years). The accuracy and reliability of climate change information was also a consideration for determining the temporal scope. The co-lead agencies would continue to re-asses the operations and maintenance of the CRS at regular intervals to ensure that accurate and high quality information is considered in managing the CRS.
32237	2	wildlife.wwu@gmail.com	N/A	(2) The abbreviated EIS development and review period undermine public engagement, EIS quality assurance, and confidence in the process. By compressing time between release of the DEIS and ROD signing, the schedule reduces extent and quality of public review of the DEIS and it curtails ability of the agencies to revise and adapt the EIS according to public input.	The public had several ways to submit comments such as the online comment form and through the mail. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined the 45-day public comment period was adequate as per NEPA regulations. The agencies used the extensive public comments to update the EIS, where appropriate.
32237	3	wildlife.wwu@gmail.com	N/A	(3) Purpose and Need for Action: this section recognizes opportunities for recreation on System lakes and reservoirs, but it omits recreational opportunities on free-flowing rivers. Values of recreation on free-flowing rivers may exceed those associated with reservoirs in economic, health, and	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The EIS evaluates actions within the current authorities of the co-lead agencies, as well as certain actions that are not within their authorities, based on the District Courts observations about alternatives that could be considered and comments received during the scoping process.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				aesthetic characteristics. The net effect on recreation of any CRSO alternative requires consideration of activities on both reservoir and free-flowing reaches. Recreation on free-flowing rivers should be added to the Purpose and Need statement, and included in analysis of the alternatives.	Recreation opportunities on a more normative river were evaluated as part of MO3, which includes breaching the four lower Snake River dams (Section 3.13). It is important to note that even with the four lower Snake River dams breached, flows are regulated above these dams.
32237	4	wildlife.wwu@gmail.com	N/A	(4) CRSO Objectives: three objectives concern need to improve ESA-listed fish, but they lack standards and criteria with which to evaluate improvements. The objectives should be clarified to state the kind (criteria) and quantity (standards) of improvement necessary to fulfill ESA mandates.	Each of the objectives list criteria for evaluation (e.g., anadromous salmonid juvenile fish rearing, passage, and survival). The criteria and standards the commenter referenced for fulfilment of ESA mandates can be found in the U.S. Fish and Wildlife Service and National Marine Fisheries Services Biological Opinions in the Final EIS, Appendix V, but NEPA and ESA have individual requirements under the respective statutes.
32237	5	wildlife.wwu@gmail.com	N/A	(5) The DEIS appears to maintain a false equivalency between Congressional legislation, executive orders, and treaties. Because treaties with sovereign nations take precedence over legislation and executive orders, treaties must be honored above legislation or orders sanction developments that would violate treaties. This issue is apparent in DEIS comments about CRS facilities and infrastructure predating environmental legislation and executive orders, as an apparent excuse for non-compliance with those laws and orders. Because treaties with Indigenous nations pre-date all CRS facilities and because those treaties have priority over Congressional authorization for CRS facilities, CRSO must rectify violations of those treaties. Timing of CRS development vs. legislation and orders is not relevant to this issue. The imperative to bring CRSO in compliance with treaty rights has particular relevance to Columbia River System Operations DEIS 13 April 2020 -2- inundation of cultural and harvest sites recognized by the tribes, and reduction of wild fish populations below harvestable levels. In this context, the DEIS should evaluate each alternative relative to extent to which it restores treaty rights.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
32237	6	wildlife.wwu@gmail.com	N/A	(6) The DEIS misconstures hatcheries as measures to address mandates to restore ESA-listed fish. The following statement is illustrative. The co-lead agencies have funded an extensive hatchery program these examples help provide context for the level of effort that has gone into improving conditions for fish within the basin. Hatchery programs may support harvest in the near term, but they do not improve conditions for ESA-listed fish. Rather, hatchery programs often impact wild fish due to inbreeding, food competition with wild fish upon release into natural habitats, and selection for domesticated traits. The ESA and Northwest Power Act require improving conditions for wild fish regardless of hatchery programs. As revealed in the DEIS, CRSO emphasis on hatchery programs is symptomatic of a production mentality that favors providing hatchery fish for harvest to the detriment of restoration of wild stocks1 whose restoration is mandated by ESA. The EIS should evaluate hatchery impacts to ESA-listed fish under each alternative, to comply with the U.S. District Court Opinion and Order2 to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species.	Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Hatchery origin fish are often included in the ESA-listed for an ESU/DPS. Hatchery origin fish are very important to Tribal and sport harvest within the CRB, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
32237	7	wildlife.wwu@gmail.com	N/A	(7) Most CRSO alternatives considered are inadequate relative to several criteria. 7.1 Every alternative, except perhaps MO3, falls short of the ESA mandate to restore listed fish to all or a significant portion of [their] range[s]. Without measures to more substantially increase ESA-listed fish populations, CRSO perpetuate extinction risk of those populations. This concern is particularly severe for fish associated with the Snake River, whose current abundances are mostly 1% or less of historic levels.3 In addition, CRSO that maintain fish abundances at such low levels risk extinction of populations associated with smaller tributaries. Extinction of enough of those tributary populations would constitute failure to protect the listed ESUs in a significant portion of [their] range, also an ESA violation. 7.2 None of the alternatives fulfills the Purpose and Need for Action legal provision to protect Native American treaty and reserved rights. Under every alternative, CRSO inundation of usual and accustomed areas used by tribes for fishing and harvesting would continue, effectively denying access rights to those sites guaranteed by the treaties. This conflict between CRSO and the Purpose and Need provision to protect treaty rights is particularly ironic, because some CRS dams were constructed for the explicit purpose of eliminating tribal fishing.4 The EIS should include an evaluation of the extent to which each alternative violates treaty rights by obstructing access to the tribes usual and accustomed sites. 7.3 Except for MO3, every alternative considered in the DEIS fails to protect treaty rights to a harvestable abundance of fish. As stated in the report from the Confederated Tribes of the Warm Springs Indian Reservation of Oregon (Appendix P), the United States Supreme Court affirmed a decision by the Ninth Circuit Court of Appeals which determined that the Columbia River Tribes Treaties guaranteed the right to have fish to take, not just the right for the tribes to dip their nets into empty waters devoid of salmon. They further invoked the appeals court decision: The Indians did not understand the Treaties to promise that they would have access to their usual and accustomed fishing places, but with a qualification that would allow the government to diminish or destroy the fish runs. Governor Stevens did not make, and the Indians did not understand him to make, such a cynical and disingenuous promise. By not including measures to increase salmon and steelhead to harvestable levels, most alternatives in the DEIS would perpetuate treaty violations and do not meet the CRSO legal purpose to protect treaty rights. The EIS should determine the extant of this failure for each alternative. To fulfill treaty obligations and the CRSO legal purpose, the EIS should include additional alternatives that would restore fish to harvestable abundances. Columbia River System Operations DEIS 13 April 2020 -3-	Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
32237	8	wildlife.wwu@gmail.com	N/A	(8) Contextual statements in the DEIS regarding alternative MO3 suggest that dam breaching was included to fulfill a court order, but without serious consideration. This concern is revealed in the following DEIS statement. However, the [dam breaching] measures are carried forward in the analysis to align with the District Courts Opinion and Order, as well as in response to comments received during public scoping. Doubts about consideration given to MO3 are reinforced by apparent biases in DEIS analysis, described below. The following three comments pertain to elements needed to adequately evaluate CSRO impacts, but that were omitted from the DEIS.	The Draft EIS provides a comprehensive and unbiased analysis of MO3 in a manner consistent with NEPA. The statements referenced in the comment were to provide context for why the agencies were looking at an alternative outside its existing authorities and to note the public's interest in asking the co-lead agencies to analyze this alternative as part of the draft EIS.
32237	9	wildlife.wwu@gmail.com	N/A	(9) Population viability analysis for each ESA-listed fish population. The DEIS reports LCM and CSS model estimates of changes in population abundances and migration survival rates, but it does not provide measures of uncertainty of those estimates. A model might predict an average increase in SAR of 28% under the Preferred Alternative, but there is a non-zero probability SAR would decrease under that alternative. That probability, and its analog for each fish and alternative, must be included in the EIS if decision makers are to make informed risk assessments for ESA-listed fish. More generally, the EIS should include population viability analysis to determine extinction risk for each fish under CRSO alternatives. Similarly, the EIS should apply similar analysis to determine the probability of restoring each wild fish population to harvestable levels within the assessment time frame.	Population viability analysis with salmon typically involves time series of adult recruitment or spawner abundance. Survival during the Smolt-to-Adult lifestage as well as early juvenile lifestages contributes to the viability trend of adults. NOAA has estimated extinction risk of populations using its Life Cycle models (Zabel and Jordan 2020). The comment about estimating time to reach ESU recovery or good levels of harvest could be linked to the extinction risk analysis. The separate NOAA Harvest BiOp for the Columbia Basin contains some of this analysis. Confidence intervals for in-river survival is included in the appendix, although the commenter is correct that confidence intervals were not published along with mean estimates in the main tables of the EIS. It is challenging to estimate uncertainty around metrics spanning multiple life stages such as SAR and adult abundance which reflect variance both from the 80-year water record and data uncertainty from historical fish survival estimates. Population viability analysis is most relevant to recovery planning efforts. Based on the EIS analysis, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs. Broad-sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
32237	10	wildlife.wwu@gmail.com	N/A	(10) Assessments of CRSO impacts on the ESA-listed Southern Resident Orca (SRO) population. That population has declined to perilously low abundances in recent decades, primarily due to lack of Chinook salmon their principal food source. Similarly, rates of SRO survival and fecundity are below sustainable levels due to low Chinook abundances and resultant starvation.5 CRS Operations have impacted the SRO population by reducing abundances of the largest source of Chinook salmon. Breaching the LSRD provides the greatest potential to increase Chinook abundance in SRO habitat. Conversely, continued CRS operation that maintains low Chinook abundances may consign SRO to extinction in coming decades. Because effects of CRSO on the ESA-listed SRO population are so strong and direct, the EIS must evaluate anticipated effects of each alternative on SRO restoration and extinction risk.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
32237	11	wildlife.wwu@gmail.com	N/A	(11) Continuity of tribal cultural traditions. All or most tribal elders with personal knowledge and experience of the LSR and other reaches with cultural significance are likely to die within the 25-year EIS assessment period. If the LSRD (and other CRS dams) are not breached, the tribes will lose all living memory of a free-flowing Lower Snake River and cultural association with it. Such a loss would compound prior breaks in cultural continuity caused by government-imposed family separations, language suppression, and banning of cultural practices. The EIS should evaluate anticipated impacts of each alternative on this break in cultural continuity.	The co-leads appreciate your comments and participation in the development of the Draft EIS. The co-lead agencies will continue to consult with the Kootenai Tribe of Idaho throughout this process.
32237	12	wildlife.wwu@gmail.com	N/A	The following seven comments pertain to factors contributing to misleading analysis of DEIS alternatives. (12) The DEIS applies the No Action Alternative as a reference to evaluate effects of the other five alternatives. Because the No Action Alternative was determined to cause unacceptable impacts, it is not an appropriate reference. An alternative could perform unacceptably relative to CRSO objectives, but still represent improved performance relative to the No Action Alternative. The CRSO objectives (refined as described above) provide more relevant and objective standards for evaluating EIS alternatives. Evaluations in the EIS should be revised using the CRSO objectives as baselines.	The co-lead agencies developed the No Action Alternative consistent with regulations implementing NEPA, which allow agencies to use the "status quo" from the time of the Notice of Intent to Prepare the EIS.
32237	13	wildlife.wwu@gmail.com	N/A	(13) Fish modeling: assumptions in the analyses need justification and clarification. Results of LCM and CSS analysis for each alternative depend sensitively on assumptions of latent mortality levels. The values of those levels should be justified, along with plausible evidence that such levels are likely to be realized.	The results of third-party review, both the Corps' Independent Expert Peer Review as well as a recently released ISAB review of the CSS results will be included in the Final EIS. Initial review of the results of the peer review do not indicate fundamental flaws in either the CSS or NMFS approach and both models will continue to frame the potential outcomes associated with all MOs and the Preferred Alternative. Survival estimates from the University of Washington TDG model were not relied on for decision-making purposes but will be used to assess relative exposure indices. Section 3.5 has been updated based on IEPR and ISAB reviews The model results presented in Section 3.5 and Chapter 7 address latent mortality and reservoir mortality. Multiple mechanisms of delayed mortality or 'carryover effects' between experiences in one lifestage influencing survival or physiology in subsequent lifestages (Gosselin et al. 2018). These include transportation related delayed mortality, injuries caused by passing multiple dams via any route, delays caused by reservoir and dam passage, and exposure to toxins. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Lifecycle model results. Reservoir mortality is captured in the juvenile survival metrics presented in Chapter 3. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the Draft EIS. In their 2007 report the ISAB stated, "The ISAB concludes that the hydrosystem causes some fish to experience latent mortality, but strongly advises against continuing to try to measure absolute latent mortality. Latent mortality relative to a damless reference is not measurable. Instead, the focus should be on the total mortality of in-river migrants and transported fish, which is the critical issue for recovery of listed salmonids. Efforts would be better expended on estimation of processes, such as in-river versus transport mortality that can be measured directly." Gosselin, J. L., Zabel, R. W., Anderson, J. J., Faulkner, J. R., Baptista, A. M., & Sandford, B. P. (2018). Conservation planning for freshwater-marine carryover effects on Chinook salmon survival. Ecology and evolution, 8(1), 319-332.
32237	14	wildlife.wwu@gmail.com	N/A	(14) Water quality: qualitative evaluations of water temperature impacts are not appropriate. Temperature criteria for fish health and survival are quantitative and well understood. Water temperature forecasts are Columbia River System Operations DEIS 13 April 2020 -4- readily available. Given these knowledge resources, it would be inappropriate to jettison quantitative precision in water temperature assessments by using a qualitative approach.	The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best available information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Water quality analysis completed for this EIS used a combination of numerical models (CE-QUAL W2 and HEC-RAS), past studies and expert knowledge to predict the impacts of the EIS alternatives on water quality. Results were provided to the fish team for incorporation into NMFS COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. The fish team also used water quality outputs to qualitatively examine effects to fish species based upon known relationships between water temperatures and fish responses specifically for stocks such as sockeye salmon and fall Chinook salmon where quantitative models were not available. In this way, the team was able to discuss effects on time and locality scales that may not be detected by the models.
32237	15	wildlife.wwu@gmail.com	N/A	(15) Assessments of impacts to ESA-listed fish do not account for cumulative impacts of climate change. Failure to include climate change impacts on vulnerable fish populations leads to a false sense of security. Alternatives that provide modest improvements in fish populations actually could lead to extinctions under anticipated climate change. Conversely, stronger mitigation measures than those included in the DEIS are likely to be required to prevent extinctions when CRSO impacts combine with climate change.	Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). A full assessment of considerations of climate change and water temperatures are in section 3.4 Water Quality, Chapter 4 Climate, and Chapter 7 of the Preferred Alternative of the analysis.
32237	16	wildlife.wwu@gmail.com	N/A	(16) Many embedded costs of alternatives that retain LSRD are ignored, while costs of LSRD breaching are accounted explicitly. For example, costs of LSRD turbine replacement would be incurred in alternatives that retain LSRD, but those costs are not accounted for. Conversely, costs of turbine replacement would be obviated by breaching, but that cost savings is ignored.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework (see 40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Turbine replacement and other capital requirements to maintain the four lower Snake River projects are included in the cost analysis for the appropriate alternatives, as described in Section 3.19 and Appendix Q (see Section 4.2). Estimated costs for capital and O&M are $107 million annually for the four lower Snake River projects. Under MO3, the Lower Snake River Compensation Plan would no longer be funded, with a cost savings of $34 million. Bonneville's Fish and Wildlife Program costs are systemwide costs. Breaching the lower Snake River dams may result in changes to Bonneville's Fish and Wildlife Program. However, funding decisions for the Fish and Wildlife Program are not being made through the CRSO EIS process. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
32237	17	wildlife.wwu@gmail.com	N/A	(17) Assessments of greenhouse gas emissions ignore methane emissions from reservoirs. This oversight constitutes a bias against MO3, in favor of alternatives that retain the LSRD.	The EIS does include an evaluation of reservoir methane emissions. Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS projects, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
32237	18	wildlife.wwu@gmail.com	N/A	(18) The DEIS limits consideration of cultural resources (section 3.16) to objects and places. No consideration is given to cultural importance of living resources or the role that stewardship of those resources plays in contemporary tribal cultures.	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources." This is consistent with Federal laws and regulations, which focus on specific bounded properties. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Appendix P includes copies of tribal perspectives that were submitted by tribes and considered by the co-lead agencies. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS.
32237	19	wildlife.wwu@gmail.com	N/A	The following comments concern DEIS recommendations. (18) Since evaluations of the alternatives do not reference performance relative to ESA-mandated restoration of listed fish populations, selection of the Preferred Alternative was premature. Contingent on additional information described above, it appears that all alternatives (except perhaps MO3) do not meet ESA mandates to protect and restore listed fish species. In particular, all alternatives except MO3 would maintain Snake River stocks at 1% to 1.5% of historic abundances, with persistent risk of extinction. In this context, selection of the Preferred Alternative must be reconsidered.	There are many factors that effect salmonid populations that are outside the authority of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
32237	20	wildlife.wwu@gmail.com	N/A	(19) Tribal comments in Appendix P express consistent opposition to CRSO that perpetuate low fish abundances, inundation of cultural sites, and obstruction of cultural practice. The DEIS recommendation of the Preferred Alternative ignores tribal voices, in favor of contemporary hydropower operation.	The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 and the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
32237	21	wildlife.wwu@gmail.com	N/A	In summary, the DEIS perpetuates a bias toward current operations, without adequate consideration of lessons learned, response to current and anticipated future threats, and tribal voices. I urge you to make revisions to the EIS as described in my comments above.	NEPA requires federal agencies to assess the environmental effects of their proposed actions prior to making decisions. The Draft EIS provides a comprehensive and unbiased analysis of the effects of the No Action Alternative, the Multiple Objective Alternatives, including the Preferred Alternative, while also considering cumulative effects within the basin. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
32262	1	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 1.9.7.3; 1-45, ll. 1303-07 If Grand Coulee Dam (Lake Roosevelt) only has a very weak thermal stratification, it is unclear how this can result in Grand Coulee Dam releasing the coolest water possible during the hot summer months. The statement should emphasize that Lake Roosevelt effectively has a uniform temperature and, as a such, Grand Coulee Dam releases the coolest water in the winter months and warmest water in the summer months, with little opportunity to thermally regulate any portion of the Columbia River anadromous fish migration corridor. As written, the statement is misleading because it suggests that Grand Coulee releases could be used to cool downstream reaches of the river. Rather, because of its near uniform temperature, Grand Coulee cannot be used for temperature mitigation by selectively withdrawing cooler water.	The commenter is correct that effectively the temperatures in the forebay are uniform during the summer months, with little opportunity to thermally regulate releases. Consistent statements are made in Section 3.5 and Appendix D. The statement concerning summer operations releasing the coolest water possible is correct, and does not insinuate more can be done to cool downstream reaches of the river.
32262	2	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 2.4.2.1; 2-22, ll. 726-30 In our comments on the ADEIS (Dec. 24, 2019), we provided the following comment regarding this paragraph: Although it is true that [t]hroughout the year, spill is allocated to the Chief Joseph project as needed to manage TDG on a systemwide basis for the benefit of aquatic species, including ESA-listed species, my comment is that spill in the spring and early summer months negatively affects the Colville Tribal fishery immediately below Chief Joseph Dam. The DEIS should acknowledge that impact. The co-lead agencies responded to the CTCRs comment tracker that Discussion of these effects will be added to Chapter 3. However, we could not find any such discussion. Please identify where this discussion occurs in the DEIS. We also note that this comment was raised early in the process. See Oct. 25, 2016, comment submitted at a scoping meeting by Randy Friedlander, Director of CTCRs Fish and Wildlife Program.	Thank you for the comment. The co-lead agencies have added text to the FEIS in section 3.5.4.1 and to section 7.7.19 to acknowledge this issue.
32262	3	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 3.5.3.1; 3-356 et sea. In our comments on the ADEIS (Dec. 24, 2019), we provided the following comment regarding Section 3.5, lines 11639 and 11653: Suggest consider adopting the CSS Snake River spring/summer Chinook survival, travel time, powerhouse passage values associated with the lower Columbia River projects for UCR Wenatchee spring Chinook abundance to provide CSS estimate. Although not generated with UCR specific data, it would provide a better range of potential benefits incorporating both COMPASS and CSS concepts than simply projecting at 10%, 25% and 50% increase from the NAA. The response of the co-lead agencies was: No Change - data is not available at this time. We understand that our suggestion, which was first made well before we reviewed the ADEIS, may not be possible in the time available. However, considering the favorable reception by agency staff to this idea and the increasing attention that UCR Spring Chinook will receive in the NOAAs BiOp for the Preferred Alternative and other processes due to their imperiled status, we strongly encourage the agencies to commit to developing this proposed approach so the data and methodology is available for future analyses and identify this effort in the EIS as a topic for additional study.	The co-lead agencies will continue to pursue the processes described in this comment into the future. Both CSS and NMFS continue efforts to develop Life Cycle models for stocks from the upper Columbia ESUs and DPS. As noted in the comment, the co-lead agencies were not able to refine the analysis presented in the Draft EIS, however, we feel that NMFS' sensitivity ranges of 10%, 25%, and 50% likely encompass the outcome that would be predicted by CSS models using Snake River stocks and accounting for passage only between McNary Dam and Bonneville Dam as juveniles. Stocks from the upper Columbia ESUs and DPS pass four Federal projects and the duration they are influenced by passage events and CRS operations is shorter than for those stocks emigrating from the Snake River. Because of this, the co-lead agencies expect that any operations that are beneficial to Snake River stocks would also benefit upper Columbia stocks, just to a lesser degree. We appreciate this comment and will continue to work with regional modeling teams to continue to refine Life Cycle modeling efforts for upper Columbia stocks.
32262	4	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 3.7.4; 3-962, ll. 28917-18 The text states that Details of the monetary value are provided in Chapter 4 of Appendix H. As requested by CTCR, no details of the monetary value are actually provided, so it should be changed to Details of the Colville payment are.	The text in the Final EIS has been updated as requested.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32262	5	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.6.4.1; 7-39, ll. 1271-22 We dont think this characterization is entirely correct. Many off-site mitigation efforts mitigate for impacts directly caused by the CRS, but which are unable to mitigate in-kind and in-place. For example, Chief Joseph Hatchery, downstream of Chief Joseph Dam, is partial mitigation for the construction and operation of the CRS, but an anadromous hatchery above the blocked area was not considered at the time of construction as no fish passage (adult or juvenile) existed at Chief Joseph Dam or Grand Coulee Dam. Thus, the hatchery was built downstream from the impact of no passage. For habitat actions, the lower Columbia federal projects kill fish from the UCR, so habitat actions in those basins in the UCR that produce the fish killed at the federal projects are partially mitigating for impacts directly caused by the CRS.	The co-lead agencies consider actions not at the CRS dam and reservoir projects to improve conditions for fish affected by the CRS as offsite mitigation actions. This is consistent with the co-lead obligations under various applicable Federal laws, including the ESA and the Northwest Power Act.
32262	6	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.6.4.1.; 7-42; Table 7.5 FRCPS Mitigation Hatcheries - Programmatic It is not clear what FCRPS Mitigation Hatcheries Programmatic means. Does this include continued BPA funding for O&M and M&E actions associated with fish hatcheries attached to the NPCCs Fish and Wildlife Program, including those that support harvest and conservation of nonlisted salmon species? These types of hatcheries should be treated in the Preferred Alternative similar to the LSRCP hatcheries. We note that while the DEIS is geared toward ESA-listed species, the hatcheries funded by the co-lead agencies associated with the LSRCP produce salmon that are not listed but they are included in the DEIS as Measures Included in the Preferred Alternative to Benefit Endangered Species Actlisted Fish that are Being Carried Forward from Previous Commitments by the Co-Lead Agencies. See DEIS at 7-43.	The actions listed in Table 7.5 would be continued with the Preferred Alternative. These actions are described in more detail in the Biological Assessment found in Appendix V, Part 1. Funding decisions for the Bonneville F&W Program are not being made as a part of the CRSO EIS process. However, a range of potential F&W Program costs are included to inform the broader cost analysis for each alternative in the EIS. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements.
32262	7	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.6.4.1.; 7-42; Table 7.5 Inland Avian Predation Although the co-lead agencies have provided some information to CTCR that indicates that dissuasion efforts regarding inland avian predation will also be included in addition to monitoring identified in Table 7-5, the DEIS still only identifies monitoring. The measure should be changed to include dissuasion and monitoring with a description of the details as to the level of monitoring and dissuasion to be provided so that the reader can better understand the scope of the measure and be able to assess whether or not the actions are sufficient. The level of monitoring and dissuasion provided must be consistent with the level provided by Grant County PUD in recent years.	The Preferred Alternative includes several measures to reduce avian predation including: East Sand Island Caspian tern dissuasion, Double-crested cormorant hazing, and the Inland Avian Predation Management Plan. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. The co-lead agencies will continue to work closely with other entities in the region to mitigate impacts from pinniped and avian predators.
32262	8	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.6.4.2; 7-44, ll. 1269-74 We have previously recommended that the co-lead agencies define delay for purposes of this provision and specify the regional forum in which it will be discussed, evaluated and decided.	As mentioned in the Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS (Appendix R, Part 2), the co-lead agencies anticipate working collaboratively with regional sovereigns to develop a more detailed adaptive management plan which would include defining the Temporary Extension of Performance Standard Spill Operation measure.
32262	9	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.6.4.2; 7-44, l. 1275 There is no mention of Northern Pike. The co-lead agencies should consider another potential invader just upstream: it is just a matter of time before Northern Pike reach the anadromous zone. Mitigation should include development of Northern Pike Species Management Plan and/or Rapid Response Plan for when Northern Pike enter ESA-listed salmon waters in the Columbia River. In addition, the Northern Pikeminnow Management Program (DEIS 7-42, Table 7-5) should be expanded to include Northern Pike. There is currently no mitigation in the EIS for CRS impacts to native resident fish. The CRS created reservoir/lake habitat conducive for nonnative predators like Northern Pike, and the EIS should address this imminent problem facing both salmonids in the anadromous zone and resident native fish species above Chief Joseph Dam.	Line 1275 of the CRSO Draft EIS "Invasive Species Management Plans" refers specifically to invasive aquatic vegetation plans in response to water level changes at Libby reservoir. Regarding northern pike, the co-lead agencies recognize and appreciate the importance of northern pike invasion as a regional issue, and did include analysis where alternative operation, maintenance, and configuration of CRS projects could affect them. An analysis of northern pike invasion in Region B, resident fish noted minor effects to northern pike in the Lake Roosevelt/Chief Joseph Dam area due to a minor change in boat ramp access for ongoing suppression efforts in wet years. In this EIS process the co-lead agencies only develop mitigation for moderate to major effects of the multiple objective alternatives as compared to the No Action Alternative. The assertion that no mitigation is included for resident fish is inaccurate. In most cases, effects to resident fish were either beneficial or minor. Mitigation for the minor resident fish effects is included in the Preferred Alternative as follows: Line 1263: Plant native wetland and riparian vegetation (up to 100 acres) on the Kootenai River downstream of Libby. Line 1281: Spawning habitat augmentation at Lake Roosevelt Line 1330: Bull trout access to perched tributaries in Kootenai River Line 1344: Study offseason surface spill for downstream passage of adult steelhead (and bull trout)
32262	10	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.1.1; 7-61, l. 1647 The co-lead agencies should indicate how they expect to be able to discern wet years from dry years in January and February when forecasting goes through March.	The modeling uses forecast uncertainty in its evaluation. This process is described in the H&H appendix (Appendix B). The forecasts are perturb so that wet and dry years are both tested with forecasts that are too high and too low. The results of this forecast uncertainty are therefore accounted for in the results.
32262	11	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.1.1; 7-61, l. 1649 Colville Tribes again encourage co-lead agencies to study this operation and impacts of new operations to determine impacts and mitigate accordingly.	The effects from the modifications to operations at Lake Roosevelt are discussed later in the document. Specifically, effects to resident fish are discussed in Section 7.7.5.2 of the Final EIS. To offset any potential effects to resident fish from the changes in operations, mitigation has been included as part of the Preferred Alternative and is described in Section 7.6.4.2 of the Final EIS under the measure titled Spawning Habitat Augmentation at Lake Roosevelt.
32262	12	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.5.2; 7-128, l. 3707 Sturgeon are already impacted by current operations (i.e. no recruitment). The co-lead agencies should rephrase this sentence to indicate the real issue and impacts of current operations.	Throughout the document, the analyses of effects of each alternative approach to operations, maintenance, and configuration is compared to the No Action Alternative. Where current operations will continue from the No Action Alternative to the Preferred Alternative, the effects of those operations will continue, including resulting very limited natural recruitment, as is described in Section 3.5.3.3. Ongoing tributary habitat restoration will continue to improve spawning habitat.
32262	13	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.5.2.; 7-129, l. 3718 The statement should also indicate that entrainment is high in summer when power peaking occurs.	This sentence is comparing levels of entrainment as a result of the Preferred Alternative to that which occurs under the No Action Alternative. The Preferred Alternative would have similar peaking as the No Action Alternative. Effects of the No Action Alternative are described in Section 3.5.3.3. Only effects differing from the No Action Alternative are described in Section 7.7.5.2. Entrainment risk was considered a factor of retention time and outflows, which would be lower than the No Action Alternative is some water year types, as stated in the Draft EIS.
32262	14	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.5.2.; 7-130, l. 3795 The entrainment study was not species specific. The co-lead agencies should remove the percentage of each species entrained because this is unknown. Please include a citation.	The report referenced (LeCaire 2000) is cited in the No Action Alternative effects analyses and did provide estimates by species based on gill net data that accompanied the hydroacoustics entrainment estimates. The reference was inadvertently not included in this sentence, but is found in Section 3.5.3.3 on page 3-426, line 12134.
32262	15	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.5.2.; 7-131, ll. 3818-19 This statement is inconsistent with the fall refill objective: if fall refill is the end of October and the start of kokanee spawning is mid to late September, then how would the elevations be above 1283 feet? Additional description or qualification of this statement should be provided.	You are correct, the end of September pool elevation would be below 1283 feet in 40 percent of years. This sentence will be revised. "...but would still be above..." will be replaced with "and in 40 percent of years would be below...".
32262	16	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.5.2; 7-133, l. 3889 Summer power peaking is another source of entrainment that should be identified here.	Agreed that summer power peaking could be identified as another mechanism of increased entrainment in summer, but peaking would be the same under the Preferred Alternative as under the No Action Alternative (as described in Section 3.5.3.3). Where effects were consistent between the No Action Alternative and the Preferred Alternative, they were not discussed in the referenced section.
32262	17	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.8.5.; 7-201, l. 5848 Increased temperature also impacts spawning and access to spawning habitat.	The co-lead agencies agree that increased temperatures due to climate change could affect spawning and access to spawning habitat for resident fish.
32262	18	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.13.1; 7-182, ll. 5337-38 DEIS states recreation changes at Grand Coulee and Chief Joseph are negligible compared to the No Action Alternative. This seems nave in light of BOR, NPS and CTCR efforts to enhance recreational access to Lake Roosevelt, including camping and boating improvements. CTCR also desires extending existing boat ramps as part of the socio-economic considerations caused by reservoir drawdowns. The result is likely to be a drastic increase of recreation on an annual basis. Whether or not it is an ongoing impact, by accepting the Preferred Alternative, increased recreation usage is perpetuated, which constitutes a direct, indirect and cumulative impact, particularly with respect to cultural resources. The connection between increased recreation at these reservoirs and impacts to cultural resources should be mentioned and evaluated.	Section 7.7.13 describes the changes in water-based recreational visitation and access affected by water-surface elevations under the Preferred Alternative when compared to the No Action Alternative. Changes in water surface elevations in Region B at Lake Roosevelt (Grand Coulee Dam) are very small with small increases in May and June and decreases in September and October, with very small changes to water-based visitation overall under the Preferred Alternative compared to the No Action Alternative. Recreation at other reservoirs would not be affected by changes in water surface elevations under the Preferred Alternative as compared to the No Action Alternative; in other words, there are no differences between the two alternatives. Visitation in 2017 and 2018 is assumed to represent visitation in future years under the No Action Alternative, which is supported by recent visitation trends at Lake Roosevelt and communications with recreation managers. Visitation data at Lake Roosevelt where NPS data is available back to 1941has been relatively flat over recent decades despite growth in population and changes in other factors. Based on this evidence, in concert with input from recreation managers at the Corps and uncertainty about future changes to other factors that affect recreation, current visitation is assumed to continue in future years under the No Action Alternative. Section 3.16 describes the impacts to cultural resources associated with the alternatives, including impacts to archaeological resources, traditional cultural properties, elements of the built environment, and sacred sites. Mitigation proposed under each of the alternatives is described in Chapter 5 and in Section 7.6.4.2, including extension of the Inchelium-Gifford Ferry ramp. The co-lead agencies do not have the authority to provide recreation mitigation for the effects to private infrastructure such as boat ramps or docks.
32262	19	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.13.1; 7- 187; Table 7-45 For Region B, it is CTCRs sense that boat-based visits to the area are increasing far more than 0.1% per year. With ever-increasing fishing in both Lake Rufus Woods and Lake Roosevelt, the co-lead agencies should conduct a long-term trend analysis to substantiate any statements about changes in boat-based visits. Data from NPS, CTCR, the Spokane Tribe, BOR and the Corps should be used to model such changes.	Table 7-45 in Chapter 7 (Section 7.7.13.1) of the Draft EIS describes the difference in visitation, social welfare, regional economic effects, and social effects for the Preferred Alternative compared to the No Action Alternative. In Region C at Lake Roosevelt, water levels would be slightly higher under the Preferred Alternative than under the No Action Alternative in a typical year, with a resulting small increase in visitation, social welfare, and regional economic effects. Visitation in 2017 and 2018 is assumed to represent visitation in future years under the No Action Alternative, which is supported by recent visitation trends at Lake Roosevelt and communications with recreation managers. Visitation data at Lake Roosevelt where NPS data is available back to 1941has been relatively flat over recent decades despite growth in population and changes in other factors. Based on this evidence, in concert with input from recreation managers at the Corps and uncertainty about future changes to other factors that affect recreation, current visitation is assumed to continue in future years under the No Action Alternative.
32262	20	Rodney Cawston	Confederated Tribes of the	Sec. 7.7.18.1; 7-191, ll. 5525-26 The co-lead agencies assertion that the Preferred Alternative would not result in any major increases in the acre-days exposure of archaeological resources must be balanced with the above comment above regardingchanges in recreational use of the Lake Roosevelt and Lake Rufus Woods area, which is increasing greatly. Rather than acre-day exposure of archaeological resources, the formula should instead reflect	Based on the analysis of recreation conducted in Section 7.7.13 in the Draft EIS, the differences in recreation between the No Action Alternative and the Preferred Alternative are expected to be negligible. Therefore, for the analysis conducted as a part of this Draft EIS, the co-lead agencies do not foresee a concomitant increase in impacts to archaeological resources. The best available information does not substantiate the commenter's assumption of a 1:1 ratio between an increase in visitation at these reservoirs and an increase in damage to archaeological resources.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
			Colville Reservation	increases in the acre-days exposure multiplied by the increase in visitation to cultural resources. The DEIS does not appear to reflect the intensity of exposure of archaeological resources, and should be changed to include this information.	
32262	21	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.18.1; 7-191, ll. 5537-38 There are ample publications on erosion and landslide predictions, and multiple years of aerial photographs to construct a model of loss of shoreline historically, and then extrapolate ongoing rates. In the end, the banks will erode all sediment back to bedrock, as predicted by Kiver and Stradling over two decades ago. By displaying the change in rate of erosion relative to the No Action Alternative, this analysis circumvents the 'System Operation Review' concept.	The Kiver & Stradling study summarized erosion between 1942 and 1995 without any attempt to correlate erosion to specific operations, and the study would not support the kind of analysis (i.e., extrapolating rates of erosion), as suggested by the commenter. The EIS examines the differences between the No Action Alternative and the Multiple Objective alternatives. The EIS does not compare current conditions to conditions that were in place at the time of the System Operations Review.
32262	22	Rodney Cawston	Confederated Tribes of the Colville Reservation	Sec. 7.7.19; 7-195, ll. 5669-63 The assertion that trust lands identified during the geospatial database query and tribal outreach are located outside of any direct or indirect effects identified in the alternatives is flat-out incorrect. There are thousands of acres within the zone of direct effects on the Colville Reservation from River Miles 545 (the Chief Joseph tailrace) to 689 (the northern Colville Reservation Boundary). There are also several trust holdings in the former North Half of the Colville Reservation that are in the zone of direct effects zone, almost to the Canadian border.	The co-lead agencies requested the CTCR identify those trust lands within the study area. The Tribe provided geographical information system data that identified lands of various status. This information was incorporated into the EIS in Section 3.17.1.1.
32262	23	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx G; G-5-1; Table 1-1 Table1-1 should include methane. Sources that have water quality standards for compounds created by dams needs to be added to the table, such as the elevation of particulate matter in the drawdown zones when winds blow the sand and dust into the air.	Appendix G, Chapter 5 in the Draft EIS includes a literature review and analysis of reservoir methane emissions. Additionally, Section 3.8.3 evaluates the effects of the alternatives on windblown dust and particulate matter associated with exposed sediment from reservoir drawdown. There is no Table 1-1 in Appendix G, so this response focuses on where the information on methane is contained in the main body of the EIS and Appendix G.
32262	24	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx G; G-5-1, l. 82; Table 1-2 Lake Roosevelt also has elevated metals including heavy metals from Teck Cominco that can alter the product of oxidation/reduction reactions.	The comment is consistent with the analysis in the EIS. As discussed in Appendix D, Lake Roosevelt sediments are polluted from metals mining and smelting operations. From 1896 to 1995, smelting waste products (primarily slag and wastewater) were discharged into the Columbia River a few miles north of the U.S.-Canada border, introducing zinc, mercury, arsenic, lead, and other metals and contaminants into the lake. Contaminated smelting wastewater continues to be discharged into the river. Some metals have bioaccumulated through the food chain of plants and animals in and surrounding the lake, with the greatest levels of bioaccumulation occurring closest to the location of smelting operations. Movement of slag, wastewater, and sediments that have been contaminated is unclear. However, elevated surface water metal concentrations associated with wastewater releases have been reported near Grand Coulee Dam. Additionally, during high flow events, the surface waters of downstream Rufus Woods Lake can have elevated levels of zinc, suggesting that flow events can facilitate downstream movement of smelting wastewater contaminants. Sediment in Rufus Woods Lake contains elevated levels of metals such as zinc, lead, mercury, and cadmium. Elevated concentrations of metals can bioaccumulate, and if concentrations are very high, can kill aquatic organisms, and fish consumption advisories are made when levels of contaminants in fish tissue render their consumption a health hazard. Mobilization and exposure of contaminated bed sediments is affected by Lake Roosevelt drawdown depths and durations.
32262	25	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx G; G-5-5, ll. 304-14 References to the importance of assessing reservoirs for the production of methane are provided yet those reservoirs that have high potential for methane production are not assessed. We appreciate the addition of a section on methane production at dams.	The EIS does include an evaluation of reservoir methane emissions. Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River System, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
32262	26	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx G; G-5-9, ll. 464-66 While this may be true of free-flowing sections of the Columbia River, the DEIS should also describe how methane production will be occurring in shallow flats of reservoirs behind dams where retention time can be longer (LR average retention time is 45 days). The lower reaches of the Columbia River in recent years are heating to lethal or near lethal temperatures for salmonids during the summer months, significantly impacting returning adults and continuing to impact the number or out-migrating juvenile and adult returns for several years. Reservoir flats are often located in large coves encompassing acres of land where water is shallow and have long periods of drawdown that expose the lakebed and allow terrestrial grasses to grow. These shallow areas warm up quickly once inundated. Statements about the entire Columbia River do not assess the areas where annual growth of terrestrial vegetation occurs and decomposition releases methane, and a more thorough evaluation should be included.	The EIS does include an evaluation of reservoir methane emissions. Appendix G, Chapter 5 of the Draft EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River System, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
32262	27	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx G; G-5-13, l. 600; Table 5-3 Please clarify where the Sample site Lake Roosevelt behind Grand Coulee Dam is located. The reservoir is 150 miles long, so a specific location would be helpful. We would expect very different results depending on whether the location was directly behind the dam in the water column or in a shallow cove area.	The comment is referring to a study from 2004 titled "Greenhouse Gas Emissions from Reservoirs of the Western United States" which was evaluated in the EIS, see Chapter 5 of Appendix G. The study evaluated four different Lake Roosevelt sample sites in September 2001, accounting for variation in water depth and proximity to the dam. The location of the four sampling sites described in the study are: 4754N; 11846W at a depth of 45m 4756N; 11849W at a depth of 7m 4756N; 11858W at a depth of 106m 4757N; 11855W at a depth of 17m Additional details on the sampling and analysis can be found in the article at: https://agupubs.onlinelibrary.wiley.com/doi/full/10.1029/2003GB002197.
32262	28	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx G; G-5-15-19, ll. 642-46, 788-90 Grand Coulee experiences deep drafts during seasonal FRM operations. Again, it appears that the DEIS ignores this part of the Basin. The DEIS states that the age and frequent fluctuation of the reservoirs decreases the organic matter available to produce methane annually. However, the deep drawdowns for FRM at Grand Coulee expose large areas that support the growth of terrestrial gasses, supplying fresh organic matter. The DEIS states that Unfortunately, due to time and resource constraints, a full suite of scientific data collection and analyses is simply not feasible at this time. Data and knowledge gaps imperative to quantifying CH4 emissions from hydroelectric reservoirs in the Columbia River basin and determining their contribution to the global carbon budget are detailed below. The co-lead agencies have done extensive literary research but you conclude on lines 788-790 that The major knowledge gaps listed above need to be filled by future research to better understand CH4 production overall and to better estimate regional and global carbon budgets. The subjects and locations of this future research, including the effects of climate change, should be specified in the DEIS. After acknowledging the major data gaps the DEIS concludes on line 822 that the methane contribution from CR dam reservoirs is relatively minor. It is not clear whether this is a valid conclusion based on the available data. Again, we urge the agencies to conduct studies of the CRS contributions to methane production to address this important aspect of the CRS impacts and inform the development of mitigation measures. The importance of additional information and analysis on this topic is underscored by its relationship to the DEIS analysis of climate change impacts and the agencies emphasis on the CRS as a source of low-carbon source of power.	Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS dam and reservoir projects. While the assessment acknowledges uncertainty related to the level of methane emissions across the CRS project reservoirs, it relies on the highest quality information to evaluate the potential impacts of the alternatives. Specifically, a 2017 Northwest Power and Conservation Council evaluation of available information found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS, but described that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams. Additionally, as the commenter requests, the Corps' Walla Walla District conducted a study in 2016, which concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue.
32262	29	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx I; I-1-4, ll.903-11 This section discusses the elevation of TDG caused by lack of power demand, high stream flows with lack of turbine capacity. There is no discussion about the TDG created at Grand Coulee when Lake Roosevelt elevation is below 1265 and the slip tubes on the face of the dam are used to spill whatever cannot be used for generation, driving TDG to very high levels in Lake Rufus Woods (RW). The Tribes raise trout in our net pens at the Pacific Aquaculture (PAI) Facility about 20 miles below Grand Coulee. Significant losses have occurred several times at this facility. The Tribes have often have been forced to release these fish early into RW and forego planned releases to lakes and streams across the Reservation Because it is thought that some will survive the high TDG levels.	The spill appendix B 4.18.7, discusses how TDG is attempted to be minimized when Grand Coulee is below 1265': Flows at Grand Coulee typically get high enough to induce force spill between May and July. There are two general routes to spill water past Grand Coulee, the regulating outlets on the face of the dam (40 total, 2 rows of 20) or over the 11 drum gates. If the forebay elevation is above 1,266 feet (NGVD29), Reclamation releases the water evenly across the 11 spillway gates. If water is released through the outlets, when the pool elevation is below 1,266 feet, then it is released evenly through the upper and lower gates. An over/under spill pattern for the outlets is used to minimize TDG generation. This impact is also discussed in Appendix D and E as well. The co-lead agencies acknowledge the elevated TDG generated when spilling through the ROs in Appendix D, Water Quality, and in Appendix E (see quoted text from Table 3-75). Entrainment: Flows affect entrainment but do not have it quantified. Could also be similar effect entraining food similar to kokanee tab in Lake Roosevelt. Fish typically spawn on shorelines. Few tributaries. Lake elevations typically stable during day but wide fluctuations at night.
32262	30	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx I; I-4-7, ll.1124-1126 Short discussion on irrigation water pumped to Banks Lake states that irrigation water can be returned to Lake Roosevelt. This is contrary to our understanding that irrigation water is not returned and should be explained more fully.	The primary purpose of pumping from Lake Roosevelt is for irrigation purposes; However, the John W. Keyes Pump Generating Station also has pump generators that allow targeting opportunities to generate power. The language in Appendix I has been updated to provide clarity.
32262	31	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx I; I-4-11; ll. 1133-42 This section discusses meeting flows below Priest Rapids Dam but doesnt discuss the flows supported by Grand Coulee to meet the chum elevation of 11.3-12.5 below BON from October through April emergence. This action often results in leaving Lake Roosevelt elevation below the end of March FRM elevation often by several feet. This also can leave us below the April 15th and April 30th FRM elevation. Inflows are then used to refill Lake Roosevelt rather than having that water available for the spring migration. Very little if any concern is brought to the table about impacts to Mid-Columbia salmon species migration.	The analysis does acknowledge that in some years, chum flows may be in conflict with spring flow objectives. This is mentioned in Chapter 3 [Section 3.5 about Chum Survival]. Additionally, in Chapter 7 (Table 7-5 in the Draft EIS), the EIS also acknowledges that the operations to support chum flows will continue to be coordinated through the regional forum, specifically the Technical Management Team. Details about how Grand Coulee Dam operates to no lower than 10 feet below the VDL to support chum in the winter through the spring can be found in Appendix B, Section 4.7.3 Chum Spawning and Incubation.
32262	32	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx J; J-xi, l.301; J-5-1, l.3142 Mentions a document called the P&T Socioeconomic Appendix. Per phone call with Birgit Koehler, she said this is actually Appendix H. All applicable references in Appendix J should be revised accordingly.	The comment is accurate that the name of the appropriate appendix is Appendix H, Power and Transmission. The Final EIS corrects this reference.
32262	33	Rodney Cawston	Confederated Tribes of the Colville Reservation	Appx M, M-8-5, ll. 1577-79; Table 8-5 There appears to be an error in Region B Lake Roosevelt, which states local income is $1,000 and Non-local $7,000 for a total of $8,000 not $7,000. The total weighted numbers are useless and should be removed. Impact to Recreation in Region B (Lake Roosevelt) - States decrease in boat ramp access would negatively impact recreation by 6% in high water years and 24% in low water years. This is counter-intuitive to our sense that there is more impact in high water years when deep drawdown prevents access to the water often from February through mid to the end of June.	The discrepancy in the figures is a result of a rounding error. The unrounded numbers are $6,634 (non-local), $831 (local), and $7,465 (total). Rounding to nearest thousand, these become $7,000, $1,000, and $7,000. A footnote has been added to all tables in the appendix, where relevant, to say The summation of local and non-local results may not equal the total result reported due to rounding. The total weighted numbers present results for the entire basin (i.e., across all four CRSO regions, which some readers may find useful. The recreation evaluation considers typical water years (50th percentile), low water years (75th percent), and high water years (25th percent). The impacts associated with low water years are compared for the action alternatives compared to the No Action Alternative. For example, the comparison is between a high water year under MO4 to a high water year under the No Action Alternative (and likewise for a low water year). A change has been made under MO4 (Section 3.11.3.6): In a high-water year (i.e., 25th percentile) under MO4, water-based visitation would decrease by over 6 percent relative to a high-water year under the No Action Alternative. (i.e., similar to a typical year) while in the a low-water year (i.e., 75th percent) under MO4, water-based visitation would decrease by over 24 percent relative to a low-water year under the No Action Alternative (a major adverse effect), or about 175,000 visits."

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32262	34	Rodney Cawston	Confederated Tribes of the Colville Reservation	We are doing so under the extraordinary circumstances of the COVID-19 pandemic, which has led the Colville Business Council to institute a partial shutdown of the tribal government and required our elected leaders, staff, and attorneys reviewing the CRSO DEIS issue to greatly restrict their movements under Governor Jay Inslees Stay Home, Stay Healthy order. Despite the unprecedented situation in which we are attempting to comment on a document that is over 8,000 pages in length, CTCRs request to extend the 45-day comment period the minimum required by law by a reasonable 60 days was rejected. We sincerely hope that the co-lead agencies will be more open-minded about the limited comments we have been able to prepare in the time available than they were about ensuring CTCR and other interested parties and members of the public had a meaningful opportunity to review and evaluate the DEIS on this critically important topic during this challenging time.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period. The co-lead agencies appreciate the comments CTCR was able to submit.
32262	35	Rodney Cawston	Confederated Tribes of the Colville Reservation	II. The CRSO EIS Must Include a Detailed Analysis of Fish Passage and Reintroduction In every letter and government-to-government meeting during the long EIS process, Colville has emphasized its singular priority of achieving fish passage and reintroduction of anadromous salmon above Chief Joseph and Grand Coulee Dams and the need for the co-lead agencies to include a detailed analysis of this measure in the CRSO EIS. As we explained in our July 6, 2018, letter to the co-lead agencies, evaluation and inclusion of a fish passage and reintroduction measure in the EIS is feasible given the availability of a significant amount of information about fish passage and reintroduction at these two dams and at high-head dams in general. Furthermore, evaluation and inclusion of this centrally important measure is necessary to ensure a legally sufficient EIS and would be a significant step toward addressing the historically inadequate mitigation of the upper Columbia and upholding the agencies trust responsibility to CTCR and other tribes in the Basin. Inclusion of fish passage and reintroduction above Chief Joseph and Grand Coulee Dams is not the impossible-sounding task that the co-lead agencies make it out to be. See DEIS at 2- 79. Rather, as our previous comments have outlined, it would begin with recognition and incorporation of the Northwest Power and Conservation Councils (NPCCs) 2014 Fish and Wildlife Program measure regarding fish passage and reintroduction of salmon in the blocked areas of the upper Columbia and fully funding the phased investigation approach set out therein. See Attachment 2.2 In that measure, the NPCC outlined a phased approach to investigating fish passage and reintroduction that would include habitat assessment, pilot reintroductions and other studies to develop the information necessary to inform a stepwise evaluation process and, ultimately, a decision whether to implement full-scale passage and reintroduction. Significant work on the Fish and Wildlife Program measure has been accomplished by CTCR, the Spokane Tribe of Indians, the Upper Columbia United Tribes (UCUT), and other entities; much of theinformation generated has been available to the co-lead agencies since the early stages of the EIS process. Key studies include an assessment of available habitat above the dams, an evaluation of the risk to resident fish and other resources in the blocked area of reintroducing anadromous fish, and a review of fish passage projects at high head dams.3 Relying on this information, analyses using a lifecycle model, and other studies, UCUT prepared a Phase 1 Report in May 2019.4 The Phase 1 Report synthesizes and evaluates the available information regarding fish passage and reintroduction in the blocked area and concludes that it is feasible. At the request of the NPCC, the Independent Scientific Advisory Board (ISAB) conducted a thorough review of the Phase 1 Report and concluded that it provides significant information about fundamental issues and management alternatives as this important effort moves forward.5 Collectively, the available scientific information provides a strong foundation for the co-lead agencies to evaluate a phased investigation of fish passage and reintroduction and include it as a measure in the EIS.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
32262	36	Rodney Cawston	Confederated Tribes of the Colville Reservation	By failing to give serious consideration to fish passage and reintroduction, see DEIS at 2-79, the co-lead agencies invite serious questions about whether their four-year effort to update and evaluate the management of the CRS for the first time in 25 years is consistent with NEPAs broad mandate to fully evaluate environmental impacts and inform agency decisionmaking. A close examination of the purpose and need statement of the EIS demonstrates that fish passage and reintroduction in the upper Columbia is responsive to the co-lead agencies reasons for preparing the document. The statement specifies the co-lead agencies need to review and update the management of the CRS, including evaluating measures to avoid, offset, or minimize impacts to resources affected by managing the CRS in the context of new information and changed conditions in the Columbia River Basin. DEIS at 1-4. This is entirely consistent with including and fully evaluating anadromous fish passage and introduction in the EIS because it would meet the agencies need to update the management of the CRS in light of new information about managing fish passage in the Basin and would offset impacts to anadromous salmonids from current CRS management, which does not provide for passage at Chief Joseph or Grand Coulee Dams despite recent advances in fish passage technology. Evaluating fish passage and reintroduction in the upper Columbia blocked area through a measure providing for a phased investigation would also assist the co-lead agencies in meeting their resource purpose of [p]rovid[ing] for the conservation of fish and wildlife resources and protect[ing] and preserv[ing] cultural resources. DEIS at 1-4. Moreover, it would meet the legal and institutional purpose in the EIS of [c]omply[ing] with environmental laws and regulations . . . including those specifically addressing the CRS such as requirements under the Northwest Power Act to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated. DEIS at 1-5 (quoting 16 U.S.C. 839b(h)(II)(A)). Indeed, by taking a hard look at fish passage and reintroduction in the manner outlined by the 2014 Fish and Wildlife Programs phased investigation measure and including it in the Preferred Alternative, the co-lead agencies would be following Congresss mitigation mandate under the Northwest Power Act6 and the federal district courts call for the agencies to develop and consider new and innovative solutions for a System . . . that cries out for a new approach and for new thinking. Natl Wildlife Fedn, 184 F. Supp. 3d at 876. Finally, inclusion of a fish passage and reintroduction measure would be consistent with the co-lead agencies purpose of [p]rotect[ing] Native American treaty and reserved rights and fulfill[ing] trust obligations to CTCR and other tribes that would experience tremendous cultural and subsistence benefits from the return of anadromous salmonids above Grand Coulee Dam. DEIS at 1-5.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
32262	37	Rodney Cawston	Confederated Tribes of the Colville Reservation	Inclusion of fish passage and reintroduction would also be responsive to Colvilles repeated expression of concern that the co-lead agencies have placed greater emphasis on developing measures to mitigate impacts of the CRS in the lower Columbia River and lower Snake River than in the upper Columbia.7 As it stands, the DEIS perpetuates these inequities by including a thorough evaluation of breaching the four lower Snake River dams as the focal point of one alternative and numerous measures (both structural and operational) in the Preferred Alternative that are intended to improve passage for salmon, steelhead and lamprey, while providing a single paragraph purporting to justify the decision not to analyze in detail fish passage at two dams where current management allows zero percent passage. See DEIS at 2-79. However, CTCR hopes it is not too late to significantly alleviate this continuing injustice and that the agencies will do so in the Final EIS by fully evaluating passage and reintroduction in the upper Columbia as outlined above.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
32262	38	Rodney Cawston	Confederated Tribes of the Colville Reservation	Finally, we briefly respond to the agencies explanation of their decision not to give serious consideration to fish passage and reintroduction in the EIS. This purported rationale amounts to the following: its too big, too complex, and too controversial, and there is not enough time. See DEIS at 2-79; Executive Summary at 13-14. Yet nowhere do the agencies acknowledge the significant information developed by CTCR and others under the NPCCs phased investigation or show that they have evaluated it in a meaningful way. This measure in the 2014 Fish and Wildlife Program provides a feasible approach to investigating and achieving fish passage and reintroduction in the upper Columbia and is subject to the agencies legal obligations under the Northwest Power Act. See, e.g., 16 U.S.C. 839b(h)(11)(A). Yet the agencies never mention it in their brief rejection of fish passage as a potential measure in the EIS alternatives.8 This glaring omission is indicative of the dismissive approach the agencies have taken for years on this issue despite Colvilles and other entities persistent efforts to explain its importance and secure agency support. The claim that fish passage is too complex and that too many data gaps preclude its evaluation in the EIS is belied by the extraordinarily complicated modeling and biological and economic analyses of the impacts to salmon and other resources from management of the CRS that are the foundation of the DEIS.9 Elsewhere, fish passage at dams where no passage currently exists has been evaluated and the benefits to salmon estimated.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
32262	39	Rodney Cawston	Confederated Tribes of the Colville Reservation	Analysis of passage in the upper Columbia would take time, but the responsibility for failing to consider available information in a timely manner lies squarely with the agencies, who were aware of studies and other relevant information as early as the scoping phase of developing the EIS,13 and failed to take action at that time and as additional information and analyses became available while the DEIS was being developed. Indeed, claiming that they dismissed fish passage as a potential measure due to insufficient time ignores that the agencies informed CTCR as early as August 30, 2017 a mere six months after receiving CTCRs scoping comments that they would not pursue this action in the EIS.14 It is also no defense that fish passage is controversial, see DEIS Executive Summary at 13-14,15 because one of the fundamental purposes of an EIS is to fully evaluate controversies in the evaluation and mitigation of environmental impacts caused by federal agency action. 40 C.F.R. 1508.27(b)(4) (identifying [t]he degree to which the effects on the quality of the human environment are likely to be highly controversial as a factor in determining whether an EIS is required). In the same paragraph that the agencies attempt to rationalize what appears to be a policy decision made at the outset of the EIS process not to conduct any meaningful analysis of fish passage and reintroduction in the EIS, the DEIS points to a potential alternate forum for addressing this issue outside of the CRSO EIS: the agencies and interested regional sovereigns are developing a framework to address critical information gaps. DEIS at 2-79. In an 8,000-page DEIS replete with detailed plans, projections, timelines, and analyses, it is striking that there is but one, vague sentence about the proposed	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.

				framework. To be clear, since the Department of Interior announced the concept of a Fish Management in Blocked Areas Initiative at a meeting with Columbia Basin tribes and the Department of State regarding the Columbia River Treaty on August 28, 2019, minimal progress has been made toward developing such a framework. At most, a brief questionnaire was distributed to regional sovereigns (including CTCR) at the end of October. See Attachment 9(Oct. 31, 2019, email from Lorri Gray and attached list of questions). While CTCR responded to the questionnaire, we are concerned that the proposed Fish Management in Blocked Areas Initiative punts the agencies obligation under NEPA to take a hard look at fish passage and reintroduction to outside the established framework of the CRSO EIS, where it may not include a binding commitment, funding, timeline, or mechanism for holding the agencies accountable. Removing fish passage from the EIS the agencies 25-year framework for managing the CRS raises serious questions for CTCR. With respect to this crucial issue, we remain skeptical about the agencies intentions, commitment to pursuing fish passage and reintroduction in good faith, willingness to devote the necessary resources, ability to accept the information developed through the 2014 Fish and Wildlife Programs measure and build on it, and openness to afford deference to those most affected by Chief Joseph and Grand Coulee Dams.16 Accordingly, CTCR continues to believe that the investigation of fish passage and reintroduction above Chief Joseph and Grand Coulee Dams rightfully belongs in the CRSO EIS as a measure in the Preferred Alternative.17	
32262	40	Rodney Cawston	Confederated Tribes of the Colville Reservation	III. In the Alternative to Including Fish Passage and Reintroduction as a Measure in an Action Alternative, It Must Be Included and Evaluated as a Mitigation Measure in the Preferred Alternative. In lieu of considering fish passage and reintroduction above Chief Joseph Dams and Grand Coulee Dams as an action alternative, the co-lead agencies should consider investigating it as a mitigation measure because, under all of the alternatives, operation of the CRS will continue ongoing extirpation of anadromous salmonids from the upper Columbia an adverse environmental effect[] which cannot be avoided. 42 U.S.C. 4332(2)(ii). As the co-lead agencies observe in the DEIS, the lack of fish passage at some dams, including Chief Joseph and Grand Coulee Dams, within the region has restricted the range of salmonids from some locations where they were historically present. Impacts such as these have adversely affected . . . tribal communities [A]ny discussion pertaining to the CRS must include actions to return salmon and steelhead . . . and to improve access to historical fish habitat. DEIS 7-2 at ll. 45-53. As the Colville Tribes detailed in our December 19, 2019, letter, incorporated here by reference, the co-lead agencies knowing rejection and omission of at minimum studying fish passage and reintroduction as a mitigation measure likely violates NEPA. See 40 C.F.R. 1502.16(h) (mandating that an EIS shall include discussions of [m]eans to mitigate adverse environmental impacts). All relevant, reasonable mitigation measures that could improve the project are to be identified, even if they are outside the jurisdiction of the lead agency or the cooperating agencies.	Measures to reintroduce salmon above CHJ and GCL were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
32262	41	Rodney Cawston	Confederated Tribes of the Colville Reservation	Here, the proposed action is the continued operation of the CRS without providing fish passage and reintroduction above Chief Joseph and Grand Coulee Dams an adverse environmental effect which cannot be avoided under any of the alternatives. 42 U.S.C. 4332(2)(ii). Accordingly, the co-lead agencies were legally obligated to include discussions of means to mitigate this adverse environmental impact, which duty CTCR brought to the co-lead agencies attention on numerous occasions. 40 C.F.R. 1502.16(h); see CTCR comments and letters cited above. Contrary to the co-lead agencies rationale proffered in the June 2019 Mitigation Toolbox for rejecting fish passage and reintroduction as a mitigation measure, relative change in effect between the No Action Alternative and a proposed action alternative is not a proper standard for determining whether the co-lead agencies must consider mitigation measures for an adverse environmental impact. See DEIS Appx R, Annex C at R-4-50, -51, -58 (The alternatives being analyzed do not change fish passage for these projects from the no action so mitigation is not needed.). Rather, the duty to discuss ways to mitigate adverse environmental impacts with regard to each alternative . . . is mandatory. Idaho ex rel. Kempthorne v. United States Forest Serv., 142 F. Supp. 2d 1248, 1263 (D. Idaho 2001) (emphasis in original). The co-lead agencies have identified no legal basis (and CTCR has found none) to support their proposition that mitigation measures may be eliminated simply because an adverse effect on a resource would be the same under both the No Action Alternative and a proposed action alternative. Notably, this rationale appears to have been abandoned by the co-lead agencies in the DEIS. The co-lead agencies rationale proffered in the DEIS and since its distribution fares no better. In response to a comment by CTCR on the Administrative DEIS that the co-lead agencies should commit to review and study FP&R as a mitigation measure, the co-lead agencies responded, reintroduction above Grand Coulee is outside the scope of this EIS. DEIS Appendix T (forthcoming); Completed Colville Comment Responses 2-10-2020FINAL, Chap. 5 sheet, cell 7H. Yet that rationale is at odds with the co-lead agencies statement in Section 5.1.1 as to the scope of mitigation measures that were considered, analyzed and captured in the DEIS: The inclusion of mitigation measures in this chapter is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. Their inclusion in this chapter serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. CRSO EIS Chap. 5 at 5-2. The co-lead agencies thus established an appropriately wide aperture for mitigation measures for DEIS discussion purposes, which aligns with the directive to identify [a]ll relevant, reasonable mitigation measures that could improve the project even if they are outside the jurisdiction of the lead agency or the cooperating agencies. 46 Fed. Reg. 18026, 19b. Under the co-lead agencies rubric, fish passage and reintroduction would be particularly well-suited as a mitigation measure because it would alert the water users, tribes, states, multiple federal agencies, and others among whom the co-lead agencies assert a coordinated approach is necessary to achieve fish passage and reintroduction in the upper Columbia blocked areas. Executive Summary at 13; DEIS at 2-79. Moreover, fish passage and reintroduction is eminently relevant as a mitigation measure that could improve the CRS because it would directly address one of the most egregious adverse effects of the CRS that is bound to continue under any alternative. Nevertheless, the co-lead agencies failed to discuss even investigating fish passage and reintroduction as a mitigation measure, claiming it was not feasible to consider. Executive Summary at 14; DEIS at 2-79. That failure is internally inconsistent with the standards set out by the co-lead agencies for selecting and including mitigation measures in the DEIS. Whats more, rejection and omission of this measure which the co-lead agencies themselves characterize as important is doubly erroneous because the co-lead agencies do in fact possess the authority to evaluate the phased approach outlined in the 2014 Fish and Wildlife Program, including the extensive data already generated through Phase 1 of that process. Executive Summary at 13; DEIS at 2-79. Evaluating existing information and making a commitment to conduct a phased investigation of fish passage and reintroduction is the core of the Colville Tribes limited and reasonable request, which is well within the scope of the co-lead agencies authority and the CRSO EIS. In sum, the co-lead agencies should reverse course and include fish passage and reintroduction as either a measure in an action alternative (preferably the Preferred Alternative) or, alternatively, as a mitigation measure. Failure to do so would be based on an erroneous rationale, internally inconsistent, and legally inadequate under NEPA.	Mitigation in NEPA is intended to address environmental effects of the proposed action if that alternative is implemented. Here, the proposed action is the continued operation and maintenance of the Columbia River System. However, mitigation for the identified alternative would include actions that are within the co-lead agencies' authorities that address the effects of the selected alternative, as compared to the No Action Alternative. New mitigation is not proposed to mitigate for the existence of the system, but rather to ameliorate the effects of the operations and maintenance of the CRS as identified in the alternative. See response to Comment 32262-40.
32262	42	Rodney Cawston	Confederated Tribes of the Colville Reservation	IV. The Preferred Alternative Does Not Appreciably Improve Conditions for ESA- Listed Salmonids in the Upper Columbia Based on NOAAs Life Cycle Model (LCM) output for improved smolt-to-adult ratio (SAR), a 3.2% increase (0.94 to 0.97) of the SAR is a minimal advancement toward recovery for Upper Columbia River (UCR) spring Chinook, which is arguably the stock at highest risk of extinction in the Columbia River Basin, notwithstanding Snake River sockeye. If the minimum positive impact projected by the LCM is the actual outcome of the Preferred Alternative, hydro- related recovery benefits for UCR spring Chinook are essentially a status quo continuation of the No Action Alternative, and future hydro operations under the Preferred Alternative and will not meaningfully advance recovery of UCR spring Chinook. Additional, more aggressive measures such as flow for juvenile passage, greater spill at John Day and The Dalles, and greater pinniped and avian predation reduction measures than those provided in the Preferred Alternative would likely be required to achieve greater minimum improvements in survival and productivity of this at-risk stock. As with UCR spring Chinook, the LCM projected improvements for affected metrics in the Preferred Alternative is essentially status quo performance compared to the No Action Alternative and equates to no anticipated survival improvements for ESA-listed UCR summer steelhead. Including greater flow and spill for juvenile passage and aggressive avian predation measures in the inland portion of the Basin (including substantive dissuasion efforts, similar to those funded by Grant PUD is recent years) as measures in the Preferred Alternative would increase the anticipated survival improvements for UCR steelhead.	While flow levels from upstream federal CRS dams effect upper Columbia species from the time they enter the mainstem Columbia River from their tributaries, those stocks only physically pass 4 projects which limits the CRS operational impacts to those stocks. The Preferred Alternative had the largest potential positive impact to upper Columbia River stocks compared to the No Action Alternative, or any of the Multi-Objective Alternatives. In addition to continued habitat restoration and hatchery mitigation, the operational changes in spill levels at McNary, John Day, and Bonneville Dams, combined with federal efforts to reduce predation, and decrease the effects of overwintering fallback of mid-Columbia steelhead are all expected to provide benefits compared to the No Action Alternative. Details of these actions are found in chapter 7 of the FEIS as well as the proposed action submitted to NMFS and the US Fish and Wildlife Service. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
32262	43	Rodney Cawston	Confederated Tribes of the Colville Reservation	Finally, both listed species in the UCR would benefit from expanded habitat actions in the Preferred Alternative in the extant anadromous zone in addition to those measures currently specified in the NPCCs Fish and Wildlife Program and by the Mid-Columbia PUDs Habitat and Tributary Committee.	The co-lead agencies concur that habitat actions will continue to be implemented as described in the proposed action. The analysis of the benefits of those actions will be developed by NMFS and by the US Fish and Wildlife Service in their biological opinions. Those final Biological Opinions will be appended to the final EIS in appendix V.
32262	44	Rodney Cawston	Confederated Tribes of the Colville Reservation	While the co-lead agencies have improved the description of what is now a single Lake Roosevelt Additional Water Supply measure in the DEIS by making clear the shift in timing of Odessa Subarea withdrawals, CTCR continues to have concerns about the inclusion of the 1.15 million acre-feet withdrawals for the Columbia Basin Project in three of the four Multi-Objective Alternatives (MO1, MO3 and MO4) and the analysis of re-shaping the approximately 179,000 acre-feet withdrawals for the Odessa Subarea. As we explained in our July 8, 2018, letter, it is problematic to include the measure providing for 1.15 million acre-feet of additional withdrawals during the irrigation season in so many of the action alternatives19 because removing such a large volume of water when juvenile salmon need higher spring flows to assist their migration to the ocean undermines many other measures intended to benefit fish. While we did not oppose inclusion of this measure in one of the alternatives, we advocated for it to be removed from	The CRS is a complex system with multiple, sometimes competing, congressionally-authorized purposes. The Purpose and Need and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. This EIS was developed to evaluate the operation and maintenance of the CRS over the next 25 years, with the expectation that the co-lead agencies will continue to meet the multiple, authorized purposes until directed differently by Congress. Although Fish and Wildlife is one of the authorized purposes, it is not the only purpose, and the co-lead agencies must balance all resources, and sometimes focus some purposes over others. The analysis of the Multiple Objective (MO) alternatives reflect these trade-offs and have allowed the co-lead agencies to understand the effects of emphasizing some purposes over others in order to find the most acceptable balance for future operations. The MO alternatives relied on preliminary analysis of the single-objective alternatives to inform the combination of alternatives analyzed in the final range. The measures in the final range of alternatives were combined in deliberate ways to display the trade-offs inherent in the operation of such a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Multi-Objective alternatives MO3 and MO4 so the fish benefits of those alternatives could be more fully realized and explained to the public and decisionmakers. By removing the measure only from MO2 the least beneficial action alternative the co-lead agencies have likely masked additional benefits from MO3 and MO4 by retaining this measure with its clear, adverse impacts both to salmon in the anadromous zone and to the Lake Roosevelt environment. The decision to include this measure in three of four Multi-Objective alternatives is particularly suspect given the co-lead agencies subsequent decision to greatly decrease the volume withdrawn to 45,000 acre-feet (approximately 4% of the original volume) in the Preferred Alternative. The agencies should include the reduced volume for this measure in MO3 and MO4 for the Final EIS.	
32262	45	Rodney Cawston	Confederated Tribes of the Colville Reservation	We appreciate the greater transparency with which the DEIS describes the shift in timing of Odessa Subarea withdrawals since the Administrative Draft EIS. However, there are still significant problems that carryover from the earlier draft that must be addressed before the Final EIS. First, the agencies describe a mitigation measure resulting from ESA consultation, namely that the refill target at Grand Coulee is decreased by 0.25 feet to compensate for the additional 45,000 acre-feet withdrawn during the April-October irrigation season. DEIS at 7-48. However, this fails to account for the re-shaping of 179,000 acre-feet for the Odessa Subarea, which will, going forward, also be withdrawn during the irrigation season (as opposed to September and October under the BORs 2013 Record of Decision). This effectively adds almost four times the volume of irrigation-season withdrawals as the proposed increase of 45,000 acre-feet for the Columbia Basin Project. If the refill target, which appears to only correspond to a withdrawal of 45,000 acre-feet, required adjustment for this additional volume, it would be approximately 1.0 additional feet of drawdown. A full accounting, including in appropriate models, of all of the new irrigation-season withdrawals under this measure is required for an accurate and transparent evaluation, and appropriate mitigation for both downstream flows and the Lake Roosevelt environment should be included in the Final EIS. We also continue to oppose and question the wisdom of proceeding with re-shaping the Odessa Subarea withdrawals. As we explained previously, when BOR was evaluating the project a decade ago, it changed the proposed withdrawals from the irrigation season to the fall because of concerns raised in the ESA consultation process regarding impacts to salmon. If it was biologically necessary and appropriate to wait to refill Banks Lake until the fall at that time, we see no justification to deviate from that timing now.20	The Preferred Alternative includes a measure to allow for an additional 45,000 acre-feet of water delivery from Lake Roosevelt; this measure also includes an adjustment to operations to allow the timing of delivery of recently developed water supplies for the Odessa Subarea of the Columbia Basin Project from September and October to when the water is needed as described in Section 7.6.3.6. This measure allows continued delivery of water for current demand and supports near-term additional development of authorized project acres. The Preferred Alternative analysis determines that the combined changes from Region A upstream of Grand Coulee and changes in operations at Grand Coulee result in relatively small changes to river flows, with median monthly average flows typically within 1 percent of those under the No Action Alternative. To reduce these small impacts from the Lake Roosevelt Additional Water Supply measure Reclamation would adjust the refill target of Lake Roosevelt, as described in Section 7.6.4. The effects of the alternatives on fish is included in Section 7.7.4. Previous consultations on the Odessa Subarea withdrawals reduced flow impacts by largely restricting pumping to refill Banks Lake in the fall, this was less because of known biological impacts and more related to limited time to analyze the flow changes and those impacts on anadromous fish migration. The change to water supply delivery, both the additional 45,000 acre-feet and the reshaping flow impacts are included in table summaries in Appendix C. Additionally, the system operations modeling results were provided to NMFS for their analysis, and inclusion in their LCM and COMPASS models
32262	46	Rodney Cawston	Confederated Tribes of the Colville Reservation	VI. Resident Fish Impacts and Mitigation CTCR previously expressed concerns regarding the Fall Operational Flexibility for Hydropower (Grand Coulee) measure, DEIS at 7-32, and its impact on native resident fish access to tributary spawning and overwintering habitat, and reduced shoreline habitat in Lake Roosevelt. Under this measure the end-of-September refill to an elevation of 1283 feet would be delayed in some years to the end of October for greater power generation flexibility and to meet downstream flow objectives. The DEIS indicates that in low water years, this may delay refill to 1283 feet past September 30 in approximately 40% of years. DEIS at 7-129. The co-lead agencies should explain that the end-of-September refill date was established in the NPCCs 2003 Mainstem Amendments to the Fish and Wildlife Program,21 and that the agencies have interpreted this provision as a mandatory target. See, e.g., 2019 Water Management Plan at 33 (Attachment 12). As such, even if this measure is approved in the agencies Record of Decision, it should be noted that it must still be modified by the NPCC in a future amendment to the Fish and Wildlife Program, as BPA attempted to do during the 2019- 2020 amendment process.22 More details about the criteria for delaying refill should be specified, including the water level which would typically trigger a delay, and whether the operation would be available in all years, regardless of water levels. CTCR is concerned that greater flexibility will result in annual refill delays without a clear commitment to work with CTCR to specify the criteria governing this operation. The DEIS should also identify the anticipated power benefits from increasing flexibility and the downstream flow objectives that also inform the agencies desire to increase their flexibility in the operation of Grand Coulee and impose the attendant impacts on CTCR and Lake Roosevelt.	The operational measure discussed in this comment pertains to fall reservoir elevations at Lake Roosevelt. Another measure for flood risk management also affects Lake Roosevelt reservoir elevations in the spring. The comment suggests that the target date and elevation for Lake Roosevelt refill in the fall should be mandatory, based on related guidance from the Northwest Power and Conservation Councils (Council) 2003 Mainstem Amendments to the Columbia River Basin Fish and Wildlife Program (Program). The co-lead agencies disagree that the Councils Program guidance constitutes a mandatory fixed target. First, the plain language of the 2003 Mainstem Amendments allows for flexibility in the fall refill operation. For example: As much as possible, manage the reservoir and dam discharges to minimize fluctuations and ramping rates and produce steady flows across each season and each day to minimize reservoir fluctuations and ramping rates. Attempt to draft no lower than 1283 feet by the end of August. From September through December, attempt to maintain a minimum elevation of 1283 feet to maximize water retention times and protect kokanee access and spawning. Federal operators, fish and wildlife managers, and others should consult with the Council to determine how to provide the biological benefits of a 1283 operation while meeting biological opinion requirements, including chum flows and operating to protect flows for the Hanford Reach. 1/ In addition, past practice since the Councils adoption of the 2003 Mainstem Amendment demonstrates that the nature of this guidance is flexible, not mandatory. As anticipated by the Councils language in the quote above, subsequent biological opinions impacted the ability to refill Lake Roosevelt to 1283 by the end of August, so this elevation target was moved to later in the season. Further, the comment appears to acknowledge that the refill target date is flexible, given that it references an end-of-September target, which already reflects a modification to the August date included in the 2003 Mainstem Amendment. The co-lead agencies note as well that the purpose of the fall refill guidance in the 2003 Mainstem amendments was related to protecting kokanee access to spawning habitat. Consistent with the NPCC language quoted above, Bonneville worked with fish and wildlife managers on a mitigation project to provide the biological benefits of a 1283 operation (that is, kokanee spawning access) even while balancing the need for flexible operations related to downstream flows for biological opinion purposes. Specifically, Bonneville funded a culvert replacement project at Barnaby creek that enabled kokanee passage down to a reservoir elevation of 1257 to restore tributary access and ecological function. 2/ The comment also suggests that changes to the Councils Program would need to be adopted to allow for any additional flexibility in the fall refill operation. The co-lead agencies disagree that the Councils Program, on its own, can prescribe a particular refill operation that the agencies must follow. The flexible language in the 2003 Mainstem Amendment and the fact that subsequent changes to the target refill date were driven by factors other than the Councils Program, as described above, reinforce this position. However, as the comment notes, Bonneville made initial proposals for changes to Council Program guidance on this issue to clarify the acceptability of additional flexibility in the fall refill operation; a future clarification on this point would still be useful. Finally, the co-lead agencies remain willing to work with regional partners to determine where to conduct mitigation actions, consistent with Chapters 5 and 7. Relevant mitigation guidance in the Councils Program could inform this discussion, and would be more in line with the Councils Programs statutory role that is, to guide fish and wildlife mitigation for system operations, not to prescribe the operations themselves. Finally, consistent with previous years when this operation was implemented, the operation may occur due to anticipated low streamflow conditions, downstream operational constraints, and changes in power supply. Additionally, consistent with past years, this flexibility would result in a shift in timing for refilling Lake Roosevelt, but the overall flow volume would remain unchanged between August 31 and November 1 and would be coordinated with tribal fish managers, including CTCR. Finally, the power benefits the Preferred Alternative, including this potential operation are included in Section 7.7.9, Power Generation and Transmission. 1/ See Northwest Power and Conservation Council, Mainstem Amendments to the Columbia River Basin Fish and Wildlife Program (2003), at 26-17 (emphasis added), available at https://www.nwcouncil.org/fish-and-wildlife/previous-programs/2003-mainstem-amendments-to-the-columbia-river-basin-fish-and-wildlife-program. 2/ See Colville Tribes Fish & Wildlife Department, Barnaby Creek Culvert Replacement Project 20 (July 2012).
32262	47	Rodney Cawston	Confederated Tribes of the Colville Reservation	CTCR appreciates the agencies proposal to mitigate for the effects of this measure by augmenting kokanee and other affected species spawning habitat in Lake Roosevelt. DEIS at 7- 44 to 7-45, ll. 1282-88. However, we are disappointed that the DEIS does not reflect the proposed changes to this poorly defined mitigation measure that were discussed with agency staff in February. See Attachment 13 (February 7, 2020, email from Bret Nine to Sonja Kokos and Eric Rothwell and attached modification to the Administrative DEISs explanation of this mitigation measure). In particular, we question whether the proposed mitigation, which would limit potential habitat augmentation to 100 acres in a 150-mile reservoir, is appropriate prior to conducting a study of the impacts of delayed refill and determining the extent of such impacts. Given the significant benefits the agencies apparently would derive from the greater flexibility in refill timing, it is appropriate to fully study and mitigate the impacts to the already over-impacted reservoir. We again request that the proposed changes to this mitigation measure communicated with agency staff in February 2020 be incorporated into the Final EIS.	In response to the suggestions provided to the Co-Lead agencies the description of the mitigation measure in Lake Roosevelt for resident fish has been updated. This update includes consideration of available and future studies to guide the implementation of this measure; additionally this measure will require site specific NEPA that may guide the location and approach to offset the impacts from these proposed operational changes.
32262	48	Rodney Cawston	Confederated Tribes of the Colville Reservation	A. Cultural Resources General Comment Throughout the EIS process, CTCR has provided comments to assist the co-lead agencies in adequately evaluating the tremendous impacts that the CRS has caused to Colville cultural resources. In general, CTCR has found the agencies effort in this respect to be inadequate to address the devastation to tribal culture and lifeways caused since the first construction of dams in the Columbia Basin. Of particular concern is the continuing failure to include fish passage in the management of [Chief Joseph and Grand Coulee Dams]. Appendix P at 18 (CTCR Tribal Perspectives document at 6). We acknowledge that the inclusion of the Tribal Perspectives documents provides an important vehicle for tribes to give voice to their views of CRS impacts ranging from tribal culture to daily life. See DEIS Section 3.17.2; Appendix P. The shortcoming of the co-lead agencies effort is that it is not clear that tribal views expressed in these documents changed the development of the Preferred Alternative in a measurable way, especially with respect to cultural resources connected with anadromous salmonids in the upper Columbia. In order to demonstrate that tribal perspectives influenced development of the Final EIS, the agencies need to include a meaningful response to repeated requests by Colville and other upper Columbia tribes to restore anadromous salmonids to the area where the CRS has blocked them for nearly 80 years. As we have explained throughout the process and underscore in this letter, the agencies response has been a failure.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
32262	49	Rodney Cawston	Confederated Tribes of the Colville Reservation	We also have concerns regarding the scope of the agencies cultural resources review in the DEIS. In the mid-1990s, the agencies conducted the System Operation Review and began applying federal cultural resource laws to the Columbia Basin. This change was prompted by tribes insistence that cultural sites be protected. However, this DEIS demonstrates the shortcomings of how the co-lead agencies are applying NEPA, which is not restricted to evaluating impacts to the four identified categories of cultural resources recognized by the agencies: archaeological resources, traditional cultural resources, built environment, and sacred sites. DEIS at 7-190. These four imposed categories are artificially narrow and do not reflect the full scope of impacts of the CRS to Colville cultural resources. As CTCR described in its Tribal Perspectives document, our view of cultural resources is necessarily more inclusive: For the purposes of the Columbia River System Operations (CRSO) EIS, the Confederated Tribes of the Colville Reservation (Tribes or CTCR) take a broad view of cultural resources.24 These include, but are not limited to, cultural resources defined in applicable laws directed toward tangible resources. They also include cultural heritage that is not necessarily site-specific such as ritual, ceremony, language, traditional teachings, etc., and they include resources such as the land, water, air, and animals. These resources consist of individual artifacts, sites, natural resources, and ecosystems. Of particular importance is the recognition of natural resources like fish, wildlife and water as cultural resources of the Colville people. This includes the anadromous salmon and steelhead that previously returned to the upper Columbia in such abundance that they formed a cornerstone of our culture.25 Certainly, for purposes of the CRSO EIS, cultural resources should not be restricted to bounded properties. Times change, perceptions change, and interpretation of regulations change: the co-lead agencies should expand their review to reflect contemporary, wholistic views of cultural resources.26 We are hopeful that the Preferred Alternative may have somewhere in its provisions sufficient flexibility to adapt to new directions and landscape-level application of historic preservation through creative mitigation or another viable mechanism. From CTCRs perspective, it appears that the co-lead agency staff is accepting of the new directions and may be willing to work with tribes in this regard. However, this evolving view must be	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources," as this is consistent with Federal laws and regulations, which focus on specific bounded properties. Tribal interests and holistic perspectives on the integration of Native American culture with the environment were addressed throughout the EIS and by inclusion of statements from the tribes. The co-lead agencies note that many of the traditional cultural properties analyzed in the Draft EIS include aspects of the natural and social environment. Please see Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas; Section 3.17.2 for Tribal Perspectives Summaries; and, Section 3.17.3 for Tribal Interests. The co-lead agencies will continue to pursue the commitments outlined in the Systemwide Programmatic Agreement and ensure their ongoing efforts for compliance with Section 106 of the National Historic Preservation Act continue into the future.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				memorialized in the EIS so that CTCR and other tribes are not, once again, stuck with a 25-year-old preservationist view of the resources essential to our living cultures. In contrast, it would be clearly inadequate to continue relying on the existing FCRPS Cultural Resource Program to implement mitigation actions, which the DEIS indicates is the preferred mitigation measure under the Preferred Alternative.27 Additionally, the CRS imposes indirect impacts on shrub/steppe habitat, an important Colville cultural resource. Shrub/steppe habitat is important to Colville people for spiritual and cultural uses and provides habitat for several culturally significant plants. The CRS is managed in part for irrigation, and irrigation from the Columbia River is increasing the conversion of culturally significant shrub/steppe habitat into agricultural croplands. The increase in irrigated agricultural activity decreases the amount of shrub/steppe habitat and diminishes Colville access to culturally significant plants that are gathered for medicine, as a subsistence food source, and for other cultural and ceremonial activities.	
32262	50	Rodney Cawston	Confederated Tribes of the Colville Reservation	With regard to Indian Trust Assets (ITAs), the co-lead agencies continue to perpetuate two errors in the DEIS. First, the co-lead agencies fail to recognize that that Colville Tribal trust lands are in fact located within areas of effects under all of the alternatives, including the Preferred Alternative. Second, the co-lead agencies employ an unduly narrow definition of ITAs that is out of step with federal law and the agencies own internal guidance, and which erroneously excludes important trust assets of the Colville Tribes and its members. The Colville Tribes have brought these concerns to the attention of the co-lead agencies on several prior occasions, incorporated here by reference. See Colville Tribes letters and comments to the co- lead agencies Sept. 6, 2018; May 30, 2019; Dec. 24, 2019 (Chap. 3.17 sheet, row 8); February 7, 2020 (Chap. 7 sheet, row 38).	The co-lead agencies requested the CTCR identify those trust lands within the study area. The Tribe provided geographical information system data that identified lands of various status. This information was incorporated into the EIS in Section 3.17.1.1. The co-lead agencies have analyzed ITAs consistent with applicable statutes, regulations, and guidance. Neither the rights of fishing, hunting, and gathering, nor the resources subject to those rights, are "assets held by the federal government" within the meaning the Interior Department Manual, 303 DM 2.5(c). As a result, the co-lead agencies do not consider the rights our resources to be ITAs. The agencies' analysis nevertheless considers effects to the resources subject to the Tribe's rights, as well as the cumulative effects to those rights as a result of effects to underlying resources.
32262	51	Rodney Cawston	Confederated Tribes of the Colville Reservation	1. Colville Tribal trust lands The co-lead agencies erroneously conclude that [t]rust lands identified during the geospatial database query and tribal outreach are located outside of any direct or indirect effects identified in the alternatives. DEIS at 3-1399, ll. 7421-23; id. at 7-217, ll. 6347-75. They fail to account for areas of Colville Reservation trust lands that will be directly and indirectly affected under the proposed alternatives, despite recognizing such effects elsewhere in the DEIS. For example, the co-lead agencies have identified that under all of the alternatives, increased drawdown of Lake Roosevelt for flood risk management will affect the Inchelium- Gifford Ferry, causing it to be inoperable for additional days each year. Id. at 5-21, ll. 736-41; 5- 26, ll. 864-67; 5-35, ll. 1113-15; 5-46, ll. 1341-42; 7-179, ll. 5217-25. The Inchelium-Gifford Ferry provides an essential conduit between Colville trust lands and services off the Reservation. See, e.g., id. at 5-21, ll. 740-41. The co-lead agencies acknowledge that [t]he effect would isolate tribal members on Reservation, id. at 5-21, ll. 738-39, and that [e]ffects would primarily occur on the Confederated Tribes of the Colville Reservation. Id. at 7-179, ll. 5225-26. Thus, Colville Reservation lands are clearly located within the area of this effect. Other effects on Colville Tribal trust lands include: Exposure and submersion of lands along Lake Roosevelt and adjacent to Colville Reservation lands contributing to mass wasting of Reservation lands above the 1310 feet elevation boundary; TDG, temperature and other downstream impacts of Grand Coulee Dam operations affecting shore and submerged Colville Tribal lands (including a Tribal recreational fishing site and aquaculture net pen operation) along Lake Rufus Woods; and TDG, temperature and other downstream impacts of Chief Joseph Dam operations affecting Colville Tribal trust lands between Chief Joseph Dam and the Okanogan River. Thus, the co-lead agencies conclusion that there are no trust lands within the area of any direct or indirect effects is erroneous as it pertains to Colville Tribal trust lands. Accordingly, the Colville Tribes are concerned about the accuracy of information contained in the BOR geospatial database, upon which the co-lead agencies purport to have relied as part of the process for identifying ITAs and evaluating effects. Id. at 3-1396, ll. 7320-22. In addition, by failing to acknowledge the Colville Tribes off-Reservation trust lands, which are located throughout the upper Columbia Basin, the co-lead agencies leave unresolved the question whether the co-lead agencies included off-Reservation trust lands in its consideration of the Colville Reservation or whether Colvilles off-Reservation trust lands are absent from the BOR geospatial database. If the latter, the co-lead agencies conclusions in the DEIS regarding the Indian trust lands and effects thereupon are fundamentally flawed because the co-lead agencies analysis was based on incomplete data regarding the location and extent of Colville Tribal trust lands.	The co-lead agencies requested the Confederated Tribes of the Colville Reservation to identify those trust lands within the study area. On April 30, 2020, the co-leads received this information that identified parcels along the Okanogan, Columbia, and Snake Rivers. Those lands located along the bank of the Okanogan River are not considered in this analysis because those areas are outside the area affected by the Columbia River System operations, maintenance and configuration. This information was incorporated into the EIS in Section 3.17.1.2.
32262	52	Rodney Cawston	Confederated Tribes of the Colville Reservation	2. Non-proprietary ITAs The scope of ITAs recognized by the co-lead agencies in the DEIS is improperly narrow and excludes an array of legally recognized trust assets beyond the limits of real property owned by the United States in trust for CTCR. These ITAs include (but are not limited to) the Colvilles federally reserved fishing, hunting and water rights, and the fish, game and water that are the res of those trust assets. Agency policies and legal doctrine both establish that ITAs encompass non-proprietary tribal interests. The BOR Manual on Indian Policy defines ITAs as legal interests in land, water, minerals, funds rights, or other property . . . which may include ownership or the use interests. NIA P10 at 2 (emphasis added). The NEPA Handbook to Procedures to Implement Indian Trust Asset Policy expressly identifies hunting and fishing rights, water rights, and instream flows as examples of ITAs. Pg. 1. The Ninth Circuit has observed that a tribes unqualified [federal reserved water] rights . . . constituted an Indian Trust Asset. Navajo Nation v. Dept of Interior, 876 F.3d 114, 1159 (9th Cir. 2017). If CTCRs use interests, which are secured by federally reserved fishing and hunting rights and supported by its reserved water rights, do not qualify as ITAs in the agencies evaluation of a federal action directly and significantly affecting those same resources, it is not clear where, if anywhere, such use rights would qualify. Notwithstanding that clear guidance, the co-lead agencies insist that ITAs require first a possessory interest; that is, the asset must be held or owned by the Federal government as trustee. DEIS 3-1395, ll. 7285-86. In response to the Colville Tribes December 24, 2019 comment concerning the definition of ITAs propounded in the Administrative DEIS, the co-lead agencies merely amplified their emphasis on ownership status as the determinative characteristic of ITAs.28 Hewing to property concepts as the paramount metric for discerning ITAs is poorly suited for critical natural resources like fish, wildlife and water, which are integral to the Colville Tribes culture and spirituality and in which the Tribes hold federally confirmed, vested rights. See Tee-Hit-Ton Indians v. United States, 348 U.S. 272, 277-78 (1955) (citing United States v. Creek Nation, 295 U.S. 103, 109-110; Shoshone Tribe v. United States, 299 U.S. 476, 497; Chippewa Indians v. United States, 301 U.S. 358, 375-376; United States v. Klamath Indians, 304 U.S. 119; Sioux Tribe v. United States, 316 U.S. 317, 326). Such resources are not amenable to conventional possessory interests or property boundaries, but rather migrate across and between trust lands, public lands, private lands and beyond. Nonetheless, these resources constitute the res of the Colville Tribes trust assets embodied in our federally recognized and protected fishing, hunting and water rights. The co-lead agencies omission of fish, wildlife and water, among other resources, as Colville ITAs is consequential as they acknowledge that DOI requires that all effects to [ITAs], even those considered nonsignificant, be discussed in NEPA analyses and appropriate compensation and/or mitigation implemented. DEIS at 3-1395, ll. 72724-76. By construing ITAs so narrowly as to exclude the important resources that are necessary to fulfill the purposes of the Colville Reservation and meet the fundamental subsistence and cultural needs of the Colville people, the co-lead agencies improperly avoid their obligation to mitigate and/or compensate Colville for the effects of the CRS on CTCRs trust asset resources. In sum, because both the geographic and definitional scope of ITAs employed by the co- lead agencies in the DEIS are indefensibly constrained and omit important Colville ITAs, the co-lead agencies (particularly BOR) should revise their analysis, fully evaluate the effects of the CRS on Colvilles ITAs, and develop appropriate mitigation and/or compensation for these impacts.	The co-lead agencies have analyzed ITAs consistent with applicable statutes, regulations, and guidance. Neither the rights of fishing, hunting, and gathering, nor the resources subject to those rights, are "assets held by the federal government" within the meaning the Interior Department Manual, 303 DM 2.5(c). As a result, the co-lead agencies do not consider the rights or resources to be ITAs. The agencies' analysis nevertheless considers effects to the resources subject to the Tribe's rights, as well as the cumulative effects to those rights as a result of effects to underlying resources. Section 3.17.1.1 provides the legal definition of an Indian Trust Asset. That section states: "Treaty-reserved rights, for instance, fishing, hunting, and gathering rights on and off reservation, are usufructuary rights that do not meet the Department of Interior (DOI) definition of an ITA." Given the importance to the tribes of these resources that do not meet the Department of Interior's definition of an Indian Trust Asset, effects to those resources are discussed in Section 3.17.2, Tribal Perspectives Summaries.
32262	53	Rodney Cawston	Confederated Tribes of the Colville Reservation	The Preferred Alternative would exacerbate the ferry outage in high water years from an average of 27 days per year to 31. DEIS at 7-179. This increase is significant for tribal members, particularly because the outage would be over a contiguous period of time. As a result, in certain years, the ferry would be out of service for a full month. Reliable and convenient access to health care and other vital services has become all the more important under the COVID-19 pandemic and the resulting business closures, gaps in service, and uncertainty it has caused. Colville appreciates the co-lead agencies inclusion of a mitigation measure in the Preferred Alternative to extend the boat ramp for the Inchelium-Gifford Ferry. DEIS at 7-45, ll. 1289-94. This measure will mitigate a disparate impact on Colville tribal members and address a long-standing problem for many of our residents. The description of the mitigation measure should be clarified and improved in several respects. First, it should be noted that while the incremental increase in the ferry outage in the wettest years would be four days, it would result in a total outage of 31 consecutive days on average. See DEIS at 7-179. The proposed measure would mitigate for the entirety of this adverse impact, not just the incremental impact of the Preferred Alternative. Second, more details about the process for extending the ramp should be described, including a lead agency, timeline for planning, design, and construction, and the source of funding the agencies will utilize for the project. Discussion of the ferry ramp extension has occurred for years, without action, and it cannot be allowed to flounder further.	Thank you for your comment. In the Final EIS, Table 7-6 Mitigation Summary for Preferred Alternative has been added which describes the effect after the mitigation of extending of the Inchelium-Gifford Ferry as "potentially providing a beneficial effect from the No Action Alternative." To the second point, after the Record of Decision is signed, the mitigation measures of the Preferred Alternative, including this ferry extension, would be further refined and fully developed during implementation phases.
32262	54	Rodney Cawston	Confederated Tribes of the Colville Reservation	In addition, in our review of the Administrative DEIS, we discovered that BPA had not properly accounted for the adjustment in the formula for a portion of the pumping loads at Grand Coulee. While this change is not expected to significantly affect the estimated payment amount, we reiterate this comment as a reminder to make the correction in the Final EIS.	The updated calculation of the 181d payment in the Final EIS corrects this error. Other changes made between the Draft EIS and the Final EIS (discussed at the end of Section 3.7.3.1) also affected the payment. Section 3.7.4 for Power and Transmission Tribal Interests and Section 3.18, Environmental Justice presents the payment information for alternatives Multiple Objective alternative 1 through Multiple Objective alternative 4. Section 7.7.20 presents the payment information for the Preferred Alternative. Appendix H, Chapter 4, Section 4.1.1.3.1 presents the 181d payment information for all alternatives in one table.
32262	55	Rodney Cawston	Confederated Tribes of the Colville Reservation	X. Environmental Justice The co-lead agencies environmental justice (EJ) analyses in the DEIS fall short by entirely overlooking the disproportionate adverse effects of the CRS in the upper Columbia, including on CTCR. The co-lead agencies longstanding inequitable treatment of the upper Columbia is exacerbated by their continued inattention to acknowledging and mitigating the most glaring impact of the CRS in the upper Columbia: the complete blockage of anadromous salmonids by Grand Coulee and Chief Joseph Dams and resulting extirpation of those fish from the upper Columbia. See also CTCRs letter and comment Nov. 28, 2017; February 2, 2020, at row 39. To right the imbalanced treatment of the upper Columbia to date, the co-lead	This EIS does not propose mitigation for the existence of dams. The EIS compares the effects for alternatives including the Preferred Alternative from the No Action Alternative. Environmental justice populations were identified in section 3.18.3.1 Affected Environment: Populations of Interest. Unique pathways of influence including intensity of use are discussed in section 3.18.4.2 Resource Analysis and 3.18.4.3 Effects Analysis. New disproportionate effects that are greater than "minor" due to the EIS alternatives are mitigated. No disproportionately high and adverse effects remained after mitigation. Measures to reintroduce salmon above Grand Coulee and Chief Joseph were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				agencies must commit in the Final EIS to studying the phased approached to fish passage and reintroduction outlined in the 2014 Fish and Wildlife Program as a means to mitigate the disproportionate effects of the CRS on the Colville Tribes and the other upper Columbia tribes all constituents of an EJ protected class. As the co-lead agencies observe in the DEIS, federal agencies that engage in NEPA processes are directed to consider the composition of the affected area, to determine whether minority populations, low-income populations, or Indian tribes are present in the area affected by the proposed action, and if so whether there may be disproportionately high and adverse human health or environmental effects on [those EJ protected classes]. CEQ, Environmental Justice Guidance Under the National Environmental Policy Act, Dec. 10, 1997, at 8; CRSO DEIS at 3- 1417, ll. 8044-47; id. at 7-196, ll. 699-702. The CEQ guidance specifically calls on agencies to recognize that different patterns of living, such as subsistence fish . . . consumption may result in unique impacts on EJ protected classes, including Indian tribes, due to a communitys distinct cultural practices. CEQ, Environmental Justice Guidance, at 14. The Colville Reservation is a community that calls out for consideration in this EIS because it meets several of the CEQs criteria it is located in a rural and poor area of Washington state, is comprised predominantly of Native Americans, has poor access to health care, and was situated on the Columbia River to ensure access to the salmon on which the Colville people depend. For nearly eight decades, the CRS has extirpated anadromous salmonids from the upper Columbia an area encompassing 40% of the anadromous habitat in the entire Columbia River Basin which action has imposed disproportionately high and adverse human health and environmental effects on the Colville Tribes and the other tribes of the upper Columbia. No other region of the Columbia has suffered such a complete and drastic effect from the CRS on fish and, commensurately, on tribes as an EJ protected class. Yet the co-lead agencies fail to mention this impact whatsoever in their discussion of the no action alternatives EJ effects relative to fish. They note four species of freshwater fish that are important resources to the Indian tribes in Region B, DEIS at 3-1435, ll. 8538-39, but any discussion of the once-abundant species of anadromous salmonids that populated this stretch of the Columbia and provided a cornerstone of upper Columbia tribes diet, lifeways and spirituality is noticeably absent. See id. at 3-1435-36, ll. 8538-50. Instead, the co-lead agencies collapse the disproportionate impact of the CRS on upper Columbia fish runs and tribes into a generalized and blithe nod to the [a]dverse effects associated with the absence or reduced levels of fish due to the operation and maintenance, or existence of the CRS on Indian tribes as well as other subsistence fishers throughout all regions of the Columbia. Id. at 3-1446, ll. 8793-98 (emphasis added). The co- lead agencies failure to recognize in the DEIS much less discuss mitigation for the disproportionate impacts suffered by the Colville Tribes and the other tribes of the upper Columbia as a result of the CRSs extirpation of anadromous fish in this portion of the River demands correction. Whats more, the co-lead agencies conclude that for each of the proposed action alternatives, including the Preferred Alternative, there would not likely be a disproportionately high and adverse effect on environmental justice populations, despite the fact that none of the alternatives discuss study of fish passage and reintroduction at Grand Coulee and Chief Joseph Dams as a mitigation measure for this grave ongoing harm. Id. at 3-1452, ll. 9053-54 (regarding MO1); id. at 3-1458, ll. 9262-63 (regarding MO2); id. at 3-1466, ll. 9572-73 (regarding MO3); id. at 3-1472, ll. 9828-29; see also id. at 7-196, ll. 5704-05 (concluding that based on the effects analysis for the Preferred Alternative, there is not likely to be a disproportionately high and adverse effect on low income, minority or tribal populations). By contrast, the co-lead agencies are attentive to the potential reduction in operation of the Inchelium-Gifford Ferry that may result under all of the alternatives, and observe that this effect would primarily fall on the CTCR. Id. at 3-1449, ll. 8918-19; id. at 3- 1455, ll. 9151-52; id. at 3-1460, l. 9350; id. at 3- 1468, ll. 9688-89; see also id. at 7-179, ll. 5225-26.29 CTCR appreciates the co-lead agencies attention to this navigation and transportation impact on Colville people as an EJ protected class and the agencies provision of mitigation (extending the ferry ramp) for this prospective adverse effect. See id. at Section 5.4. The extirpation of anadromous salmonids above Chief Joseph Dam a continuing and unavoidable adverse effect of CRS management under every alternative, including the Preferred Alternative also merits attention and mitigation by the co-lead agencies, not least of all because of the disproportionate impact it has on CTCR and other upper Columbia tribes as an EJ protected class. The EJ analyses memorialized by the co-lead agencies in the DEIS remain inadequate because they perpetuate the co-lead agencies disproportionate treatment of the upper Columbia and ongoing failure to manage the CRS to provide for fish passage and reintroduction, adverse effects that will continue to impact Colville and our sister tribes along the upper Columbia. We strongly urge the co-lead agencies to address, evaluate and mitigate this longstanding environmental injustice.	differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas. Effects on the tribe from reduced service days of the Inchelium-Gifford Ferry are addressed by additional measure incorporated in the PA that will extend the ramp. Finally, the commenter is correct that the history of anadromous fish in the Upper Columbia River is not discussed in the Environmental Justice analysis. The focus of the Environmental Justice analysis is on resources that would change under the No Action and proposed alternatives, and the presence of anadromous fish would not change under any alternative. Although it is not expressly stated in the Environmental Justice section of the EIS (section 3.18), section 3.17 includes a discussion of this issue as part of the summary of the CTCR's Tribal Perspective. Specifically, it recognizes that "nineteen dams and their corresponding reservoirs affect traditional use areas of the CTCR constituent tribes and bands, including the continued total blockage of anadromous salmonids by the construction of Grand Coulee and Chief Joseph dams. This 'devastation of the Tribes ancestral fisheries caused (and continues to cause) irreparable harm to the culture, subsistence, religion, health, social structure, and economy of all twelve constituent tribes and bands.' Climate science projections will continue to adversely impact anadromous species, their potential habitats, and CTCRs concerted efforts to reintroduce salmon into the upper Columbia River. The boundaries of the Colville Reservation were defined with the intent to include fisheries important to the tribes assigned to the Reservation. The completion of the Grand Coulee Dam, and later the Chief Joseph Dam, inundated these fisheries and the regionally important fishery at Kettle Falls and, more significantly, prevented salmon and other anadromous species from reaching much of the Colville Reservation lands, and the lands and waters of the former North Half of the reservation, rendered as public domain in 1891, to which CTCR members retain federally protected reserved hunting, fishing and gathering rights. Consequently, the Tribes food system and subsistence fishing economy has been destroyed along with the diminishment of many of the cultural traditions associated with salmon fishing.
32262	56	Rodney Cawston	Confederated Tribes of the Colville Reservation	XI. Biological Assessment As noted above in our comment on the co-lead agencies evaluation of re-shaping the withdrawal from Lake Roosevelt of 179,000 acre-feet for the Odessa Subarea, it is important that this measure be described clearly. Although the DEIS does reflect the re-shaping measure in the Preferred Alternative, DEIS at 7-32, the Biological Assessment (BA) does not. The Odessa Subarea withdrawals are discussed in Appendix A of the BA. DEIS Appx V at Appx A (page A-17). There, the BA does not refer to the change in timing of withdrawals, and we could not identify any place in the BA where this change is identified. Moreover, because of the National Marine Fisheries Services (NMFSs) concerns about the timing of withdrawals during consultation on the project in 2013, NMFS should carefully evaluate the proposed change. It is not sufficient (or accurate) to imply, as the co-lead agencies do, that because NMFS consulted on the Odessa Subarea withdrawals in 2013, the proposed measure does not merit attention in the current ESA consultation.	The Preferred Alternative includes a measure to allow for an additional 45,000 acre-feet of water delivery from Lake Roosevelt; this measure also includes an adjustment to operations to allow the timing of delivery of recently developed water supplies for the Odessa Subarea of the Columbia Basin Project from September and October to when the water is needed as described in Section 7.6.3.6. This measure allows continued delivery of water for current demand and supports near-term additional development of authorized project acres. The Preferred Alternative analysis determines that the combined changes from Region A upstream of Grand Coulee and changes in operations at Grand Coulee result in relatively small changes to river flows, with median monthly average flows typically within 1 percent of those under the No Action Alternative. To reduce these small impacts from the Lake Roosevelt Additional Water Supply measure Reclamation would adjust the refill target of Lake Roosevelt, as described in Section 7.6.4. The effects of the alternatives on fish is included in Section 7.7.4. Previous consultations on the Odessa Subarea withdrawals reduced flow impacts by largely restricting pumping to refill Banks Lake in the fall, this was less because of known biological impacts and more related to limited time to analyze the flow changes and those impacts on anadromous fish migration. The change to water supply delivery, both the additional 45,000 acre-feet and the reshaping flow impacts are included in table summaries in Appendix C of the Biological Assessment. Additionally, the system operations modeling results were provided to NMFS for their analysis, and inclusion in their LCM and COMPASS models
32262	57	Rodney Cawston	Confederated Tribes of the Colville Reservation	A shift back to irrigation-season timing - as the Preferred Alternative proposes to do - should be of equal or greater concern now than it was in 2013 because it would be "likely" to take listed salmon. Id. Yet the DEIS does not indicate NMFS was aware of or considered this significant modification. See DEIS at 7-48 (ESA-related mitigation measure to adjust Lake Roosevelt refill target refers to the 45,000 acre feet of new withdrawals during the irrigation season for the Columbia Basin Project but not the re-shaping of Odessa Subarea withdrawals for 179,000 acre-feet, which is effectively four times the volume of the new withdrawals). Given this history (including the sole reasonable and prudent measure of the 2013 biological opinion), it is incumbent on the co-lead agencies to amend the BA to account for the Preferred Alternative's divergence from BOR's 2013 Odessa Subarea record of decision and NMFS's biological opinion in terms of withdrawal timing.	The change to water supply delivery, both the additional 45,000 acre-feet and the reshaping flow impacts are included in table summaries in Appendix C of the Biological Assessment. Additionally, the system operations modeling results were provided to NMFS for their analysis, and inclusion in their LCM and COMPASS models
32263	1	ted@tcklaw.com	Spokane Tribe of Indians	The Tribe notes that the Agencies did not provide an extension of the public comment period even though they received numerous requests related to the Covid-19 pandemic, but for unknown reasons have chosen to overlook the pandemic's impact on the Region's governments and publics ability to review such a significant document during these difficult times.1 With that said, the Tribe's government is currently shutdown and some staff have been unavailable to review these comments and the DEIS. Accordingly, the Tribe will supplement these comments, if necessary, and fully expects the Agencies to consider any supplemental comments submitted by the Tribe.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
32263	2	ted@tcklaw.com	Spokane Tribe of Indians	The Objectives do not recognize the all of the Agencies' mandatory duties under the Northwest Power Act In the multiple and some places differing lists of "Resource Purposes" the Agencies acknowledge only a portion of their duties under the Northwest Power Act ("Act"). The Agencies misunderstanding is most concisely stated in Section 8.3.6 of the DEIS: Provisions of the Northwest Electric Power Planning and Conservation Act of 1980 (Northwest Power Act) (16 U.S.C. 839 et seq.) require Bonneville to balance multiple public duties and purposes: helping to ensure the Pacific Northwest has an adequate, efficient, economical, and reliable power supply; promoting energy conservation and the use of renewable resources; and, consistent with the program developed by the Northwest Power and Conservation Council (NW Council), protecting, enhancing, and mitigating fish and wildlife to the extent affected by the development and operation of the Federal Columbia River Power System (FCRPS), which includes the Columbia River System (CRS). Bonneville complies with these provisions of the Northwest Power Act through the Fish and Wildlife Program and other actions. Under the Northwest Power Act, Bonneville, the Corps~ and the Bureau of Reclamation (Reclamation) exercise their responsibilities of operating the CRS in a manner that provides equitable treatment for fish and wildlife and with the other purposes for which CRS facilities are operated and managed. In addition, the co-lead agencies consider in their decision making the NW Council's Fish and Wildlife Program and Mainstem Amendments to the fullest extent possible. (DEIS at 8.3.6) (Emphasis added). The Act requires far more. To illustrate, the Act requires that "[f]ollowing the adoption of the plan [Power Plan] and any amendments thereto, all actions of the Administrator pursuant to Section 839d of this title shall be consistent with the plan and any amendment thereto, except as otherwise specified in the chapter." 16 U.S.C. 839b(d)(2). Further, BPA must fund the protection, mitigation and enhancement of fish and wildlife "to the extent affected by the development and operation of any hydroelectric project of the Columbia River and its tributaries in a manner consistent with the plan, if in existence, the Program adopted by the Council under this subsection, and the purposes ofthis chapter." 16 U.S.C. 839b(h)(10Xa). As stated above, the Agencies mention some of the duties in 16 U.S.C. Section 839b(11)(A), but fail to address the mandate of the entire section: (11) (A) The Administrator and other Federal agencies responsible for managing, operating, or regulating Federal or non-Federal hydroelectric facilities located on the Columbia River or its tributaries shall– (i) exercise such responsibilities consistent with the purposes of this chapter and other applicable laws, to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated; (ii) exercise such responsibilities, taking into account at each relevant stage of decisionmaking processes to the fullest extent practicable, the program adopted by the Council under this subsection. If, and to the extent that, such other Federal agencies as a result of such consideration impose upon any non-Federal electric power project measures to protect, mitigate, and enhance fish and	The agencies are aware of their responsibilities under all applicable laws, including their responsibilities under the Northwest Power Act at 16 U.S.C. 839b(h)(11), and demonstrate compliance in Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders in the Final EIS and in their decision document. Section 4.f of the commenters letter suggests that the agencies have failed to fulfill their responsibilities under 16 U.S.C. 839b(h)(11) specifically, to take into account the Councils Fish and Wildlife Program to the fullest extent practicable by not incorporating mitigation recommended through the Councils Fish and Wildlife Program into the EIS. However, the agencies responsibility to take the Councils Program into account under this statutory provision pertains to their shared management and operation of the system. The provisions of the Councils Fish and Wildlife Program cited in the comment, however, do not include any recommendations related to operations or management of the CRS for the agencies to consider. Instead, the comment focuses on the Councils recommendation for non-operational enhancement actions proposed for Bonneville to fund as off-site mitigation under a separate Section of the Northwest Power Act, 16 U.S.C. 839b(h)(10)(A). As described in Chapter 7 of the EIS, such mitigation funding decisions for the Bonneville Fish and Wildlife Program are not being made as part of the CRSO EIS process, and therefore, need not be considered at this stage of decision-making. Furthermore, under 16 U.S.C. 839b(h)(10)(A), such recommendations for off-site mitigation apply only to Bonneville; neither the Corps nor Bureau of Reclamation need consider them. For additional information on existing and proposed mitigation measures, please see Chapters 2, 5 and 7 of the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				wildlife which are not attributable to the development and operation of such project, then the resulting monetary costs and power losses (if any) shall be borne by the Administrator in accordance with this subsection. (B) The Administrator and such Federal agencies shall consult with the Secretary of the Interior, the Administrator of the National Marine Fisheries Service, and the State fish and wildlife agencies of the region, appropriate Indian tribes, and affected project operators in carrying out the provisions of this paragraph and shall, to the greatest extent practicable, coordinate their actions. 16 U.S.C. Section 839b(h)(11).	
32263	3	ted@tcklaw.com	Spokane Tribe of Indians	The Tribe has the following recommendations. First, the Agencies, should rewrite the purposes of the DEIS to include all of the purposes of the Northwest Power Act, not just the sections favorable to the Agencies' desired outcome. Second, the Agencies should include and consider their full range of duties pursuant to the Act, not just the provisions they have chosen to focus on. The Agencies' misunderstanding of their mandatory duties under the Act is a problem that is woven through several of the following identified issues.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The Preferred Alternative includes a combination of measures that meet the Purpose and Need Statement and objectives of the Columbia River System Operations (CRSO) EIS, while providing a balance to the authorized purposes of the 14 Federal dam and reservoir projects that make up the CRS. The co-lead agencies are aware of their responsibilities under the Northwest Power Act as demonstrated in Chapters 1, 2, 3, 5, 7 and 8. The co-lead agencies will also demonstrate compliance with the Northwest Power Act in their Record of Decision.
32263	4	ted@tcklaw.com	Spokane Tribe of Indians	Given the above mandatory duties, Tribe began its scoping comments with a focus on the Council's Fish and Wildlife Program. (Attachment 1). Then in the fall of 201 7, the Tribe began to understand that its concerns were not being considered. The Agencies were instead considering multiple alternatives, one of which would imagine an alternate reality where the Endangered Species Act and the Northwest Power Act did not exist. The Tribe sent a letter outlining its concerns with this concept and requested that instead of playing imagination far outside the scope ofthe Agencies authority (repealing the Endangered Species Act and Northwest Power Act), they instead should conduct the logical alternative based on full implementation of the Council's Plan and Program. (Attachment 2). This recommendation seemed reasonable given the Act's direction to the Council for developing the Fish and Wildlife Program: The Council shall promptly develop and adopt, pursuant to this subsection, a program to protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, on the Columbia River and its tributaries. Because ofthe unique history, problems, and opportunities presented by the development and operation of hydroelectric facilities on the Columbia River and its tributaries, the program, to the greatest extent possible, shall be designed to deal with that river and its tributaries as a system. 16 U.S.C. 839b(h)(l). The Program is developed through an extensive public process while "giving due weight to the recommendations, expertise, and legal rights and responsibilities of the Federal and the region's State fish and wildlife agencies, and appropriate Indian tribes." 839b (h)(7). Even though the Program is supported by the Act and developed and approved by the Region as its chosen path to mitigate for the CRS (which is part of the FCRPS), the Agencies dismissed this request even though it should be the logical starting point when considering any mitigation measure for the FCRPS or CRS. The Agencies informed the Tribe that they had no intention of properly considering the Fish and Wildlife Program to the extent required by the Act (Attachment 4) and had no intention of "taking into account at each relevant stage of decision making processes to the fullest extent practicable" the Council's Plan or Program or for that matter the entirety of purposes of the Northwest Power Act. Unfortunately, this initial failure to properly take into account the Council's Plan and Program led to problems throughout the DEIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. As stated in Chapter 8, a biological assessment (Appendix V) was submitted to both NMFS and USFWS, to support development of Biological Opinions (BiOps). The NMFS and USFWS BiOps are also included in Appendix V and demonstrate compliance with ESA. Chapter 8 of the EIS also demonstrates the co-lead agencies' compliance the Northwest Power Act. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based this fish analysis in Section 7.7.4, the Preferred Alternative will make a meaningful contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The comment seems to take issue with the EIS analysis of an alternative that emphasizes hydropower generation, and suggests that, in doing so, the co-lead agencies necessarily imagine an alternate reality in which the Northwest Power Act does not exist. The commenter raised a similar point earlier in this EIS process, characterizing a draft preliminary alternative focusing on hydropower generation as a concerning pre-Northwest Power Act alternative. The co-lead agencies provided a letter response (cited in this comment as commenters Attachment 4). The letter explained the analytical benefit of considering such an alternative: to help understand the tradeoffs between hydropower and other operations and to show the impacts of various operations on affected resources. Such evaluation of potential tradeoffs and various effects of different system operations is appropriate analysis to consider within this EIS. In addition, consideration and analysis of system operations emphasizing hydropower generation does not equate to ignoring the existence of the Northwest Power Act, as the comment suggests. No alternative considered in the EIS suggests that that the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program, or mitigation implemented consistent with that Program under the Northwest Power Act, would cease to exist. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Moreover, the comment misreads or mischaracterizes the co-lead agencies earlier response letter (cited in this comment as commenters Attachment 4). Nowhere in that letter do the co-lead agencies state that they have no intention of considering the Councils Fish and Wildlife Program. The co-lead agencies have taken into account the Councils Program and the Northwest Power Act in this EIS. For example, under the Councils Fish and Wildlife Program, the overarching anadromous fish goal includes a smolt-to-adult return of 2-6%. The EIS analyzed and considered SAR implications of the various alternatives. In addition, the CSS model predicts that certain smolt-to-adult return rates under the Preferred Alternative would increase from 2.0% to 2.7%, within the range included in the Council Program goal for anadromous fish.
32263	5	ted@tcklaw.com	Spokane Tribe of Indians	Of all the issues identified by the Tribe, the Agencies complete failure to consider any aspect of reintroduction of salmon and steelhead above Chief Joseph ("CJD") and Grand Coulee Dams ("GCD") is by far the most troubling. Troubling because this issue has been analyzed by various federal Agencies to varying degrees since at least 2002.2 Further frustrating the matter has been BPA's failure to adequately fund the Fish and Wildlife Program's Phased Approach to reintroduction, even though it began conducting its own internal process to look into reintroduction as far back as 2014, including attempts to have an outside contractor perform a project for BP A away from the public's review. 3 Further, documents received in response to a recent FOIA request sent to BOR include undated talking points for BOR that state the following: Upstream volitional passage through conventional fish ladders is technically feasible, but would be enormously expensive and probably very difficult to justify. On the other hand, a trap and haul operation that captures adults below Chief Joe and trucks them somewhere above Grand Coulee would be much more affordable and effective. Probably the most costly and technologically challenging issue is providing safe downstfeam passage of smolts through the two dams. Its never been attempted on facilities even half the size of Grand Coulee Dam. Its also not known if a smolt swimming down the upper Columbia River could find its way through the hundred mile long Lake Roosevelt and even get to Grand Coulee Dam. I think those are the kinds of thing we have to put some study into before anybody commits to implementing reintroduction. We have to remain open to possible low tech and low cost solutions as well. Its doubtful reintroduction could ever successfully restore populations to near pre-dam levels. But if we could figure out a low cost low tech solution that achieved even a small fraction of historic run sizes, and didn't threaten the current benefits these facilities produce for the region, then maybe we can all find a happy median.4 Unfortunately, the Agencies have clearly considered reintroducing salmon and steelhead above CJD and GCD outside of the public's view, but have decided to ignore all of the public information developed by the Agencies and others in the Region on reintroducing salmon and steelhead above CJD and GCD pursuant to the 2014 Fish and Wildlife Program. If not corrected, a flawed Record of Decision will be approved and serve as an operations manual for the next 25 years for the CRS. In general, the Agencies' stated the following in regards to ignoring the Tribe's repeated requests to ensure that reintroduction is included in an alternative and/or as mitigation. The excuse being articulated by the Agencies is this statement: Reintroduction of salmon above Grand Coulee Dam and installation of fish passage at Grand Coulee and Chief Joseph Dams is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not currently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. DEIS, Executive Summary at 13-14. This statement and others is not an excuse based on the current available information, nor does it provide for the appropriate level of consideration of the Fish and Wildlife Program. Sadly, this single sentence is the most problematic: "Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary." It is the most problematic statement because consideration of the reintroduction of salmon and steelhead above CJD and GCD has occurred and is ongoing via the Fish and Wildlife Program and implementation of it. The Program is developed through a robust process that includes ample amounts of statutorily prescribed involvement by all the entities listed in the Act, which are the same entities listed in the Agencies CRSO DEIS. Again just as in the 2014 Fish and Wildlife Program5, in 2019-2020 all of the same process was followed. The same Tribes, States, Federal Agencies, irrigators, power customers, transportation providers, commercial fishing interests, along with the general public provided their review and input, and again the Council adopted and stated the following in the 2020 Addendum to the 2014 Fish and Wildlife Program: Implementer: Bonneville and others Continue to make progress on the program's phased approach to evaluate the possibility of reintroducing anadromous fish above Grand Coulee and Chief Joseph dams. Continuing to assess the feasibility of reintroducing anadromous fish is one measure in the suite of mitigation measures recommended by the Spokane Tribe ofIndians (see previous measure). Continuing to make progress on this measure received substantial support in the amendment process from many governmental and non-governmental entities. 2020 Addendum at Page 5, Pre-Publication Version. It is impossible to square this direction from the Program, which the Agencies are required to be "taking into account at each relevant stage of decision making processes to the fullest extent practicable," with what is stated in the DEIS regarding their justification for failing to consider and include reestablishing salmon and steelhead above Chief Joseph and Grand Coulee Dams within an alternative and/or in the mitigation. See 16 U.S.C. Section 839b(h)(11). In short, the Region through the Congressionally designed public and transparent process has decided how the Region wants to handle the Agencies prior decisions to operate and manage CJD and GCD without fish passage facilities, but the Agencies simply have chosen to ignore this Congressionally sanctioned process. Unfortunately this is nothing new, the Agencies have done this for the past six - (6) years by failing to meaningfully fund Phase One of the 2014 Fish and Wildlife Program, and again by proposing that a new novel process is needed or required in this DEIS6, all the while ignoring the 2020 Fish and Wildlife Program Addendum. This appears to be designed, as a way for the Federal Agencies to impose their will on the Region, and this is not supported by the Congressionally mandated method for developing mitigation for impacts of the FCRPS, the Fish and Wildlife Program. See 16 USC 839b(h). In short, this is just an attempt to avoid the Region's decisions and instead pursue the federal government's goals for our Region and our	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				resources. Recommendation: Given that the impact of this DEIS claims to look 25 years into the future, 2020-2045, Agencies must include in their analysis consideration and impacts to planned and anticipated populations of salmon and steelhead in the areas above CJD and GCD. This should include an alternative that considers salmon and steelhead migration in and out of the areas above CJD and GCD.7 In addition, to measures that can benefit both ESA8 and non-listed anadromous species that previously occupied habitats above CJD and GCD.	
32263	6	ted@tcklaw.com	Spokane Tribe of Indians	Several Tribes, including the Spokane Tribe are currently conducting reintroduction efforts that include the release of adult salmon for ceremonial and educational purposes into the areas above GCD. The Spokane Tribe is also releasing tagged juvenile salmon above GCD.9 The Tribe exercising its regulatory authority over parts of the Columbia and Spokane Rivers, along with other tributaries within its Reservation approved these actions. The preferred alternative's direct and indirect effects on these activities was not analyzed in the DEIS. Recommendation: The Agencies should include an analysis of the preferred alternative's impacts on the current and ongoing reintroduction, and educational and cultural salmon releases conducted by the Tribes.	While changes to operations could affect any salmon that are released above Grand Coulee Dam for ceremonial or educational purposes, effects, if any, would likely be minor, but information is lacking that impedes an effects analysis. The Upper Columbia United Tribes Fish Passage and Reintroduction Phase 1 Report (https://ucut.org/habitat/fish-passage-and-reintroduction-phase-1-report/) found that the reintroduction of salmon to the U.S. portion of the upper Columbia River upstream of Chief Joseph Dam is likely to achieve identified tribal goals given (among other factors) "Current dam operations" and "Existing riverine and reservoir habitat conditions". The divergence from the current dam operations (as represented by the No Action Alternative) and the Preferred Alternative riverine and reservoir habitat conditions consists of minor changes in reservoir elevations, inflows, and outflows. These minor changes could affect released salmon. Effects to released sockeye salmon and summer/fall Chinook salmon in Lake Roosevelt and tributaries, as well as the transboundary reach of the Columbia River could be similar to effects for kokanee, as analyzed in the Draft EIS in Section 7.7.5.2 Region B. However, specific information regarding their habitat use such as spawning and rearing areas, migration timing, and use of reservoir habitats is not available; this impedes a meaningful effects analysis at this time.
32263	7	ted@tcklaw.com	Spokane Tribe of Indians	Environmental Consequences Chapter 3 fails to address the consequences to the Tribe's plans and polices to reintroduce salmon and steelhead to its waters and Reservation lands. The Environmental Consequences section must discuss and consider: "Possible conflicts between the proposed action and the objectives of Federal, regional, State, and local (and in the case of a reservation, Indian tribe) land use plans, policies and controls for the area concerned." 40 CFR Section 1502.16(c) As the Agencies are aware, the Spokane Tribe of Indians retains ownership to the beds and banks of the all of its Reservation boundary waters. This includes the bordering sections of the Columbia River, the Spokane River and Tshimikain Creek, along with numerous small tributaries within its borders. The Tribe retains significant regulatory authority over these water bodies that are within its Reservation. The following are highlights of that authority, but by no means a complete description. The Tribe was granted treatment as a state status under the Clean Water Act in 2002, and EPA approved its first water quality standards in 2003. The Tribe's water quality standards apply to sections of the area impacted by the federal agencies management of the CRS. Additionally, the Five Party Agreement states the following in regards to the Spokane Tribe's Reservation Zone of Lake Roosevelt: The Spokane Tribe shall manage, plan and regulate all activities, development, and uses that take place within that portion of the Reservation Zone within the Spokane Reservation in accordance with applicable provisions of federal and tribal law, and subject to the statutory authorities of Reclamation, and consistent with the provisions of this Agreement subject to Reclamation's right to make use of such areas of the Reservation Zone as required to carry out the purposes of the Columbia basin Project. Lake Roosevelt Cooperative Management Agreement, IV.(D)(3)(c). Important to the discussion here, the Tribe's adopted 2008 Integrated Resource Management Plan includes the following: "The long term goal is to restore anadromous salmon to those areas now blocked by Chief Joseph and Grand Coulee Dams."10 Finally, in pursuit of this goal, after review of the current scientific and policy information and in light of its regulatory authority, the Tribe, by Resolution 2018-422, granted permission and provided policy direction to its Department ofNatural Resources to implement salmon and steelhead reintroduction into the Tribe's waters. (Attachment 5). This action was further supported by the Tribe with its approval of the UCUT Phase One Report via Resolution 2019-206. (Attachment 6). In short, the Tribe is responsible for regulating a portion of the area impacted by the federal agencies management, and operation decisions contemplated in the DEIS. Accordingly, the Agencies are required to consider the Tribe's "plans, policies and controls for the area concerned."11 Recommendation: To address the potential impacts on these "plans, policies and controls for the area concerned" the Tribe urges the Agencies to develop an alternative that includes a measure that takes the required hard look at a future where one or more anadromous species are migrating in and out of the areas above CJD and GCD. The existing life cycle model and information discussed below, along with the information developed by the Columbia River Partnership Taskforce of the Marine Fisheries Advisory Committee12 can be used to support the Alternative's development. Furthermore, since the adoption of the Northwest Power and Conservation Council's 2014 Fish and Wildlife Program's Phased Approach to the reintroduction of anadromous fish into the blocked areas above Chief Joseph and Grand Coulee Dams, multiple entities in the Region completed the vast majority of Phase One of the Fish and Wildlife Program's reintroduction approach. This work includes the following documents, which are hereby incorporated by reference into the Administrative Record and can be utilized by the Agencies in developing the recommended alternative measures and mitigation. The Upper Columbia United Tribes -Phase One Report available at https: / ucut.org/wp-content/uploads/20 19/05/Fish-Passage-and-ReintroductionPhase-!- Report. pdf (Attachment 15) ISAB Review of the UCUT- Phase One Report available at https: /www.nwcouncil.org/reports/isab20 19-3 (Attachment 14) The following documents, which directly contribute to the Phase One Report, are all incorporated into the Administrative Record and available at https://ucut.org/habitat/fishpassage- and-reintroduction-phase-1-report/ Baldwin 2018 - Assessment of Sockeye Spawning Habitat in Sanpoil Baldwin and Bellgraph 2017- Above Chief Joseph Redd Capacity Tech Memo Bellgraph, B.J., C. Baldwin, L. Garavelli, Z. Haque, W. Perkins, M. Richmond, M. Howell, J. McLellan. In Review. 32263	8	ted@tcklaw.com	Spokane Tribe of Indians	Mitigation (a) The DEIS does not address the Agencies'.continued management and operation of GCD and CJD without providing for salmon and steelhead reestablishment into the habitats above those facilities As many regional FERC regulated entities have discovered through recent reintroduction efforts driven by their FERC hydropower license renewals, fish passage is possible at high head facilities with significant reservoir elevation fluctuations, and is clearly the most in-kind and in-place mitigation for impacts to salmon and steelhead caused by these dams.13 Furthermore, the BORis pursuing fish passage and reintroduction at Cle Blum Dam, which includes a reservoir that fluctuates "over 100 feet" depending on the season.14 (The Tribe incorporates into the Administrative Record by reference all documents, including video links contained in the footnotes). Finally, there are numerous other facilities throughout the Region that are discussed in more detail in the Council's Staff Paper, Review ofFish Passage Technologies at High-Head Dams. 15 Unfortunately, the Agencies in the DEIS decided not include or even discuss reestablishment of salmon and steelhead above GCD and CJD as appropriate mitigation. (1) The Agencies preferred alternative was chosen without considering operation and management CJD and GCD for the next 25-years with the inclusion of fish passage facilities to address those facilities impacts on extant and planned salmon and steelhead populations. The DEIS mitigation section identifies "inkind and in-place mitigation to address impacted resources at the location of impact" as the most preferable option of mitigation when impacts cannot be avoided. However, even with this being the preferred type of mitigation the Agencies ignored their operations and management impact. (2) The Tribe has documented Redband trout populations below GCD and CJD. A portion ofthe Redbandjuveniles begin their lives above GCD, go through smoltification, and make their way to the Pacific. 16 This directly challenges the Agencies statement that "[t]he co-lead agencies are not proposing any mitigation measures in Regions A orB (upstream of Chief Joseph) for impacts to anadromous fish because there are no anadromous fish above Chief Joseph Dam." DEIS 5.4.1 .2. Currently, those wild steelhead (Redband) have no passage back to the Tribe's Reservation, such as truck and haul facilities used elsewhere in the CRS. This does not mean, "there are no anadromous fish," it means the Agencies are choosing to manage CJD and GCD as if there are no anadromous fish. Recommendation: Agencies must consider and analyze fish passage and reestablishment at CJD and GCD as a mitigation measure in the CRSO DEIS. This is necessary to address the historic blockage, but also the current impacts to the Tribe's current reintroduction efforts within their Reservation and its waters, and to the current Redband trout populations above GCD.	Please see response to Comment 32263-5.
32263	9	ted@tcklaw.com	Spokane Tribe of Indians	Lake Roosevelt "Fall Flex" The preferred alternative includes changes in Lake Roosevelt's elevation targets in the fall. This particular operation was a contentious issue addressed in the development of the Fish and Wildlife Program's 2020 Addendum. The situation is best described in the Findings on Recommendations and Responses to Comments for the 2020 Addendum to the 2014 Fish and Wildlife Program ("Findings"). The discussions and correspondence around Fall Flex are accurately described in the Findings: The Spokane Tribe of Indians recommended that the existing program language regarding operations at Grand Coulee Dam remain in the program and be implemented. In an exchange of comments on the recommendations, Bonneville and the Spokane Tribe of Indians and the Confederated Tribes of the Colville Reservation differed over whether conditions were ripe for the program to call for a more flexible approach to fall operations at Grand Coulee Dam, permitting the operators to manage Lake Roosevelt to a minimum elevation of 1,283 feet by the end of October rather than the end of September. After discussions, Bonneville, the Spokane Tribe of Indians and the Colville Tribes asked the Council not to address this issue in the Addendum, effectively retaining the language on Grand	The operational measure discussed in this comment pertains to fall reservoir elevations at Lake Roosevelt. Another measure for flood risk management also affects Lake Roosevelt reservoir elevations in the spring. Given the potential resident fish habitat impacts from reservoir elevation changes associated with this operation, the agencies proposed a mitigation measure intended to augment spawning habitat to offset expected impacts. The co-lead agencies evaluated the impacts and based on their expertise, proposed the addition of gravel to augment spawning habitat. Based on the results of ongoing and future studies of the impact of this operation, the agencies may adapt the mitigation action, as appropriate, in coordination with the fish and wildlife managers. This approach tracks with statements in the Northwest Power and Conservation Councils Findings to its 2020 Program Addendum suggesting need for further evaluation and discussions with fish managers relating to Lake Roosevelt refill timing. The comment notes that this issue has been considered in the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program and that the Council did not make a specific proposal in its recent addendum, leaving prior Program guidance on this issue in place at the request of Bonneville, the Spokane Tribe, and the Colville Tribe. Relevant guidance from past Council Programs dates back to the 2003 Mainstem Amendments and included guidance for Grand Coulee operations to attempt to refill Lake Roosevelt to 1283 feet in August. Subsequent biological opinions impacted the ability to refill by the end of August, so this elevation was moved to later in the season. Given the aspirational language in the Mainstem amendments and the fact that subsequent changes to the target refill date were driven by other factors other than the Councils Program, the co-lead agencies disagree that the Council Program can dictate whether or not it is permissible

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Coulee Dam operations in the 2014 Program. Any proposal to shift the fall operation needs further evaluation, information generation, and discussions between the project operators and the fish managers before proceeding.17 The Agencies included the elevation change in the Preferred Alternative with very specific mitigation that is not anchored to the above-described path. Instead the Agencies developed their own mitigation proposals with no input from the Tribe(s): The co-lead agencies propose to place appropriate gravel spawning habitat at locations up to 1 00-acres along the reservoir and tributaries. Prior to placement, the co-lead agencies would conduct site surveys post operations of an alternative to determine where to site spawning habitat at Lake Roosevelt for burbot, kokanee, and redband rainbow trout. DEIS at 5-17. This Agency chosen mitigation is further described in the Preferred Alternative chapter as: Increased flexibility of refilling Lake Roosevelt that may occur through the month of October, depending on the annual water conditions, may impact the spawning success of kokanee, burbot and redband rainbow trout. In 2019, Bonneville funded year one of a 3-year study to determine if modifications in Lake Roosevelt refill would impact resident fish access to spawning habitat. If the results indicate that resident fish spawning habitat is impacted by the operation, the co-lead agencies would supplement spawning habitat at locations along reservoir and tributaries (up to 100 acres). DEIS at 7-44, 7-45. A three-year study was funded in 2019 to address this specific change in operations. The three-year Lake Roosevelt "fall flex" study was funded in September of2019 after continuous pressure from the Spokane Tribe to investigate the potential tributary habitat loss as a result of delayed refill. BP A had been considering the use of Lake Roosevelt "fall flex" outside of the CRSO process for a number of years, and the funding for the investigation went to the Spokane Tribe, the agency to conduct the field work and data analyses, with no stated connection to the CRSO. The work was funded immediately before the fieldwork began. Therefore, the initial study was designed quickly and only examined Blue Creek. More importantly, while the study is being conducted, the Agencies have now predetermined the mitigation for "up to 100 acres" when the impacts are not understood. The findings from this preliminary study have not been submitted and as such the 1 00-acre nuniber is almost certainly arbitrary. Furthermore, one-time mitigation of 100 acres of gravel along shorelines and in drawdowns will not mitigate for the loss of habitat due to the fall drawdown. Eroding sand from wave action will cover mitigation gravels over time. And there are many other impacts (temperature increases, no pools, no complexity, no large woody debris, and visual exposure offish to predators due to no riparian channel cover, etc.) that will not be mitigated for by adding gravels. One could also argue that adding gravels in drawdowns would reduce in-stream flows and decrease available habitat by increasing hyporheic flows with gravel addition. Recommendation: Remove the predetermined mitigation and instead state that the mitigation will be developed in accordance with study outcomes in collaboration with fish and wildlife managers of Lake Roosevelt. Clearly state that if the fish and wildlife managers along with the Agencies cannot agree upon appropriate mitigation Fall Flex will not be implemented. Additionally, future mitigation must include operations that have adaptive management principles at 3-year intervals to ensure Redband trout populations do not incur negative impacts that are left unaddressed. Importantly, the DEIS identifies "habitat and spawning success effects from the earlier draft of Lake Roosevelt in above average water years" including "minor to moderate effects from increased stranding of kokanee and bur bot eggs and potential increased spawning habitat access issues for Redband rainbow trout" (Chapter 7, Lines 3703-3706). Investigation into tributary habitat losses in the fall may be ill-suited to address mitigation needs in the winter when the drawdown begins. This should be considered in any future studies on the preferred alternative.	to implement operations that result in variations to the Lake Roosevelt refill timing. However, the co-lead agencies remain willing to work with fish and wildlife managers to determine appropriate mitigation of impacts identified through studies if or when the operation occurs. Relevant mitigation guidance in the Councils Program would inform this discussion, and would be more in line with the Programs statutory role that is, to guide fish and wildlife mitigation for system operations, not to prescribe the operations themselves.
32263	10	ted@tcklaw.com	Spokane Tribe of Indians	Spokane Arm of Lake Roosevelt Dissolved Oxygen impairment The Mitigation Chapter and the Preferred Alternative chapters fail to address mitigation measures to address the dissolved oxygen impairments that can occur in the Spokane Arm of Lake Roosevelt during certain time periods. The preferred alternative will continue to impact the this portion of Lake Roosevelt that is subject to the Tribe's EPA approved water quality standards and the Tribe expects the Agencies to provide appropriate mitigation for this impact. The issue of dissolved oxygen impairments within the Spokane Arm was raised during the development of the Spokane River DO TMDL. At that time EPA blamed this impairment on the current management and operation of GCD: Scenario #4 predicts that SOD is the most important factor affecting DO in the Spokane Arm (Figure 78). When SOD is reduced by 50%, DO levels in the deeper portions of the Arm increase to above 3 mg/L, and anoxic conditions are eliminated. While conditions are improved, they still do not achieve the 8 mg/1 riverine standard. The elevated SOD in the Spokane Arm is a legacy of the accumulation of oxygen-demanding pollutants in sediment. Sediment accumulation is, in tum, caused by the hydrologic regime created by Grand Coulee dam. These results indicates that improving SOD is critical to improving water quality, and that assumptions about SOD will have a significant impact on the estimation of "natural conditions" within the Arm.18 Recommendation: The Agencies should develop mitigation to address the Sediment Oxygen Demand ("SOD") impact that the Agencies' preferred alternative will continue to have on the water quality of the Spokane Arm.	The co-lead agencies agree that dissolved oxygen (DO) impairment in the Spokane Arm occurs in the No Action Alternative. In two alternatives, MO2 and MO4, in only the driest years and for short periods, there were indications in the model results that the DO impairment in the Spokane Arm could impact more of the water column. The Preferred Alternative water quality analysis does not demonstrate an increase in DO impairment in comparison to the No Action Alternative.
32263	11	ted@tcklaw.com	Spokane Tribe of Indians	Mercury There is considerable risk of increased mercury methylation in the reservoir due to the extended drawdown period and between-year water level fluctuations, which could result in higher human health risk than characterized by the current fish advisory. This risk is acknowledged in the DEIS, yet dismissed as comparable to the NAA for the Preferred Alternative given that 'changes in reservoir elevation are small' (Chapter 7, Lines 2115-2116). Literature on the nature of mercury methylation in reservoirs (e.g., Willacker et al. 2016, cited in the DEIS) suggests that increased duration of sediment exposure as well as increased variability of between-year reservoir elevations can also be a significant factor in the process. The increased drawdown duration is influenced by measures present in the Preferred Alternative including the reduced drafting rate and Lake Roosevelt 'Fall Flex' . Recommendation: No mercury mitigation is included in the DEIS. The Agencies must adequately fund regular fish tissue monitoring and commit to additional mitigation in the event of increasing mercury concentrations. The Spokane Tribal water quality standards are based on a fish consumption rate of 865 grams per day; relatively small changes in fish tissue mercury concentrations can further reduce the capacity of Tribe's membership to pursue traditional practices. Potential mercury impacts were identified as impacts of not only Fall Flex measure, but additionally the Lake Roosevelt Additional Water Supply Measure.	The co-lead agencies agree that there is an increased risk of mercury methylation in the reservoir due to the increase in water level fluctuations in some of the alternatives. The analysis relied on the modeled reservoir water elevations compared to the No Action Alternative and was determined to be a small increase in the risk associated with the water surface elevation changes. The Planned Draft Rate at Grand Coulee measure only impacts the duration of exposed sediments in the wettest years; and the Fall Operational Flexibility for Hydropower (Grand Coulee) measure results in minor elevation changes for a short duration in some years, mostly likely in the driest years. The Lake Roosevelt Additional Water Supply measure allows for additional water withdrawals, in comparison to the No Action Alternative, from Lake Roosevelt that reduce flows downstream of Grand Coulee but does not impact Lake Roosevelt pool elevations.
32263	12	ted@tcklaw.com	Spokane Tribe of Indians	Northern Pike The preferred alternative predicts that Northern Pike would "continue to invade downstream" and that there would be a "minor decrease in the ability for boat-based Northern Pike suppression" (Chapter 7, Lines 3714-3715). The Alternative then fails to provide any mitigation to address this impact. Recommendation: The Agencies must address and add mitigation to ensure this impact is fully mitigated given its threat to the entire Columbia River.	The co-lead agencies recognize the ongoing threat of downstream invasion of northern pike under the No Action Alternative and there would be a minor decrease in boat suppression efforts under the Preferred Alternative. The analyses showed there would be a minor effect (up to one week of boat ramp access impeded) in wet years only, and the resulting overall effect to the invasion of northern pike would be minor. The co-lead agencies recognize and appreciate the importance of northern pike invasion as a regional issue, but, in this EIS process, the co-lead agencies developed mitigation for moderate to major effects of the multiple purpose alternatives as compared to the No Action Alternative. Because the impact to northern pike was minor, mitigation was not appropriate for this effect.
32263	13	ted@tcklaw.com	Spokane Tribe of Indians	Mitigation Generally in the Areas above Grand Coulee Dam As stated above the Agencies are required to exercise their authorities in managing the CRS consistently with the purposes of the Northwest Power Act, consider to the fullest extent practicable the Fish and Wildlife Program during every step of the their decision making, and are required to consult with the Tribe(s) and attempt to coordinate their actions "to the greatest extent practicable." See 16 U.S.C. Section 839b(11)(A). Here, thus far the Tribe's requests that the Agencies provide appropriate mitigation consistent with the Fish and Wildlife Program have fallen on deaf ears. Beyond the previously discussed requests by the Tribe to include salmon and steelhead reintroduction within the DEIS (Alternative and Mitigation), the Agencies have completely failed to act consistently with or follow the guidance of the Council's 2020 Addendum to the Fish and Wildlife Program directing an increase in mitigation to the areas above GCD. The 2020 Addendum states the following: Implementer: Bonneville Implement a broad suite of actions to mitigate for the complete loss of anadromous fish and the losses to other fish and wildlife species in the Lake Roosevelt and Spokane River areas above Grand Coulee and Chief Joseph dams, as well as ongoing operational impacts. Increase significantly the level of mitigation for these losses without compromising the substantive protection and mitigation activities elsewhere in the basin. 2020 Addendum, at 4. 19 The Agencies in the preferred alternative explain that there will be increased impacts to the areas above GCD, but only propose two new measures. (1) Related to the Inchelium-Gifford Ferry, and (2) the other related to proposed changes in the hydropower operations within Lake Roosevelt in the Fall Flex section (discussed above "up to 100 acres"). Beyond that all other impacts are left unmitigated, and the above-section of the Fish and Wildlife Program 2020 Addendum is not considered at all by the Agencies in their decision-making process. Recommendation: The Agencies should expand and include significant new mitigation for the continuing and the proposed new impacts of the preferred alternative within the areas above Grand Coulee Dam as directed by the Fish and Wildlife Program.	The co-lead agencies are aware of their Northwest Power Act section 4(h)(11)(A)(ii) duty to take the Northwest Power and Conservation Councils (Council) program into account to the greatest extent practicable in their decision making on issues related to Columbia River System (CRS) operations and management. This is distinct from section 4(h)(10)(A) that applies only to Bonneville's responsibility to mitigate fish and wildlife affected by the CRS in a manner consistent with the Councils program. 16 U.S.C. 839b(h)(10)(A). The comments recommendation appears to apply the latter standard to all three co-lead agencies when section 4(h)(10)(A) of the statute applies to Bonneville only. Please also see Section 5.1.2 in the Draft EIS. The comment also contends that the co-lead agencies have not consulted or coordinated with state and tribal fisheries managers as required by section 4(h)(11)(A) of the Act. State and tribal fisheries managers were either consulted as cooperating agencies under the EIS or as part of the three-tiered government-to-government consultation process established for this EIS. The comment further asserts that the co-lead agencies are responsible for mitigating the complete loss of anadromous fish and the losses to other fish and wildlife species in the Lake Roosevelt and Spokane River areas above Grand Coulee and Chief Joseph dams. The co-lead agencies understand the nature and extent of the adverse effects arising from the development and operation of these two dams. The comment, however, overstates those impacts at least with respect to Grand Coulee Dam effects on Spokane River fish and wildlife. There are seven dams on the Spokane River, from Post Falls Dam at the outlet from Lake Coeur d'Alene to Little Falls Dam. Non-Federal entities built these dams between 1890 and 1922, and none of these dams have fish-passage facilities. Little Falls Dam, completed in 1911 at river mile 29, stopped the fish from returning farther upstream.1/ In addition to these dams, the Spokane Tribe recently co-authored a report that said, [u]pper Columbia River salmon runs were largely depleted in the 1880s and 1890s by commercial fisheries and the advent of salmon canning in the lower Columbia.2/ The historical development of hydropower on the Spokane River and the legacy impacts of commercial fishing in the late 19th-century indicate that Grand Coulee Dam is not the sole cause of the complete loss of anadromous fish and other species of fish and wildlife in the Spokane River area. Therefore, this comment, and the provision of the Northwest Power and Conservation Councils 2020 Addendum it cites, are not wholly accurate and do not offer appropriate guidance to the co-lead agencies. Finally, the comment argues that the Agencies should expand and include significant new mitigation for the continuing and the proposed new impacts of the Preferred Alternative within the areas above Grand Coulee Dam as directed by the Fish and Wildlife Program. Bonneville has funded a significant amount of mitigation in the Upper Columbia River Basin, consistent with past and current Northwest Power and Conservation Council Fish and Wildlife programs. Recent examples include hatchery construction and improvement actions for Chinook, sturgeon, burbot, and trout; habitat restoration actions mitigating operational impacts; and new resident fish mitigation protecting thousands of acres in Montana, including extensive trout habitat that also provides significant wildlife benefits. In the 2020 addendum, the Council based its recommendation for additional mitigation in the Upper Columbia on an incomplete record that did not include all of the work currently underway or completed.3/ A complete tally would show Bonneville alone is currently funding three dozen projects to address Chief Joseph and Grand Coulee impacts.4/ Moreover, the Agencies note that reporting on www.cbfish.org, CB Fish, shows the area above Chief Joseph Dam, the Intermountain Province, falls mid-way at the mean annual funding level of the 11 provinces described by the Council and used for mitigation tracking. 5/ In their recommendation, the Council also failed to acknowledge the significant Federal Columbia River Power System (FCRPS) operations performed routinely to protect fish affected by Chief Joseph and Grand Coulee. These mitigation efforts comply with applicable statutory mandates. Indeed, this level of effort comports with the Councils longstanding general policy, consistent with the intent of Section 2(6) of the Act, in which the Council has directed most of its habitat restoration funds for anadromous fish below blocked areas.6/ 1/ Council website, History of the Columbia River Basin, Spokane River https://www.nwcouncil.org/reports/columbia-river-history/spokaneriver 2/ Columbia River Basin Tribes and First Nations, PASSAGE AND REINTRODUCTION INTO THE U.S. AND CANADIAN UPPER COLUMBIA BASIN at 32 (2015) (citing (Scholz et al. 1985)). 3/ Council, 2020 FINDINGS at 81.

32263	14	ted@tcklaw.com	Spokane Tribe of Indians	Bald Eagle Nest and Roosting Site Loss The Tribe has lost numerous Bald Eagle nests and roosting sites along Lake Roosevelt and the Spokane Arm due to erosion undermining tree root structure causing downed trees. The DEIS fails to address this impact to the Tribe's resources caused by the operations and maintenance at GCD. Recommendation: Agencies should develop appropriate mitigation for this unaddressed impact.	Section 3.6. (Vegetation, Wetlands, Wildlife, and Floodplains) described minor or negligible impacts to habitat and wildlife for Lake Roosevelt in Region B from the alternatives. Effects to eagles were addressed in Section 3.6 and 7.7.8 in sensitive species. In addition, the River Mechanics Section 3.3 indicated negligible change in shoreline exposure for Lake Roosevelt for all alternatives, including the Preferred Alternative, compared to the No Action Alternative. The co-lead agencies did not propose mitigation measures for minor or negligible impacts.
32263	15	ted@tcklaw.com	Spokane Tribe of Indians	Spokane Arm Wildlife Impacts Caused by Ice Formation The Tribe's wildlife resources are impacted by the formation of ice within the Spokane Arm that historically did not occur. Numerous deer, moose and elk are lost on the ice each year. The ice formation is a direct impact caused by the operations at GCD. Recommendation: The Agencies should develop appropriate mitigation for this unaddressed impact.	Section 3.6 and 7.7.7 (Vegetation, Wetlands, Wildlife, and Floodplains) described only minor or negligible impacts to habitat and wildlife for Lake Roosevelt in Region B from the Preferred Alternative and the other alternatives. Under the Preferred Alternative, the River Mechanics Section 7.7.2 described a negligible (~0.1 feet) change to shoreline exposure at Grand Coulee and the Cultural Resources Section 7.7.18 found no change to shoreline erosion at Grand Coulee, both relative to the No Action Alternative. The No Action Alternative discusses the elk falling through the ice on Lake Roosevelt (Section 3.6.3) and that effect is carried forward through each alternative as the impact does not change for any alternative. The co-lead agencies did not propose mitigation measures for minor or negligible impacts.
32263	16	ted@tcklaw.com	Spokane Tribe of Indians	Landslides Landslides on the Tribe's Reservation are directly caused by Reservoir operations. They cause significant loss to the Tribe's Reservation Land base and pose threats to human safety. Additionally, they cause impacts to the Tribe's cultural resources, environmental impacts and economic impacts. Unfortunately, no mitigation is proposed to address the landslides that occur due to the operations at GCD. Recommendation: The Agencies should develop appropriate mitigation for this unaddressed impact.	The co-lead agencies analyzed potential erosion resulting upstream from Grand Coulee operations. The analysis shows that shoreline slope stability should improve as a result of decreasing reservoir draft rates. In light of that improvement over conditions under the No Action Alternative, the co-lead agencies have not proposed mitigation.
32263	17	ted@tcklaw.com	Spokane Tribe of Indians	Cumulative Effects The "Reasonably Foreseeable Future Actions and Trends" ("RFF A") section fails to identify several actions. Fails to Identify (a) The current and future reintroduction of salmon and steelhead into the habitats above CJD and GCD; (b) Fails to identify the Proposed Banks Lake Storage Project. (FERC License 14329) and the future LOPP process.20 Recommendation: The Agencies should review and expand the RFF As considered in the EIS to include the above.	Reintroduction of salmon and steelhead into habitats above Chief Joseph Dam and Grand Coulee Dam are not currently part of a proposal or plan (with current funding/budget) and are therefore not considered a reasonably foreseeable future action. To meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available. The co-lead agencies recognize there is a proposed pumped storage project at Banks Lake. Too many uncertainties surround the potential operation and design of the proposed project, however, to analyze cumulative effects in a way that informs the co-lead agencies' decision making.
32263	18	ted@tcklaw.com	Spokane Tribe of Indians	Lake Roosevelt Additional Water Supply Measure The need for the additional45,000 acre-feet ofwater supply is not explained, nor are the potential impacts to the Spokane Tribe's revenue payments21 caused by this additional withdrawal analyzed or addressed. Finally, as discussed above, how this additional pumping will interact with the new proposed Banks Lake Project described in Footnote 19 is not discussed or analyzed. Recommendation: The Agencies should analyze the additional pumping's impacts on revenue payments and the impacts of the new proposed Banks Lake Project.	This operational measure was included in MO1, MO3, and MO4 where an additional 1.15 million acre-feet could be pumped from Lake Roosevelt at Grand Coulee above what was provided in the No Action. This measure was updated for the Preferred Alternative to pump up to 45,000 acre-feet of water above the No Action Alternative due to the uncertainty over the timing and extent of the development of new water supply projects for the full volume. Additionally, this measure would change the timing of delivery of recently developed water supplies for the Odessa Subarea of the Columbia Basin Project (164,000 acre-feet for irrigation and 15,000 acre-feet for municipal and industrial (M&I) of the current supplies) from September and October to when the water is needed, on demand. The 45,000 acre-feet water supports near-term additional development of authorized project acres. Water pumped from Lake Roosevelt would be delivered as the demand arises during the irrigation season (March to October). In Section 7.7.9.7, the EIS states that "The Confederated Tribes of the Colville Reservation and the Spokane Tribe of Indians (likely starting in 2021) receive annual payments from Bonneville as compensation for tribal lands inundated by Lake Roosevelt. The payment is based on annual average generation produced at Grand Coulee Dam as well as the power used to pump water to Banks Lake for irrigation. Based on the combination of changes in generation (reduced), at Grand Coulee, and market prices of power, the Preferred Alternative results in upward payment pressure of about 1 percent relative to the No Action Alternative."
32263	19	ted@tcklaw.com	Spokane Tribe of Indians	Climate Change The DEIS focuses on climate impacts up to the year 2050. This timeframe fails to properly address climate change's impact on the Region. It allows the Agencies to avoid considering the most significant impacts that will occur after the 2070s, which is the time:frame utilized in most modeling and many of the Agencies reports and documents.22 This is important given that the winter of2014-2015 was similar to what the models predict an average winter in 2070 will be.23 That year included numerous and significant problems throughout the Region's ecosystem and economy. The Agencies chose a socioeconomic analysis timeframe of 50 years, given that the climate models tend to agree on climate impacts in the 2070s and 2080s utilizing the shorter timeframe of 2050 for climate change overlooks and avoids the significant impacts that will occur in the Columbia River caused by rising temperatures. Recommendation: The Agencies should use the year 2070 at a minimum for their analysis of the impacts of climate change. The climate change analysis should match the 50-year timeframe for socioeconomic impacts.	The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally high air and water temperatures result in water quality standard exceedences and are beyond the ability of the CRS to cool; climate change will stress the system even further. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). An adaptive management plan has been developed for this EIS that captures potential actions that could be employed during drought or lower water years to prevent fish mortality. This information can be found in Appendix O.
32263	20	ted@tcklaw.com	Spokane Tribe of Indians	Several of the UCUT Tribes have engaged as cooperating agencies in the analysis necessary for the Draft EIS, and we are writing to urgently request that you extend the public review and comment deadline for the CRSO Draft Environmental Impact Statement that was released on February 28, 2020 with a 45-day comment period. The 45-day deadline has become impossible for our member Tribes to meet given the outbreak of COVID-19. Each of the UCUT Tribes' governments have restrictions on staff and are under partial shutdowns to do their part to help flatten the curve and control the spread of the virus. Just as the federal government has limited work within your agencies and shifted focus to this National Emergency, the UCUT Tribes too are managing this crisis while needing to keep their government's operational to meet their citizens' basic needs. Ultimately, the constraints from this unexpected National Emergency must be considered and the comment period must be extended. A 120-day period was allowed for the preliminary scoping step for the CRSO EIS. Also, a comment period of 120 days or more would be consistent with the sworn statements from your agencies to the Court in NWF v. NMFS, No. 01-640-SI (D. Or.). As you are well aware, each of our member Tribes has trust and/or treaty resources that will be impacted by the federal decisions made within the preferred alternative and eventual Record of Decision . It is well within your federal trust responsibility owed to the Tribes to extend the arbitrary deadline. With limited staff during this pandemic our member Tribes are simply unable to meaningfully review and comment by the 45-day deadline. Therefore, we request that you extend the comment period to 120-days or more to allow for meaningful involvement for our member Tribes during this time of crisis.	See response to Comment 32263-1.
32264	1	Donald Michel	Upper Columbia United Tribes	With this letter, UCUT insists that the co-lead agencies include and fully evaluate fish passage and reintroduction above Chief Joseph and Grand Coulee dams as a measure within the preferred alternative and calls for the agencies to engage the UCUT Tribes on the issues of managing invasive species and protecting cultural resources of the Tribes, both of which are likely to be exacerbated by the proposed operational changes in the preferred alternative of the DEIS. The upper Columbia River continues to be the most impacted and least mitigated area in the Columbia River Basin. The UCUT Tribes feel strongly that one of the principal purposes of the CRSO EIS must be to ensure that adverse environmental and cultural effects of the Columbia River System are equitably addressed across the Columbia River Basin. This long-standing inequity has resulted in and continues to cause disproportionate harm to the federally protected rights and resources of the UCUT Tribes. The February 2020 DE IS maintains this inequity by providing significant consideration of the breaching of the lower Snake River dams and focusing a vast majority of the new measures in the preferred alternative on improvements to projects in the lower Columbia River and Snake River while rejecting or ignoring a majority of the recommendations by the UCUT Tribes, particularly that of fish passage and reintroduction above Chief Joseph and Grand Coulee dams. After receiving early input from the UCUT Tribes that the EIS Purpose and Need statement needed to include both the expansion of equitable mitigation throughout the Columbia River Basin and the priority of restoring river and habitat connectivity, the DEIS continues to provide the region an inequitable and inadequate implementation plan that rejects the need for restoring connectivity where it has been lost in the upper Columbia. The co-lead agencies must give the Columbia River System's impacts in the upper Columbia River the same level of consideration and analysis as the salmon-specific issues of Judge Simon's order. The colead agencies must consider the comments of the UCUT Tribes within this letter to begin to address equitable mitigation.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
32264	2	Donald Michel	Upper Columbia United Tribes	Finally, the UCUT Tribes would like to express their displeasure in the exceptionally brief public comment period and the agencies' reluctance to support an extension in the face of a National Emergei"!CY and an international pandemic. Attachment 21 is the extension request letter submitted by UCUT on March 20, 2020. Each of the five UCUT Tribes have been on a partial shutdown since mid-March and will continue to be operating in this limited capacity for the foreseeable future, which has made a thorough and thoughtful review of the 8,000+ page DE IS impossible. In his 2016 opinion ordering the co-lead agencies to prepare an EIS, Judge Simon stated that, "the purpose of a single EIS is so that the Action Agencies, the public, and public officials can take a hard look at the programmatic plan to offset adverse effects of the FCRPS and consider the reasonable alternatives." To achieve that purpose, the National Environmental Policy Act requires meaningful public involvement in agency decision-making, which the co-lead agencies neglected for the public comment portion of the NEPA process.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32264	3	Donald Michel	Upper Columbia United Tribes	The UCUT Tribes once relied on abundant salmon, steelhead, and lamprey for sustenance until the construction of Grand Coulee Dam, which blocked passage of an estimated annual migration of three-million fish in 1939. Examining and including salmon reintroduction above Grand Coulee and Chief Joseph dams in the preferred alternative would clearly address Judge Simon's order of examining a new approach beyond another habitat restoration effort. Plus, failure to provide fish passage at Grand Coulee and Chief Joseph dams continues to deprive the UCUT Tribes of their First Foods and the upper Columbia region of the once abundant anadromous fish that were cornerstones of the Tribe's culture and sustenance. The consideration and inclusion of salmon reintroduction above Chief Joseph and Grand Coulee dams within the EIS is a requirement to meet the mandates of the National Environmental Policy Act and the Northwest Power Act. The Upper Columbia United Tribes have provided extensive comment and pertinent information on this issue to the co-lead agencies throughout the CRSO EIS process, yet the co-lead agencies chose to ignore our requests and instead noted this as an "area of controversy" to be dealt with in another forum. The UCUT Tribes have continually received this message from federal agencies who insist that the feasibility of reintroduction above Grand Coulee and Chief Joseph dams should be determined within various regional processes such as the Columbia River Treaty, the Northwest Power and Conservation Council's Fish and Wildlife Program, the Bonneville Power Administration's implementation of the Fish and Wildlife Program, and the CRSO EIS. No agency has taken responsibility for analyzing this issue, and the UCUT Tribes persist in this effort despite the illegal, unfair, and unethical abdication of the trust responsibility to the Tribes. Moreover, the fact that an issue is controversial is not a valid reason to exclude it from the co-lead agencies' NEPA analysis. The very function of an EIS is to involve the public in decision-making, and that principle applies with equal force to the issue of fish passage and reintroduction in the upper Columbia basin. The final CRSO EIS must include a measure within the preferred alternative for fish passage and reintroduction above Grand Coulee and Chief Joseph dams. The UCUT Tribes have long endured inequitable treatment by the federal agencies mandated to protect, preserve, and enhance fish and wildlife resources and sovereign Tribal Treaty and Executive Order rights. Our region continues to be the most impacted by the Columbia River System and least mitigated. The Purpose and Need Statement of the DE IS states that the colead agencies must: Comply with environmental laws and regulations and all other applicable federal statutory and regulatory requirements, including those specifically addressing the System such as requirements under the Northwest Power Act "to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated." 16 U.S. C. A. 839b{11}{A). The co-lead agencies cannot continue to avoid the Northwest Power Act's purpose, plus the federal government's trust responsibility to the UCUT Tribes requires that the federal agencies meaningfully consider the UCUT Tribes' interests. To follow the mandate required under the Northwest Power Act and to meaningfully consider the Tribes' interests, the CRSO EIS must include detailed analysis and consideration of salmon and steel head reintroduction to the habitats upstream of Grand Coulee and Chief Joseph dams. The Northwest Power and Conservation Council's 2014 Columbia River Basin Fish and Wildlife Program (Attachment 14), the 2020 Addendum (Attachment 15), and the 20011ntermountain Subbasin Plan (Attachment 17) all include science-based steps to determine the feasibility of reintroduction and fish passage above Chief Joseph and Grand Coulee dams. This has also been analyzed in intrinsic potential work done by NOAA in 2007, and BPA in 2014 and 2017 with NOAA's assistance. Following the science-based phased approach in the 2014 Fish and Wildlife Program, the UCUT Tribes completed donor stock, risk, and habitat assessments; reviewed fish passage technologies; and produced a life cycle model. This resulted in the UCUT Phase I Report (Attachment 1), which helped the UCUT Tribes and the region better understand the capacity for salmon production in the upper Columbia, appropriate donor stocks, disease risks and their management, available fish passage technology for both adults and juveniles, and, most importantly, that restoring these habitat areas will deliver cultural and economic benefits for all. This report was distributed widely and was subject to a thorough and favorable science review by the Independent Scientific Advisory Board (Attachment 2). Regardless, the co-lead agencies persist in the notion that reintroduction is a fringe concept not worthy of inclusion in any of the CRSO EIS alternatives. The Northwest Power and Conservation Council, in its legal findings (Attachment 16) for the 2020 Addendum to the 2014 Columbia River Basin Fish and Wildlife Program states that: "Salmon and other fish and wildlife losses in the area above Grand Coulee due to the development of Grand Coulee and Chief Joseph dams- and the ongoing effects of operating Grand Coulee – are as great or greater than anywhere in the Basin. 11 And while extensive mitigation is occurring elsewhere throughout the Basin, "the breadth and scale of mitigation being implemented [in the upper Columbia region] is not comparable. 11 The 2020 Addendum (Attachment 15) to the 2014 Columbia River Basin Fish and Wildlife Program calls on Bonneville and others to continue to make progress on the program's science based, phased approach to evaluating the possibility of reintroducing anadromous fish above Grand Coulee and Chief Joseph dams, a measure and priority that continues to receive substantial support in the program amendment process from many governmental and nongovernmental entities. The 2020 Addendum emphasizes that the Bonneville-funded hydrosystem mitigation program under the Northwest Power Act has a significant role for reintroduction, and the authority for that role. However, rather than follow the mandate of the Northwest Power Act and the guidance of the Northwest Power and Conservation Council, the co-lead agencies chose to focus significant attention to the alternative to breach the lower Snake River dams. This disparity thrust yet another inequity on the upper Columbia basin, as consideration of reintroduction and fish passage above Grand Coulee and Chief Joseph dams is every bit as important to restoring and recovering salmon affected by the CRSO as breaching the Snake River dams. Because there is no defensible reason under NEPA to ignore this issue in the CRSO EIS, the colead agencies should undertake a robust analysis and include this measure in the preferred alternative. Given the clear mandate from Judge Simon, it should not require additional litigation to force the co-lead agencies to abandon the status quo and conduct this analysis. Instead, the co-lead agencies should operate within their legal and moral obligation to include a full analysis of fish passage and reintroduction above Grand Coulee and Chief Joseph dams in the Final EIS. The UCUT Tribes expect as much.	Please reference response to 32264-1.
32264	4	Donald Michel	Upper Columbia United Tribes	Additionally, the co-lead agencies understand that climate change is a reality facing the region; however, they do not give it proper weight in the DEIS. The DEIS utilizes a 50-year timeframe for the socioeconomic analysis, but only analyzes impacts from operations up to the year 2050 even though severe impacts of climate change are expected beyond 2050. Reintroducing anadromous fish in the upper Columbia would significantly increase available habitat higher in the basin in waters that are cooler in temperature, thereby improving the future for all upper basin stocks in the face of climate change. The co-lead agencies should be consistent for the impact analysis and use a 50-year timeframe when considering climate change impacts.	The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with USACE climate change policy and guidance. The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. Water temperature modeling for each alternative is described in Chapter 3, however, as you note it was not conducted for conditions of future climate change. Information to develop, drive, and analyze specific projections of future water temperature and fish characteristics were not available on the timeline of this report. Measures to reintroduce salmon above Grand Coulee and Chief Joseph were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
32264	5	Donald Michel	Upper Columbia United Tribes	Finally, according to the DEIS, the agencies and "interested regional sovereigns" are collaborating on a framework to address critical information gaps, set goals, and establish a decision-making framework. This vastly overstates what the agencies have done in this regard. To date, there has been limited communication about the proposed effort and no firm commitment to the UCUT Tribes to follow through on it (see Attachments 18 and 19 for communication received by the co-lead agencies). The UCUT Tribes must be included in this workgroup and demand to know why they have not been as of the date of this letter.	Please see response to Comment 32264-1.
32264	6	Donald Michel	Upper Columbia United Tribes	In addition to consultation with the UCUT Tribes, the co-lead agencies should use the following resources to inform the inclusion and detailed analysis of a measure for reintroduction and fish passage above Grand Coulee and Chief Joseph dams in the CRSO EIS: Attachment 1: UCUT (Upper Columbia United Tribes). 2019. 32264	7	Donald Michel	Upper Columbia United Tribes	Invasive Species Management The DEIS describes a plan for the Army Corps of Engineers to complete and implement a management plan to address the proliferation of invasive species that will likely occur with the new hydro operations at Libby Dam. With the deeper draw down of reservoir waters, more shorelines will be exposed, allowing for invasive species such as flowering rush to take hold and/or expand. The effects of this could be seen throughout the Kootenai and Columbia rivers, including Lake Roosevelt. An increase in flowering rush habitat in Lake Roosevelt will set back the work occurring to suppress Northern Pike in Lake Roosevelt. This will have a direct impact not only on the budgets and efforts of the co-managers of the reservoir-Confederated Tribes ofthe Colville Reservation, Spokane Tribe of Indians, and Washington Department of Fish and Wildlife-but other fish and wildlife managers downstream as Northern Pike pass Grand Coulee and Chief Joseph dams. The Army Corps of Engineers must work with the UCUT Tribes in the planning, development, and implementation of the invasive species management plan. The UCUT Tribes have been the lead on monitoring and suppression efforts of Northern Pike-a non-native invasive species introduced into the Columbia River-in the Pend Oreille and Coeur d'Alene river systems and in Lake Roosevelt and its tributaries. According to the 2019 Independent Scientific Advisory Board's predation report (Attachment 20), Northern Pike were likely brought to the upper Columbia by human illegal introductions. Both Northern Pike and flowering rush have found success in the Columbia River Basin due to the management of the hydropower system causing fluctuating levels of the river and its reservoirs. Drawdowns of the reservoirs result in an increase of exposed riverbank where flowering rush can take hold and grow rapidly turning open water into highly vegetated water. When the reservoir begins to fill again, that flowering rush is prime habitat for Northern Pike, an ambush predator who prefers to hide in highly vegetated water and prey on unsuspecting open water fish, such as salmon ids, passing by. Studies conducted in Montana have shown that juvenile Northern Pike numbers increase dramatically with the addition of flowering rush. It is only a matter of time before these piscivorous fish enter the anadromous waters below Chief Joseph Dam and cause irreparable damage to the ESA-listed salmon and steelhead populations downstream. The region must gain better control of this species to reduce its impacts. In addition to consultation with the UCUT Tribes, to inform the planning stages of this management plan the Army Corps should use the following resources: Attachment 20: ISAB. 2019. Review of Predation Impacts and Management Effectiveness for the Columbia River Basin, ISAB 2019-1. Accessible at: nwcouncil.org/sites/default/files/ISAB%202019-1%20PredationMgmt3May.pdf. Northern Pike webtool developed in 2019 by the Northwest Power and Conservation Council and Washington Invasive Species Council; accessible at: pike.nwcouncil.org/.	Analysis in the CRSO EIS focuses on effects of the operation, maintenance, and configuration of the CRS projects. Effects of this action on vegetation are analyzed in Sections 3.6 and 7.7.7 and Chapter 4. Effects on fish are analyzed in Section 3.5 and 7.7.4, including Northern Pike. Outside of the scope of the CRSO EIS, through the Corps' Aquatic Plant Control program, the Corps is expecting to initiate a 50% cost reimbursement program for Flowering Rush surveys, monitoring, and control in Washington, Idaho, Montana, and Oregon beginning in 2020. Actions in Lake Roosevelt by the Confederated Tribes of the Colville Reservation and Spokane Tribe of Indians, through partnership with the Washington Department of Ecology are included in the Aquatic Plant Control Flowering Rush plan. The 'Draft Integrated Letter Report and Programmatic Environmental Assessment: Flowering Rush Control in Idaho, Montana, Oregon, and Washington through the Aquatic Plant Control Program' includes in the justification as one of the costs of not controlling Flowering Rush would be acceleration of Northern pike population growth. Flowering rush is very susceptible to control in spring when the reservoir is drawn down, and the exposed plants are treated through this Program.
32264	8	Donald Michel	Upper Columbia United Tribes	Cultural resource protection Given the proposed and new hydropower operations throughout the Columbia River System, cultural resources and historical sites of importance to the UCUT Tribes will face an increased risk of exposure and damage as a result of deeper and longer drawdowns. The co-lead agencies must work closely with the UCUT Tribes in the protection of cultural resources and historical sites of Tribal importance along the Columbia River, Kootenai River, Pend Oreille River, Coeur d'Alene River, the North Fork of the Clearwater, and their tributaries and reservoirs. Pursuant to the Native American Grave Protection and Repatriation Act (NAGPRA), the federal agencies must do the following when there is an "inadvertent" discovery of human remains: "Take immediate steps, if necessary, to further secure and protect inadvertently discovered human remains, funerary objects, sacred objects, or objects of cultural patrimony, including, as appropriate, stabilization or covering" 43 CFR 10.4(d). Pursuant to the regulations and statutes the federal agencies have a duty to devise a plan that is acceptable to the UCUT Tribes and that creates a long-term solution to this problem. See Yankton Sioux v. Army Corps of Engineers, 194 F.Supp.2d 977, 985-86 (D.S.D. 2002). The UCUT Tribes have contractual agreements with hydropower operators to address the current impacts to cultural resources. This proposed operation of the Columbia River System will put those monitored sites and ones yet recorded in danger. The CRSO EIS must include actions that can stop or significantly improve the current situations impacting UCUT Communities by erosion created by the Columbia River System and reservoir management.	The co-lead agencies have consistently followed 43 CFR 10.4 when it comes to handling inadvertent discoveries of human remains at the Projects that make up the CRS. This process has included the legally required consultation with individual Tribes regarding protocols for handling human remains and cultural items. The co-lead agencies in Section 8.4.4 describe their compliance with NAGPRA and its implementing regulations, such as addressing inadvertent discoveries of human remains and work to repatriate remains and associated funerary objects. This includes not only human remains and cultural items found since 1990, but also human remains and cultural items that are part of museum collections. The agencies also state that these activities will continue under the Preferred Alternative. The impacts under the Preferred Alternative are largely similar to the No Action Alternative, as shown in Section 7.7.18, with details highlighted in Table 7-47 of the Draft EIS. The co-lead agencies will continue to rely on the Federal Columbia River Power System (FCRPS) Cultural Resources Program to monitor sites and address impacts to cultural resources (see Section 5.2.1.6 for further information).
32267	1	Steve Ulrich	Town of Lamont	The Snake River and its four dams allow us to carry on irrigating our land and shipping crops to market.Your draft EIS confirms what we have long recognized: the dams sustain our rural economy, and without them, many family farms could not carry on. Without the ability to barge, our grain would need to be shipped solely by truck and rail. These methods of transportation, your report estimates, would cost 10 to 33 percent more than barging. In terms of producing wheat, this could add another 80 cents per bushel freight cost for farmers, already marketing a wheat crop at break-even or below cost of production. A study by the Pacific Northwest Waterways Association analyzed the economic impacts of losing barging as a transportation method. They concluded that more than 1,100 farms would risk bankruptcy if the federal government does not increase farm subsidies.	Thank you for your comment. The information provided in the comment regarding the increase in cost to farmers due to breaching the four lower Snake River dams is consistent with the findings of the EIS.
32289	1	Gary Fring	N/A	I am proposing an out of the box four (4) part solution for increasing the number of wild salmon: Item #1. Build a large breeding pond downstream of John Day Dam. Optimize the design of the pond to best simulate what the salmon need. The design should include: a). the correct size of gravel to use, b). The best depth of water. Water level to be maintained constant by the use of overflow dams at the exit side of the pond, c). Optimum water flow rate across the pond. Water to be made available from the upstream side of the Dam, d). An artificial roof over the pond, e). A fish ladder to the pond for the returning adult fish to use no matter what level the Columbia River is at. If this test pond works, the fish hatcheries could be replaced with several well placed breeding ponds. The money that is presently spent on fish hatcheries could then be utilized to restore the river and tributaries to fish friendly environments. Jim Lichatowich's book stressed the importance of improving small river environments. Item #2. Put a five (5) year moratorium on gill net fishing. Hopefully this would be enough time to increase the number of returning fish. These are the fish that have the eggs which the next generation of fish depend on. Item #3. Get rid of the seals downstream of the Bonneville Dam. Item #4. Keep doing what is already in the plans such as new turbines, better fish ladders, environmental upgrades to rivers, etc.	Thank you for your in depth suggestions. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. Hatchery programs are discussed briefly in the Affected Environment to give the reader general information on hatchery programs that are a part of the ESU/DPS described. Additional hatcheries, or spawning ponds like those mentioned in this comment are appreciated but are largely out of scope. Previous efforts to create spawning channels and ponds have been attempted previously below McNary Dam but additional ponds were not considered as viable alternatives in this current process. Harvest and catch limits are outside the scope for this EIS, but the EIS does acknowledge that changes in abundance may affect harvest and catch limits. However, NMFS recently completed an EIS that analyzed effects of harvest on Columbia Basin salmon and steelhead. The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure that operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped (sea lion) and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Under the Preferred Alternative, actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with ESA as described in Section 7.6.4.1, Ongoing Programs, including ongoing measures to haze and monitor pinniped predators. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
32294	1	John Sigler	N/A	It always amazed me that the National Environmental Policy Act was a process controlled by the proponents of a proposed federal action. The National Environmental Policy Act (NEPA) established the Council on Environmental Quality (CEQ) in 1970 within the Executive Office of the President. CEQ	The co-lead agencies used a multi-disciplinary and science-based approach to analyze the alternatives in the EIS analysis. The co-lead agencies invited a number of entities, including Tribes, states, and local agencies, from across the region to participate in the EIS process as cooperating agencies, and more than 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review to the development and analysis

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				oversees Federal agency NEPA implementation and develops and recommends national policies to the President that promote the improvement of environmental quality and meet the Nation's goals. In addition, CEQ is assigned various duties and responsibilities under other statutes, Executive Orders, and Presidential Memoranda, including with regard to Federal ocean policy, Federal sustainability, and timely environmental review and permitting processes for infrastructure development, and other matters. While the concept of independent review of federal agency actions was discussed in the early 1970s, no action has ever been taken to ensure that federal NEPA documentation, written by agency staff of hired third-party contractors is ever reviewed by those within the government WITHOUT a vested interest in the outcome of the process or reviews. Environmental Protection Agency (EPA) has been given the review responsibility for federal NEPA actions. EPA does not necessarily have expertise in salmon and steelhead biology, ecology of inland waters or other relevant aspects of the current EIS proposal. In addition, CEQ guidelines require EPA to review NEPA documents for "adequacy," which is such an obscure term that it becomes irrelevant. This flawed process, in place for 50 years, has allowed the CLAs for this EIS to obfuscate, selectively present both facts and opinion to support the status quo and deny the public full access to all relevant information on power costs, grid and alternative power replacement costs, precipitousness of Idaho salmon and steelhead extinctions.	of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River System and are not required to seek a third party reviewer for a NEPA document. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative meets the objectives of the EIS for ESA-listed juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
32294	2	John Sigler	N/A	Executive Summary Page 13. Bias and perspectives of the CLA are immediately reflected in Figure ES-3 showing fish passage through Snake and Columbia River dams, including the turbines, with no fish adversely affected. Not possible. Spillways kill juvenile fish due to gas pressure changes, turbines kill juvenile salmon and steelhead by grinding them into small chunks.	Survival rates for yearling Chinook and steelhead through spillways is consistently around 98%. Turbine survival varies widely with project operations and water temperatures and ranges from 80%-99% (average turbine survival is 89%) as estimated by telemetry studies. The turbine estimates just described are known to be low because of the extra mass of the transmitter required for the study; however these estimates are used in the COMPASS model because the magnitude of the bias is unknown (Carlson et al. 2012). These types of telemetry studies represent the best available scientific information. Combined springtime survival at an individual dam though all routes at most of the lower Snake and Columbia river dams is >96%. Cumulative survival rates from Lower Granite Dam through all eight dams, including dam and reservoir effects and any natural sources of mortality ranges between 40% and 60% depending on water conditions and fish species. https://www.nwd.usace.army.mil/CRSO/Documents/#top_P_Thomas J. Carlson, Richard S. Brown, John R. Stephenson, Brett D. Pflugrath, Alison H. Colotelo, Andrew J. Gingerich, Piper L. Benjamin, Mike J. Langeslay, Martin L. Ahmann, Robert L. Johnson, John R. Skalski, Adam G. Seaburg & Richard L. Townsend (2012) The Influence of Tag Presence on the Mortality of Juvenile Chinook Salmon Exposed to Simulated Hydroturbine Passage: Implications for Survival Estimates and Management of Hydroelectric Facilities, North American Journal of Fisheries Management, 32:2, 249-261, DOI: 10.1080/02755947.2012.661384
32294	3	John Sigler	N/A	Executive Summary-Page 12 AREAS OF CONTROVERSY Lower Snake River Dam Breach. The co-lead agencies received important feedback from tribal engagement, cooperating agencies, and through public scoping pertaining to breaching the four lower Snake River dams. Breaching the four lower Snake River dams has been a topic of public discourse for decades. This EIS provides an updated analysis of the many biological and sociological variables and the costs and benefits of retaining or breaching the lower Snake River dams. In combination with other sources of information and analysis available in the public domain, this document can help inform the regional conversation on this complex and often polarizing issue. New congressional authority and associated funding would be required to implement the dam breaching measures evaluated in the EIS. However, the measures are carried forward in the analysis to align with the District Court's Opinion and Order, as well as in response to comments received during public scoping. All of the facts associated with the effects of breaching the four LSRDs have been known since the 1990s. There is no actual controversy regarding the science of the success potential for salmon and steelhead survival should the dams be breached. There is only the court-defying intransience of the CLAs. PATH is the Plan for Analyzing & Testing Hypotheses, a collaborative process for formulating & testing hypotheses surrounding Columbia River Basin (CRB) Anadromous Fish Recovery (Marmorek et al 1998). This report was commissioned by the federal agencies responsible for dam operations and salmon and steelhead protection with input from over 30 contributors with personal, scientific knowledge of Snake River salmon and steelhead. PA TH concluded the Natural River (Breach) is the only option that will provide recovery. This option has the highest certainty of success and the lowest risk of failure. PATH reported their findings in 1998 and for the past 20+ years independent scientists and scientific review panels have consistently reaffirmed PATH conclusions. Recent collaborative scientific report that confirms PATH: Comparative Survival Study report (CSS 2019), predicts a 2-3-fold increase in salmon abundance with removal of the four LSRDs and a 4-fold increase if breach is coupled with maximum spill over the Columbia River dams. Dam breaching as the only mechanism to save Idaho salmon and steelhead is supported by the scientific evidence. Had the PATH recommendations been implemented in 1998, we would have already achieved recovery of Idaho's salmon and steelhead	The agencies used current high-quality information consistent with the National Environmental Policy Act and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over twenty years old and does not reflect current CRS operations. The commenter is correct that EIS analysis of MO3 (the alternative that includes a measure to breach the lower Snake River dams) would provide more certainty of long-term survival and recovery for Snake River salmon and steelhead than the other alternatives analyzed in the EIS. However, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
32294	4	John Sigler	N/A	Executive Summary - Page 16 Resource Purposes Provide for a reliable level of flood risk by managing the System to afford safeguards for public safety, infrastructure, and property, Provide an adequate, efficient, economical and reliable power supply that supports the integrated Columbia River Power system Provide water supply for irrigation, municipal, and industrial uses Provide for waterway transportation capability Provide for the conservation of fish and wildlife resources, including threatened, endangered, and sensitive species throughout the environment affected by System operations Consider and plan for climate change impacts on resources and on the management of the System Provide opportunities for recreation at System lakes and reservoirs Protect and preserve cultural resources When one of the resource purposes is listed as "waterway transportation capability," the deck is pretty well stacked against any option without it. There are NO flood issues associated with removal of the four LSRDs. Adequate, efficient (more than hydropower) economical, economic and reliable power supply can be constructed using any number of currently available efficient technologies. There is no irrigation from any of the LSRDs except Ice Harbor. Again the CLAs cast loss of irrigation, including from the McNary Pool as lost when McNary Pool irrigation will not be affected in any way following breach of the LSRDs. What municipal and industrial uses are referenced that cannot be served by withdrawals from a river as is done in tens of thousands of locations across the United States? Waterway transportation capability is almost certainly a congressionally mandated "Resource Purpose' connived by the CLAS to solidify their status quo management of the lower Snake River and can certainly be reversed by another "act of Congress." Despite the expenditure of millions of dollars in taxpayer funds over the last several decades, the CLAs have failed completely to provide for the conservation of fish and wildlife resources, including (particularly) threatened, endangered and sensitive species throughout the environment affected by System operations. In addition, no consideration has been given to the life stages ofIdaho salmon and steelhead in the upper Snake and Salmon River drainages or in the tributaries of the Snake where these species used to complete their life histories. What considerations and plans have been made for climate change impacts on resources and management of the System? A definitive and realistic change that is coming is related to warmer waters and water flow peaks at times different from in the past. None of the mitigations offered by the non breach alternatives address these concerns adequately. Again, an egregious misuse of the writers in setting tone is noted in the provision for recreation at System lakes and reservoirs. Water based recreation is successfully accomplished People in flood-prone areas have an interest in FRM in the Northwest. Maintaining existing FRM levels is important to those interests, as are accurate flood forecasting efforts for efficient reservoir storage and water releases. Some have expressed concerns regarding impacts experienced in the upper Columbia River Basin from reservoir FRM operations aimed at protecting flood-prone areas along the lower Columbia River. There are absolutely NO flood risk issues in the vicinity of the four LSRDs. It is disingenuous of the CLA to continue to inject this scare tactic into discussion of alternatives and operations where it is not an issue.	It is unclear what the commenter is referencing regarding flood risk in Region C or D. The EIS evaluation concluded there would be no increase in flood risk, and additionally identified the lower Snake River projects are run-of-river, not storage projects, and do no operate for flood risk purposes. In Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion. This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For Multiple Objective alternative 1, Multiple Objective alternative 2, Multiple Objective alternative 4 (MO4), and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects on anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
32294	5	John Sigler	N/A	1.6.2.4 Power Generation Hydropower provides low cost electricity, helps meet state and local carbon emission goals, provides resiliency to the interconnected power system and, when available, is a low-cost flexible resource that can be used to integrate alternative energy resources into the power grid. At times both Federal CRS dams and non-Federal dams produce large quantities of excess electricity that is surplus to meeting regional firm power load demands. Such surplus power is regularly offered for sale to purchasers throughout the western United States and Canada. Many parties stressed how vitally important hydropower is to the regional economy. Numerous commenters expressed concern that clean, historically affordable hydropower might be replaced with other energy resources like fossil-fuel powered generation such as natural gas power or small modular nuclear reactors. These other types of energy may be more expensive, unproven, or more ecologically damaging. Commenters expressed concern that this EIS process may result in decisions that would compromise the region's historic hydropower resource base. Other power-related concerns included energy conservation, increased generating efficiency, and keeping electricity rates low. 1.6.2.5 Anadromous Fish Tribes, states, the public, commercial and sport fishing groups, and Federal fishery management agencies are concerned about how the projects affect, and will continue to affect, anadromous fish survival and recovery. Many expressed the importance of the salmon and lamprey contribution to the environment, regional economy, and ecosystem of the Pacific Northwest. Sections 1.6.2.4 and Section 1.6.2.5 reflection the institutional bias of the CLAs. Over 100 words are used to detail "many parties that stressed how vitally important hydropower" is to the regional economy and concern regarding clean, historically affordable hydropower might be replace with other energy sources. Only 50 words were used to document the concerns of tribes, states, public and sport fishing groups, to say nothing of the hundreds of individuals which are and will continue to be economically impacted by the continued operation of the LSRDs in their current patterns. More dissembling on the part of the CLAs.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32294	6	John Sigler	N/A	Chapter2 - Section 2.5 Page 270 Table 2-11. List of Draft Single Objective-Focused Alternatives Spill to 125% TOG with Extended Duration; Juvenile Anadromous Fish Survival; Adult; Anadromous Fish Survival; BSA-Listed Resident Fish Survival; Hydropower Generation; Water Management; Water Supply; Lower Snake River Dam Breach. Despite multiple federal court orders requiring review of the "breach the dam" options, the CLAs continue to formulate alternatives which defy the court orders and leave realistic, achievable alternatives out of the discussion and off the table with regard to preservation of salmon and steelhead	The CRS is a complex system with multiple, sometimes competing, congressionally authorized purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. This EIS was developed to evaluate the operation and maintenance of the CRS over the next 20 years, with the expectation that the co-lead agencies will continue to meet the multiple, authorized purposes until directed differently by Congress. Although Fish and Wildlife is one of the authorized purposes, it is not the only purpose, and the co-lead agencies must balance all resources, and sometimes focus some purposes over others. The analysis of the Multiple Objective (MO) alternatives reflect these trade-offs and have allowed the co-lead agencies to understand the effects of emphasizing some purposes over others in order to find the most acceptable balance for future operations. The MO alternatives relied on preliminary analysis of the single-objective alternatives to inform the combination of alternatives analyzed in the final range. The measures in the final range of alternatives were combined in deliberate ways to display the trade-offs inherent in the operation of such a complex system.
32294	7	John Sigler	N/A	Chapter 2 - Section 2.5.8 Page 2-74 Objectives are what the federal agencies are trying to accomplish (the "why"). They are statements of the desired outcome of the EIS, as identified by the federal agencies and from scoping comments. An example of an objective is to improve BSA-listed anadromous salmonid adult fish migration within the project are. 2.5.8 Single Objective Focus Lower Snake River Dam Breaching Alternative The Single Objective Focus Lower Snake River Dam Breaching Alternative was not an objective focused alternative. It was developed based on formal scoping comments specifically requesting analysis of this action. The hypothesis for this alternative was that habitat conditions for 4 of the 13 listed anadromous species in the Columbia River Basin could potentially be restored. The alternative proposed breaching the four lower Snake River dams (Lower Granite, Little Goose, Lower Monumental, and Ice Harbor) by removing the earthen embankments at each location. The reservoirs behind the dams would be drawn down slowly to avoid damage to adjacent infrastructure (e.g., roads, bridges, and railroads) and ensure life safety of downstream populations. The concrete portions of the dams would remain in place, but the powerhouses would be mothballed. The generators would be modified for use as outlets during a controlled reservoir drawdown. The breaching would occur over a 2-year period, with the two upstream dams (Lower Granite and Little Goose) breached first and followed the next year by Lower Monumental and Ice Harbor. Spreading the breaching over 2 years allows the work to occur during the in-water work window, when very few BSA-listed fish are present in the reservoirs and inflows are relatively small. This alternative was refined and included in M03 for analysis in this EIS. Despite the strong public support for an adequate analysis of the breach alternative, the CLAs again have opted to confuse and modify the suggested solution. As noted above in the PATH analysis, hundreds of informed, professional fisheries scientists have provided way more than adequate rationale for removal of the four LSRDs. Failure by the CLAs to complete this simple task (in accordance with federal court orders), is sufficient justification for EPA to deem the document and its conclusions inadequate and to reject the findings in their entirety.	The co-lead agencies presented a range of alternatives for the continued operation and management of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. A single-objective alternative for breaching the four lower Snake River dams would not provide a complete plan for management of the CRS since there are 10 other dams in the CRS. Changes to these projects must also be made either to accommodate breaching or to update existing operations. Thus, a single-objective dam breaching alternative, which leaves the remaining CRS projects at No Action Alternative operation levels would not meet the Purpose and Need Statement and the objectives of the EIS, which means the single-objective alternative is not within the reasonable range of alternatives. Analysis from the dam breaching single-objective alternative was used to inform development of Multiple Objective Alternative 3, which includes breaching the four lower Snake River dams. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Finally, the co-lead agencies used current, high quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over twenty-years-old and does not reflect current CRS operations.
32294	8	John Sigler	N/A	Affected Environment Chapter 3 Page 3-1 CHAPTER 3 - AFFECTED ENVIRONMENT AND ENVIRONMENTAL CONSEQUENCES 3.1 INTRODUCTION AND BACKGROUND This chapter presents both the affected environment and environmental consequences, as required by the National Environmental Policy Act (NEPA). It is organized by resource topic, with the status of the affected environment described first, followed by the impacts of each alternative described within each resource section. Each resource has defined the area of analysis consistent with where that resource may experience effects. The affected environment sections provide a description of different aspects of the human environment that may be affected by the No Action Alternative and four Multiple Objective Alternatives (MOs). The environmental consequences sections provide a description of the impact assessment methodologies, and potential direct and indirect effects. Many natural resources are of importance both currently and historically to Native American tribes. As such, effects to these resources, and relationships to tribal interests, are discussed within each applicable resource section as well as in sections such as Indian Trust Assets, Tribal Perspective and Tribal Interests, and Cultural Resources. In an Environmental Impact Statement (EIS) the "Affected Environment/Environmental Consequences" and Chapter 4, "Cumulative Impacts" are the heart and soul of the document. It is the intent of NEPA, and all federal agency NEPA guidance, that the an EIS provide the public, interested patties, stakeholders and decision makers with not only an adequate framework for describing what resources are in the project area, it is essential that the "affected environment" be described factually and in sufficient detail so as to provide from a decision making framework. This EIS fails completely in these required mandates.	The Draft EIS provided the public, interested parties, stakeholders and decision-makers with an adequate description of the affected environment based on the high-quality, available information. This information is included in Chapter 3 of the EIS and informs the analysis in Chapters 4 (Climate), 5 (Mitigation), 6 (Cumulative Effects) and 7 (Preferred Alternative). Consistent with the Council on Environmental Quality (CEQ) June 24, 2005 guidance and interpretation of CEQ's Regulations for Implementing the Procedural Provisions of NEPA (40 C.F.R parts 1500-1508), "Agencies are not required to list or analyze the effects of individual past actions unless such information is necessary to describe the cumulative effect of all past actions combined... Generally agencies can conduct an adequate cumulative effects analysis by focusing on the current aggregate effects of past actions without delving into the historical details of individual past actions." However, the analysis of current conditions includes the ongoing effects of the existence of the system, inclusive of a host of other factors influencing natural and cultural resources of concern to potentially affected tribes.
32294	9	John Sigler	N/A	Figure 3-106 Page 3-234 reflects that no water quality analysis or evaluation was included in the EIS for 90 percent of the Snake River watershed.	The scope of this EIS focused on the operation of the 14 Federal dams in the CRS as described in Section 1.3 Scope of the Project of the EIS. The entirety of the Snake River was out of scope for alternatives development, and as changes to water quality from any of the alternatives under consideration were not anticipated beyond the lower Snake River, a discussion of the effects to water quality were not extended.
32294	10	John Sigler	N/A	Region C of the "Affected Environment" description includes the four LSRDs Region C of the "Affected Environment" description includes the Clearwater River and approximately one-third of the Idaho salmon and steelhead habitat in Idaho. The vast majority of the Snake River and its thousands of miles of main stem and tributary stream spawning areas for salmon and steelhead, are, apparently, not analyzed in this EIS.	Thanks for this comment illustrating the potential for misunderstanding the maps in the Affected Environment description. The shaded areas of Regions A, B, C, and D show, in general, areas of the habitat, with resident fish habitat within each area noted with the lines overlaid on the rivers. The resident fish scope in the Snake and Clearwater rivers was defined by the range of populations of migratory fish such as bull trout that may be affected by the projects. The anadromous fish action area is defined in line 6764 as "Other rivers...where measurable changes in the abundance of salmon, steelhead, lamprey, and other key fish species have altered components of the ecosystem", and in the habitat section (line 6791) as ..."all locations in the study area that are accessible to fish species." In actuality, the Draft EIS does consider effects throughout the action area shown in Region C, including the Snake River, Clearwater River, and thousands of miles of mainstrem and tributary spawning areas for salmon and steelhead in Idaho. These analyses are evident in Section 3.5.3.
32294	11	John Sigler	N/A	According to Figure 3-2 Page 3-16 some 90 percent of the Snake River drainage was not considered in the "affected environment portion of the EIS, Chapter 3 - 3.2.2 Area of Analysis Page 3-16 The area considered in this hydrology and hydraulics evaluation is the CRS reservoirs and the river reaches downstream. The modeling of the system for this analysis is described in the H&H Appendix (Appendix B) and the Hydroregulation Appendix (Appendix I). The order of discussion goes from upstream locations to downstream locations, and is organized by the physiographic NEPA regions shown in Figure 3-2.	The commenter is correct in identifying that the upper Snake River basin, upstream of Anatone, WA, is not included in the scope of this EIS. The upper Snake River basin has a combination of Federal and non-Federal dams and reservoirs, but these projects are not operated in coordination with the CRS projects. The flows from the upper Snake River basin are included in the modeling, just as flows from other tributaries are included, as boundary conditions.
32294	12	John Sigler	N/A	Chapter 3 - 3.4.1 Area of Analysis Page 3-233 The area considered in this water and sediment quality evaluation consists of the Columbia River and tributaries (Snake, Clearwater, Pend Oreille, Flathead, and Kootenai Rivers) from the U.S.Canada border to downstream of Bonneville Dam. This includes the Federal dams of Hungry Horse, Libby, Albeni Falls, Grand Coulee, Chief Joseph, Dworshak, Lower Granite, Little Goose, Lower Monumental, Ice Harbor, McNary, John Day, The Dalles, and Bonneville (Figure 3-106). The water quality analysis for this EIS focused on the area of largest impact both upstream (in the reservoir) and downstream (in the tailrace) of each CRS dam. Area of Analysis Wasting thousands of words and likely millions of dollars, the CLAs, ignoring federal court orders and the preponderance of scientific information accumulated over the last 70 years, elected to complete analysis on an area representing nearly half of the western United States rather than on the simple, easily defined geographic and geologic area bounded by the upper limits of the Clearwater, Lochsa, Salmon rivers and their tributaries, the area in which Idaho's salmon and steelhead are being driven to extinction by actions being taken hundreds of miles distant. It would have been a simple matter to define the relationship between the four LSRDs, their operating protocols over the last several decades and the effects these protocols have had on Idaho salmon and steelhead. This analysis would have analyzed the failed policies of the past 50 years as tweeks, adjustments, major revampings, water spills and other wasted efforts were tried, tried and tried again. Einstein's insanity quote comes to mind: "The definition of insanity is doing the same thing over and over again and expecting different results." Massive fail and lost opportunity on the part of the CLAs.	The scope of this EIS focused on the operation of the 14 Federal dams in the CRS as described in Section 1.3 Scope of the Project of the EIS and the measurable changes to water quality from those actions. That said, the system water quality model's extent includes the entire mainstem river, from the international boundary above Grand Coulee Dam to just downstream of Bonneville Dam at Warrendale, Oregon. The co-lead agencies chose to pull model output from the fixed monitoring stations, located upstream and downstream of each dam, since these are the typical locations where data is utilized when making real-time water management decisions and ensuring compliance with water quality standards.
32294	13	John Sigler	N/A	Chapter 3 - Section 3.4 Water Quality Page 3-232. The water quality of the Columbia River Basin is affected by many past and present influences, including human population growth and associated pollutants, water withdrawal for municipal and industrial water and irrigation (and irrigation return flows), dam structures and operations (Federal and non-Federal), and land use practices including mining, domesticated livestock, agriculture, industry (pulp and paper mills), logging (silviculture and forest management), and recreation (e.g., shoreline erosion). New pollutants are continually being identified, such as pharmaceuticals. The existing National Pollutant Discharge Elimination System programs regulate certain identified compounds from point sources, but other pollutants may also be present and unaccounted for. Nonetheless, surface water in the Columbia River Basin supports a wide variety of resident and anadromous fish and other aquatic organisms and wildlife. The 14 Federal dams within the CRSO study area have affected water and sediment quality due to the creation of reservoirs throughout the system. Prior to the construction of these and other dams, the Columbia River and its tributaries were free-flowing, natural rivers. These rivers experienced seasonal flow and temperature changes. The seasonal peak flows would have moved sediment downstream over time. Water depths would have been comparatively shallow (more shallow than the current reservoirs) which has implications for water velocity, water temperature, and ecological processes. Water in the river was fully mixed as the water flowed downstream. The river conditions dictated the water and sediment quality, which in turn dictated the habitat and species found in the habitat. Water quality in the CRS is indeed affected by the four LSRDs. The overall effect of temperature, slack water, lack of significant directional flow and the repetitiveness of the conditions in the reservoirs all work to confuse and slow downstream migrants from Lewiston, Idaho to the Bonneville Dam.	As noted in this comment, there are many contributing factors that effect water quality. It is well understood that the CRS dams have an impact on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS document.
32294	14	John Sigler	N/A	. 3.4.2.1 Water Quality Page 3-236 Water temperature is one of the most important physiochemical constituents of surface water and has been modeled as part of the CRS EIS analysis. It controls the rate of all chemical reactions, directly affects fish and benthic macroinvertebrate growth and reproduction, and can be acutely toxic (fatal) to fish if drastic temperature changes occur or if temperatures exceed 25C for salmon and steelhead. Water temperatures in many reaches do not meet the regulatory standards in the summer and early fall. System operations can impact both water temperature and TDG in the Columbia River Basin, and given this the impact, the analysis in the CRSO EIS focuses on how both parameters may change with a change in operation as described in the MOs as compared to the No Action Alternative. 3.4.3.2 Impact Framework Page 3-246 A framework was developed to define the overall level of water temperature and TDG impact for each CRSO EIS alternative as compared to the No Action Alternative. For water temperature, the level of impact (negligible, minor, moderate, or major) was defined based on the absolute change in the maximum and	It is well understood that the CRS dams have an impact on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS. A system water quality model was developed to look water temperature and TDG effects throughout the Columbia and Snake River system. These results were provided to the fish team for incorporation into NMFS COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. The fish team also used water quality outputs to qualitatively examine effects to fish species based upon known relationships between water temperatures and fish responses specifically for stocks such as sockeye salmon and Fall Chinook salmon where quantitative models were not available.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				minimum water temperatures as averaged over the 5-year simulation period (2011-2015). If the absolute change in water temperature between the MO Alternative and No Action Alternative was less than 0.4 degree Fahrenheit, the water temperature impact was considered negligible. If the absolute change in average minimum and maximum values was greater than 0.4 degree Fahrenheit, but less than 2 degrees Fahrenheit, the impact was considered negligible, minor or moderate based on the time of year (season) the impact occurred and whether the impact increased the number of days that State water quality standard (WQS) criteria was not met and by how much. Absolute water temperature changes of >2 degrees Fahrenheit, or an increase in water temperature WQS exceedances of greater than 10 days, were considered a major impact. None of this discussion addresses the multiplicative effects of one slack, warm water reservoir after another between Lewiston, Idaho and the Bonneville Dam. One slap side the head is one thing - four then eight in a row is a different story, the cumulative impacts of the eight dams should have been analyzed with respect to physiological effects and timing.	
32294	15	John Sigler	N/A	Chapter 3, Page 3-298 Affected Environment Construction and operation of Federal and non-Federal dams in the Columbia River Basin have impacted longitudinal connectivity by blocking or otherwise affecting migratory fish corridors, changing stream flow patterns, and altering natural water temperature regimes that in many areas can cause delay of migration or even form thermal barriers. An outright admission in the EIS that the federal dams in the CRS, including the four LSRDs, adversely impact Idaho salmon and steelhead: eight of them but particularly the outdated LSRDs.	The co-lead agencies used the best available science in the analysis of the 2019 CRS EIS. This analysis includes the effects of operating and maintaining CRS dams, including the 4 Lower Snake River Dams, on Snake River steelhead and salmon, water quality, water quantity, and host of other resources. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. This information is presented in Chapters 3 and 7 in the Draft EIS. With respect to the preferred alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives of the study for resident fish, hydropower, water management, water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy.
32294	16	John Sigler	N/A	Chapter 3 Page 3-304 (Line 7316) Multiple factors have contributed to the historical decline and current status of salmon and steelhead. The construction and operations of the Columbia River System are among the many factors that have adversely affected these species. The adverse impact of past Columbia River System operations has been reduced over time, and multiple mitigation actions have improved habitat, hatchery operations, and predator management, thus increasing survival rates of individuals in these ESUs, reducing extinction risk, and thereby contributing to improvements in the likelihood of recovery. Another section where CLAs admitted that the CRS, including the four LSRDs, are part of the reason Idaho salmon and steelhead are afforded protection under the federal Endangered Species Act. The brief paragraph above do not have acknowledge the fact that the proponent agencies are in control of the CRS and the four LSRDs, affording them and only them with the discretionary prospect of first, evaluating the effects of the four LSRDs and second, acknowledging that removal of the dams is feasible by any engineering, economic or social standard. Another opinion PORTLAND, Ore.- The U.S. Army Corps of Engineers, Bonneville Power Administration and Bureau of Reclamation today released the first step of a court-ordered National Environmental Policy Act review of the federal system of dams and reservoirs in the Columbia-Snake River Basin. The review was supposed to detail all credible recovery alternatives for endangered salmon and steelhead But instead it gives short shrift to the only viable alternative for saving salmon and ultimately orcas - removing the four lower Snake River dams. "Instead of taking the one step identified by scientists as absolutely crucial for salmon recovery, these agencies failed our region yet again, " said Meg Townsend, an endangered species attorney with the Center for Biological Diversity. "The science shows that pulling out the four lower Snake River dams is the only way to save Columbia river salmon and the Southern Resident orcas that depend on them. " In May 2016 the U.S. District Court in Portland invalidated the federal agencies' 2014 biological opinion for salmon and steelhead endangered by the federal dams and reservoirs on the Columbia-Snake rivers. This was the fifth consecutive analysis rejected by the courts since the 1990s. Currently only 72 Southern Resident orcas remain. Orcas are starving to death as their primary food source, salmon, continue to face significant declines in the region. The Columbia River System dams cut off more than 55% of salmon spawning and rearing habitat. Many wild salmon runs in the region have as low as 2% or less of their historic populations. The federal government has spent more than $16 billion on regional salmon in the past two decades, yet has so far failed to recover any of the thirteen wild salmon and steelhead populations in the Columbia Basin at risk of extinction today. In a Feb. 11 letter to Washington Governor Jay Inslee, Oregon Governor Kate Brown called for the removal of four dams in the lower Snake River as a better path toward restoring salmon runs in both states.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
32294	17	John Sigler	N/A	Alternative power sources such as wind and solar are rapidly becoming cost competitive to any hydropower project, particularly those over 50 years old which require continual maintenance and turbine replacement to remain functional. Alternative power sources such as wind and solar, which are rapidly becoming cost competitive could easily be used to replace portions of the current ground based materials transport systems such as rail and traffic. For instance, did the CLAs even countenance the prospect of using electric trains and electric trucks to move grain and other materials through the EIS analysis area? Several NGOs are currently developing both electric over-the-road trains and transport trucks.	For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. No cost estimates or production functions specific to electric trains or trucks were available or utilized as part of the navigation and transportation analysis.
32294	18	John Sigler	N/A	Throughout this EIS, it appears the COE and their proponent partners have used the frequently seen COE "overbuild" model for this EIS. Rather than provide lucid, understandable documentation on the portions of the CRS relevant to adult and juvenile losses at the four LSRDs, CLAs have elected to pile thousands of pages of material into the EIS which does not address the directions for the several federal court directions in the last several years.	The co-lead agencies analyzed the integrated operation, maintenance, and configuration of the 14 projects that comprise the CRS. Because the CRS has a broad geographic reach, is subject to numerous legal mandates, and implicate numerous complicated and contested subjects, the analysis is necessarily lengthy. The intent of the Executive Summary is to serve as a primer and broad summary of findings. The Final EIS will expand the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices.
32294	19	John Sigler	N/A	More Math - EIS released with a 45-day period for review and comment. 2000+ pages of main text plus several thousand more pages of appendices. 2000/45 requires to read, understand and comment on 45 plus pages of highly technical material every day while writing and formulating comments in an organized fashion. Shame on the CLAs! ! Reverting to the Executive Summary to try to grasp the realities of the effect of the four LSRDs on Idaho salmon and steelhead mired one in opaque analyses, glittering generalities regarding fisheries science and some sketchy data regarding actual costs of breaching the LSRDs and replacing that power generating capability with sustainable wind and solar.	Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined the 45-day public comment period was consistent with NEPA regulations. The intent of the Executive Summary was to serve as a primer and broad summary of findings. The Final EIS will expand the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices.
32294	20	John Sigler	N/A	Line 7244 To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CRS. Commendable but hardly rising to the federal court rulings over the last several decades which mandated actions which actually move Idaho salmon and steelhead toward recovery. Figure 3-312 Page 3-301 Percentage Survival at Each LSRD Lower Granite 98%, Little Goose, 98.2%, Lower Monumental 98.7, Ice Harbor (assumed 98 %) Do the math. 100 Idaho salmon and steelhead arrive at the confluence of the Snake and Clearwater Rivers near Lewiston, Idaho. Lower Granite Dam kills 2 of them, 98 continue to Little Goose Dam, two more die there, leaving 96 to travel downstream to Lower Monumental Dam where 2 more die, leaving 94. Another 2 die at Ice Harbor leaving 92 and these 92 go through four more dams before reaching the ocean. Even given that these numbers are correct, iffy since they do not reflect delayed mortality or other known but undefined factors, successful returns to the mouth of the Columbia have already been reduced by nearly 10 percent. Species Status-Chinook Salmon. Following guidelines of the Idaho Department of Fish and Game and federal standings, Chinook Salmon are ranked as secure (GS) range wide, but the Snake River populations are ranked as critically imperiled (TI) and in Idaho they are ranked as critically imperiled (S 1). Sockeye Salmon. Sockeye Salmon are ranked as secure (GS) range wide, but the Snake River populations are ranked as critically imperiled (TI) and in Idaho they are ranked as critically imperiled (S 1). Steelhead. Steelhead are ranked as vulnerable to imperiled (G5T2T3) range wide and vulnerable (S3) in Idaho. (Sigler and Zaroban, 2018),	The per-dam survival metric is both accurate and useful in measuring changes in near-field survival at the dams due to structural modifications (e.g., surface passage routes) or operational changes (changes to spill levels or spill patterns). The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past 10 years has been shown to contribute to improvements in total in-river survival of smolts migrating through the CRS, especially for steelhead. These figures were used to provide context in the Affected Environment Section. The focus of the CRSO EIS and the analysis presented in Section 3.5 and Chapter 7 hinged around total in-river survival, travel time, powerhouse passage rates, and Smolt-to-Adult (SAR) return rates. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. With respect to the Preferred Alternative, the CSS model predicts that average SAR return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council (Council) recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. These improvements are expected to benefit all of the stocks listed in this comment if latent mortality is reduced through higher spill levels.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32294	21	John Sigler	N/A	EIS References - Looking at the impressive list ofreferences cited in Chapter 11, one can't help but be impressed. A quick review, however reveals an interesting truth: Among the recognized professional fisheries managers throughout the Pacific Northwest, a handful are cited once or twice. Bonneville Power, or adjuncts contributed some 20 publications, all apparently gray literature, never subjected to peer or public review, never scrutinized by any but BPA staffers. Even a significant portion of the references authored by credible fisheries and other scientists were BP A documents, not peer reviewed. Thus BP A for decades formulated management policy, wrote it down in internal documents and proceeded to facilitate the status quo of killing Idaho salmon and steelhead while "shielding" the public from the foundational documents used to make these decisions. Exact same thing is true of the COE publications: written, shelved, never to see the light of public review or be subjected to peer review.	The Draft EIS uses high-quality, best available references. All Bonneville-funded projects are available at cbfish.org. This includes all reports applicable to the various fish and wildlife projects Bonneville funds. Moreover, the co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as Cooperating Agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the CRS system. Finally, the co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
32295	1	Rob Mercer	Columbia-Snake River Irrigators Association	CSRIA Policy/Technical Comments on the Draft CRSO ESA BiOp-EIS The Columbia-Snake River Irrigators Association (CSRIA) is providing policy and technical comments on the Draft Columbia River System Operations (CRSO) ESA BiOp-EIS, as Defendant-Intervener in the pending Biological Opinion litigation before U.S. District (OR) Judge Michael Simon. This litigation has involved a remand of the 2014 BiOp (2016), injunctive relieve for full hydro project spill operations (2018-19), and preparation of a new environmental impact statement (EIS) that specifically includes an examination of breaching the Lower Snake River dams. The Draft EIS preferred alternative identified by the CRSO agencies is principally based on the 2014 BiOp, with an Interim BiOp (2019) advancing revised project spill regimes, along with other operations. The remaining Draft EIS alternatives include other water management operations, Lower Snake River dam breaching actions, reservoir drawdown measures, and a broad range of supplemental system/project implementation features. Policy Comments-the Draft EIS Alternatives: Given the conflicting policy-political visions surrounding Lower Snake River dam breaching and its overshadowing litigation forum, the CSRIA has little confidence in the resilience of the Draft EIS preferred alternative. From CSRIA's perspective, the only way it could have prevailed is through an ESA Exemption decision; and the CRSO agencies' WA-DC leadership has largely foreclosed that course of action.	Thank you for your comment.
32295	2	Rob Mercer	Columbia-Snake River Irrigators Association	So being, CSRIA is aware of a growing number of voices from the broader environmental, governmental, industrial, and utility communities calling tor something other than what is portrayed by the Draft EIS alternatives. In effect, this call is tor a "new regional alternative." While those seeking further discourse are short on offering specifics, other Lower Snake River project operations apparently are open tor review, as well as additional mitigation or compensation measures. The CSRIA recommends that the CRSO EIS managers work, now, with the principal stakeholders and litigation participants to define system operation measures that should be included in the Final EIS, as representative of a new regional alternative. This redefinition of a new regional alternative could be part of a status conference with Judge Simon, or it could be led by one or more of the state governors' offices. Through its own dam breaching review, Washington State representatives have expressed a willingness to mediate discussion of a new EIS alternative; the CSRIA would support Gov. Inslee's representatives doing so. This expedited process should not depend on consensus, but pragmatic compromise. Simply grinding on with the current EIS alternatives and ignoring the high degree of regional rejection, invites more hostile litigation in 2021. There is ample time to modify the Draft EIS in an attempt to define a subset of compromise measures, rather than accept that the existing EIS will be reshaped by the federal court. The EIS need not become a classical Greek tragedy.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions on the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion.
32295	3	Rob Mercer	Columbia-Snake River Irrigators Association	Technical Changes and Observation: Irrigation Sector Impacts: Under the four Lower Snake River dam breaching alternative, the irrigation sector impact area is substantially underestimated, and the estimated direct net economic value impacts are only partially correct. These factors have been discussed with the USBR and Corps EIS managers, and they have been provided with the CSRIA Risk Mitigation Response Alternative White Paper (see complete White Paper at CSRIA.org/Risk Mitigation). The Draft EIS irrigation sector impact area should be expanded (see attached Maps). While the Ice Harbor Pool irrigated acres are slightly less that the CSRIA estimate (about 54,000 acres), the Draft EIS fails to account tor the McNary Pool acres (about 37,000) that will be affected by breaching/pool drawdown. Under dam breaching, it is not realistic to expect the reach below Ice Harbor Dam to the mainstem Columbia River to remain "stable" or "the same" as under existing physical conditions. The inflows to this reach will be at a much higher water velocity, coming from a much narrower channel; and with very high silt and debris concentrations (as noted in the EIS). Irrigation pumping stations along the entire impact area, including the Upper McNary Pool reach, are highly sensitive to pool elevation drawdowns and siltation issues. The breaching (and/or MOP) operations will definitely impact the pump stations and conventional operations. These are high dollar impacts.	McNary pool elevations are not anticipated to drop below current operating minimums under any alternative. The breaching of the lower Snake dams in MO3 may cause a temporary increase in sediment, which may require increased maintenance.
32295	4	Rob Mercer	Columbia-Snake River Irrigators Association	Within the Risk Mitigation Response Alternative White Paper, the CSRIA has provided the EIS managers with information and further guidance on the regulatory and legal framework tor estimating the direct net economic impacts. The Draft EIS analyses should have relied on the market analysis for willingness-to-pay values, as opposed to county assessment values used for property taxation purposes. The actual market values in the attached tables reveal the full asset values attributable to the irrigation operations, and should be applied or explicitly identified within the Final EIS.	The land value approach, as explained in Appendix N, is an acceptable approach for measuring the social welfare value of irrigation water. The Principles and Guidelines (P&Gs) describe two methods for evaluating the social welfare effects associated with irrigation, farm budget analysis and land value analysis. The land value method is based on the use of land values as a measure of the lands income-producing capability from farm production. The P&Gs land value method call for a with and without comparison of irrigated and non-irrigated lands. When using land values to estimate the social welfare effects of irrigation water, the land values used for estimating the value of the water must be based only on the lands income-producing capability from crop production so other factors not related to irrigation water supply are excluded from the social welfare effects. As explained in Appendix N, the market value of land often differs from the agricultural use value and includes premiums unrelated to irrigation water. The differences may occur when market values are influenced by non-agricultural activities such as urban development.
32295	5	Rob Mercer	Columbia-Snake River Irrigators Association	For the McNary-John Day pools, the Draft EIS appears to establish the operating range baseline as being minimum irrigation pools (MIP) during the spring-summer period. CSRIA supports this operating protocol.	Thank you for your comment.
32295	6	Rob Mercer	Columbia-Snake River Irrigators Association	Navigation-Transportation Impacts: Concerning dam breaching, the navigation-transportation analysis in the EIS has omitted a very critical and essential component: the availability of the WATCO-Union Pacific rail line from Lewiston to Lyons Ferry (along the north side of the Lower Snake River), to the main Union Pacific rail route east to Wallula, Boardman, and Portland (see attached WA State rail map). This rail route would be the primary rail route for grain shipments diverted from barge traffic under dam breaching-pool drawdown operations. The EIS principal investigator for the rail alternative analysis did not calibrate the WSU TOM dispatch model to include the WATCO-UP line, a highly viable rail route. CSRIA representatives have examined this rail route in detail, given multiple contacts and information requests from the WATCO-UP operations managers. They have confirmed the ability of the rail lines to handle additional wheat shipments (1-3M tons), and their ability to make relatively quick modifications to staging areas to absorb incremental loads. The detailed discussions between CSRIA representatives and WATCO-UP managers confirm that the EIS principal investigator failed to contact the rail managers. For the EIS analysis, this is an invalid research protocol and inadequate rail alternative verification process. The EIS principal investigator should be directed to rerun the TOM model with the WATCOUP alternative rail operations. This new EIS analysis, for inclusion in the final EIS, also should be reviewed with the WATCO-UP operations managers to confirm operational viability and dispatch capabilities.	The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID, to Ayer Junction, WA. Research conducted as part of the EIS suggested that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers.
32295	7	Rob Mercer	Columbia-Snake River Irrigators Association	Power Impacts: The CSRIA members depend on a reliable electric power supply. Although this predominantly consists of a summer peaking load, the food production industry depends on winter peaking power to operate food processing-distribution facilities. While we are cognizant of state legislative/regulatory planning constraints, it is absolutely crucial for the EIS managers (particularly BPA managers) to include the full peaking power capacity from existing and planned combustion turbines/combined-cycle combustion turbines for (available) future power resources. The Pacific Northwest regional power demand cannot be met without these units-there is no reasonable scenario, of any kind, to provide "replacement" peak power alternatives. With or without dam breaching or pool drawdowns, the CT/CCCTs must be operational to sustain future loads, as well as for the integration of more costly wind and solar (with some battery capacity) resources. The CO2 footprint of the gas -fired CT/CCCTs is negligible, as the region decommissions coal-fired units and further changes the operational profile of hydro power projects (including BPA's forecast climate change impacts). While we do not discount continued efforts for conservation-efficiency measures and demand response programs, the CT/CCCT units must be in operation. The same is true for the future of small modular nuclear reactor siting. The Idaho National Laboratory and the Dept. of Energy's Hanford Operations (and contractors) may be bullish on modular reactors, but it is unrealistic to assume these units will be sited without confirmation for a permanent commercial nuclear waste siting facility (existing and future waste), more regulatory review by the states, and widespread public acceptance. To the extent such units come on-line, perhaps operating as base load power stations, they should not be presumed to dislodge the need for CT/CCCTs, for readily dispatchable peaking capacity.	The EIS uses the GENESYS and AURORA models to simulate the effects of the regional power system under each alternative. These models account for the capabilities of all existing regional power plants, such as the combustion turbines mentioned by the comment. For all of the Multiple Objective alternatives (MOs) the EIS models two potential replacement portfolios: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). In the Draft EIS, see Section 3.7.3.5, at pages 3-904-910. The conventional least-cost portfolios includes gas fired resources to meet the Loss of Load Probability of the No Action Alternative, as suggested by the comment. For the zero-carbon replacement portfolio, the EIS finds that new zero-carbon resources can restore the regional reliability to that of the No Action Alternative, though at considerable cost. Consistent with the discussion in the comment, the EIS power modeling finds that existing peaking plants (CT/CCTs) increase power generation when renewable resources replace the hydropower output lost under the Preferred Alternative, MO3, which includes breaching of the four lower Snake River dams, and Multiple Objective alternative 4 (MO4). Under MO3, a sensitivity study was considered for the full replacement capabilities with non-carbon emitting portfolios that include pumped storage and Small Modular Nuclear Reactors (SMRs). See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS. It is acknowledged that the Northwest Power and Conservation Council (Council) does not consider these resources to be primary resources at this time. However, pumped storage will likely be considered a secondary resource in the Councils Eighth Power Plan as it is a proven technology with several sites that have moved through the permitting process.
32295	8	Rob Mercer	Columbia-Snake River Irrigators Association	Lower Snake River Fish Passage Survival Modeling: The Final EIS should highlight more clearly the dependence of Snake River fish survival to the existing juvenile fish transport program versus proposed in-river survival strategies. As concisely displayed in Table 1 analysis (attached), without the dams and .juvenile fish transport collection facilities, the overall "average" juvenile fish in-river survival would have to be at least 56%, through Lower Granite Pool to the Bonneville Dam tailrace. Based on existing empirical data and analyses (NOAA Fisheries, CSS Study), this "average" 56% survival rate would not be achievable under low-flow, high water temperature conditions like 2015. The TIR for 2015, approximately 4.0, far exceeds any potential in-river survival benefit from dam breaching-not mathematically possible. This type of basic analysis can be applied further to evaluate other operations for the Lower Snake River projects not incluc:led in the Draft EIS, but reviewed in previous Corps and Fish Passage Center studies. In Figure 2 (attached), it is assumed that some deep pool (spillway crest) drawdowns occur and the survival rates for the other Columbia River projects remain at historical levels, and with	The Preferred Alternative in the CRSO EIS does not include dam breach or deep pool drawdowns. That said, the co-lead agencies acknowledge the importance of using all available tools to enhance the life cycle survival of lower Snake River salmon and steelhead. Transportation will continue to be an operation that the co-lead agencies will utilize in the Preferred Alternative. Through adaptive management and monitoring, the co-lead agencies will continue to analyze the Smolt-to-Adult returns (SAR) of fish that were transported to those that migrated in-river. The region's ability to assess these effects will be enhanced with new PIT-monitoring facilities that are now available in the surface passage spill route at Lower Granite Dam.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Lower Monumental and Ice Harbor projects at optimal survival rates without deep pool drawdowns. Under this operating condition, Lower Granite Pool/Dam and the Little Goose Pool/Dam would each have to have a 97% fish survival rate (94% survival through entire reach) to equal the "average" system rate of 56%. Stated differently, deep spillway crest drawdowns at Lower Granite-Little Goose projects would have to have a 97% survival rate to equal or exceed the "average" survival rate provided by the existing juvenile fish transportation program. Under 2015 water-year conditions, the deep pool drawdowns would be ineffective to provide sufficient fish survival rates, even with fish transport remaining at Lower Monumental Dam.

Responses to the comments associated with these references are provided in the individual comment responses where the comments utilized these references.
32296	1	Adam Domanski	ECONorthwest	1. The DEIS does not properly consider the costs of a replacement power portfolio The Lower Snake River Dams produce a small share of the energy needs for the region and account for less power than BP A currently exports to other regions, primarily California.3 While the dams add useful capacity to ensure system reliability during certain months of the year, those capacity services could be provided by other resources at a relatively low cost. The DEIS assumptions result in a higher estimate of rate pressure outcomes associated with dam removal compared to prior studies. The DEIS estimates rate increases of 9.6 percent to 19.3 percent, depending on the replacement portfolio.4 In contrast, The Lower Snake River Dams Power Replacement Study, authored by Energy Strategies for the Northwest Energy Coalition found that the increase in the regional revenue requirement would be two to three percent higher after removal of the dams.5 Although the DEIS comments that the difference is because the Energy Strategies report has "older load data and natural gas price forecasts, has lower estimates for transmission-related costs, and therefore underestimates impacts to Bonneville ratepayers",6 the large difference suggests that the DEIS is using an unnecessarily high estimate for rate impacts that does not prioritize cost savings. Furthermore, the estimates of grid reliability in the DEIS greatly exceed current market estimates of those resources. In their 2018 study, Energy Strategies ran a simulation of the Pacific Northwest grid without the LSRD and noted how the loss of load probability changed for each month. Removing the LSRD increases the loss of load probability over one percent for four months: September, October, December, and January. While no formal market exists for this reliability service in the Pacific Northwest, California utilities are required to contract for "resource adequacy". Applying the price of adequacy contracts in California of approximately $4.34 per kW per month7 to the 1,000 MW operating capacity for the four months during which 3 Figure 1-3: BPA Average Monthly Generation (aMW) frolll 2007-2015 from Energy Strategies. (2018). Lower Snake River Dams Power Replacement Study: Assessing the technical feasibility and costs of clean energy replacement portfolios. Prepared for NW Energy Coalition. Retrieved from https://nwenergy.org/wpcontent/uploads/2018/04/LSRD_Report_Full_Final.pdf 4 DEIS, page 3-920, lines 27784-27785. 5 Energy Strategies. (2018). Lower Snake River Dams Power Replacement Study: Assessing the technical feasibility and costs of clean energy replacement portfolios. Prepared for NW Energy Coalition. Page 12. 6 DEIS, page 3-913, lines 27526-27528. 7 Chow, L., & Brant, S. (2017). The 2016 Resource Adequacy Report. California Public Utilities Commission. Retrieved from: http://www.cpuc.ca.gov/WorkArea/DownloadAsset.aspx?id=6442453942 the LSRD are needed to provide regional reliability sums to $17.4 million per year. This is substantially lower than the DEIS's estimate of $82 million to $371 million per year.8 The DEIS's reliance on the construction of new infrastructure ignores the true market price of these services and indicates that the DEIS' s cost estimates are likely overstated.	The comment is consistent with the EIS in stating that there are times the region is often surplus, that the four lower Snake River dams provided needed capacity during important times of the year, and that power from the four lower Snake River dams could potentially be replaced by other resources. The Loss of Load Probability (LOLP) level increases from 6.6 percent under the No Action Alternative to 14 percent under Multiple Objective (MO) Alternative 3, which includes breaching the four lower Snake River dams, which suggests that the four lower Snake River dams have a relatively large role in the region in terms of reliability. See Section 3.7.3.5, Effects on Power System Reliability, at 3-903 and Appendix H, Table 2-1 in the draft EIS. For example, under average water conditions and 80-year water data, the four lower Snake River dams produce between 460 aMW to upwards of 1400 aMW of power during the winter months of December through February, which are typically energy intensive months in the Northwest. See Section 3.7.3.5, Changes in Power Generation, Table 3-159 in the draft EIS. The comment cites the Northwest Energy Coalition (NWEC) report in suggesting that the EIS overestimates the effect of breaching the four lower Snake River dams on loss of load probability, and thus, overestimates resulting replacement resource needs and rate pressure effects. As described in the draft EIS in Appendix H, Power and Transmission and Section 3.7.3.5, the EIS considered the NWEC study cited in the comment, but it is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. The EIS used a load forecast prepared by the Northwest Power and Conservation Council (Council) and published in July 2017 for the 2022 Resource Adequacy Assessment. This load forecast includes all cost-effective conservation from the Council's 7th Power Plan. See Appendix H, Power and Transmission, Section 2.2, H-2-3 in the draft EIS. The Energy Strategies load forecast was from the Councils 7th Power Plan issued in February 2016. Thus, a direct comparison between the LOLP results is not possible. Appendix H, Power and Transmission, Section 2.4 p. H-2-16 in the draft EIS discusses the differences between the EIS and NWEC analyses in more detail. The EIS describes the operational characteristics of the four lower Snake River dams in the draft EIS in Section 3.7.3.5 ,Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). While the comment is correct that the four lower Snake River dams account for a small portion of total regional power generation, they are a larger portion of the Federal Columbia River Power System, from which Bonneville markets power. They also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of sustained peaking capability in certain months of the year (see Table 3-160 in the draft EIS). The ramping capability is valuable for system balancing, which is used to serve load (consumed energy by houses, business, industry) and to balance out the variability that renewable generation causes to the system. The comment suggests that the EIS did not prioritize cost savings and thus overestimated rate pressures. The basis for developing replacement resource portfolios may be found in Section 3.7.3.1, Methodology in the draft EIS. The EIS power analysis included all cost-effective conservation from the Councils 7th Power Plan in the load forecasts and identified the most cost-effective resources to improve reliability for each alternative. See Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H in the draft EIS for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (see Section 3.7.3.1). Similarly, the cost proposed in the comment for reliability and adequacy contracts is not consistent with the approach of the EIS. The EIS analyzed regionally specific loss of load probability (LOLP) and added capacity until the average annual LOLP was the same as the No Action Alternative level instead of focusing solely on pricing capacity lost in each month LOLP was reduced as discussed in the comment. The final EIS includes the de-escalating cost curves prepared by National Renewable Energy Laboratory that will likely be used by the Council in the 8th Power Plan. The EIS did not study capacity contracts with California because the study used the regional planning standard to determine when new capacity was needed to maintain reliability. By definition, the draft EIS identifies when existing capacity is not enough and more capacity needs to be built. Therefore, it is inappropriate to apply todays market price as an estimate for the cost a utility would have to pay to build new capacity. Further, a short-term market price of capacity is an inappropriate method to estimate the long-term cost of capacity. Short-term and long-term capacity purchases are inherently different products that frequently carry different prices particularly when evaluated over a single snapshot of the market that captures the market conditions at a particular moment in time. While there are times, such as during seasonal periods of low demand that the price of short-term market capacity could be very inexpensive, there are also times when the short-term market capacity would be more expensive than the long-run marginal cost of capacity, such as during times of high demand. It is also possible, as suggested by the LOLP analysis in the Draft EIS, that the short-term capacity market would not be available at all and reliability would be at risk. Taken together, the approach adopted by the EIS is more reasonable in that it uses resources as determined by the Councils 7th Power Plan, updated with the Mid-term Update and other information. This analysis estimates cost effective resources based on optimization models and other metrics developed by the Council, which provide a more robust picture of future availability of resources than a volatile spot-market capacity price.
32296	2	Adam Domanski	ECONorthwest	2. The DEIS does not fully account for the market value of foregone power Any reduction in generating load at any of the four Lower Snake River Dams results in an operating cost borne by BPA. This decrease in load can occur naturally through a reduction in river flow, anthropogenically through increased spill over the dams to enhance downstream fish passage, or artificially through oversupply events to manage total dissolved gas levels below the dams. The DEIS prices the oversupply events using a value of $29.22 per MWh which represents the 11 average historical price paid to generators displaced for FY2012-FY2019".9 Although this price is a function of negotiated contracted rates, it does not reflect the market conditions for surplus power generated from (or needed by) the BPA power grid. These negotiated rates are a function of BPA's substantial market power in the region. As a federal managing agency, evaluation of the gains or losses from different operating regimes should not rely on BPA's role as a regulated natural monopoly to identify public benefits and costs, but rather objective indications of the true market value of its services and resources. Fortunately, a market for the exchange of regional power does exist, in the form of the MidColumbia trading hub of the Inter-Continental Exchange (ICE). A comparison of BPA's negotiated rates and those posted on the ICE show that market conditions result in generally lower values of power when spill occurs in the spring due to excess capacity in the system from spring runoff.10,11 The DEIS itself references how market prices for power at the Mid-Columbia trading hub vary throughout the year depending on Il streamflow, generation, demand, and market factors".12 The DEIS's reliance on negotiated rates is an insufficient measure of the value because it does not account for the lowest cost alternative of purchasing the power on the open market to replace the power lost from the spill. The Bonneville negotiated rate of $29.22 is higher than Mid-Columbia trading hub rates of $21.02 per MWh for heavy load hours and $16.66 per MWh for light load hours (2019 dollars)."13 This price differential demonstrates the misleading estimates that can potentially result from not using a market-based rate to value the cost of increased spill in the alternatives. 8 DEIS, page 3-924, lines 27925-27926 and DEIS, page 3-925, lines 27932-27933. 9 DEIS, page 3-838, lines 25559-25562. 10 ECONorthwest. (2019). Lower Snake River Dams Economic Tradeoffs ofRemoval. July. Figure 3. 11 DEIS page 3-851, Figure 3-175. 12 DEIS page 3-851, lines 25922-25923. 13 DEIS page 3-851, lines 25920-25921.	The comment suggests that the EIS overvalues power generated from the four lower Snake River dams, suggesting that the values do not represent the market conditions observable at the Mid-C market price hub. The comment is conflating two distinct analyses in the EIS, one being the oversupply rate sensitivity analysis and the other, the primary base case analysis. While the comment is correct that the oversupply sensitivity analysis does use the higher average cost of $29.22, this is solely applied in the rate sensitivities for oversupply and is based on historical oversupply events. This was not the market price used in the rate pressure analysis or the social and economic analysis, which relied on monthly estimates from the Mid-C trading hub (see Section 3.7.3.1 Methodology in the draft EIS). Consistent with the suggestion in the comment, the EIS power analysis (Section 3.7) used the AURORA model to estimate average monthly Mid-C market prices of $21.02/MWh for heavy load hours (6 a.m. to 10 p.m. Mon-Sat, non-holidays) and $16.66/MWh for light load hours (10 p.m. to 6 a.m., plus Sunday and holidays) under the No Action Alternative (see page 3-851 of the Draft EIS). For each alternative analyzed, the average monthly Mid-C prices were used in the Bonneville wholesale rate pressure analysis, the social welfare analysis and retail rate analysis (see Section 3.7.3.1 Methodology and, in Appendix H, Sections 4.1.2, Market Prices and 5.1.1, Social Welfare Effects Based on the Market Price Method in the Draft EIS).
32296	3	Adam Domanski	ECONorthwest	3. The DEIS performs an insufficient accounting of the greenhouse gas implications of alternatives The electric power sector is the second largest source of CO2-equivalent emissions in the United States.14 Any changes in the power-generating grid can have potentially significant implications for CO2 emissions, as well as resulting climate change impacts. Identification of the sociallyoptimal alternative must consider both the upfront costs of power generation, as well as the resulting social costs of carbon emissions. This evaluation can be conducted two ways: 1) evaluate the cost of a fully renewable power generation portfolio, or 2) calculate the social value of the associated increased CHG emissions using the existing mix of new power generating sources coming online. The DEIS does an insufficient job of evaluating either. The DEIS asserts that during peak demand there would not be sufficient capacity to meet demand in the zero-carbon resource portfolio without fossil fuel generation.15 This assumption ignores the possibility of structural changes that would allow for peak-demand to be met with renewable resources. The finding that coal emissions would increase by one percent more in the "zero-carbon replacement portfolio" (eight percent) compared to the "conventional least-cost resource replacement portfolio" (seven percent) demonstrates that the resource mix chosen for the zero-carbon replacement portfolio is not structured for the lowest carbon emissions.16 If the DEIS did select a portfolio that was truly zero-carbon, it would be possible to meet CHG emissions objectives while also removing the four Lower Snake River dams. Although this may be accomplished at a higher cost, it may still create a socially optimal alternative by offsetting the social costs of increased CO2 emissions. The DEIS also does not comprehensively consider all of the available options for reducing electricity use. Although demand incentives are referenced, there is limited mention of energy efficiency incentives for private industries or similar options. The "zero-carbon" portfolio selects only "the lowest-cost carbon-free resources (e.g., solar, wind, or non-generating tools such as demand response)".17 The analysis artificially constrains the options available by not including higher cost resources to reduce emissions that would allow for zero increases in CHG emissions under MO3.	The comment is correct that any changes in how power is generated can affect greenhouse gas emissions (see Section 3.8.2.2 of the Draft EIS, Greenhouse Gas Emissions from Energy). Sections 3.7.3 and 3.8.3 of the Draft EIS consider two alternative replacement resource portfolios to replace the reduction in hydropower generation under the alternatives. One of these portfolios relies solely on building or acquiring renewable resources for replacement, finding that this scenario still results in some increase in greenhouse gas (GHG) emissions under Multiple Objective alternative 3 due to the need to maintain reliability during periods when the renewable resources could not ramp up to meet power demand. The comment is correct that the EIS analysis did consider the relative costs of renewable resources for this portfolio. However, the selection of the replacement resources additionally considered other aspects of their performance, including how they would contribute to regional reliability, imports, exports, and the potential effects on fossil fuel generation. Section 3.8.3 of the Draft EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements could bring other options. Regarding demand-side resources and potential structural changes to reduce peak demand, the EIS included the Northwest Power and Conservation Council's Seventh Power Plan 600 MW target for Demand Response in the renewable resource portfolio and all cost effective conservation in the load forecast for the power analysis (see Section 3.7.3 in the Draft EIS). All cost effective conservation in the region is assumed to be acquired consistent with existing law and mandates regardless of the status of the four lower Snake River dams.
32296	4	Adam Domanski	ECONorthwest	4. The DEIS does not fully evaluate the cost of replacement irrigation infrastructure The DEIS's approach to irrigation relies on the assumption that costs are "prohibitive" to modify the existing pump system for the Ice Harbor Reservoir.18 By not attempting to evaluate the cost of pump modifications, the analysis does not have sufficient information to state that 14 U.S. Environmental Protection Agency. (2020). Draft Inventory of U.S. Greenhouse Gas Emissions and Sinks: 19902018 Executive Sunmary. February 12. Retrieved from https://www.epa.gov/sites/production/files/2020-02/documents/usghg-inventory-2020-chapter-executive-summary.pdf 15 DEIS, page 3-1010, footnote 19. 16 DEIS, page 3-1010, lines 30404-30413. 17 DEIS, page 3-820, lines 25028-25030. 18 DEIS page 3-1267, lines 3246-3247. "all irrigated acres receiving water from the current pumps would no longer be irrigated".19 The DEIS assumes that all irrigated lands would no longer be irrigated and estimates the lost agricultural land value resulting from that change. Labeling costs as "prohibitive" would generally require some cost-estimation to indicate that they would not occur under existing market	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. Design plans and construction cost need to adhere to Federal guidance for engineering design and cost estimating. The Federal costs and assumptions must be used to be comparable with the dam removal costs.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				conditions. The DEIS does not independently conduct such analysis. Our report [attached] relied on a mitigation approach to identify the costs of dam removal to existing irrigators. This approach yields an estimate of $160 million in infrastructure adaptation surface water and groundwater costs.20 This is a substantially lower estimate than the $331 million to $458 million in lost irrigation value in the DEIS,21 and certainly not prohibitive. The DEIS also does not fully consider alternative water supply sources, such as the transition from surface water to groundwater sources, or obtaining water from the Columbia River rather than the Snake River. The DEIS references that the 2002 EIS suggested this possibility because the 2002 EIS "assumed that 21 percent of the irrigated land might support the development of alternative water supplies to replace lost irrigation water".22 However, the current DEIS does not provide a sufficient explanation for why these alternatives were not evaluated.	
32296	5	Adam Domanski	ECONorthwest	5. The DEIS does not appropriately estimate the increase in transportation costs resulting from the alternatives The Lower Snake River serves as a transportation corridor, enabled by the lock system operated at each of the four dams. Shippers in the region have multiple transportation mode alternatives in addition to the river, including rail and truck transportation. Given existing market conditions, it can be assumed that shippers are choosing the optimal mode for their goods based on price, timeliness, and reliability. Any shift in transportation mode as a result of the alternatives is likely to affect existing shippers in at least one of those three dimensions. Those resulting mode changes can impose public costs as well. The DEIS, however, fails to properly account for the full mix of private and public costs associated with the alternatives, for the following four reasons: The DEIS relies on a stakeholder survey conducted by the Social and Economic Sciences Research Center (SESRC) at Washington State University referenced in Appendix L.23 However, neither the survey nor associated response data are provided in the DEIS supporting materials, making it difficult to evaluate the appropriateness of the survey instrument or methodology. The DEIS does not provide sufficient information to estimate the expected increases in transportation costs. The transportation analysis relies on assumptions about how much rail rates would increase, using zero, 25 percent, and 50 percent increases in rail rates as 19 DEIS, page 3-1267, lines 3248-3250. 20 ECONorthwest. (2019). Lower Snake River Dams Economic Tradeoffs ofRemoval. July. Appendix 11.4. 21 DEIS, page 3-1259, lines 2959-2962. 22 DEIS, page 3-1267, lines 3248-3250. 23 DEIS, Appendix L, page L-3-3, lines 179-185. arbitrary assumptions.24 As acknowledged in the DEIS, rail rates increased by 35 to 40 percent during historical lock closures.25 However, these represent short term costs without any increase in rail capacity, and thus likely serve as upper bounds. The DEIS does not clearly identify net changes in dredging costs. In one section, the DEIS states "Dredging operations are expected to remain similar to the No Action in other reaches of the Columbia navigation channel, with an estimated cost of $67.1 million annually. In total, annual dredging costs would increase about 4.4 percent under MO3, from $70.1 million annually to $73.2 million."26 However, in another section, the DEIS states that "Annual navigation costs of approximately $10 million, including $3 million in dredging costs, would no longer be authorized at the four lower Snake River projects under MO3."27 These two statements appear contradictory. The DEIS fails to consider the true social value of the use of the lower Snake River as transportation infrastructure. As described in our report, "Significant federal appropriations are dedicated to operating transportation infrastructure on the LSRD that are not recovered via the USACE fuel surcharge and are borne by the federal government. A comparison of solely the transportation costs and the federal appropriations indicates that barge transportation along the LSR would not be viable without this subsidy".28 The DEIS fails to reference this fact or the cost savings from ceasing federal appropriations for operation of the locks.	How rail rates would change without lower Snake River shallow draft barging can not be known with certainty. Therefore, in order to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable. Additional sensitivity analysis has been added to Appendix L in the FEIS. Regarding the availability of survey data in the published documents, those documents were withheld for confidentiality reasons (confidential business information). Section 3.19 and Appendix Q describes the costs associated with navigation, including dredging. Changes in dredging operations are also described in Section 3.10.3.5. The document has been revised to reflect the most recent figures for dredging. Under the No Action Alternative, the Portland District dredging (lower Columbia River) were estimated to be $67.1 million annually over the 50-year period. Section 5.1.1.3 describes dredging costs for Walla Walla District projects, estimated to be $2.7 million annually over the period of analysis. A total of $84.2 million in navigation costs under the No Action Alternative annually were estimated, of which $69.8 million is related to dredging. Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
32296	6	Adam Domanski	ECONorthwest	6. The DEIS does not properly account for the economic impacts resulting from all spending associated with the alternatives The DEIS does not fully account for the increase in jobs, labor income, value added, and output that would result from the construction and mitigation spending associated with the various alternatives. Of note, the DEIS acknowledges that removal would be funded by federal appropriations: "An important assumption in the MO3 rate analysis is that the Bonneville would not pay for the cost of dam breaching. Rather, for this EIS, it is assumed that the cost of dam breaching would be covered by congressional appropriations."29 However, this increase in economic activity is not clearly accounted for in the DEIS. The local economic impact of this new spending in the region should be considered, not only for the direct labor and income it supports, but also for how that spending could stay in the local economy and support other jobs. This deficiency also presents itself in the DEIS's analysis of transportation costs and is clearly acknowledged: "This estimate does not include potential impacts associated with reduced 24 DEIS, page 3-1118, lines 33052-33055. 25 DEIS, page 3-1125, lines 33227-33229. 26 DEIS, page 3-1131, lines 33366- 33369. 27 DEIS, Appendix Q page Q-5-4, lines 702-704. 28 ECONorthwest. (2019). Lower Slmke River Dams Economic Tradeoffs ofRemoval. July. p.116. 29 DEIS, page 3-918, Footnote 75. demand for barge employment or an increased demand for trucking employment that would accompany these shifts."30 Similarly, although the DEIS acknowledges that dam breaching could increase recreation in the long term, economic impacts are only estimated for the loss of reservoir recreation and not the potential gain from fishing opportunities or free-flowing river-based recreation.31 These fundamental changes in spending patterns should be included, so that the public has a full appreciation of the net change in economic activity as a result of the different alternatives.	The EIS considers the jobs supported by the implementation and CRSO EIS system costs, including mitigation costs described in Chapter 5 and in Annex B of Appendix Q. The regional economic effects of the CRSO EIS expenditures are described in Section 3.19.3 of the EIS and in Annex C of Appendix Q. The EIS provides a regional economic evaluation in the resource Sections in Chapter 3, for example for Recreation (Section 3.11) and Navigation (Section 3.10). The regional economic effects were estimated for the reduction in reservoir recreation in the short-term under MO3; in the long-term after dam breach, the EIS describes that visitation in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The EIS also describes how the transition to river-based activities would require that tourism businesses, such as retail, rental businesses, and service providers, adapt to the new type of visitor who may demand different types of activities, services, gear, and retail merchandise. A range in visitation is described in the lower Snake River post dam breach based on the evaluation in the 2002 Juvenile Salmon Migration Feasibility Study and EIS. The social welfare values and regional economic effects associated with river recreation post dam breach were not estimated because of the uncertainty and large range in visitation and consumer surplus values and visitor expenditures among users. In addition, the timeline of the EIS precluded an extensive survey and evaluation of post dam breach recreation. Section 3.10.3.5 acknowledges that trucking is more labor intensive than barge operations, and therefore increased trucking demand would likely increase employment demand for shipping handlers. However, the EIS also points that stakeholders have noted that, in the short term, an already tight market for truck drivers would be made even tighter when demand increases under MO3.
32296	7	Adam Domanski	ECONorthwest	7. The DEIS does not properly account for the full suite of benefits stemming from recovery of endangered salmonids in the Columbia and Snake Rivers. Any accounting of the benefits and costs of the different alternatives must include all relevant types of economic value. This includes direct monetary benefits and costs (i.e. changes in transportation spending, the costs of dam removal, etc.), but must also include non-market values, including the non-use or existence value of restored ecosystems. Non-use values are measures of the economic tradeoff that an individual is willing to make to assure the protection of a natural resource even if they will not visit or use the resource.32 These values are not revealed by choices in the marketplace (unlike many local public goods),33 and must be measured using stated-preference survey-based approaches.34 Stated preference surveys have questions that help to reveal the monetary tradeoff an individual would make concerning the value of goods or services. Non-use values serve an important role across a broad set of policy arenas. For example: Pennsylvania used contingent valuation in a benefit-cost analysis of additional incarceration versus rehabilitation programs for serious juvenile offenders.35 Non-use value estimates were used to measure the value of developing vaccine policies in Africa.36 30 DEIS, page 3-1142, lines 33700- 33702. 31 DEIS, page 3-1223, lines 1976-1979. 32 Carson, R. Cost-effectiveness of new-generation oral cholera vaccines: a multisite analysis. Value in Health, 12(6), 899-908. Stated preference surveys have been used to measure the willingness of the U.S. public to pay for climate change measures.37 Stated preference surveys have been used by state and federal natural resource trustees to estimate natural resource damages in the Exxon Valdez oil spill (1989), Montrose Chemical contamination (2000), Oklahoma v Tyson case (2010), and Deepwater Horizon oil spill (2010).38 Stated preference surveys have been used to evaluate the benefits of dam removal on the Elwha River39,40 and the Klamath River.41 Federal courts and agencies have also long acknowledged the importance of non-use values, in particular: The U.S. Forest Service's 2012 Planning Rule required that planning activities consider ecosystem services as part of an integrated resource management focus.42 The White House issued memorandum M-16-01 in 2015, which directed "agencies to develop and institutionalize policies to promote consideration of ecosystem services, where appropriate and practicable, in planning, investments, and regulatory contexts."43 DC Circuit Court of Appeals: "option and existence values may represent 'passive' use, but they nonetheless reflect utility derived by humans from a resource, and thus, prima facie, ought to be included in a damage assessment."44 The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA): Compensable value includes "all of the public economic values associated with an injured resource, including use values and nonuse values such as option, existence, and bequest values."45 37 Aldy, J. E., Kotchen, M. J., & Leiserowitz, A. A. (2012). Willingness to pay and political support for a US national clean energy standard. National Oceanic and Atmospheric Administration (NOAA): 11well conducted CVM studies can produce estimates reliable enough to be the starting point of a judicial process of damage assessment, including lost passive values."46 BoR: "The state of the natural environment affects people both in how they use the environment and how they would prefer the environment to be. Thus,	The EIS (Section 3.15.2.2) describes the existing literature on passive use values for salmon, including the studies referenced in this comment, and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each MO (as different fish are affected positively and adversely), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				both use and non-use values need to be considered when assessing impacts to the human environment."47 Despite this, the DEIS neglects to directly estimate non-use values. Notably, however, the DEIS does acknowledge their importance and likely broad geographic extent. Specifically, the DEIS states that: 11This analysis acknowledges that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching."48 Non-use values are widely accepted in the economic literature and among federal agencies, including an instance where the BoR directly implemented a non-use valuation study to evaluate the benefits of removal of the Lower Klamath Dams. It is clear that the DEIS's omission of quantified non-use values makes it an insufficient tool to reach conclusions about alternatives.	
32296	8	Adam Domanski	ECONorthwest	8. The Preferred Alternative does not maximize benefits associated with endangered species The DEIS relies on a "scorecard" approach, where alternatives are rated based upon their ability to meet narrowly defined objectives, rather than evaluating the magnitude of differences in outcomes between alternatives. The most detrimental impact of the scorecard approach for comparing alternatives is the failure to account for the significantly higher benefits to anadromous fish species in MO3 compared with all other alternatives. As described in the Executive Summary, "Model estimates for MO3 showed the highest predicted potential smoltto-adult returns (SARs) for Snake River salmon and steelhead among the alternatives".49 Specifically, for Snake River salmon and steelhead, SARs would increase by 170 percent relative to the No Action Alternative.50 In contrast, the preferred alternative would increase SARs by approximately 30 percent for Snake River Chinook and steelhead and may actually decrease SARs for Snake River Chinook, depending on which model is used.51 46 Arrow, K., Solow, R., Portney, P. R., Leamer, E. E., Radner, R., & Schuman, H. (1993). Report of the NOAA panel on contingent valuation. Federal register, 58(10), 4601-4614. 47 Glen Canyon Environmental Impact Statement (1996) USDOI, BOR. 48 DEIS, page 3-1322, lines 5083-5086. 49 DEIS, page 25 of Executive Summary 50 DEIS, page 25 of Executive Summary. 51 DEIS, page 33 of Executive Summary. The scorecard structure used in the DEIS to evaluate the benefits to anadromous fish is narrow in scope and fundamentally unable to weigh a full suite of benefits and costs. When relative magnitudes of effects are considered, our analysis clearly indicates that the benefits of dam removal outweigh the costs. Since the primary purpose of the DEIS and the ESA listing of anadromous fish is to aid in their recovery, every reasonable effort should be taken to truly weigh the magnitude of benefits and costs of outcomes. In their selection of the preferred alternative, the federal managing agencies are willing to make a tradeoff in the survival of endangered species, without properly accounting for the price of doing so.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The co-lead agencies acknowledge that model estimates for MO3, which includes breaching the four lower Snake River dams showed the greatest predicted potential Smolt-to-Adult returns (SARs) for Snake River salmon and steelhead among the alternatives. The purpose of the analysis in the EIS is not limited to salmon issues, however. The EIS analysis provides analysis of multiple objectives and resources affected by CRS operations maintenance, and configuration. The CRS operations are balanced for multiple purposes, including flood risk management, water supply, hydropower generation, fish and wildlife conservation (including a variety of other species than salmon and steelhead), navigation, cultural resources, recreation and other environmental and socioeconomic resources. In addition, the CRSO EIS seeks to identify a Preferred Alternative that achieves a reasonable balance of multiple river resource needs and co-lead agency mission requirements. In addition to the benefits for Snake River salmon and steelhead of dam breaching, the analysis showed major adverse impacts, particularly to navigation, irrigation, and power supply and reliability. Under the ESA, in particular Section 7(a)(2), the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
32327	1	Wallace Ruff	N/A	I propose that a four-year moritorium be placed on ALL fishing, sport, commercial, native Indians, on the Snake and Columbia Rivers and in a 200-mile zone of the Pacific Dams along th Northwest Coast. This moritorium would establish the true salmon population that can be expected in today' s climate. It would dictate how improvements might be made, not only in the rivers, but off shore, too.	The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. An evaluation of the West Coast fisheries is outside the scope of this EIS. Fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (e.g., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors.
32328	1	Mitchell Hawkins	N/A	The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. A rise in energy costs would mean greater hardships for people already struggling to make ends meet. We are seniors on a fixed income and would be directly affected by a large increase in our electrical rates.	The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. See Section 3.7.3.5, at 3-918 to 924 in the Draft EIS; see also Table 3-166. The statement that costs could increase by up to 50 percent is also consistent with the findings of the EIS. The Environmental Justice analysis (Section 3.18.3) provides further detail on potential disproportionate effects including to Tribal, low-income, and minority populations.
32335	1	Jan Ostlund	N/A	Regarding the removal of the Snake River dams, is it possible to compromise and remove two of the dams thus providing SOME hydroelectric power and SOME irrigation water leaving two less dams for the salmon to navigate?	The four lower Snake River dams were jointly authorized and function together as a system with the other ten projects analyzed in this EIS; having only two out of the four dams functioning would not allow the co-lead agencies to meet navigation, greenhouse gas, or power reliability objectives, while also not likely making a substantial change for migrating salmon in the Snake River based on analysis of breaching all four projects and in comparison to other alternatives. The Draft EIS examined the operation and maintenance of the 14 projects in the Columbia River System. Other dams are not within the scope of the EIS or the purview of the co-lead agencies.
32345	1	Roman Gillen	Consumer Power Inc. CPI	We appreciate the great care taken to provide detailed information used in the entire analysis, especially the information concerning significant differences between the Comparative Survival Study and Life Cycle Model fish modeling approaches. We would like to see proposed actions and a process to address this issue.	Chapter 7 provides detail at a similar level to Chapter 3 and provides estimates for all elements of the co-lead agencies' Preferred Alternative. The Preferred Alternative will include an adaptive management program that will include updates and assessments of both the CSS and NMFS Life Cycle models. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
32345	2	Roman Gillen	Consumer Power Inc. CPI	Our main concern with the PA is increased spill up to 125% total dissolved gas (TDG) levels, resulting in higher power costs for CPI members and possibly adverse effects to ESA-listed species. We support higher spill levels (e.g. up to 125%) and the resulting higher power costs only if scientific analyses clearly show a meaningful benefit to ESA-listed species.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
32345	3	Roman Gillen	Consumer Power Inc. CPI	Additionally, we urge you to include in the final Record of Decision (ROD) strengthened and expanded measures to mitigate the predation of tens of millions of ESA-listed juvenile fish each year, particularly in the lower Columbia River, by various birds and predatory fish. We also expect the federal agencies to take full advantage of the provisions of the Endangered Salmon Predation Prevention Act to strengthen and expand protections for returning adult fish and would like to see a strong commitment to do so reflected in the final ROD.	The Endangered Salmon Predation Prevention Act authorizes NOAA to issue permits to states and Tribes to kill sea lions in the lower Columbia River and some tributaries in order to protect certain fish from sea lion predation. The co-lead agencies do not have authorities to administer the Act. However, the co-lead agencies have supported actions to mitigate adverse effects to listed species from CRSO operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue as described in Chapter 7.
32345	4	Roman Gillen	Consumer Power Inc. CPI	Our support for the P A is also based in large part on substantially preserving bulk power system reliability and avoiding blackouts (a.k.a. Loss of Load Probability), especially compared to Multiple Objective Alternatives 3 and 4 (M03 and M04), which are clearly unacceptable. As Northwest states enact policies that support intermittent, non-firm, renewable generating resources over dispatchable, firm, carbon-based generating resources, our concern for the reliability of our bulk power system has turned to genuine alarm as the risk of blackouts rises dramatically each year. Thousands of our members, many of whom are seniors and those on fixed- or low-incomes, live in rural areas without access to alternative energy sources. They are heavily dependent on the electric service we provide to not only heat their homes and power their appliances, but to also provide domestic water and even septic service in many cases. They are particularly vulnerable to increased risks of blackouts and escalating power costs, which makes the P A worthy of our support in terms of its lower risks in these areas compared to other DEIS alternatives, namely M03 andM04.	Thank you for your comment.
32345	5	Roman Gillen	Consumer Power Inc. CPI	The worst-case wholesale rate impacts of using zero carbon resources to replace the generation lost by removing the four lower Snake River Dams (LSRDs) as proposed in M03 are stunning- a whopping 50% - and M04 is only slightly less damaging. The average monthly bill for residential CPI members is currently $124.55 and would jump more than $30 per month to $155.70 under the worst-case scenario for M03, assuming that we would have to raise our retail rates by 25% in order to cover a 50% increase in wholesale power costs. It is important to keep these financial impacts in perspective for rural communities like ours that have incomes below regional and state averages. These increases in power costs are not a simple shift from disposable and discretionary income to pay for essential services like electricity. Rather, they mean that CPI members are forced to make difficult choices about which essentials like food, medicine, utilities, and such they have to sacrifice.	The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The wholesale power rate effects described in the comment are consistent with the findings of the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 and Chapter 7 of the EIS) provides further detail on this as well as the potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment.
32352	1	Bruce LePage	N/A	15% of our monthly, northwest electric bills go toward salmonid recovery. This cumulatively adds up to billions of dollars.	As described in section 3.7.2.7 (see Power Revenue Requirement), Bonneville is a self-funded, not-for-profit government entity that is required by statute to ensure that the rates it charges are set to recover its costs consistent with sound business principles. Bonneville recovers its costs by establishing a revenue requirement, which is a list of projected costs for a rate period that must be paid by revenues generated from rates. The revenue requirement for power rates is comprised of three major categories: Program costs (O&M, employee costs, fish & wildlife, conservation); Debt payments including principal and interest; and Costs calculated through the rate setting process (Residential Exchange Program, power purchases, cost of transmission, and rate discounts). Figure 3-165 in the draft EIS describes how each dollar of its power revenues is spent. Roughly 17 cents of each dollar are spent on fish and wildlife mitigation, including Bonneville's Fish and Wildlife Mitigation Program. The Bonneville Fish and Wildlife Program funds hundreds of projects each year to mitigate the impacts of the federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. The full impact of fish and wildlife mitigation on power revenue equates to roughly 24 cents of each dollar due to the costs of lost power generation that results from spill and other operational requirements for fish and wildlife. The projected program costs are discussed through a public process, the Integrated Program Review, prior to the initiation of the rate setting process.
32355	1	Glen Squires	Washington Grain Commission	Washington wheat and barley farmers pay all handling and transportation costs to move their crops to domestic and export locations. The river system is crucial as an essential corridor to move grain and has also served as a competitive buffer against rising rail rates. Approximately 60 percent of all Washington wheat is moved by the Snake/Columbia River System to export ports. The river system serves as important national navigation infrastructure for international trade. According to the DEIS, under MO3, transportation costs would increase seven to 24 cents or 33 percent if the dams are breached, a range the WGC believes errs on the low end of what could occur based on the rates of captive shippers elsewhere (and on shortcomings of the DEIS as noted later). That is, of course, also assuming railroads have the capacity to move the nearly four million tons of commodities that currently travels on the river without a significant investment in other transition costs which have not been accounted for in the DEIS.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, was completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The analysis found that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects section in Section 3.10.3.5.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Removal of river navigation (a competitive alternative) and then the assumption that rail rates would not rise disproportionately goes against years of observation of freight rates as a whole when competition is removed, including PNW wheat freight rates. The cost of rail freight will increase for all grain throughout the Pacific Northwest, even for the grain or other commodities that do not currently move by barge. Not only will rates go up, but other costs, such as the cost of additional trucks a farmer or entity has to purchase to accommodate turnaround times at harvest for example must be accounted for. Whiteside & Associates analysis of current and historical rail rate behavior given changes in modal competition provides valuable insight regarding backhauls, truck movement to Portland and associated impacts, and other freight impacts outside of the immediate Snake River locale, including Montana that should be factored into any analysis of grain flow cost impacts. (Whiteside & Associates transportation analysis is included at the end of the WGC comments). Mention is made in the DEIS of upwards of $86 million that would be needed for rail upgrades and new facilities, but there are also safety costs, property value costs, and a myriad of transition costs that are not captured or specific costs identified, many of which will be ultimately borne by the farmer. The farm producer is unique because they operate in an environment where they do not have any control over the price they receive for their crop and they must bear the increases in costs, including transportation costs, without any possibility to pass those higher costs on to others. We believe the identified upgrades, new facilities and transport costs to be low and misrepresent and even understate the impacts of breaching the Snake River dams. Further analysis by the FCS Group for example, reveals that: The DEIS understates the true cost of highway and rail capacity improvements; Understates the national cost of removing dams; Does not account for grain storage and highway capacity costs; Quantifies transportation impacts, but does not account for non-grain shipments; and Understates the increased truck movements that will result (example: the DEIS acknowledges that 38 percent of the movement on the Snake River is not accounted for in the analysis); and assumption that short line rail costs, which seem low, will automatically be paid is questionable. The short line system is already underfunded now. The discrepancy between both the Whiteside & Associates and FCS study analysis and the DEIS regarding transportation are sufficient such that the WGC encourages the Federal Agencies to review and update their transportation findings in the DEIS. Relative to M03 and the Final EIS, all potential local and national direct and indirect costs to the transportation network, farmers and the farm economy, communities and the state of Washington should be accounted for, with costs listed. (FCS transportation analysis is included at the end of the WGC comments).	Assumptions made in the EIS and within the transportation optimization model are informed by plans released by WSDOT. In particular, a discussion with several experts at WSDOT is cited in Section 3.10.3.2 in which WSDOT provided input on the future of the Palouse River and Coulee City Rail (PCC), which are also presented in the WSDOT 2019 Draft Rail Plan. Additional insights into the capacity of Eastern Washington's short line capacity were also provided by WSDOT that informed the EIS. Additionally, given that it is the Class I railroads that decide where they will invest in their infrastructure and when, there was no reasonable process for predicting how and where they choose to invest to maximize profits on a national rail network that moves far more products than wheat from the northwest. Research conducted as part of the EIS suggested that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers.
32355	2	Glen Squires	Washington Grain Commission	Notably absent in all the discussion about lower Snake River dams' role in salmon recovery are the dams that totally block fish migration because of no fish passage capabilities, including those on the Snake and Clearwater rivers upriver from Lower Granite Dam. Perhaps fish passage should be explored.	Section 1.9.7.2 discusses dams eliminating access to historical range, specifically discussing Chief Joseph, the Hells Canyon Complex, and Dworshak. Fish passage over Dworshak was a measure considered early in process, but was eliminated from further analysis and not included in the range of alternatives. The Hells Canyon complex are private dams and not in the scope of this EIS. The purpose of the EIS is not to explore salmon recovery options, but only to update the Operations and Maintenance, and Configuration of the 14 dams operated as the CRS, while complying all applicable laws and meeting multiple purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Several of the objectives of the EIS used to evaluate measures were to improve conditions for fish.
32355	3	Glen Squires	Washington Grain Commission	More gains are also clearly possible by addressing the heavy predation on salmon by sea lions and bird colonies.	As described in the Preferred Alternative, the co-lead agencies propose several measures to reduce avian and marine mammal predation to mitigate adverse effects to listed species from CRS operations. Ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam.
32357	1	Chase Mattoon	N/A	I tried to respond at the web site listed in the newsletter, but it wouldn't work	The co-lead agencies are sorry you had difficulties. The public had several ways to submit comments such as the online comment form and through the mail. We are glad to see you were able to provide comments.
32358	1	Brant Hinze	N/A	Lowering Lake Pend Oreille's summer lake level in low water years, thus eliminating our long understood stable summer lake elevations, would have devastated our local economy, which is predominantly dependent on water base recreation. This change would have prevented boat access at countless locations around the lake, prevented close to 90% of waterfront landowners from mooring their boats, reduced property values, and crippled the summer economy. Given that we are on the shallow end of the lake we require full pool to take advantage of our boat lift and dock.	The Recreation Section 3.11.3.6 describes the adverse social welfare, regional economic, and social effects associated with reduced water surface elevations at Lake Pend Oreille during the summer months in low water years under MO4. MO4 was not selected as the Preferred Alternative.
32359	1	Anna Lindstedt	Fall River Rural Electric Cooperative	Any new costs to the FCRPS as a result of these proposed actions should be equitably allocated and not borne exclusively by BP A's public power customers ~specifically, to the extent that the PA results in additional costs allocated entirely to public power. It is time to find ways to build on existing federal law to more broadly share these regional costs.	The financial responsibility for all proposed actions is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish and wildlife mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by an established cost allocation, and this allocation is recovered through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). As described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Program expenditures incurred mitigating the Columbia River System operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
32359	2	Anna Lindstedt	Fall River Rural Electric Cooperative	Fall River is concerned about the results of the competing fish modeling used to determine the impact of increased spill on juvenile and returning adult salmon and would request that the agencies continue to monitor and study the net effect on salmon.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
32359	3	Anna Lindstedt	Fall River Rural Electric Cooperative	We support the use of adaptive management to protect ESA-listed salmon from any unintended consequences of unprecedented and untested levels of spill. Proposed spill is not proven to help fish. The Cooperative is also concerned that additional spill will de-optimize the federal hydro system and have a negative impact on the region's goals of decarbonization.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Appendix R, Part 2 describes the principles for implementation of the flexible spill operations and guidance for adaptive management. One of the principles focuses on federal power system benefits, which will be as determined by Bonneville Power Administration. The understanding is that Bonneville must, at a minimum, be no worse financially compared to the 2018 spring fish passage spill operations ordered by the Court. This principle is directly related to Objective 5 of the CRSO EIS: Provide an adequate, efficient, economical and reliable power supply that supports the integrated CR Power System. The co-lead agencies have determined that the Preferred Alternative meets this Objective. In addition, the Preferred Alternative places additional rate pressure for wholesale power rates of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs it has significant control. The Preferred Alternative does not meet the objective for Greenhouse Gas Emissions across the region. Hydropower generation would decrease resulting in increased generation from existing gas and coal plants resulting in increased greenhouse gas emissions.
32359	4	Anna Lindstedt	Fall River Rural Electric Cooperative	Fall River encourages cooperation with environmental and tribal groups to work on plans that bolster a sustainable salmon and steelhead population. Specifically, we support efforts to manage avian impact and other predation of salmon populations.	Thank you for your comment.
32359	5	Anna Lindstedt	Fall River Rural Electric Cooperative	Thousands of our members, many of whom are seniors or those on a fixed or low income, live in rural areas without access to alternative energy sources. They are heavily dependent on the electric service we provide to not only heat their homes and power their appliances, but also to provide	Thank you for your comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				domestic water and even septic service in many cases. They are particularly vulnerable to increased risks of blackouts and escalating power costs, which makes the P A worthy of our support. Compared to other DEIS alternatives, it presents lower risks in these areas.	
32365	1	Susan Blende	N/A	Lowering Lake Pend Oreille's summer lake level in low water years, thus eliminating our long understood stable summer lake elevations, would have devastated our local economy, which is predominantly dependent on water base recreation. This change would have prevented boat access at countless locations around the lake, prevented close to 90% of waterfront landowners from mooring their boats, reduced property values, and crippled the summer economy. Our own access to the lake for boating would have been eliminated since the dock and boat lift structures have been built to be used at the summer lake level that has been agreed to and maintained for generations. The ramp from the boat house, which is usable at the long established summer lake level, would not have reached a depth to be usable.	The Recreation Section 3.11.3.6 describes the adverse social welfare, regional economic, and social effects associated with reduced water surface elevations at Lake Pend Oreille during the summer months in low water years under MO4. MO4 was not selected as the Preferred Alternative.
32365	2	Susan Blende	N/A	Lowering Lake Pend Oreille's summer lake level in low water years, thus eliminating our long understood stable summer lake elevations, would have devastated our local economy, which is predominantly dependent on water base recreation. MO4 was not selected as the Preferred Alternative.
32366	1	Georg Behrens	N/A	Any new costs to the FCRPS resulting from these proposed actions should be equitably allocated and not borne exclusively by BPA's public power customers. Specifically, to the extent the preferred alternative results in additional costs allocated entirely to public power, it is time to find ways to build on existing federal law to more broadly share these regional costs amongst all parties benefitting from the CRSO.	The financial responsibility for proposed actions is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish and wildlife mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by an established cost allocation, and this allocation is recovered through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). As described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the Columbia River System, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the Columbia River System operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
32366	2	Georg Behrens	N/A	Fall River has concerns about the impact of increased spill on juvenal and returning adult salmon and request the agencies continue to monitor and study the net effect on salmon. Proposed spill is not proven to help fish. The Cooperative is also concerned that additional spill will de-optimize the federal hydro system and have a negative impact to the regions goals of decarbonization.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin. Appendix R, Part 2 also describes the adaptive management approach for the flexible spill operational measure. The co-lead agencies will continue to evaluate the impacts of this measure while it is implemented and work through the Regional Forum to address any unintended consequences.
32366	3	Georg Behrens	N/A	Fall River encourages cooperation with environmental groups to work on plans which do bolster a sustainable salmon and steelhead population.	Thank you for your comment.
32370	1	Curtis Short	Blanchly-Lane Electric Co-op	The DEIS concluded that breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." This is not an acceptable outcome to our mostly lower income rural consumers. A 50% increase in BPA's rate could lead to rate increases our electric cooperative consumers just cannot afford, especially as they work hard to recover from the economic impacts of the COVID- 19 outbreak, the depths of which we have yet to know.	The statement that the loss of hydropower under MO3 could require substantial renewable replacement resources with costs resulting in rate pressures up to 50 percent is consistent with the findings of the EIS. See Section 3.7.3.5, at 3-918 to 924 in the Draft EIS; see also Table 3-166. For further information on the potential socioeconomic impacts of MO3, see Section 3.7.3.5 Social and Economic Effects of Changes in Power and Transmission.
32373	1	Randall Ririe	N/A	Have just attempted to leave my comments on your website, I was informed the comments did not appear va lid and could not be submitted.	The co-lead agencies are sorry you had technical difficulties. The public had several ways to submit comments such as the online comment form and through the mail. We are glad to see you were able to provide comments.
32373	2	Randall Ririe	N/A	Have just attempted to leave my comments on your website, I was informed the comments did not appear va lid and could not be submitted.	The co-lead agencies are sorry you had technical difficulties. The public had several ways to submit comments such as the online comment form and through the mail. We are glad to see you were able to provide comments.
32376	1	Rodney Cawston	Confederated Tribes of the Colville Reservation	I am writing to request a 60-day extension for comments on the CRSO Draft EIS. Under ordinary circumstances, the 45-day comment period established for the CRSO Draft EIS would be challenging given the document's immense volume, detailed technical analysis, and the broad geographic and topical scope. Moreover, the Confederated Tribes ofthe Colville Reservation (CTCR) is affected directly and significantly by the CRSO, and we have dedicated significant resources to participating as a Cooperating Agency in the agencies' development of the Draft EIS. However, the current public health emergency related to the COVID-19 pandemic makes this already-insufficient period for drafting comments patently unreasonable. The region and the nation are being dramatically affected in countless ways by the pandemic. On March 18 the Colville Business Council ordered a partial government shutdown lasting through- at a minimum- April 1. Many of our staff are working from home if that is feasible, which makes coordination on a large project such as the CRSO EIS more challenging. Because of the state-wide closure ofK-12 schools through- at a minimum- April24, many of us are dealing with the demands of full-time parenting and overseeing lesson plans for children while attempting to stay on top of normal work responsibilities. In addition to our staffwho are integral to the CTCR's preparation of comments on the CRSO Draft EIS, our lead attorneys who work on this issue are located in Seattle, which has experienced severe disruptions as one of the epicenters of the COVID-19 outbreak in the United States. Additionally, on March 23, Governor Jay Inslee issued a "Stay Home, Stay Healthy" proclamation for Washington for all non-essential personnel. We understand that the CRSO EIS is a massive undertaking by the co-lead agencies and that the Administration's requirements have forced an accelerated schedule for completion. However, in the course of a few short weeks the country has changed in dramatic ways not experienced in generations - if ever before - from this pandemic. We respectfully request a modest extension of 60 days so that our staff will have a fair opportunity to provide meaningful and thorough comments on the Draft EIS. The importance of this topic calls for nothing less.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
32412	1	handerson@cec-co.com	N/A	Central Electric is seriously committed to delivering clean, affordable, reliable electricity to our members. The DEIS concluded breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." Increased spill-as envisioned by M04-would also increase costs up to 41%. A 40-50% increase in BPA's rate could impose an additional several hundred dollars a year on our members. The most impacted by these rate increases will be our vulnerable populations senior citizens and those on fixed incomes -who shouldn't have to choose between medicine, food, or paying their electric bills.	The rate pressures identified in the comment are consistent with the findings under Multiple Objective 3 and Multiple Objective 4 in the EIS. See Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS and Section 3.7.3.6, Electricity Rate Pressure, at pages 3-945-950, Table 3-182 in the Draft EIS. The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 and Chapter 7) provides further detail on this as well as the potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment.
32412	2	handerson@cec-co.com	N/A	Central Electric proudly touts its clean energy profile, with an energy resource nearly 100% carbon-emission free. According to the DEIS, breaching the dams would create an additional 3.3 million metric tons (MMT) of C02 - a staggering 10% increase in power-related emissions across the Northwest. M04 shows similar carbon impacts. The DEIS demonstrates breaching the Snake River dams or spilling excessive amounts of water would be a step backward from decarbonization efforts in our region.	The 3.3 MMT CO2 increase in greenhouse gas (GHG) emissions under Multiple Objective alternative 3 (a 8.9 percent increase in regional power sector emissions) described in this comment is associated with a scenario in which only natural gas resources are developed or acquired to offset losses from the four lower Snake River dams. The analysis additionally considers a scenario assuming all renewable replacement resources (at a higher cost as discussed in Section 3.8). Under this scenario, the analysis finds a 2.7 percent increase in regional CO2 emissions relative to the No Action Alternative. Given that policy and legislative decisions in Oregon and Washington are targeting large reductions in GHG emissions, the EIS describes that even the 2.7 percent increase in CO2 emissions makes these goals more difficult to achieve. The Preferred Alternative estimates that GHG emissions would increase by 1.5% or 0.54 million metric tons compared to the No Action Alternative.
32412	3	handerson@cec-co.com	N/A	The DEIS also noted the co-lead agencies have made substantial improvements for fish passage at the lower Snake River and lower Columbia River dams. Our cooperative has helped fund this multi-billion-dollar effort to improve fish passage at the dams, which is meeting targets of 96% survival rates for migrating juvenile fish. We believe it is important to build upon this successful fish passage program instead of taking the drastic measure envisioned in M03 and M04. Finally, CEC offers cautious support for the Preferred Alternative (PA) proposed by the co-lead agencies. Though experimental, and without risk to the Endangered Species Act's listed species, CEC is encouraged that the underlying principles and model of constructive collaboration established through the "20 19-2021 Spill Operation Agreement" ("the Agreement" or "Flexible Spill Agreement") reached in December 2018 was carried forward in the P A To the extent that the co-leads finalize the Flexible Spill operation (as the backbone ofthe PA) as part of this EIS process, CEC insists the three objectives of the Agreement remain intact: provide additional fish benefits by increasing spill; manage power system costs and preserve hydro system flexibility; and, retain operational feasibility.	The co-lead agencies intend to keep the three objectives from the Flex Spill agreement intact as stated in Appendix R, Part 2.
32412	4	handerson@cec-co.com	N/A	CEC remains concerned, however, about the wide variability around the two bodies of fishery science considered in the Draft EIS (i.e., NOAA's Life Cycle Model and The Fish Passage Center's Comparative Survival Study model). The extended operation at 125% Total Dissolved Gas ("TDG") at these federal projects called for in the Flexible Spill Agreement (and the basis for the P A) is an unprecedented action. We appreciate that the co-lead agencies understand the potential controversy around the different assumptions made by each of the fish models when it comes to assessing the biological risks versus benefits of operations like the P A, which incorporate increased and un-tested spill levels. To address this issue, we request the adoption of reliable fish monitoring and adaptive management solutions.	To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin.
32412	5	handerson@cec-co.com	N/A	Throughout the implementation of Flexible Spill, and as further adopted in this EIS, CEC urges the co-lead agencies to closely monitor the PA's untested operational approach, particularly, spill to 125% TDG. Efforts must include continual analysis of the proposed action and its impacts on ESA species, and	The co-lead agencies agree. The Preferred Alternative will be implemented using adaptive management that includes a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the development of a robust monitoring approach and public platform to provide transparent feedback. We also encourage the co-leads to develop and improve upon an adaptive management framework to ensure their actions do not jeopardize the continued existence of any listed species.	
32418	1	William Keeton	Central Electric Cooperative, Inc.	Cautious support for the Preferred Alternative ("P A") proposed by the co-lead agencies. However, we are concerned with the unprecedented and untested spill to 125% Total Dissolved Gas ("TDG"). The two vastly different scientific findings included in the DEIS around the impacts of increased levels of spill on fish, make it difficult to embrace this experimental approach fully.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
32418	2	William Keeton	Central Electric Cooperative, Inc.	Support for fishery monitoring and adaptive management. We support the development of a robust approach to monitoring to see how fish respond to new levels of spill. We also encourage the co-leads to develop and improve upon an adaptive management framework to protect ESA-listed species from unintended consequences that may arise due to operations that utilize enhanced spill.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
32418	3	William Keeton	Central Electric Cooperative, Inc.	Support for further study regarding socio-economic impacts of blackouts. We encourage the co-lead agencies to sharpen their analysis around this issue before issuance of the Record of Decision.	The commenter is correct that there could be socioeconomic effects if blackouts occur. The EIS methodology includes the full incremental replacement resource cost necessary to return the region to a level where the likelihood of blackouts is equal among all the alternatives, such that comparisons can be made among the alternatives on an equal basis. The EIS assumes for each Multiple Objective alternative (MO) that sufficient resources are acquired to reduce the risk of blackouts to the level of risk that existed prior to implementation of the MO. Once replacement resources have been acquired, the risk of a blackout for each MO is effectively the same as the No Action Alternative. The EIS evaluates the costs of replacement resource portfolios that would be required to avoid increasing the risk of an outage. See Draft EIS, Section 3.7. The approach in the analysis is to first evaluate the increased risk of power outages related to an alternative, and then identify what resources are needed to avoid that increased risk of an outage. Thus instead of identifying the potential socio-economic costs of power shortage, the analysis identifies the costs of replacement resource portfolios that would be required in order to avoid increasing the risk of an outage. If the EIS had then also added to each MO the additional cost of a blackout, then the MOs would have double-counted the impact of blackout risk (i.e. the MOs would have included the cost of avoiding blackouts and the costs of blackouts). The analysis identifies that the expected outcomes of MO3 and Multiple Objective alternative 4 (MO4) would be an increase in the cost of power and not in the risk of an outage. See Draft EIS, Sections 3.7.3.5 (MO3) and 3.7.3.6 (MO4). Because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary.
32425	1	Kevin Davis	N/A	The impact on the entire Pacific Northwest would be staggering. The BPA has been providing clean hydro-power to the region for as long as I can remember. What alternatives are there for comparably priced energy?	Breaching the four lower Snake River dams was evaluated in Multiple Objective 3 but was not included in the Preferred Alternative identified in the EIS. The comment may be referring to the loss of hydropower generation under MO3, which includes breaching of the four lower Snake River dams. The EIS identified two potential replacement portfolios, one with natural gas power and one with solar plus storage, that would maintain regional reliability under MO3 at the same level as the No Action Alternative (See Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS). As suggested by the comment, these replacement portfolios would increase the cost of regional electricity. See Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
32425	2	Kevin Davis	N/A	How much research has gone into the financial impact of not only the cost of power to homes and industry but what is the impact on agriculture. Many producing areas rely on the water behind these dams to provide irrigation for crops.	Please see Section 3.12, Water Supply, for a discussion of irrigation and the effects on agriculture. In Region C (lower Snake River) and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, the MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion. This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. In Region C, under the MO3 alternative this analysis accordingly concludes that pumps are unable to deliver water to an estimated 48,000 acres.
32425	3	Kevin Davis	N/A	With active efforts in the northwest and here in Montana to close down coal fired power plants and without an available explanation on where the power will come from to replace these essential power sources, both hydro and coal fired, we are left to wonder what miracle will occur to replace this energy. And, while I realize the Columbia Hills, the flat lands of eastern Oregon and Washington, and the Snake River Plains are the sights of numerious wind farms they can't begin to replace the energy produced by these dams.	The commenters statement that potential additional coal power retirements would decrease power reliability in the region is consistent with the findings in the EIS. Existing coal projects were presumed to be online when developing the No Action Alternative. See draft EIS, Section 3.7.3.1, Base Case Methodology and Cost Sensitivity Analysis, at page 3-816; see also Id. at page 3-823. Since development of the draft EIS, additional coal retirements have been announced. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See draft EIS, Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842 and Section 3.7.3.2, Table 3-123. The EIS examines several alternative resource portfolios that have characteristics similar to, though not complete replacements for, the attributes of the four lower Snake River dams that would be lost if breaching occurred under Multiple Objective Alternative 3, including natural gas and zero-carbon (solar and wind) replacement portfolios (See Section 3.7.3.5, Potential Replacement Resources and Associated Costs at page 3-904).
32429	1	Vernon Brown	N/A	THE POLLUTION ON THE PUGET SOUND IS A MAJOR CAUSE OF CONCERN FOR ALL THE SPECIES DEPENDANT ON CLEAN WATER FOR SURVIVAL. I HAVE FITNESSED THE PROLIFICATION OF FISH FARMS IN ALMOST EVERY BAY AND INLET IN BRITISH COLUMBIA THAT HAVE POISENED WILD FISH AND THEIR FEED. I HAVE SPENT A LOT OF SUMMER TIME IN SOUTHEAST ALASKA, AND THE INCREASE IN WHALE POPULATION CONTINUES YEAR AFTER YEAR, INCUDING THE ORCAS, BUT ESPECIALLY HUMPBACKS. DEMAND FOR FEED IS IN ITS GREATEST NEED AND DECLINE. NONE OF THIS IS CAUSED BY DAMS.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the effects of the operations, maintenance, and configuration of the CRS projects and therefore of this EIS. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
32434	1	Howard Jensen	Sunheaven Farms	Dams Provide Affordable Electricity - As a consortium of farms, power costs are one of our greatest expenses. If any of these dams were to be breached, and or removed it would have devastating consequences upon all of our operations. In your EIS it indicates that replacing lost generation from dam removal with carbon-free resources could result in 50% increase in power costs. Those of us in the agriculture community are "Price Takers, and not Price Makers." Our margins are determined for us by the Marketplace. This potential increase in expense could have a devastating impact on not only our profitability, but also our continued business operations. However, it would not only impact the agriculture world, but also all of those who use energy. Everyone in our communities would be negatively impacted.	The statement that the loss of hydropower under MO3 (which includes breaching the four lower Snake River dams) could require substantial renewable replacement resources with costs resulting in rate pressures up to 50 percent is consistent with the findings of the EIS. See Section 3.7.3.5, at 3-918 to 924 in the Draft EIS; see also Table 3-166. However, the 50 percent figure is for wholesale power. The retail rate impact would be lower. For further information on the potential socioeconomic impacts of MO3, see Section 3.7.3.5 Social and Economic Effects of Changes in Power and Transmission.
32434	2	Howard Jensen	Sunheaven Farms	Dams Positive Impact on the Food Chain and Feeding the World: The Dams on the Lower Snake River and the Lower Columbia River have played an influential part in the development of the Lower Columbia Basin and Horse Heaven Hills areas (Southeastern Washington). The ability to irrigate acreage	Thank you for your comment; the comments are largely consistent with the findings in the EIS in that breaching the lower Snake River dams would have adverse effects to farmers and irrigation. Currently, and in the No Action Alternative, water is available from the reservoirs of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				that was previously dry-land has flourished and created a Food Basket that literally feeds our Country, and the World. A wide variety of commodities from Wheat, Fruits, Vegetables, are produced as a result of the water resource (irrigation) being provided from the pools created from these Dams. Removal of any of these Dams will have far lasting negative consequences. Some of these would include a reduction in agricultural acreage, commodities provided to the Food Chain, increase costs to improve irrigation systems necessary to operate as a result of the Pool Levels changing, and the ability for those in the agriculture community to provide a way of life for their families and those they employ.	inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected.
32434	3	Howard Jensen	Sunheaven Farms	Dam are only one Factor in Salmon and Orca Survival: Those proponents of breaching/removing the Four Lower Snake River Dams are fixated on this being the only method, solution to the survival of Salmon and Orca. They propose working together to find a solution to this issue but seem to be talking out of both sides of their mouth, because their actions clearly show their final agenda, which is- "Removal of the Dams." If Salmon and Orca survival rates is their top agenda item, then one only needs to look at the level of fishing that takes place in our Oceans by foreign countries, native fishing on the rivers, sea lions at the mouth of the Columbia River, and most of all the pollution levels in the Puget Sound. These four items are clearly greater causes on Salmon and Orca's potential survival rates. Science has clearly shown the current methods in place under the present ESA-BiOP have led to increase numbers of Salmon Runs. Current rates of survival under these required methods has led to numbers as high as 97% in certain areas. Controlling the issues mentioned above is a far better use of time and money in order to save our Salmon and Orca's if that is their ultimate agenda.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. The four items listed in this comments are beyond the scope of this EIS. Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
32437	1	Blaine Hulse	N/A	Further, the dams in Oregon and Idaho would need removed as well. The spawning rivers upstream would still not be accessible for the fish because there are no fish ladders at the Oxbow, Brownlee and Dworshak. Why not improve the ladders on the lower Snake Dams, and add ladders upriver? Build more hatcheries, and seriously fight those predators that feast on the young migrating fish. Capture and transport the seals to places that cannot harm the salmon, or terminate them. There are many good arguments for retaining the dams.	The co-lead agencies are authorized to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The scope of this EIS analyzes the effects associated with the operation and maintenance of the 14 CRS projects. The Oxbow and Brownlee dams are not part of the CRS. Fish passage at Dworshak was considered, but eliminated from further analysis. The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. The Draft EIS did not consider additional mitigation programs such as hatchery production or habitat restoration projects; mitigation program measures are described in the EIS in Chapter 5. Many of the considerations for structural changes proposed in the EIS would be to address downstream juvenile passage and survival, as well as habitat concerns. The technology of fish cannons or similar devices (for adult passage) will continue to be evaluated for future applications. Lastly, to comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
32469	1	Leon Waldron	N/A	Many in our community, include seniors and those on fixed or low incomes, are dependent on the electric service provided by Fall River to heat their homes, power appliances, provide hot water and even pump water from their well. I'm concerned about escalating power costs. Our electric Cooperative, Fall River Rural Electric Cooperative, is serious about their mission of delivering clean, affordable, reliable electricity to us, its members. The DEIS concluded that breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." A 50% increase in wholesale power costs would be financially devastating to our household. It is important to keep these financial impacts in perspective for rural communities like ours where incomes are below regional and state averages. These increases in power costs are not a simple shift from disposable and discretionary income to pay for essential services like electricity. Rather, they mean that some neighbors and family will be forced to make difficult choices about which essentials like food, medicine, utilities, and such they have to sacrifice.	The comment that power costs in the region would increase under Multiple Objective 3, which includes breaching of the four lower Snake River dams, is consistent with EIS findings. See Section 3.7.3.5, at page 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. The Environmental Justice analysis (Section 3.18.3 of the EIS) provides further detail on potential disproportionate effects to Tribal, low-income and minority populations under MO3. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers. The EIS also discusses the fact that Bonneville customers, such as cooperative mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Section 3.7.3.5, Residential Effects, at page 3-929 in the Draft EIS, and Chapter 5 of Appendix H, Power and Transmission. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
32470	1	Alice Didier	N/A	If dam removal was implemented, damage from the monumental passage of accrued sediment from behind these dams would decimate fish breeding grounds, and it would be years before the Snake would recover from this action. Why are we not addressing other factors concerning salmon survival such as the sea lion and tern problem, over-fishing, allowing foreign fishing within our 200-mile limit, and the environmental concerns surfacing in the Puget Sound area as concerns the Orca whale?	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. The four items listed in this comments are beyond the scope of this EIS. Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
32479	1	Ilene Harrel	N/A	The DEIS identified significant impacts that breaching the four dams would have, including: Costing close to one billion dollars to construct other carbon-free electrical generation facilities, construct new long-distance transmission lines and install untested amounts of utility-scale batteries	The statements in the comment regarding potential effects of dam breaching on the regional power system are consistent with the findings in the EIS. See Section 3.7.3.5, Effects on Power System Reliability, at page 3-903 in the Draft EIS; see also Appendix H, Table 2-1.
32479	2	Ilene Harrel	N/A	Loss of irrigation to tens of thousands of acres of agricultural land that produce crops that contribute to the national economy	The information in this comment is consistent with the findings in the EIS, specifically in Section 3.12.
32479	3	Ilene Harrel	N/A	Increasing wholesale power rates by as much as so% which would result in local power rates increasing, perhaps by as much as 25%	The statement that wholesale power rates would increase up to 50% under Multiple Objective 3 (MO3), is consistent with the findings of the EIS. See EIS, Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. The EIS finds that the highest county-level retail rate pressure is 29 percent under MO3. See Section 3.7.3.5 Electricity Rate Pressure, at page 3-929 in the Draft EIS. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
32479	4	Ilene Harrel	N/A	Undermine regional efforts to reduce carbon emissions as the trucks to haul ag products, rather than transporting them by barge, will result an additional 23.8 million miles annually	The EIS finds that breaching of the four lower Snake River dams would increase greenhouse gas emissions from trucks, consistent with the concern voiced in the comment. The EIS finds that truck ton-miles may experience an increase of up to 84 percent under Multiple Objective alternative 3 when compared to the No Action Alternative. See Section 3.8.3.5 of the Draft EIS. Multiple Objective alternative 3 was not identified in the Draft EIS as the Preferred Alternative. The Preferred Alternative is estimated to increase greenhouse gas emission by 1.5%, or 0.54 million metric tons, over the No Action Alternative.
32482	1	Matt Ruane	N/A	Modeling infers that the removal of many small dams is better for fish. Using the Elwha River's two private dams as a model, removal of 318 vertical feet added 70 square miles of spawning ground. Removal of 2000 private (40 dams and approximate 50 feet each) vertical feet of concrete on primary and secondary streams could add about 9440 miles of spawning grounds. All four Snake River dams add up to only 398 vertical feet. Furthermore, the Elwah dams, had no fish ladders like many archaic and primate dams.	Without reference to a specific model, the co-lead agencies cannot address what model the commenter is addressing. There have been many dam removals that have had significant fish benefits. Comparison of the lower Snake River dams to the Elwha provides little value. The Elwha provided no fish passage or economic benefits. In contrast, the lower Snake River dams have upstream and downstream fish passage. The lower Snake River dams also produce power, and provide navigation and recreation opportunities. For power, the lower Snake River dams have great provide economic benefits to the region by producing power, navigation, and recreation.The four lower Snake River dams produce upwards of 1,100 aMW of power, which is approximately 13 percent of the average power produced by the FCRPS. See EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 900,000 homes in the Pacific Northwest. See EIS Section 3.7.3.5, Summary of Effect, at 9-935.
32482	2	Matt Ruane	N/A	The criteria for removing smaller dams has already been established. Why spend time and money reinventing the wheel? Oregon's Fish Passage Priority List could be used a model. It's been going for about five years now. Oregon's FPPL program focuses on discerning and removing smaller, unused or inefficient dams to improve fish habitat. Hells Canyon Dam, and a lot of other Eastern Oregon dams are on the remove/fix list. I'm sure with just a phone call from you, you could find out how successful the FPPL has been.	Thank you for the information regarding Oregon's program. Modeling of alternatives for the Draft EIS did not consider effects of elements of the mitigation programs such as hatchery production or habitat restoration projects. Mitigation program measures are described in the EIS in chapter 5. The current Northwest Power and Conservation Council mitigation program allocates a substantial amount of funds to habitat restoration projects planned with regional partner agencies in Idaho, Washington and Oregon, as well as research and monitoring to assess effectiveness of proposed actions http://www.cbfish.org. Over 150 barriers to fish passage in tributary streams and the estuary have been breached as part of the program during the past dozen years.
32487	1	Ronald & Ceona Chitwood	N/A	Item 1: As I drive on Highway #14 along the Columbia River I see Indian nets every J4 to ~ mile at least from White Salmon to McNary Dam. They are in the river when Sports Fishing is CLOSED. I thought Indians were supposed to get 50% of the salmon, not all of them. The nets make no distinction between hatchery and wild stock, how fair is that?	For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., National Marine Fisheries Service), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
32487	2	Ronald & Ceona Chitwood	N/A	3: Priest Rapids Dam outflow during the March-May time frame is critical in this last flowing Columbia River Reach. During the construction of WNP-1 and WNP-4 a low flow test was run in April to determine if the river level was adequate to cover the water intake during low licensed flow conditions. The test determined it was but when the biologists ended the test and advised Priest Rapids to return the flow to normal they did but for them during a	The operation and management of Priest Rapids Dam is outside the scope of this EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				low demand power situation it was minimum flow. The result was thousands of salmon fry still in egg sacks and in the gravel died. This was only noted because biologists were on site, it could and probably does happen every now and then but no one is around to note it. That is why item No.3 is so important. If you investigate this you will find that Battelle Northwest, United Engineers and Constructors and perhaps Energy Northwest funded a substantial expansion of the Priest Rapids Hatchery.	
32491	1	Edward Henderson	N/A	At 8,000 pages it is impossible to read, digest and understand the DEIS. The deletion of the public comment meetings due to the COVID-19 pandemic while necessary only exacerbates this problem. The presentation of so much extraneous misinformation, 8,000 pages! Obscures the main issues that the court ordered examined. Namely actions required to restore the endangered species of salmon and steelhead fish in the Columbia and Snake Rivers. The short time available for comment appears to be a deliberate strategy to limit public critique and involvement.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
32491	2	Edward Henderson	N/A	While the DEIS does recognize the breaching of the four lower Snalce River dams as the most certain means to restore the endangered salmon, the quick dismissal of this alternative in favor of continued economy active as usual is clearly a preordained outcome reached without considering the evidence. First you set up a false choice between salmon and energy, and then you ignore replacement of the 'lost capacity of the existing dams with clean and affordable energy. The ongoing cost of continuing the current means is disregarded. The U.S. Government has spent 17 to 18 billion dollars on barging salmon smolts around the dams and more recently has enhanced spill, all to simply stave off extinction. The avoided replacement cost of the hydroelectric turbines and generators that have reach the end of their economic life is not considered, the machinery is worn out!	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. While the four lower Snake River dams account for a small portion of the total number of dams in the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. They provide approximately 1,000 aMW of carbon-free energy on average, enough to power about 730,000 Northwest homes, and 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. Additionally, the four lower Snake River dams are among Bonneville's lowest cost resources. Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
32491	3	Edward Henderson	N/A	The DEIS fails to consider the economical, ecological and cultural benefits that would accrue from restored abundant salmon.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting tourism businesses. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries subsection and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries subsection of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Most sections of Chapter 3 include a Tribal Interests Section at the end that attempts to summarize issues by topic.
32492	1	John Thoren	N/A	As is pointed out in the study, a major cause of the decline in salmon numbers is most likely overfishing in the late 19th and early 20th centuries, a time before any dams on the Columbia River. The challenge now is how do we rebuild the runs to the highest level possible given the much-changed environment of today versus that in the later 19th and earlier 20th century. The changes are not only in terms of the physical environment but also from the difference in populations and their needs today versus that at 1900. Because of all these changes, it is impossible to point to any one item and assume that by implementing it, all the problems will be solved.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. In doing so, the co-lead agencies developed a reasonable range of alternatives and compared those alternatives to the No Action Alternative, which is the baseline condition of operations in 2016 when the effort to develop the EIS began. Declines in salmon numbers in the 19th and early 20th centuries are outside the scope of this EIS, as is harvest and fisheries management. The assumptions regarding harvest in this EIS are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
32492	2	John Thoren	N/A	Another point for discussion is the added GHG emissions that would result from (1) the substitution of rail or truck transportation for the products that are currently moved by barge and (2) the use of coal or natural gas fired power generation plants to provide on-demand power ifthe dams were breached. Yes, salmon, steelhead and eels are an issue but added GHG emissions are a global issue that probably have a greater potential impact on earth's survival	The Draft EIS analysis is consistent with this comment. Table 3-209 in the Draft EIS summarizes the emissions by mode (barge, rail, truck) for Multiple Objective alternative 3 and shows that emissions are estimated to slightly increase as compared to the No Action Alternative. The analysis for MO3, demonstrates that pursuing a least-cost portfolio of replacement resources (natural gas), would result in an increase of 3.3 MMT CO2 in greenhouse gas (GHG) emissions, a 8.9 percent increase in regional power sector emissions (Table 3-207, Draft EIS). The analysis additionally considers a scenario assuming all renewable replacement resources (at a higher cost as discussed in Section 3.8). Under this scenario, the analysis finds a 2.7 percent increase in regional CO2 emissions relative to the No Action Alternative. Given that policy and legislative decisions in Oregon and Washington are targeting large reductions in GHG emissions, the EIS describes that even the 2.7 percent increase in CO2 emissions makes these goals more difficult to achieve. The Preferred Alternative estimates that GHG emissions would increase by 1.5% or 0.54 million metric tons compared to the No Action Alternative.
32492	3	John Thoren	N/A	The tradeoffs may best be illustrated with the dual goals of protecting the California Sea Lions and the migrating salmon. Both are federally protected species, but one is an intruder and is having a significant impact on the resurgence of the other. Can we just eliminate the sea lions to save the salmon? Probably not. Can we take actions to make the sea lions less welcome? Most likely. The recommended action appears to make a balanced assessment of the many issues and charts a course to address the many issues that have conspired to create the problem.	As described in the Preferred Alternative, the co-lead agencies propose several measures to reduce avian and marine mammal predation to mitigate adverse effects to listed species from CRS operations. Ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam.
32499	1	Marc Thomsbury	Port of Klickitat	While the above comprises the fundamental purpose of this letter, we also wish to express concern regarding the estimated costs associated with Multiple Objective Alternative 3 (MOA3). As noted in the DEIS, a vocal constituency "assert breaching the dams [a key component of MOA3] will result in large improvements to certain salmonid populations, and this in turn would have beneficial impacts to the overall function of the Northwest ecosystem." This position appears to be based, in part, on a presumption the restoration of salmon populations to historic levels is of overwhelming value relative to all other CRS objectives (combined) and the projected costs of dam removal are sufficiently limited so as to make it a viable alternative. Although the report notes significant costs resulting from dam removal, we are concerned a number of elements in the projections for MOA3 are low when compared with data provided by others. The Port of Klickitat is not qualified to assess the accuracy of the data in the report or that obtained from others, but we urge the parties to the DEIS to reassess the cost projections concerning MOA3 and reach out to key entities engaged in the various sectors involved so as to ensure the DE IS does not underreport the actual costs of dam removal and, as a result, create the impression it represents a least-cost solution	The EIS evaluates the costs to operate and maintain the lower Snake River dams, including capital costs, under the No Action Alternative, all MOs and the Preferred Alternative. Summary level results of implementation and system cost analysis are provided in Section 3.19 and Chapter 7 of the EIS. A more detailed presentation of cost analysis methodology, data sources and assumptions is provided in Appendix Q. As described in Chapter 2, Overview of Approach in Appendix Q, an extensive effort was undertaken to obtain a comprehensive perspective of the costs to operate the Columbia River System under the No Action Alternative as well as how these costs would change under the multiple objective alternatives. The implementation and system operations costs were developed by Corps, Bonneville, and Reclamation technical specialists, including hydrology and hydraulics engineering, operations, cost engineering, budget, asset management, project-specific specialists, fish, navigation, and hydropower provided input to the cost analysis. Separate from the implementation and system operations costs, the EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives.
32499	2	Marc Thomsbury	Port of Klickitat	In particular, we believe a more thorough analysis of the following areas is warranted: The loss of cost-effective transportation for agricultural products from eastern Washington, Idaho, and the mid-West states (including increased transportation costs, reduced farm income, and the loss of foreign sales to competitors). The environmental impact and infrastructure costs associated with an increase in truck and rail trips (including increased fuel consumption, carbon emissions, and necessary improvements to increase road and rail capacity). The loss of irrigation and the effect on agriculture (including food supply and rural economies). Increased electric power costs (including the impact to low-income, rural communities and the effect of reduced power supply stability resulting from a lack of on-demand, renewable generation alternatives). The loss of river tourism revenue in rural	The potential environmental, economic and social effects from breaching of the lower Snake River dams are evaluated and described throughout the EIS organized by resource area. These include several socioeconomic-related resource areas including Power and Transmission (Section 3.7), Navigation and Transportation (Section 3.10), Water Supply (Section 3.12), and Recreation (Section 3.11). Environmental and human health impacts associated with increased emissions to shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (3.8), and increase health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				communities where it represents an important element in their economy (including direct effects on ports and vessel services and indirect effects on retail, recreation, food service, and hospitality sectors).	
32502	1	Francis Aiello	N/A	Certainly we all want to see salmon numbers improve for their benefit and also for the orca. But have we really dealt with other mitigating factors? Puget Sound is nowhere near the pristine body of water of SO years ago when there was a public ruckus about increasing ship traffic and refineries within the Sound. Today Puget Sound is probably one of the country's most polluted waterways. Then there are the long liners on the high seas indiscriminately ravaging the ocean of all species of fish. The protected seals devouring scores of salmon. Then there are commercial fishermen in the lower Columbia. Drive along the Lower Columbia in September and tell me how any fish can escape getting past any of the nets. How many thousands of young salmon are eaten by terns at the mouth of the Columbia? Have we honestly dealt with all of these sources of salmon decline?	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Under the Preferred Alternative, actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
32531	1	Keith Brooks	Douglas Electric Cooperative	To be candid, the residents of Douglas County are struggling economically, and have been for some time. Douglas County, like many rural communities in the Northwest, has not benefited from the economic recovery in the same manner as others in the state. For instance, the average median household income in Oregon is $63,426. In Douglas County it is $44,023. We estimate that breaching dams on the Snake River would add about $360 dollars a year to our average members power bill. That is the equivalent to adding two extra power bills a year for each member. People here are already burdened with failing infrastructure, and increased expenses for pretty much everything including necessary utilities such as power, water and sewer. A declining timber industry has caused an exodus of young workers as they continue to pursue opportunities outside of the area. Older residents, many on fixed incomes, remain to shoulder the increasing costs. We hear their stories everyday as they agonize over which essential service they will have to go without until they can find help.	The comment that power costs in the region would increase under Multiple Objective 3, which includes breaching of the four lower Snake River dams, is consistent with EIS findings. See Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers. The EIS also discusses the fact that Bonneville customers, such as cooperatives, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Section 3.7.3.5, Residential Effects, at page 3-929 in the Draft EIS, and Chapter 5 of Appendix H, Power and Transmission. The Environmental Justice analysis in Section 3.18.3, provides further detail on potential disproportionate effects to Tribal, low-income and minority populations from MO1, MO2, MO3 and MO4. Appendix O, Environmental Justice, recognizes that 36 census block groups in Douglas County, Oregon, meet the EIS's low-income criteria. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
32531	2	Keith Brooks	Douglas Electric Cooperative	Like the struggles our members are facing, DEC also has it challenges. Last year we faced the worst snowstorm in our company's 80-year history. To put the size of the storm in context, our costliest storm event prior to February 2019, resulted in approximately $350,000 in damage. This last storm cost approximately $9.5 million. While some of those expenses will be covered by FEMA, millions will still be owed after reimbursement. Our financial write-offs have doubled in the last 6 months as members have become so far behind on their bills that many have chosen to abandon their homes in desperation. Fire season is nearly upon us. To address the emerging threat of wildfire, DEC has dramatically increased our vegetation management budget by about 30 percent. Added to these challenges, our costs for energy, materials and labor continue to rise while our kilowatt-hour sales continue to decline. As we have embraced conservation to reduce our members' bills, we now struggle to cover operating expenses. We have had to borrow heavily on our equity to weather these events. Eventually those bills will be passed on in the form of rate increases to our members who can ill afford them. If the picture painted above sounds bleak, that wasn't my intent. It is intended to give you a realistic understanding of the challenges companies like DEC are facing. These things are irrespective of the uncertainty surrounding the future of our power supply. But even with all these pressures, we are still hopeful about the future. We see the draft DEIS conclusions as a positive that validates many of the things we have believed for years.	The comment is consistent with information and discussions in the EIS about the potential effects of increasing power rates on vulnerable groups. The Environmental Justice analysis (Sections 3.18.3 and 7.7.20 of the EIS) provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. The EIS also discusses the fact that Bonneville customers, such as the cooperative mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Section 3.7.3.5, Residential Effects, at page 3-929 in the Draft EIS, and Chapter 5 of Appendix H, Power and Transmission. The EIS recognizes the concern voiced in the comment regarding increasing power rates. Under the Preferred Alternative, which includes juvenile fish passage spill operations contemplated under the 2019-2021 Spill Operation Agreement, Bonneville's wholesale power rate pressure is 2.7 percent relative to the No Action Alternative. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement, and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1 at page 3-187.
32531	3	Keith Brooks	Douglas Electric Cooperative	We support the Preferred Alternative (PA) outlined in the DEIS. This could help us avoid further economic turmoil while at the same time, protect fish, birds and other animals covered under the Endangered Species Act (ESA). However, some debate exists about the benefits of allowing spills up to 125 percent oftotal dissolved gas. There is credible evidence to the contrary. An independent analysis should be completed to determine whether it is detrimental to the fish we are trying to help.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
32531	4	Keith Brooks	Douglas Electric Cooperative	We oppose any scenario that calls for the breaching of any dams. We believe, and it is confirmed in the draft EIS, that this would dramatically impact electric rates and financially devastate the citizens of the Northwest. It is this resource that also allows our power resource mix to be over 96 percent non-carbon emitting. Removing dams would setup a scenario where at times of extreme need, there would be a possibility of rolling blackouts. It would also leave us with no other option but to find alternative, reliable energy sources and ultimately add carbon to the atmosphere. This fact alone should make this a non-starter.	MO3, which includes the measure to breach the four lower Snake River dams, is not identified as the Preferred Alternative in the Draft EIS. The comment that costs in the region would increase under MO3 is consistent with EIS findings. In the Draft EIS, see Section 3.7.3.5, at pages 3-918-924; and Table 3-166. The Environmental Justice analysis in Section 3.18 and Chapter 7 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. The comment that without power replacement, breaching the four lower Snake River dams would increase the frequency of power shortages is consistent with EIS findings. In the Draft EIS, see Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1. Also consistent with the comment, the EIS finds that greenhouse gas emissions would increase under the two resource replacement portfolios analyzed under MO3. In the Draft EIS, see Section 3.7.3.5, Potential Replacement Resources and Associated Costs, and Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation for emissions implications.
32536	1	Russ Sapp	N/A	I am concerned with the loss of load probability (LOLP) associated with MOl (11.2%), M03 (13.9%) and M04 (29.6%), all of which are absolutely unacceptable. Given the extreme concern about the future reliability of our electric grid and the region's goal to integrate large amounts of renewable energy without the addition of carbon producing thermal plants, a robust hydropower system is vital to successfully keeping the lights on.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. Juvenile Fish Passage Spill Operations are included in the Preferred Alternative identified in the Draft EIS as described in Section 7.6.3.10. The effects of the Preferred Alternative (PA) on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability (LOLP) was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. In the Draft EIS, see Section 3.7.3.5, at pages 3-904-910. Under these replacement portfolios, regional power rate pressure increases. Without replacement resources, however, the statement that LOLP would increase under MO1, MO3, and MO4 is consistent with the findings of the EIS. The comment that hydropower generation is important for integrating renewable power resources is consistent with the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS.
32547	1	Ted Case	ORECA	The DEIS concluded that breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." Increased spill as envisioned by M04 would also increase costs up to 41%. A 40-50% increase in BPA's rate could lead to an increase of several hundred dollars a year on our members. The most impacted by these rate increases will be our vulnerable populations living on the margins - senior citizens and those on fixed incomes - who shouldn't have to choose between medicine, food or paying their electric bills. Even before the economic disruption of the global pandemic, there is still a significant rural-urban divide in the state when it comes to economic prosperity. According to the State of Oregon Employment Department, in 2019 Oregon's overall growth rate was nearly double that of eastern Oregon. The rate increases projected in M03 and M04 will neutralize one of rural Oregon's greatest assets- access to affordable hydropower- and deepen the rural-urban divide. We also take seriously our commitment to keep the lights on for our members. The DEIS concludes the dam breaching alternative would "more than double the region's risk of power shortages." M04 creates an even higher risk of brownouts and blackouts in the Pacific Northwest, which again would harm our co-op's most vulnerable populations.	The comment that breaching of the four lower Snake River dams under Multiple Objective 3 (MO3) and increased spill under Multiple Objective 4 (MO4) would a drive up costs in the region is consistent with EIS findings. See EIS, Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. If replacement resources were not built, the EIS finds that MO3 and MO4 would adversely affect regional power reliability. The comment that increases in utility costs can adversely affect vulnerable groups is also consistent with discussions in the EIS. Regarding the vulnerable populations mentioned in the comment, the Environmental Justice analysis in Section 3.18.3 and Chapter 7 provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
32547	2	Ted Case	ORECA	It is unimaginable to ponder a less than reliable electric grid during a global pandemic, but we also should not settle for anything less than maximum reliability in the most normal of times. Oregon's electric cooperatives are also proud of our clean energy profile, with a power supply that is consistently over 90% carbon-emission free. According to the DEIS, breaching the dams would create an additional3.3 million metric tons (MMT) of C02 - a staggering 10% increase in power-related emissions across the Northwest. M04 shows similar carbon impacts. Let me put in perspective what 3.3 million metric tons of C02 means for our environment. According to the Environmental Protection Agency, it is the equivalent greenhouse gas emissions of 712,944 passenger vehicles driven for a year or 18,14 7 railcars' worth of coal burned. Oregon Governor Kate Brown and the Oregon Legislature have made decarbonization a centerpiece of their agenda. This is also the case in Washington state. The DEIS clearly demonstrates that breaching the Snake River dams or spilling excessive amounts of water would be a devastating step backWards from those efforts.	The 3.3 MMT CO2 increase in greenhouse gas (GHG) emissions under Multiple Objective 3 (a 8.9 percent increase in regional power sector emissions) described in this comment is associated with a scenario in which only natural gas resources are developed or acquired to offset losses from the four lower Snake River dams (Draft EIS, Table 3-207). The analysis additionally considers a scenario assuming all renewable replacement resources (at a higher cost as discussed in Section 3.8). Under this scenario, the analysis finds a 2.7 percent increase in regional CO2 emissions relative to the No Action Alternative. Given that policy and legislative decisions in Oregon and Washington are targeting large reductions in GHG emissions, the EIS describes that even the 2.7 percent increase in CO2 emissions makes these goals more difficult to achieve.
32547	3	Ted Case	ORECA	ORECA supports the Preferred Alternative in the DEIS, but we caution against spill levels that are not supported by scientific evidence. We urge flexibility to adjust the spill levels if evidence over time shows them as not having the beneficial impacts to fish anticipated in the DEIS.	The co-lead agencies used current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts to juvenile migrants.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
32549	1	Louis Meissner	N/A	I discussed the matter with a fish biologist with 19 years experience. He told me the dams were not 5% of the problem. Preditors are most of the problem. We have the seagulls eating smelt if they pass through the turbines. We have large populations of bass (that didnt used to exist), the pike minnow, sea lions at Bonneville Dam, the [unreadable] terms that exist on the islands that the Corps dredged up at the mouth of the Columbia. We used to also have fishing boats with miles of net that could wipe out a whole run of salmon. We also have Indian nets. Senator Mortore and Cathy McMorris flew from McNary dam to Bonneville dam and counted 421 Indian nets. In all that isnt enough the Idaho Dept. of fish and game poisoned all the sockeye salmon years ago. They put [?] in Red Fish Lake and same of the others. The salmon were screwing up their trout hatchery and they didnt want them.	The are a large number of factors affecting salmon and steelhead populations, including those you list. The Preferred Alternative includes measures to address many of those you listed, among which include many measures to decrease predation from fish, birds, and sea lions directly related to the CRS dams, and dredge disposal islands. Harvest and other fish management actions are outside the authority of the co-lead agencies, and the scope of this EIS.
32550	1	Allan Erickson	Port of Longview	Environmentally Preferred Mode Of the multiple transportation modes serving ports in the Pacific Northwest, barging on the FCSRS is the least carbon intensive at nearly 40% more fuel-efficient than freight trains and 270% more fuel-efficient than semi-trucks. Retaining the operation of dams slows climate change by not only increasing our renewable energy supply, but by replacing less efficient trains and trucks with barging. Consequently, changes to the power generating dams would increase diesel fuel consumption by nearly five million gallons a year as barges would have to be replaced by less efficient rail and truck modes. Maintaining continued operation of the dams directly supports Washington State's commitment to be a national carbon-reduction leader by decreasing emissions from the transportation sector.	Section 3.10 of the EIS recognizes that moving commodities on the waterway results in fewer air pollutant emissions as compared to truck and rail transportation. The EIS evaluates potential effects of MO3 on emissions that would occur under the dam breach measure due to shifts from use of barge shipping through the lower Snake River dams to road and rail transportation. The analysis does anticipate an increase in truck and rail transportation, and associated CO2 emissions, under MO3 relative to the No Action Alternative. Specifically, MO3 would increase CO2 emissions by up to 0.06 MMT CO2.
32557	1	Judy A	N/A	There's nothing in your social effects that recognizes local recreational benefits for reservoir contributions, only spending by visitors. When Lower Granite Dam is removed, 26 recreational features, which per the U.S. Army Corps. of Engineers visitation counts, show there was 1.7 million touches in FY2018 will be without management (see Attachment 1). When Lower Granite Dam is removed, the Clearwater Snake National Recreation Trail will be orphaned and Hells Canyon National Recreation Area will be less accessible (it's only accessible by boat now and in the future, but there will be far fewer boaters and commercial tour boats under MO3).	The Recreation Section 3.11.3.5 describes the social welfare, regional economic, and social effects associated with MO3, including a description of the major adverse effects that would occur to both water- and land-based recreation in the short-term in the region. The future land ownership and management under MO3 is uncertain, although it is likely that recreation on trails can be re-opened if consistent with restoration needs. Decreases in regional economic benefits and social effects associated with the loss of recreation during and following breach are described in this section. Decreased cruise line operations are described in the Navigation Section 3.10.3.5.
34222	1	N/A	N/A	In addition, sustainably generated electricity from solar and wind, along with increasing volume of biofuel production, can power the added freight load when the continuous shipping waterway is closed (ideally this would be on an improved railway).	The hydropower replacement alternatives, which include renewable power sources, and the impacts of this replacement on electricity rates, are evaluated in Section 3.8.
34587	1	N/A	N/A	ACOE should include in any cost/benefit analysis for the DEIS that ecotourism dollars drawn in by having healthy salmon populations in the Snake River	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A summary table was added in Section 7.4, which provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation and tourism (Section 3.11). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively.
37843	1	N/A	N/A	One action that would significantly increase fish populations is to completely redesign hatcheries. I urge you to watch the documentary Artifishal to gain an understanding of why this is such an important part of salmon recovery.	The co-lead agencies support hatchery science through funding conservation and safety-net hatcheries and through funding the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The Preferred Alternative includes a continuation of these programs.
38675	1	N/A	N/A	Monday, April 13, 2020 U.S. Army Corps of Engineers, Attn: CRSO EIS P.O. Box 2870 Portland, OR 972082870 Dear U.S. Army Corps of Engineers, Martin 901 Lakeview Dr Joshua, TX 760584808	The comment provided consists only of what appears to be a heading to a letter. The co-lead agencies received no attachments. Unfortunately, the commenter did not provide any contact information the co-lead agencies could use to request the comments, so a response was not provided.
50561	1	Rose Ann Witt	N/A	In Oct. 2007, I visited the Broughton Archipelago in coastal British Columbia, which used to boast the world's largest concentration of killer whales. Though my visit coincided with the best time of year to observe these orcas, which follow the spawning salmon schools, we did not see even a single 'resident' killer whale. There were no killer whales because there are insufficient numbers of salmon returning to sustain them. On average 99% of an orcas diet is comprised of salmon, particularly Chinook salmon. But many Chinook salmon populations are threatened with extinction, & its estimated that 40% of wild Chinook salmon populations from the U.S. Pacific Northwest & CA are already extinct. Because salmon are the keystone species for the area, their decline threatens ALL of the mega-fauna which depend on them for survival, including grizzly bears, wolves, bald eagles, dolphins, sea lions & killer whales. Moreover, the decomposing carcasses of spawned salmon provide the nitrogen which nourishes the rainforest, affecting every organism that lives there. Without the salmon, British Columbia, & yes the entire Pacific Northwest, may be contemplating the collapse of an entire ecosystem. This will in turn have seriously negative economic impacts on the entire region's timber, tourism & wild-caught fishing industries.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. The CRSO EIS addresses abundance of anadromous fish among alternatives, which is the driving mechanism of marine nutrient cycling. The commenter is correct that there are broad ecological effects from marine nutrient cycling. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in this Draft EIS were for the purposes of comparing the effects of operation, maintenance and configuration of the CRS projects to one another and to the No Action Alternative. For the purposes of comparing alternatives, a more detailed analyses of marine nutrient transfer throughout the spawning habitats was not completed. Section 3.5.2.3 recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin.
50591	1	Rebecca Caulfield	N/A	There are many causes to salmon loss in the Pacific Northwest (PNW): extensive land clearing, major water diversions, filling and diking of wetlands, and hydroelectric dam development, just to name a few. However, the research conducted on the effects of the four lower Snake River dams on salmon populations has shown that they are extensive. These dams have created 325 miles of slack water in reservoirs where previously, the strong current would push salmon to the Pacific Ocean as parrs and then smolts. Now, salmon have to expend more energy swimming. While in these reservoirs, the salmon are often disoriented and are susceptible to predators as they spend additional time trying to find passage alongside the dams. Delayed, they can go through smoltification at the wrong time as they are traveling to the Pacific Ocean. The result is far fewer salmon reaching this destination and even less returning to their native streams several years later as adults. The very foundation of the PNW ecosystem is largely based on the presence of robust salmon runs. Salmon have been identified as a keystone species to this region. Not only are the Southern Resident orcas suffering from the decline in salmon populations, but an estimated 135 species are also impacted. Bears, eagles, wolves, and many other inhabitants of the PNW feast on nutrient-rich salmon. Salmon carcasses dragged onto the forest floor decompose and enrich the soil from which trees and shrubs have risen. David Montgomery, a geomorphologist and professor at the University of Washington, stated that one-third of nitrogen in old growth trees in our forests swam up river as a fish. At one time, millions upon millions of salmon brought a surge of protein, phosphorous, nitrogen, and other nutrients to our rivers each year. How can we expect the PNW environment to stay healthy if its very foundation disappears? A robust plan based on scientific research must be implemented to address the plight of salmon.	The co-lead agencies concur that there are many causes to salmon loss and the importance of salmon to this region. However, regional salmon recovery planning is best accomplished collaboratively and is more suitable for completion outside of an EIS process. The EIS is being developed to update the operations, maintenance, and configuration of the 14 dams operated at the CRS. These dams each have a number of authorized purposes. In the process, the co-lead agencies identified a Purpose and Need Statement and associated objectives in order to improve conditions for salmon and resident fish. Based on the analysis in the EIS, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted biological assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
50626	1	Rona Fried	N/A	According to Scientists, removing all 4 dams would mean 1 million adult Chinook salmon are able to return to the mouth of Columbia River, providing food for critically endangered Southern Resident orcas - only 72 left!	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
56605	1	John Anderson	N/A	The truck traffic alone would negatively impact freeway use which is almost maximized currently with traffic. Wear and tear creates much more repair on both highways and rails.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear-and-tear costs may occur.
56611	1	Robert Carroll	N/A	Snake River salmon are just one part of the Orca's food chain. With these fish showing a near 97% survival on their way "to consumption" by the Orcas, we must consider another significant risk to this food chain and focus resources on its improvement. Much of the Orca's food sources are from other than Snake River Salmon, specifically the Puget Sound Chinook Salmon that are a vital part of the Orca's diet.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
56611	2	Robert Carroll	N/A	To enhance the flow of Snake River Salmon by a miniscule percentage, only to dump them into the polluted water of Puget Sound is not a responsible activity. The current flow of Snake River Salmon is adequate and the cleanup of Puget Sound is a much more worthwhile expenditure of time and energy to improve the Orca's environment and wellbeing.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
56612	1	M.J. Langevin	N/A	The greater volume of water spillage over the dams under consideration as an EIS alternative is not desirable because it would significantly limit the amount of water available for power generation. A great deal of money has already been spent on the dams to optimize the passage of fish through them. In lieu of increased water spillage and more expenditure on the existing fish ladders and equipment, I would recommend that an option such as the Whooshh Innovations (www.whooshh.com) fish cannon system be investigated for use on some or all of the Snake River dams. The Whoosh literature states that: "Our transformational solutions can restore native migratory fish runs and allow dams to remain in place." Additional features of the system allow it to separate hatchery from native fish and also to remove undesirable fish species. This system has already been successfully demonstrated at the Rosa Dam on the Yakima River as well as at other dams that do not have any fish passage structures. An on-line search will reveal more information on this impressive technology.	The wholesale power rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control. The co-lead agencies received many comments related to use of water cannons, or similar proprietary adult fish passage devices. The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. Many of the considerations for structural changes proposed in the EIS would be to address downstream juvenile passage and survival, as well as habitat concerns. The technology of fish cannons or similar devices will continue to be evaluated for future applications.
56615	1	David & Judith Becker	N/A	If preservation of the Orca whale population is a concern because of the reduction of salmon, more hatcheries should be built to raise salmon to feed the Orcas.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early

					spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
56615	2	David & Judith Becker	N/A	Another option would be to harvest the seal population and transport the seals to the ocean to feed the Orcas?	The SRKW are different than other populations and exclusively eat fish. Other populations of orcas prey upon seals or sea lions. Harvesting seals is beyond the authority of the co-lead agencies.
56654	1	Gary Fring	N/A	I have read Jim Lichatowich's book, Salmon, People, and Place: A Biologist's Search for Salmon Recovery. I have also reviewed the EIS and reviewed data on one fish hatchery. In 2017 the Leavenworth Fish Hatchery released 1,131,913 Chinook salmon with only 1,417 adults returning. I was told at the fish hatchery that they only need 1 ,000 adults to get enough eggs. Their goal though is to get a 2% return or 22,638 fish. In 1994 (apologies, that was the most updated info I could find) the cost per returning adult was $573.50. Per Jim Lichatowich's view and the data above, it doesn't look like the fish hatcheries are meeting their goals even with the large budgets they receive. I am proposing an out of the box four (4) part solution for increasing the number of wild salmon: Item #1. Build a large breeding pond downstream of John Day Dam. Optimize the design of the pond to best simulate what the salmon need. The design should include: a). the correct size of gravel to use, b). The best depth of water. Water level to be maintained constant by the use of overflow dams at the exit side of the pond, c). Optimum water flow rate across the pond. Water to be made available from the upstream side of the Dam, d). An artificial roof over the pond, e). A fish ladder to the pond for the returning adult fish to use no matter what level the Columbia River is at. If this test pond works, the fish hatcheries could be replaced with several well placed breeding ponds. The money that is presently spent on fish hatcheries could then be utilized to restore the river and tributaries to fish friendly environments. Jim Lichatowich's book stressed the importance of improving small river environments. Item #2. Put a five (5) year moratorium on gill net fishing. Hopefully this would be enough time to increase the number of returning fish. These are the fish that have the eggs which the next generation of fish depend on. Item #3. Get rid of the seals downstream of the Bonneville Dam. Item #4. Keep doing what is already in the plans such as new turbines, better fish ladders, environmental upgrades to rivers, etc.	The example you provided in 2017 at Leavenworth hatchery was a SAR of 0.1%, which is very low. Leavenworth has been identified as having SARs below other spring Chinook hatcheries in the basin (CSS annual report 2019), and below that of natural origin spawners in the Wenatchee River; there is evidence it may result from water quality challenges in the location. That said, interactions between natural and hatchery origin salmon is an active area of research. Chapter 5 describes proposed mitigation measures including hatchery and habitat restoration related actions and research. The three co-lead agencies do not manage either marine mammal populations or harvest levels on fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Harvest certainly has an impact on salmon and steelhead populations. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and
56692	1		N/A	Build canals tunnels for the fish is be [indecipherable] annual dams. The canal tunnels will be cooler and protect fish from predators. The fish can be channeled in the tunnels.	Thank you for your comment and your idea. A wide array of measures were considered through the process of measures development and during the creation of alternatives for these analyses. Canal or pipe systems were discussed for fish transport but were determined as technically infeasible.
58305	1	Sheila Scott	N/A	I am a senior citizen and if you discontinue the power generator from the dams, our electric rates are sure to rise, hurting all, but especially the people on fixed incomes such as Social Security and all retirement incomes.	The comment that power costs would rise following the breaching of the lower Snake River dams is consistent with the findings of the EIS. The comment that increases in utility costs can adversely affect vulnerable groups is also consistent with discussions in the EIS. The Environmental Justice analysis of the EIS (Section 3.18.3), describes that energy burdens are already likely unaffordable for all households with incomes below the Federal poverty level, and thus any upward rate pressure could impact low-income households for whom energy costs are a larger percentage of their income.
58338	1	Terrance Eberts	N/A	Several independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicated that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesn't consider the loss of coal generation which will also need to be replaced by carbon-free resources to reach CETA goals.	The statement regarding wholesale power rates under Multiple Objective Alternative 3 (which includes breaching the four lower Snake River dams) is consistent with the findings of the EIS. Consistent with the comment, the EIS findings indicate that the region would likely experience a significant regional deficit of power given upcoming coal retirements, which would require adding new power resources to maintain power system reliability at the No Action Alternative levels. See Sections 3.7.3.3 through 3.7.3.6 and Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS.
58342	1	Dan Hileman	N/A	I have a safety concern that to the best of my knowledge has not been addressed yet. I will use Ice Harbor Dam as an example but this issue applies to all of the Snake River darns. Ice Harbor Dam has an effective height of about 100 feet. The pool contains approximately 249,000 acre feet of water. Much of the underlying geological structure of the Columbia Basin consists of sand over a basalt base rock base. In some areas this sand is around 250 feet deep. Sand is very permeable to hydraulic invasion. Sand has some interesting characteristics. During an earthquake it can become fluid and act like water. With hydraulic pressure from below it can turn into quicksand. It is also highly susceptible to erosion. My question concerns the additional water that has been forced into the surrounding aquifers since the dam was constructed. 1. If a dam is breached, what will be the environmental impact of the waterlogged sand surrounding the river passage as the water returns rapidly to the river channel? a) Will significant amounts of sand erode back to the river channel? b) As the proportion of sand to water under ground changes, what will be the effect on the surface property surrounding the river channel? c) Will this create massive sinkholes? d) Will the soil itself become unstable, effecting its ability to support the overlaying structures, like roads and homes? e) How violent will these changes be? f) What is the risk to life and safety for those who live and work in the area? g) What will be the cost of damages to the property in the surrounding area? h) Who will be liable for those damages? I feel that these are issues that need to be seriously addressed before any project of breaching the dams in the area can be undertaken. As it is now the area is stable. Will it remain that way if a dam is breached?	Reduction in slope stability associated with the exposure of saturated soils can arise when submerged shorelines experience a rapid reduction of the adjacent reservoir water level. More specifically, as the hydrostatic pressure exerted by the reservoir is reduced, the hydraulic pore-water pressure and internal stresses within the newly exposed soils are relatively higher until they gradually drain. During this draining period, saturated slopes are more susceptible to creep and failure and this risk can be exacerbated by additional stress such as: overland drainage, upslope surcharge loading or toe erosion. The formulation of the MO3 drawdown and embankment removal feasibility plan for the four lower Snake River dams mirrored that developed in the 2002 Lower Snake River FR/EIS. The feasibility plan includes incremental reservoir drawdowns prior to breaching combined with stepped embankment breaching which are general best management practices intended to allow adjacent saturated soils to gradually dewater and reduce risk associated with slope stability. In the near-term post construction period following removal of the four lower Snake River embankments, rapid scouring of fine reservoir deposits (~80% silt/clay & ~20% sands) within the active Snake River channel extents down to the historical river base-level was predicted to occur. Reservoir sediment deposits outside the historic channel (in the pre-dam floodplain) would largely be abandoned in place following breaching, and remain stranded above the active Snake River channel. Within the lower Snake River dams corridor, there are a number of site specific factors that would need to be considered for a more detailed assessment of slope stability risk associated with the MO3 Breach Snake Embankments measure. This includes: landscape stratigraphy, localized rainfall runoff patterns, and soil properties such as permeability, compressibility, erodibility, and in-situ strength. If MO3 is identified as the selected alternative in the ROD, the co-lead agencies would further study the potential impacts and refine the removal plan design details (means, methods, and timing) as well as implementation measures to insure that slope stability and associated geologic hazards were appropriately mitigated in accordance with applicable laws and regulations. Fundamentally, in the event that breaching were to be implemented, the Corps would conduct additional study to identify in more detail best practices, methods, effects, etc. Impacts of drawdown to aquifers, soils, etc would be further identified at that time. Mitigation measures currently proposed for MO3 are described in Chapter 5.4.3
58342	2	Dan Hileman	N/A	The lock and dam system is important to Columbia I Snake River transportation. As a farm raised native of this area, I recognize that. The river system transported 14 million metric tons of wheat alone in 2017. A four barge tow hauls as much product as a 1.4 one hundred car trains or 538large semi trucks. The rail and freeway corridors already carry more than their designed load capacity and exceed their maximum allowable carbon footprint. If the dams are breached, how will we handle the all of those extra trucks and trains needed to haul the products that uses barge traffic now?	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear-and-tear costs may occur.
58709	1	Dan Robisch	N/A	t doesn't make sense to breech the lower 4 Snake River dams for additional natural habitat to bring back millions of salmon/steelhead when: In the past 30 years, coastal competing Sea Lion populations have increased 1 OX. In the past 30 years, coastal competing Harbor Seal populations have increased lOX. t Herring and Smelt populations have plummeted, the feed is not there for increased salmon numbers. Salmon body weights have shrunk. Orcas are now forced to catch 25+ salmon per day because the current salmon themselves cannot find enough food. Southern Resident Orcas are expending more energy to hunt/fish, than the food they catch for survival. Current water pollution in the Sound prevents Herring eggs from developing and hatching. Slow moving warm backwater from the Columbia River dams kill off much of the smelt trying to move downstream. Foraging Fish populations have plummeted. Southern Resident Orcas are becoming extinct because they are completely dependent on eating only salmon, and they will not leave their local territories to search for food on the Canadian coast near the Northern Resident Orcas. When the Southern Resident Orcas become extinct, they will be replaced by visiting Northern Resident Orcas. The current Eco-System cannot support feeding additional salmon/steelhead.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Additionally, Section 7.7.8 concludes that the Preferred Alternative would result in negligible impacts to Southern Resident killer whales. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. Puget Sound conditions are outside the scope of this EIS, but water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. Under the Preferred Alternative, actions for the purpose of reducing pinniped predation on listed species would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
58714	1	Ken Wilson	Midstate Electric Cooperative	A 40-50% increase in BPAs rate could lead to an increase of several hundred dollars a year to our members.The most impacted by these rate increases will be our vulnerable populations senior citizens and those on fixed incomes who shouldnt have to choose between medicine, food or paying their electric bills.	The measures from MO3 and MO4 creating the largest rate pressure impacts, were not included in the Preferred Alternative identified in the EIS. The range of rate pressure impacts referenced in the comment are consistent with the high-end of the rate sensitivity results for MO3 and MO4 presented in the EIS. Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS; Section 3.7.3.6, Electricity Rate Pressure, at pages 3-945-950, Table 3-182, in the Draft EIS. The Environmental Justice analysis in Section 3.18.3 and Chapter 7 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
58714	2	Ken Wilson	Midstate Electric Cooperative	MEC also takes seriously our commitment to keep the lights on. The DEIS concludes the dam breaching alternative would more than double the regions risk of power shortages. MO4 creates an even higher risk of brownouts and blackouts in the Pacific Northwest, which again would harm our co-ops most vulnerable populations	Neither the measure to breach the four lower Snake River dams that was evaluated in MO3 nor the measure to spill to 125% Total Dissolved Gas that was evaluated in Multiple Objective 4 (MO4) were included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative (PA) on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The comment that, without power replacement, the frequency of power outages would increase under MO3, which includes breaching of the four lower Snake River dams, and MO4 is consistent with EIS findings. See Sections 3.7.3.5 and 3.7.3.6, Effects on Power System Reliability in the Draft EIS. Should resources not be built or are not built immediately to replace lost capacity, the concern voiced by the commenter towards health and safety effects is consistent with discussions in the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
58714	3	Ken Wilson	Midstate Electric Cooperative	Our cooperative has helped fund this multi-billion-dollar effort to improve fish passage at the dams, which is meeting targets of 96% survival rates for migrating juvenile fish. We believe that it is important to build upon this successful fish passage program instead of taking the drastic measure envisioned in MO3 and MO4.	Thank you for your comment.
58717	1	Den Mark Wichar	N/A	I support restoring salmon, steelhead and other native aquatic species through breaching Lower Granite, Little Goose, Lower Monumental and Ice Harbor dams on lower Snake River in eastern Washington. Unfortunately, the DEIS is incomplete, inadequate and inaccurate in terms of its analysis of benefits of dam breaching. These benefits include not only restored fish runs, but also restored rural economies that depend on fishing and outdoor recreation, and restored cultures that have been interwoven with salmon and steelhead for millennia.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other areas under MO3 would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis qualitatively evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
58717	2	Den Mark Wichar	N/A	The DEIS dismisses overwhelming scientific research that shows restoring lower Snake River to free-flowing condition will provide salmon and steelhead with their best and likely only chance to recover, and it ignores benefits of increasing salmon runs for critically endangered Southern Resident orcas.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Broad-sense recovery efforts are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Northwest Power and Conservation Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Regarding orcas, The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
58717	3	Den Mark Wichar	N/A	The DEIS presents false choice between maintaining affordable utility bills and restoring healthy salmon and steelhead. It overstates the cost of replacing power from lower Snake River dams with clean energy, and suggests replacing their power with fossil fuels, which is unnecessary.	The EIS evaluated tradeoffs associated with the management of the system, and did not quantitatively compare the effects on power customers to the effects on salmon. The EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative levels based on two potential portfolios: one based on renewable resources and another based on natural gas resources, which are generally the least cost means to maintain reliability. See Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, at Section 2.2 in the draft EIS. In addition, the EIS does not suggest fossil fuels should be used to replace the power; the purpose of providing the range of replacement resource options is to estimate a reasonable range in potential costs. The basis for developing both of these portfolios may be found in Section 3.7.3.1, Methodology, of the draft EIS.
58717	4	Den Mark Wichar	N/A	The DEIS focuses on financial costs of salmon recovery and ignores enormous sacrifices that have already been made by Native American tribes and other Northwest residents in terms of lost fishing opportunity, reduced jobs and incomes, impacts on cultural values, and other socio-economic effects. Further, the DEIS ignores economic and community benefits of salmon recovery and investments and jobs that river restoration activities will generate.	The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS considers the jobs supported by the implementation and CRSO EIS system costs, including mitigation costs described in Chapter 5 and in Annex B of Appendix Q. The regional economic effects of the CRSO EIS expenditures are described in Section 3.19.3 of the EIS and in Annex C of Appendix Q. The EIS provides a regional economic evaluation in the resource Sections in Chapter 3, for example for Recreation (Section 3.11) and Navigation (Section 3.10). The regional economic effects were estimated for the reduction in reservoir recreation in the short-term under MO3; in the long-term after dam breach, the EIS describes that visitation in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The EIS also describes how the transition to river-based activities would require that tourism businesses, such as retail, rental businesses, and service providers, adapt to the new type of visitor who may demand different types of activities, services, gear, and retail merchandise. A range in visitation is described in the lower Snake River post dam breach based on the evaluation in the 2002 Juvenile Salmon Migration Feasibility Study and EIS. The social welfare values and regional economic effects associated with river recreation post dam breach were not estimated because of the uncertainty and large range in visitation and consumer surplus values and visitor expenditures among users.
58717	5	Den Mark Wichar	N/A	As written, the DEIS does not provide complete or accurate assessment of feasible alternatives for the lower Snake River.	As stated in Chapter 2, the co-lead agencies developed alternatives to meet the objectives and the Purpose and Need. The Purpose and Need Statement includes a desire to meet the congressionally authorized purposes of the system, which include hydropower generation, inland navigation, and irrigation, among others. Each alternative was measured against the No Action Alternative in how well it could meet both achieve the objectives and meet the Purpose and Need Statement .

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Table 7-1 in Chapter 7 summarizes these considerations. Breaching of the four lower Snake River dams would adversely affect the co-lead agencies' ability to meet those congressionally-authorized purposes, as well as does not meet, or meet as well, the EIS objectives. Operations to meet these purposes are described in the No Action Alternative. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets EIS objectives for resident fish, lamprey, hydropower generation, water management, water supply, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex, and at times, conflicting legal requirements for a complex system.
58724	1	Julie Dalsciso	N/A	It's been difficult to access the internet and documents to comment, as libraries and federal offices are closed-a comment period extension would have helped.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
58724	2	Julie Dalsciso	N/A	The Northwest Power and Conservation Council identified both technically feasible and affordable renewable energy sources that have been approved in the Northwest. These new projects already exceed power generated by the 4 Snake River Dams. Comparative reviews by independent third parties have suggested ways to realistically transition to rail cooperatives and renewable energy sources to replace barging.	The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their 7th Power Plan (7th Power Plan, page 13-5) and Mid-term Update that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. The 7th Power Plan was issued in February 2016, and the Mid-term Update was issued in February 2019. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2 The EIS examined navigation options under Multiple Objective Alternative 3 (which includes breaching the four lower Snake River dams) and found that rail freight would increase, consistent with the suggestion in the comment (see draft EIS, Section 3.10.3.5, Commercial Navigation and Transportation Systems).
58740	1	Albert Becker	N/A	There has been a lot of controversy and money ($17 billion dollars) attempting to restore and recover anadromous fish runs since construction of the 14 hydroelectric dams in the Columbia River system. I am only going to focus on the four lower Snake River dams. These dams were built in the early 1970's on the contingency that they would restore salmon and steelhead recovery. Since 2002, there has been five District Court decisions made by three different District Court Judges validating the failure of these dams to meet any hope of recovery. The Courts have rejected the Biological Opinion and/or the pertinent EIS to affirm anadromous fish recovery. Besides all of the money, the BPA and associated agencies have three decades of failure for salmon and steel head recovery! There have been numerous dam operation changes that have helped, but have not met recovery objectives. The current preferred alternative is just Deja Vu all over again with a few more twists and wrinkles.	Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing ESA consultation on the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council (Council) recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
58740	2	Albert Becker	N/A	The current Smolt-Adult Return (SAR) rate is just .07% which is an extinction spiral. It is time to take bold steps to avoid species extinctions. The lower Snake River dams have been identified by Scientific, numerous River Organizations, Biologists and Courts as major impediments for salmon and steelhead recovery. We must breach the four lower Snake River dams.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Recovery efforts referenced in this comment associated with broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
58740	3	Albert Becker	N/A	This EIS does quantify some costs with lost irrigated land from dam removal. However, I am confident that with the increased availability of currently inundated land under the reservoir, improved water pumping techniques and prospects for new revenue (not considered in this EIS from river recreation and outfitted fishing) would negate this loss.	The EIS discusses engineering solutions (pipeline extensions for example) in Chapter 3.12 section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
58765	1	Willis Stuart	N/A	Im concerned that there are underlying factors concerning orca and salmon populations at sea. These factors deserve investigations and inquiries: Orcas Is the food chain contaminated with radioactive products released from Fukashima? How about infections from sea life parasites? Salmon Food chain contamination by radioactive products or exploitation by parasites? Estimates on how many fish are illegally netted at sea and estimates effects of sea lions on salmon runs.	There are a variety of reasons that the SRKW population is declining, many beyond the scope of the CRS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Life Cycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS.
58786	1	Kathy Ledig	N/A	#NAME?	The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. Many of the considerations for structural changes proposed in the EIS would be to address downstream juvenile passage and survival and improvements for lamprey passage. Because structural changes to improve salmon and steelhead (e.g., spillway weirs) are in place at this point, there are few additional mechanistic fixes proposed in the Preferred Alternative. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead, and it also meets all the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
58787	1	Annette Creekpaum	Mason Public Utility Distric PUD 3	The Preferred Alternative Any alternative resulting in drastic increases in wholesale power costs for the Pacific Northwest would be disastrous. In fact, could not come at a worse time. It would exacerbate the economic crisis brought on by the COVID-19 pandemic. One indicator of the pandemic's effect on Washington state's economy is startling: new claims for unemployment benefits in the state reached almost 182,000 for the week of March 22. This represents a 3,500% increase compared to the same time in 2019. It is seven times the peak week during the 2008/2009 recession (WA Dept. of	The statements in the comment that the Preferred Alternative would result in an increase of wholesale power rates, up to 2.7% including rate sensitivities, and that costs in the region would increase under, MO3 which includes breaching of the four lower Snake River dams, are consistent with EIS findings. See Section 7.7.9.1, Rate Sensitivity Analysis, Table 7-32 in Draft EIS; Section 3.7.3.5, at pages 3-918-924 in Draft EIS; see also Table 3-166 in Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Employment Security). By many accounts, this economic upheaval caused by the COVID-19 emergency could last many months. The Preferred Alternative anticipates foregone electricity generation through an increased dependence on "Flexible Spill." The anticipated rate increase for Mason PUD 3 customers under the Preferred Alternative would range from .31% to 2.11%. The assumptions of this analysis are based on Mason PUD 3's budgeted wholesale power purchases from the Bonneville Power Administration for 2020. The rate increase calculations assume a direct pass-through to customers of additional costs of BPA whoiesale purchases. Under wholesale rate increases envisioned in the Preferred Alternative, between $119,536 and $813,618 of discretionary income would be lost to the local Mason County economy. [Table included in document: Preferred Alternative (0.4% Wholesale Rate Increase)] [Table included in document: Alternative (2.7% Wholesale Rate Increase)] As noted in the Columbia River System Operations Draft Environmental Impact Statement, the rate pressure may be offset if the Bonneville Power Administration uses financial management strategies to offset costs, manage debt, and find operational efficiencies. BPA has proven in the recent past that it has the willingness and ability to manage its finances to do so. By contrast, Multiple Objective Alternative 3 would mean an increase in Mason PUD 3 electricity rates by at least 6.4%, possibly as high as 39%. Wholesale power rates are only a part of the equation. Mason PUD 3 is under greater pressure than ever to meet reliability expectations of its customers and governmental entities. The cost of normal operations, capital projects, and debt service continue to increase, meaning that the rate impacts stated here will be compounded on the local level. The choice will be to pursue a continuing upward trend of rate increases to maintain a high level of reliability or forgo important capital improvements to offset higher wholesale energy prices.	These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations, as noted in the comment. The EIS analysis is not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures expected in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs for which it has significant control.
58787	2	Annette Creekpaum	Mason Public Utility Distric PUD 3	Increased spill for juvenile fish passage will reduce overall hydropower generation. However, lessons learned in the "Flexible Spill" regime may help schedule water releases to more effectively help juvenile fish, while achieving a more adaptable schedule for hydropower generation. The Preferred Alternative will maintain a Reliable & Economical Power Supply. Reliability in this alternative "is comparable to that of the No Action Alternative because other measures increase hydropower generation slightly in the winter, and more substantially in late August, and increase hydropower flexibility in some locations and periods. Therefore. no additional resources are needed to maintain regional reliability at the No Action Alternative level."	The comment that the Preferred Alternative reduces hydropower generation but maintains similar system reliability as the No Action Alternative, and therefore does not require replacement resources is consistent with EIS findings, see Draft EIS Section 7.7.9 Power Generation and Transmission. The Preferred Alternative will be implemented using a robust monitoring plan to help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin.
58787	3	Annette Creekpaum	Mason Public Utility Distric PUD 3	Multiple Objective Alternative 03 Mason PUD 3 urges the rejection of any consideration of Multiple Objective Alternative 03. The financial impacts on all public power customers in the Pacific Northwest would have dire economic and social consequences. The loss of electricity generation from the breaching of the four lower Snake River dams would result in - depending on actions taken under MO3 for replacement power - possible rate increases for Mason PUD 3 customers ranging from 6.4% to 39%. Under wholesale rate increases envisioned in MO3, between $2,467,845 and $15,038,431 of discretionary income would be lost to the local Mason County economy. The assumptions of this analysis are based on Mason PUD 3's budgeted wholesale power purchases from the Bonneville Power Administration for 2020. The rate increase calculations assume a direct pass-through to customers of additional costs of BPA wholesale purchases. [Table Included in Document: Multiple Objective Alternative 03 (Plus Fish-Related Costs, 8.2% Wholesale Rate Increase)] [Table Included in Document: Multiple Objective Alternative 03 (Plus Fish-Related Costs, 9.6% Wholesale Rate Increase)] [Table Included in Document: Multiple Objective Alternative 03 (Plus Resource Replacement Costs, 9.5% Wholesale Rate Increase)] [Table Included in Document:Multiple Objective Alternative 03 {Plus Resource Replacement Costs, 19.3% Wholesale Rate Increase)] [Table included in document: Multiple Objective Alternative 03 {Plus Resource Replacement Costs - Worst Case, 50% Wholesale Rate Increase)] To summarize the negative effects of MO3 on an adequate, efficient, economical, and reliable power supply for the Pacific Northwest: All 31 federally operated dams in the Columbia River basin produce nearly 9,000 aMW. Removing the four lower Snake River dams would reduce generation by nearly 1,100 aMW; a cut of almost 13% of all federal power generation. More than 2,000 MW of sustained peaking capabilities would be lost, including 25% of the federal power system's reserves holding potential. The risk of power shortages would be about 14% under MO3. That's once every seven years. To avert the risk of power shortages, a large amount of replacement power plants would have to be built. Washington state has adopted carbon-free energy legislation. Other Pacific Northwest states are considering similar legislation. The loss of nearly 1,100 aMW of generation, along with the assumption that no fossil-fuel power plants will be constructed as replacement, means dependence on intermittent power sources such as wind and solar. That, combined with the loss of dispatchable hydropower to integrate intermittent sources, will intensify the risk of power shortages.	Breaching the four lower Snake River dams was evaluated in Multiple Objective 3 but was not included in the Preferred Alternative identified in the EIS. The comments that breaching the four lower Snake River dams would: (a) increase the frequency of power shortages (unless and until replacement resources are acquired); and, (b) would result in increased costs in the region, are both consistent with EIS findings. Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams, would reduce generation by 1,100 aMW, absent replacement resources, and that the loss of load probability under MO3 would be 14%, which is 7.3 percentage points higher than under the No Action Alternative.(Section 3.7.3.5). Note that breaching the four lower Snake River dams accounts for about 90% of the net generation impact in MO3 (1,000 aMW). Other measures, like additional irrigation withdrawals, higher spill at the four lower Columbia River dams also reduce generation in MO3. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. The ability of hydropower to aid in grid stability and the integration of renewable power is described in the Bonneville Transmission System Reliability and Operations subsection of Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs.
58787	4	Annette Creekpaum	Mason Public Utility Distric PUD 3	Objectives: Improve Juvenile Salmon, Improve Adult Salmon, Improve Resident Fish, Improve Lamprey As a preference customer of wholesale electricity marketed by the Bonneville Power Administration, Mason PUD 3's retail customers contribute a substantial amount of funds to fish and wildlife programs in the Columbia River Basin. We estimate that 12% of each customer's retail bill goes to these programs. As such, any changes in river operations and these program costs have an impact on our community. Funding for fish and wildlife programs must be cost-effective and results-oriented. Public power customers in the Pacific Northwest have contributed nearly $1 billion for programs that don't appear to have produced the results or value originally predicted. We contend that the Preferred Alternative is the most appropriate, reliable, and cost effective approach to balancing to the statutory requirement that the Columbia River System Operations balance multiple uses of federal projects.	Thank you for the comment, and support of the Preferred Alternative.
58787	5	Annette Creekpaum	Mason Public Utility Distric PUD 3	Preferred Alternative and Flexible Spill The Preferred Alternative proposes continuation of flexible spill for salmon passage. We suggest that the Columbia River System Operations pay close attention to total dissolved gasses so they may clearly determine if risks being taken provide the reward promised from this experiment. We are puzzled by a drive to allow an increased level of dissolved gasses in the river during spill, subjecting fish to unsafe levels of gasses in their bloodstream. 110% total dissolved gasses used to be the upper limit allowed during spill. It was increased to 120%. Now, 125% total dissolved gasses are considered suitable. Total dissolved gas levels during spill activities in 2019 were permitted up to 120%. According to a memorandum from the NOAA Fisheries Science Center "The combined yearling Chinook salmon survival estimate from the Snake River trap to Bonneville Dam tailrace was 38.1% (31.6-44.6%), substantially below the long-term average of 48.9%." Adult salmon were also hindered in their effort last year (2019) to swim past Little Goose Dam because of increased spill levels. It is because of these effects on young and adult salmon that we request that close attention is paid to the spill program. And, that changes be made to reduce or eliminate spill if the water management program proves to be dangerous for fish.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies are in consultation with National Marine Fisheries Service and the U.S. Fish and Wildlife Service under Section 7 of the Endangered Species Act for this CRSO EIS. The biological opinions that result from these consultations will be appended to the Final EIS. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the CRSO EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams such as the Technical Management Team.
58787	6	Annette Creekpaum	Mason Public Utility Distric PUD 3	Multiple Objective Alternative 3 Multiple Objective 3 does not meet the test of balancing the statutory requirements for managing the Columbia River for a wide range of uses. In fact, we assert that the marginal improvements for fish and wildlife implied in MO3 are far outweighed by damage to other Columbia River System Operations Objectives discussed elsewhere in our comments. These objectives include a reliable and economic power supply, minimized greenhouse gas emissions, maximized water management, and water supply. In measuring the speculative results of lower Snake River dam breaching in MO3, we are concerned over conflicting conclusions from the Life Cycle Model and Comparative Survival Study. The CSS predicts higher returns of adult salmon in MO3 compared to the LCM. With such a disparity, and no apparent reconciliation between the two models, how can we trust the estimate of a 14% increase smolt-to-adult returns due to dam removal? The effect ocean conditions have on salmon survival and returns requires much more research before we can have confidence in the use of Comparative Survival Study to make conclusions on dam removal. CSS has simplified some assumptions (such as a constant level of harvest) to come to its deduction. Other factors are predation, food supply, and competitors for food. Also, with a warm water "blob" waxing and waning in the eastern Pacific Ocean off our coast, using simplified variables is not good science on which to base a high-stakes decision on the fate of the four federal Snake River dams.	Based on our analysis, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies concur that ocean conditions will continue to play a large role in salmon returns. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions in Chapters 6 and 7 of the EIS. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
58787	7	Annette Creekpaum	Mason Public Utility Distric PUD 3	While the breaching alternative may have marginal benefits for salmon, there is great uncertainty as to the actual benefit. A comprehensive and coordinated effort must include evaluation of the impacts of harvest and hatchery operations to support salmon population stabilization and recovery. Worldwide salmon populations are experiencing coincidental declines because of excess heat and carbon in the oceans. Removing significant carbon-free resources, like the lower Snake River dams, is a step in the wrong direction for our environment. Removal of the four lower Snake River dams under MO3 could prove problematic for improving salmon runs. All four federal dams have fish passage facilities. Immediately upstream, Idaho Power's Hells Canyon Complex effectively blocks fish passage. None of the three Idaho Power dams have fish passage. We have a shared responsibility to help salmon, and we believe there are still great opportunities in the region to collaborate around solutions that help salmon thrive without destroying critical infrastructure. These opportunities include addressing avian, aquatic, and mammal predators. Income from power generated by the dams would be lost, resulting in a subsequent loss of revenues that could be used for fish and wildlife programs.	Thank you for your comment, which aligns with the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
58787	8	Annette Creekpaum	Mason Public Utility Distric PUD 3	The Preferred Alternative seeks to accommodate, as much as possible, a balance among the Columbia River System Operations Objectives. It would have relatively minimal effect on the objectives to minimize GHG emissions, maximize adaptable water management, and provide water supply. Multiple Objective 3, through its recommendation to breach the lower Snake River Dams, would adversely affect these objectives. As noted in the Draft Environmental Impact Statement, MO3 would not meet the objective to Minimize Greenhouse Gas Emissions. Emissions would increase the most if	Section 3.8 finds that Multiple Objective Alternative 3, which includes breaching the four lower Snake River dams would make these goals more difficult to meet. The Preferred Alternative estimates that GHG emissions would increase by 1.5% or 0.54 million metric tons compared to the No Action Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the hydropower were replaced with natural gas. This would lead to an additional 3.3 million metric tons (MMT) of CO2, a 10 percent increase in power-related emissions across the Pacific Northwest.	
58787	9	Annette Creekpaum	Mason Public Utility Distric PUD 3	MO 3 would effectively eliminate the Columbia River "water highway" for barge traffic on the Snake River. Barging on the Snake alone keeps as many as 135,000 semi-trucks and 35,000 rail cars from transporting goods through the Columbia River gorge annually. A vibrant barge fleet controls carbon emissions and avoids higher highway maintenance costs, which would be associated with increased vehicular traffic.	The concerns raised in the comment are consistent with the analysis in Section 3.10 of the EIS. The EIS evaluates the addition of trucks and rail due to the dam breach measures included in MO3.
58787	10	Annette Creekpaum	Mason Public Utility Distric PUD 3	The Draft Environment Impact Statement states, " ... Cargo trucks emit three times as much NOx per ton-mile compared to rail and four times as much per ton-mile as compared with inland barges ... and create six times. as much PM. Thus, barge-based freight shipping is associated with the lowest air pollutant emissions profiles as compared with other modes of moving freight..."	Thank you for your comment.
58787	11	Annette Creekpaum	Mason Public Utility Distric PUD 3	The Columbia River trade corridor supports over SO million tons of foreign trade at a value of over $24 billion annually. The Columbia River is the nation's number one wheat export gateway and number two for corn and soybean exports. It is the third-largest grain export gateway in the world, as well as the West Coast's leader in mineral bulks, wood exports, and is a significant auto import and export gateway. Elimination of barge traffic would increase transportation costs for grain farmers between ten and 33 percent.	Thank you for your comment. The information contained in the last sentence of the comment is consistent with the findings in the EIS in Section 3.10.
58787	12	Annette Creekpaum	Mason Public Utility Distric PUD 3	The reservoirs behind Columbia River dams provide an essential source of irrigation for large areas of Pacific Northwest agricultural land that would otherwise be too dry to farm. Six percent of the Columbia River basin's yearly runoff irrigates about 7.8 million acres of Pacific Northwest farmland.	The water supply analysis is discussed in Section 3.12 with additional detail and background found in Appendix N, and the description of irrigation is consistent with your comment. The co-leads estimate that about five percent of the Columbia Basins Water is diverted for agriculture, calculated using place-of-use polygons from the individual states for acres irrigated with water from the Columbia, lower Snake, Clearwater, Kootenai, Pend Oreille, and Flathead Rivers. Irrigation water is diverted directly from the rivers, from the pools behind the storage and run-of-river projects, and pumped from groundwater wells. Diversions can vary from year to year and month to month in response to varying weather and hydrologic conditions
58787	13	Annette Creekpaum	Mason Public Utility Distric PUD 3	The loss of irrigation from the four lower Snake River Dams alone would result in a social welfare cost of nearly $500 million	In Region C (lower Snake River) and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, the MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion.
58787	14	Annette Creekpaum	Mason Public Utility Distric PUD 3	One of the lower Snake River dams, Ice Harbor, provides a crucial source of drinking water for communities in the Tri-Cities area. The dam also enables irrigation for 60,000 acres of farmland in central and southeastern Washington. Agriculture would be significantly harmed, and communities would face more severe drought conditions without these dams.	There is a physical limitation to delivering water to these lands in the absence of the dams. Removal of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms. Please see Section 3.12 and Appendix N for additional information.
58787	15	Annette Creekpaum	Mason Public Utility Distric PUD 3	Control of water flows from dams in the Columbia River Basin is essential to avoid significant floods, loss of life, and property damage. One has to only look to the 1942 Vanport disaster to see what would happen without the ability to control the flow of water during times high snowpack runoff, and excessive rainstorms in the Pacific Northwest.	Maintaining or improving FRM operations of the Columbia River System has informed both the alternative development and evaluation process. As stated in the Purpose and Need Statement of the EIS (Section 1.2), one of the purposes of the EIS is to 'Provide for a reliable level of FRM by operating the CRS to afford safeguards for public safety, infrastructure, and property. As reported in Section 3.9, Section 7.7.11, and Table 7-1, there is no elevated flood risk for any of the EIS alternatives.
58787	16	Annette Creekpaum	Mason Public Utility Distric PUD 3	Implications of the Columbia River Treaty One of the issues outside the scope of this Environmental Impact Statement is the implications of the Columbia River Treaty between the United States and Canada. The treaty supports flood control operations, release of water for efficient hydropower generation, and undefined ecosystem benefits. All three should be evaluated in the EIS to avoid duplicate efforts while ensuring cost effective management of the river system.	As stated in the CRSO Draft EIS, the information about CRT-related operations available in 2016 is applied in the Draft EIS analysis as the best-available information. The CRSO Draft EIS evaluated the implications of the CRS alternatives using the Treaty coordinated operations, including their relationship to hydropower, ecosystem, and flood risk management, with the best available information. As is also noted in the Draft EIS, if CRT-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary.
58788	1	Erik Molvar	Western Watersheds Project	The Purpose and Need for the EIS is Impermissibly Narrow The Corps defines the Resource Purposes for the EIS to include mitigating flood risk, providing a power supply, and providing waterway transportation capability (presumably for the dwindling towboat industry on the Snake and Columbia). DEIS at 1-4. These goals require leaving the dams in place and preclude the consideration of an alternative (which the Corps should consider, and which WWP would support) to decommission all the dams and return the Columbia River system, in an orderly fashion, to a network of natural and freeflowing rivers and streams, which is its natural state. By contrast, the courts have ordered the Corps to consider alternatives that would not jeopardize the continued existence of any endangered or threatened species. Id. We are concerned that the criteria outlined in the Purpose and Need are incompatible to attaining this legal directive.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Additionally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia Basin. The co-lead agencies evaluated a reasonable range of alternatives, but disagree an alternative decommissioning all dams in the CRS is a reasonable alternative given the unreasonable adverse effects to public safety that would result (e.g. blackouts, lack of irrigation and flood risk management).
58788	2	Erik Molvar	Western Watersheds Project	In the-DEIS-,-the Corps-is-dismissive of other types of renewable energy generation vis a- vis hydropower, and claims that dam removal will increase the demand for fossil fuel combustion to generate electricity. Yet the agency has not provided a comprehensive analysis that indicates that the electricity currently generated by federal dams in the Columbia system could not be replaced by other types of renewables without changing current levels of firming electricity from hydrocarbons. We would particularly like to see an analysis of the acreage of parking lots and flat rooftops in the region incorporated into the EIS, to analyze the potential for rooftop and parking-shade photovoltaic to replace and/or exceed the electricity production of Columbia River system hydropower. The Bonneville Power Administration, as a quasi-governmental entity, would much better serve the public interest by getting out of the dam-and-river-destruction business, and getting into the distributed renewable power business, and this transition could ultimately result in far greater reductions in carbon combustion in the Pacific Northwest than the BPA currently achieves through dams and hydroelectricity.	The EIS does not dismiss renewable energy generation, but rather describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative level based on a range of potential replacement resources, including one that is based on renewable resources (zero-carbon resource portfolio) and another that is based on natural gas resources (for Multiple Objective (MO) Alternative 3 see draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs). The latter portfolio of replacing hydropower generation with natural gas resources is not to suggest that natural gas is likely to be built in the region, but to provide a cost estimate for the lower-bound on costs. See draft EIS, Section 3.7.3.5 at pages 3-904-910. The commenter is correct that even with new renewable resources, the EIS analysis finds that existing carbon-emitting resources would likely increase generation to integrate the large portfolio of renewable resources. See draft EIS, Section 3.8.3.5 at pages 3-1009-1010. The renewable energy portfolio is described in the draft EIS in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. The basis for developing both of these portfolios may be found in the draft EIS in Section 3.7.3.1, Methodology, and Section 3.7.3.5, Potential Replacement Resources and Associated Costs for MO3, specifically, with more detail in Appendix H, Section 2.2 in the final EIS. The EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. Thus, distributed generation such as rooftop solar was not considered in favor of large utility scale solar. The EIS did analyze the potential amount of land required for large scale solar power as well as the potential costs of transmission interconnections for new replacement resources as part of the zero-carbon portfolio. The EIS, however, did not identify the amount of roof top or parking lot acreage needed for solar. For MO1, the EIS estimates that the 1,200 MW of solar identified in the potential zero-carbon replacement portfolio would require roughly 7,000 acres or 11 square miles. See draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, page 3-863. For MO3, the draft EIS estimates that the 2,500 MW of solar identified in the potential zero-carbon replacement portfolio would require roughly 14,000 acres or roughly 22 square miles. See draft EIS, Section 3.7.3.5, Zero-Carbon Replacement (Base Case Analysis), page 3-904. In response to public comments, the final EIS updates and slightly reduces the amount of solar power in the potential zero-carbon replacement portfolio for MO3. For MO4, the EIS estimates that the 2,500 MW of solar identified in the potential zero-carbon replacement portfolio would require roughly 30,000 acres or roughly 47 square miles. See draft EIS, Section 3.7.3.6, Zero-Carbon Replacement (Base Case Analysis), page 3-941. As to Bonneville's role in the region, Bonneville is statutorily responsible for marketing the output of the Federal Columbia River Power System consistent with its statutory mandates, which includes the four lower Snake River dams. Bonneville, in this regard, is not a quasi-government entity, but a Power Marketing Administration within the U.S. Department of Energy, a Federal agency. Bonneville's acquisition decisions are governed by its applicable statutory mandates which include, among other things, a finding of a need to acquire power. Bonneville cannot change its statutory mandates without an act of Congress.
58788	3	Erik Molvar	Western Watersheds Project	The Range of Alternatives in Im permissibly Narrow \Xlhile the Corps set out to examine 12 different alternatives, which seems like a large number of alternatives, they impermissibly restricted the range of alternatives to exclude the possibility of federal dam removal throughout the river system. The closest they came to such an alternative was a "natural rivers" alternative (quotation marks in original) in which flows would be manipulated to mimic natural river conditions with removing the migration impediments of the dams themselves (DEIS at 2-79), which would remain a major problem for migrating salmonids under such an alternative. There is no consideration at all given to an alternative to phase out and remove all federal dams on the Snake and Columbia systems (see DEIS at 2-79), an alternative that \V\W supports.	The co-lead agencies presented a range of alternatives to continued operation and management of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. The co-lead agencies analyzed alternatives capable of meeting the EIS Purpose and Need Statement and objectives. An alternative to remove every dam in the CRS was not analyzed because it is not a reasonable alternative because of its unreasonable impacts to public health and safety (e.g. power and transmission reliability events and flood risk management issues) and would not meet the Purpose and Need Statement or many objectives.
58788	4	Erik Molvar	Western Watersheds Project	Health and Human Safety, and Concerns Regarding the Soundness of Aging Dams There are 14 hydropower dams under study in the DEIS, and the C01ps needs to take a hard look at the safety of these dams, and the potential for failure and catastrophic flooding, based on the age, designed lifetime of use, and current condition. For example, when I was working for the C01ps of Engineers in the 1990s, multiple towboaters told me that John Day Dam was a "bad pour" of concrete to start with, had cracks that meant the galleries had to be pumped out from leaking water 24 hours a day, was moving downstream at a rate of half an inch a year, and for these reasons the dam itself was uniquely (among the dams of the Snake and Columbia system) closed to public visitors. To what extend are these concerns accurate? John Day Dam holds back an 80-mile fetch of the mainstem Columbia River. What would be the flooding consequences (lives lost, property damage estimates, ecological consequences) if this dam failed catastrophically, releasing the water behind it? Downstream municipalities include The Dalles, Hood River, Astoria, and the Portland-Vancouver metroplex (among others). John Day is but one example. Please evaluate and disclose the engineering specifications for expected lifespan for each dam, condition of the aging concrete and earthen structures that hold back the water, and the likelihood of dam failure under routine and extreme (flooding) conditions. Each dam would be expected to have different effects were it to fail. Dworshak Dam is very tall, and water-falling from a great height, and this together with	This EIS analyzes the environmental impacts of the operations, maintenance and configuration of 14 multiple purpose CRS dams. The Corps and Reclamation each have Dam Safety Programs in place to ensure dams are operated and maintained in a safe manner. These programs include inspections for safety deficiencies, analyzes utilizing current technologies, and corrective actions, if needed based on current engineering practices. The Corps conducts two types of dam inspections. The first one is the Annual Inspection, which is performed on an annual basis to ensure the dam is being properly operated and maintained. The Periodic Inspection is the next level of inspection and is conducted by a multidisciplinary team led by a professional engineer. The Periodic Inspection includes a more detailed, comprehensive evaluation of the condition of the dam and is conducted every five years. Components of the Periodic Inspection include evaluating annual inspection items; verifying proper operation and maintenance; evaluating operational adequacy, structural stability, and safety of the system; and comparing current design and construction criteria with those in place when the dam was built. During every other Periodic Inspection, the team performs a semi-quantitative risk analysis of the dam. Any dam that does not meet societal risk guidelines, is moved into an evaluation study which leads to development of options for mitigation, repair, or both. The primary emphasis of both Reclamation and Corps programs is to perform site evaluations and to quickly identify dams which pose an increased threat to the public, and to quickly complete the related analyses in order to expedite corrective action decisions and safeguard the public and associated resources. The cost for maintenance is included in the Draft EIS (See Section 3.19 and Appendix Q), and captures all maintenance costs associated with additional physical features evaluated in the EIS. None of the alternatives consider features that would add stressors adversely impacting dam safety.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				its location above Lewiston, Idaho/Clarkston, Washington would be expected to create a different set of circumstances that the failure of a lower dam, Little Goose for example, but which holds back a greater volume of water. A number of dams along the mainstem Columbia and Snake Rivers have concrete powerhouses but earth-fill portions as well, and during by Corps training I was instructed that if the water overtopped the earthen fill part of the dam, erosion from water descending the rubble face would very rapidly gully and then wash out the earthen part of the dam, releasing the water upstream. Please provide a detailed assessment of the worstcase scenario of environmental impacts from dam failure for each of the dams analyzed in the Columbia system. The Corps should consider performance for each dam under stressed such as natural flooding and earthquakes. In addition, effects of the failure of upstream dams on the soundness of downstream dams should also be evaluated in detail, per NEPA's 'hard look' and 'cumulative impacts' requirements.	You can find additional detail on the dam safety considerations at the below website: https://nid.sec.usace.army.mil/ords/f?p=105:1
58788	5	Erik Molvar	Western Watersheds Project	Does Flood Control Remain a Legitimate Concern on this River System? The Corps identifies "flood risk management" as a key consideration under the Purpose and Need statement. DEIS at 1-2- We believe that flood risk management is only an issue in the context of flooding involved with reservoir management and dam failure, but if the dams were removed on the mainstem Columbia and Snake Rivers, flood control would no longer but legitimate issue, because all lands on the floodplain of these rivers have already been permanently flooded by the reservoirs created by the dams in question. With dam removal, the original floodplains (though substantially altered by reservoir silt deposition) would again be dry land. These lands were condemned by the federal government, and as long as the federal government retains ownership, it can solve the flood risk issue by not selling or leasing these lands for residential or commercial development. With no structures or dwellings on the floodplain, there is no longer a substantial human issue with naturally -- - occurring floods. The Corps should evaluate the impacts of flooding under the dam removal alternative with these factors in mind.	As stated in the EIS in Chapter 1, Section 1.2, the lower Snake dams are not authorized for flood risk management, as such they do not have substantial reservoir storage capacity. However maintaining FRM operations of the Columbia River System has informed both the alternative development and evaluation process. As reported in Chapter 7, Table 7-1, there is no elevated risk to flooding in the Lower Snake River reach for any of the EIS Alternatives, including MO3. If in a future analysis, breaching were to be selected as the Preferred Alternative, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project, as well as determine appropriate management and use of currently inundated areas The Walla Walla District constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. The breaching of the lower Snake River projects under MO3 would trigger the scour of legacy sediment deposits, which would eventually lower the base level to historical river elevations, and reduce flood risk (assuming the Lewiston levees still remain in place). If breaching were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project, as well as determine appropriate management and use of currently inundated areas. The mainstem Columbia River projects (Bonneville, John Day, The Dalles, and McNary) with the exception of John Day are run-of-river projects such that removing them would also not be expected to significantly increase flood risk. John Day has a small amount of flood storage. The loss of that storage would increase flood risk, however this Draft EIS did not evaluate removing the mainstem Columbia River projects, so the impacts to flood risk management from removal of the mainstem Columbia River projects are not known with certainty.
58788	6	Erik Molvar	Western Watersheds Project	White Sturgeon While white sturgeon populations in the mainstem Columbia River are not endangered or threatened, the Kootenai River population is listed under the ESA. DEIS at 3-311, 312. The Lake Koocanoosa dam has altered river sediment deposition, smothering spawning gravels with silt. DEIS at 3-325. Dams certainly pose barriers for the natural migrations of these fish, and break up their populations into isolated units with little or no connectivity between them. In addition to breaking up connectivity, dam construction has resulted in reduced sturgeon habitat suitability and quality, with recruitment of juveniles to the populations a particular problem. DEIS at 3-313.	These statements are paraphrased directly from the EIS and accurately describe the affected environment conditions for the white sturgeon populations analyzed in this process. This information serves as the basis for analysis of the alternatives, including the No Action Alternative. These analyses are found in Section 3.5.3. The Preferred Alternative would result in minor benefits to Kootenai River white sturgeon, as described in Section 7.7.5.
58788	7	Erik Molvar	Western Watersheds Project	The Breaching or Removal of Dams Improves Anadromous Fish Survival and Recovery Each time a major dam has been breached in the Pacific Northwest, anadromous fish populations have benefited. After the breaching of Condit Dam on the White Salmon River, lamprey habitat was enhanced. DEIS at 3-308. When the Elwha River Dam was breached, salmon soon re-established spawning runs up the Elwha, and estuarine habitat for Dungeness crabs was also greatly enhanced. The Corps has yet to undertake a thorough analysis of the positive effects of dam breaching and/ or removal in its Draft EIS, to inform the relative merits of the alternatives, both considered and neglected, in regard to anadromous fish protection and recovery.	MO3 of the Draft EIS provides the analysis of breaching the lower Snake River Dams. The commenter is correct regarding success in restoration of spawning habitat and reintroduction into blocked areas following dam removal for a variety of tributary dam removals. However, these examples do not necessarily have relevance to the lower Snake River Dams. Using some prominent examples in the pacific northwest, the Elwha and Condit dams had no passage, and provided few economic benefits. In contrast, the lower Snake River dams do have fish passage and in fact passed a modern record number of salmon and steelhead as recently as 2014, while also producing power and providing navigation and recreation.
58788	8	Erik Molvar	Western Watersheds Project	Failure to Adequately Analyze Cumulative Impacts Many factors that are very important factors contributing to the decline of salmonids an other fishes in the Columbia River system are given short shrift in the EIS. For example, while irrigation withdrawal impacts on fish are mentioned in passing in the cumulative effects analysis (DEIS at 6-6), the impact of poorly constructed or maintained irrigation intake pipes, which are known to be a major source of mortality for salmonid smolts and lampreys, is not even mentioned. Indeed, most of the impacts analysis regarding irrigation focuses on impacts of dam operations on irrigators, rather than impacts of irrigation operations on fish. Livestock grazing in spawning reaches causes major impairment of salmon and steelhead spawning streams, destroying riparian vegetation that would otherwise provide shade, changing stream channel profiles to eliminate the deeper water habitats important to returning adult salmon and steelhead, directly trampling sahnon and steelhead redds and crushing their eggs while wallowing in streams and rivers, and causing erosion and siltation of spawning gravels that smothers steelhead and salmon redds in silt, killing the eggs, and degrading the spawning habitat most severely. Yet the words "cattle?" and "livestock" do not appear even once in the cumulative effects analysis. Logging is mentioned only once in the cumulative effects analysis (DEIS at 6-2), in passing, and without any analysis despite the fact that it, too, results in major erosion and siltation effects on the salmon and steell1ead spawning streams not damaged by heavy livestock grazing, particularly in heavily timbered headwater streams as are found on the Clearwater National Forest. It appears that the Corps has not even made an attempt to look at the various human-caused factors that depress steelhead and salmon survival throughout the life cycle, so that it can assess the role of dams and reservoirs, and their operational management, in the decline of these species in the Columbia River watershed.	Sections 3.5.1 and 3.5.2 describe the affected environment for aquatic resources, including fish. The co-lead agencies recognize both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Chapters 6 and 7 incorporate the past and present effects described in Section 3.5 into the cumulative effects analysis for fish.
58789	1	Marilyn Carlson	N/A	The CSS model predicts a relative improvement in SARs of 35% for Snake River Spring Chinook, the LCM model predicts a range of -7.5 to +28% improvement. Neither meets the minimum standard of >2.0 SAR fo Idaho's Spring Chinook. The range of improvement for Idaho steelhead is better, but only meets the 2.0 SAR goa! under the most optomistic projections. Only MOA 3 (breaching of the four LSR dams) and MOA 4 (24l7 spill over all eight dams) met the requirements of the ESA for Idaho's fish.	With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council (Council) recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. It should be noted that the 2-6% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
58797	1	Lorre Gefre	N/A	Most of all; I am so disappointed in lack of regard for U.S. and State Laws not enforced regarding the use of the "Publics Water". There needs to be conversation not more and more taken that is not available. RE: High water marks where flooding occurs and CAFOs built in these p[laces that Corp of Engineers could over see and do better job	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes and take these and other responsibilities very seriously.
58798	1	K. David Hagen	Cleanwater Power Co.	Furthermore, it builds on the current Flexible Spill Agreement and supports adaptive management. However, we have concerns regarding utilizing Flexible Spill as the key component of the P A. Increasing spill levels to 125% Total Dissolved Gas (TDG) is an unprecedented action resulting in higher power costs. Further examination of the potential benefits and unintended consequences of higher spill levels must be conducted in the future as the 2019 operations of the Federal Columbia River Power System (FCRPS) at 120% TDG has shown minimal benefit to ESA-listed species. There must be scientific analyses conducted in the future that clearly shows the benefits of increased spill levels to this magnitude.	The adaptive management plan in the Draft EIS will include evaluations of unintended consequences. While the 2019 flex spill operation showed minimal benefits to salmon, it should be noted that the hypothesized benefit of increased spill is to increase Smolt-to-Adult returns (SARs) due to reduced powerhouse passage. With the primary metric being SARs, an assessment of the flex spill operation will take multiple years of adult returns. One year of in-river data will not answer the question. Appendix R, Part 2 describes the principles for implementation of the flexible spill operations and guidance for adaptive management. One of the principles focuses on federal power system benefits, which will be as determined by Bonneville Power Administration. The understanding is that Bonneville must, at a minimum, be no worse financially compared to the 2018 spring fish passage spill operations ordered by the Court. This principle is directly related to Objective 5 of the CRSO EIS: Provide an adequate, efficient, economical and reliable power supply that supports the integrated CR Power System. The co-lead agencies have determined that the Preferred Alternative meets this Objective. In addition, the Preferred Alternative places additional rate pressure for wholesale power rates of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs it has significant control.
58798	2	K. David Hagen	Cleanwater Power Co.	Again, Clearwater rejects the actions laid out in M0-3 and M0-4 as they don't meet the multiple objectives laid out. The four Lower Snake River Dams (LSRD) provide more than 2,000 MWs of peaking capability and play an important role in maintaining reliability in the region. As some of the lowest cost, carbon-free generation in the Northwest, their flexibility and dispatchability are valuable components of the FCRPS. Their removal would more than double the risk of regional blackouts and would have a tremendous social-economic impact on the region. It is estimated that Bonneville Power Administration's rates would increase by approximately 50%, costing up to $1 billion a year in additional power costs. The retail rate impact on Clearwater's rural residential customers would be devastating.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative (PA) identified in the Draft EIS. The effects of the PA on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability (LOLP) was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The comments that breaching the four lower Snake River dams would increase the frequency of power shortages, unless and until replacement resources are acquired, and would result in increased costs in the region are both consistent with EIS findings. The Environmental Justice analysis in Section 3.18 and Chapter 7 provide further detail on potential disproportionate effects to Tribal, low-income and minority populations. In the Draft EIS, Appendix H, Power and Transmission, Chapter 5 and Exhibit 1, provides additional details on potential rate increases by county as well as for rural utility customers.
58798	3	K. David Hagen	Cleanwater Power Co.	Additionally, Clearwater supports strengthening and expanding measures to mitigate for avian predation in the Columbia Basin in the PA. Avian predation is a major source of mortality of ESA-listed species therefore, the Final EIS must include a thorough and detailed plan to address avian predators.	The co-lead agencies recognize the importance of addressing avian predation throughout the project area and have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. This includes continued implementation of (1) dissuasion measures at the Corps hydropower facilities as described in the annual Fish Passage Plan and coordinated with the FPOM, (2) the Inland Avian Predation Management Plan (IAPMP), (3) CATE management plan for reduction in habitat at East Sand Island, and (4) the Double-crested cormorant (DCCO) management plan at East Sand Island. Other entities in the region also have authorities and obligations to mitigate the impacts from predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. Specifically, under the ESA, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Ultimately, recovery, including predation management actions, is a broader regional goal that is the role of NMFS and the USFWS and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Based on our analysis in the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation, would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
58799	1	William Cobb	N/A	A. Many supporters of dam removal are derisive of the those who appropriately worry that the impact of the amount of truck and rail traffic needed to replace the carrying capacity of barge traffic currently plying the lower Snake River has been drastically under estimated ! As has been common in many phases of the dam removal debate, those who are the most contemptuous of those who support keeping the dams do not even live in the area impacted by the proposed dam removal, are grossly misinformed or blatantly uninformed about the current rail and truck infrastructure between Lewiston, Idaho and the Tri-Cities of Washington and their theoretical capacities. B. I have lived in the Tri-Cities since 1974, and have traveled to and from Lewiston numerous times almost every year via Hwy 124 to Hwy 12 or Hwy 12 all the way from the Tri-Cities to Lewiston. The majority of either of these two routes is two lane Hwy over hilly terrain with sparsely placed passing lanes. The routes pass through several small towns with 25 mph speed limits and narrow streets. Waitsburg, for example, using the Hwy 124/ Hwy 12 route, requires truck traffic to make two 90 turns (one right and then one left) within one city block of each other. I would submit that either or both truck routes would soon be dubbed "Blood Alley" if the dams are removed and truck and rail traffic have to fill the void.	The amount of truck and rail traffic needed to replace barge traffic under a dam breach measure is a function of volume, capacity, and location of transportation nodes. The EIS in Section 3.10.3.5 combines this information with the costs to determine the lowest cost routes absent barging under various rail rate scenarios. The truck rates overtime are considered as inclusive of driving conditions. The EIS found that truck trips under MO3, could increase from a range of an additional 14,000 to 79,000 truck trips per year (38 to 216 per day on average), which would increase air pollutant and greenhouse gas emissions and add to traffic and congestion in the region. The EIS also discusses in Section 3.10.3.1 that changes in transportation modes can also have implications for public safety. In particular, the EIS states that accident rates are generally higher for road travel than travel by either barge or rail. As such, shifts from barge to rail and truck would be anticipated to increase accident rates.
58799	2	William Cobb	N/A	C. The existing railroad infrastructure between the Tri-Cities and Lewiston is currently at or very near capacity.	Discussions about capacity concerns throughout the supply chain can be found in Section 3.10.3.5 of the EIS. There is currently very little grain that moves between Lewiston and the Tri-Cities on rail, primarily because of the Positive Train Control requirement of the Class I railroads and the inability of the shortline operator (WATCO) to meet the PTC requirements without significant investments. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
58799	3	William Cobb	N/A	D. In either case (rail or truck) changes to increase the capacity of the existing network would be very expensive because of the terrain and take multiple stages and years to complete as well as being very susceptible on a biannual basis to the transportation funding priorities of the more populated West side of the state.	The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. Ultimately, rail infrastructure investments would be at the discretion of the railroads.
58799	4	William Cobb	N/A	E. The significant increase in heavily laden truck traffic on existing and/or newly improved roadways would also dramatically increase repair and maintenance costs on the truck Hwy routes between the Tri-Cities and Lewiston after dam removal.	The EIS evaluates the additional transportation infrastructure investments that would be required. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur.
58799	5	William Cobb	N/A	F. Finally, scores and scores of trucks traversing the route between the Tri-Cities and Lewiston would also drastically increase the carbon footprint of transportation in this locale. Supporters of dam removal counter that this potential increase in our carbon footprint because of dam removal is insignificant on the global stage. That well may be true, but in reality, we as individuals or even as a country, will probably never witness any of us having any real impact on the carbon footprint of China or India or other major large carbon footprint contributors; but there will be a pronounced and unfortunate increase of our carbon footprint if the dams on the lower Snake River are removed !	Consistent with this comment, Section 3.8.3 of the Draft EIS does find an increase in greenhouse gas emissions from increased truck transport of freight under MO3. MO3 was not identified in the Draft EIS as the Preferred Alternative.
58800	1	Randy Grove	CENTRAL LINCOLN	Central Lincoln is Oregon's fourth-largest electric utility, and the second-largest consumer-owned electric utility in Oregon. The average age of our customers is 54, their average educational attainment is some college but no degree, with an average household income of $41,000 annually. We exist solely to serve our customers, and it is through this lens that we evaluate the DE IS. We support this DEIS, and the collaborative approach the Agencies took in analyzing and mitigating the impacts the Preferred Alternative will have on power generation and the SPA's rates. All of the power we supply to our 39,900 meters is purchased from the BPA, thus this matter is of the highest importance to us. A large industrial customer comprises 40% of our load, supporting a workforce of 450. Competitively-priced power is a major factor in retaining these jobs, and keeping their significant payroll dollars in our local economy. We also worry about our low- and fixed-income customers who struggle to pay for life's necessities. We think of them every time we must increase our rates.	The EIS recognizes the concern voiced in the comment regarding increasing power rates. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. The Environmental Justice analysis in Chapter 7 of the EIS finds that the Preferred Alternative is not likely to have disproportionately high and adverse effects on low income, minority, or Tribal populations.
58800	2	Randy Grove	CENTRAL LINCOLN	Concerns About the Preferred Alternative Losses in Carbon-Free Generating Capacity and Reliability Implementation of increased spring spill operations up to the proposed 125% total dissolved gas cap is projected to result in the loss of 160 aMW of hydropower generation, with as much as a 2.7% BPA rate impact. When we couple this with escalating Tier 1 power costs, primarily due to fish and wildlife mitigation efforts, we see rates that cause us significant concern. This loss in carbon-free generating capacity coupled with the expected retirement of 2,505 MW of coalfired firm generation would result not only in higher power costs, but could also result in unplanned outages or rolling blackouts. As I have outlined previously, either or both outcomes would be unpalatable to our industrial and residential customers, as well as to our commercial customers.	The EIS recognizes the concern voiced in the comment regarding increasing power rates under the Preferred Alternative. The loss in hydropower generation and the power rate increase quoted in the comment is consistent with the findings of the EIS; however, it is important to note these estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations or rates. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement. In addition, as noted in the EIS, the rate pressure associated with the Preferred Alternative may be absorbed by cost reductions. See Section 3.7.3.1, at page 3-817 in the Draft EIS. The comment that the loss of coal-fired generation in the region could increase the risk of regional power shortages unless and until sufficient replacement resources are acquired is correct. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017, and the EIS presents base case analysis first; then discusses information regarding additional sensitivities and potential cost pressures. See Section 3.7.3.1, Base Case Methodology and Cost Sensitivity Analysis, at page 3-816 in the Draft EIS; see also Id. at page 3-823 of the Draft EIS. Since development of the base case, additional coal retirements have been announced. See Section 3.7.3.1, Availability of Coal Resources, pages 3-841-842 in Draft EIS. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, pages 3-829-830 in Draft EIS. Coal-fired generation in the region is owned by investor-owned utilities. As such, Bonneville and its customers would not be responsible for the cost of replacing this generation. However, this could still affect regional power prices, as noted in the comment, through the effect on the wholesale market. See Section 3.7.3.1, Availability of Coal Resources, at pages 3-841-842 in the Draft EIS; See also Section 3.7.3.2, Table 3-123 in the Draft EIS.
58800	3	Randy Grove	CENTRAL LINCOLN	Uncertain Benefits of Increased Spill We appreciate increased spill operations are intended to provide more effective fish passage than turbine or bypass passage for juvenile salmonid outmigration. However, we are hopeful the Action Agencies will heavily monitor increased spill, as we fear it will have unintended and negative consequences for fish, particularly gas bubble trauma. We encourage you to include clear authorization language within the final EIS allowing for adaptive management if our fears are realized, and higher spills is shown to be a detriment to either adult or juvenile resident or anadromous fish.	The Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
58800	4	Randy Grove	CENTRAL LINCOLN	Predation Management As a utility serving fully one-third of Oregon's coastline, we see quite vividly the effects of large and unchecked avian and pinniped populations on our local environment. We have firsthand reason to believe avian and pinniped predation are a significant cause of endangered and threatened salmonid mortality. Central Lincoln encourages the Action Agencies to pursue even more active predation management in the final EIS to improve salmon outcomes.	The co-lead agencies recognize the value in measures to reduce predation throughout the project area and have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region also have authorities and obligations to mitigate the impacts from predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The EIS is being develop to update the operations, maintenance, and configuration of the 14 dams operated as the CRS. It is not a salmon recovery plan. The co-lead agencies are limited to implementing measures that are within the authorities of the co-lead agencies. Specifically, under the ESA, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Ultimately, recovery, including predation management actions, is a broader regional goal that is the role of NMFS and the USFWS and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Based on our analysis in the fish resources section of Chapter 7, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation, would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
58800	5	Randy Grove	CENTRAL LINCOLN	Ocean Conditions Survival rates for fish passing around, through, or over dams are just one part of a continuum that includes water temperature, ocean conditions, in-river smolt predation, and adult salmonid predation/harvest rates. Studies have shown our oceans absorb as much as 30% of the climate's excess carbon and 90% of its excess heat. This results in warmer water temperatures, higher acidity, and lower levels of oxygen in our waters. NOAA Fisheries researcher Dr. Lisa Crosier notes scientists around the world have documented "almost synchronous declines in salmon populations" due to these factors. We must do what we can to mitigate these environmental issues to restore healthy salmon populations.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. This Draft EIS analyzes the effects of the configuration, maintenance, and operation of the CRS projects in Chapter 3.4. The scope of the Draft EIS focuses on the area affected by the alternatives presented for operation, maintenance, and configuration of the CRS projects. We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions in Chapters 6 and 7 of the EIS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species.
58800	6	Randy Grove	CENTRAL LINCOLN	Clean Energy It is widely recognized the Pacific Northwest produces the cleanest energy in the U.S. primarily thanks to the FCRPS's renewable hydropower. Our system must be kept whole in order to flexibly integrate renewable but intermittent solar and wind generation onto the grid. The value derived from the FCRPS' generation must be properly calculated, and the full costs of the system equitably allocated to all beneficiaries across our region. We encourage you to give proper weight to the comments and concerns expressed by those who finance the outcomes of the final EIS. We hope you will establish a new "base case" within the Power Generation and Transmission Analysis that incorporates anticipated loss of generation, and the costs of replacing lost hydropower capability with new carbon-free resources.	The statements that hydropower is important for the integration of new renewable power resources as well as regional greenhouse gas emissions from power generation are consistent with the findings of the EIS. Consistent with the recommendations in the comment, the EIS considers multiple approaches to valuing the hydropower generation from the Federal Columbia River Power System (FCRPS) as well as the associated costs of changes in hydropower generation under each alternative including the social welfare costs and the potential replacement resources required to maintain regional reliability. See Draft EIS Section 3.8.3.1, Methodology, for additional details. The financial responsibility for the costs of all of the measures included in the Preferred Alternative is not solely allocated to Bonneville's power ratepayers. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by an established cost allocation, and this allocation is recovered through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). As described in Section 3.19 of the Draft EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them. Regarding the potential future loss of generation from additional coal power retirements, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. In the Draft EIS, see Section 3.7.3.1, Availability of Coal Resources, at pages 3-841-842; and Section 3.7.3.2, Table 3-123. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017, and the EIS presents base case analysis first before discussions of information resulting from additional sensitivities and potential cost pressures. The co-lead agencies considered the suggestion to establish a new base case, but determined that the uncertainties involved in updating the regional resource replacements for retiring coal would be too speculative to warrant changes to the base case.
58801	1	Lauri Dayton	N/A	FISH MIGRATION ISSUES The DEIS does not appear to sufficiently present anadromous fish survivability /mortality modeling, through the LSRD, omitting reference to a fundamental component of the equations: Mortality of downstream migrants will remain through a hypothetical, post-breach Lower Snake because migrant mortality is a demonstrable reality for the similar and free flowing section of the Snake system immediately upstream of the LSRDs. Known and knowable information indicate this : Discussions and tables in the DEIS, (and out in the public domain) center on "gross" survivability, such as 97% through this Dam, or 94% through that Dam, aggregating the result through the 4 or 8 dams of interest, the contentions usually being whether this or that number is accurate. The unstated assumption is that you are subtracting estimated survivability from 100%. That does not accurately reflect the difference between present experience and post breaching survival rates, which must account for estimated mortality under free flow conditions, as demonstrated in the following paragraph. Except for an oblique reference I found at Chapter 3, lines 7257-7259, "as noted ... on a per-kilometer basis, these survival rates are approaching those estimated for several free flowing river systems" the DEIS appears to be silent on this calculation. Using existing Pit-tag survivability data for free flowing upstream reaches from 4 hatcheries of origin above Lewiston and isolating out the present estimated mortality of the LG pool (about 7%) Table 25--from Table 24, "Estimated Survival of Hatchery Yearlings." of the "Survival Estimates for Passage of Spring Migrating Juvenile Salmon" (aggregate averages 1993 to 2016) fy 2016, Widener, Faulkner et al, (NOAA), allows generation of per-km mortality factors attending natural free flow conditions on the similar mid to lower Snake system, and so largely applicable to the length of the LSRD reach, once it attains ecological equilibrium in the event of breaching. The 215 km LSRD reach would yield 48.4% 55%, 57% and 81.7% survivability for Dworshak, Kooskia, Grande Round and Rapid River source fish respectively; -not particularly dissimilar results from survivability calculations for the Lower Snake in it's present condition. Further, there is a consistency in the mortality characteristics regardless of the year or quality of the runs examined. Widener, Falkner eta! is the authoritative technical reference for establishing the facts of downstream migrant survivability and related subjects such as travel time through PIT tag tracking. The point is not the actual accuracy of the calculation here but that mortality for the LSRD Reach in a "natural" state occurs and would likely be is relatively significant and that existence of such mortality should be widely understood as a fundamental constituent of the survivability equations to arrive at a true sense of the dams' impacts. The take-away notion is that potential improvements in downstream migration survivability post-breaching would not likely be as substantial as commonly supposed by proponents of breaching, or the casual public at large. I do not believe the DEIS communicates this strongly enough.	The co-agencies concur that there will still be mortality associated with passage through the Snake River, whether dams are breached or not. As noted in the comment, the co-lead agencies have attempted to estimate per-kilometer mortality rates above Lower Granite Dam compared to within. Without an undammed reference river, it is challenging to know the exact level of background mortality compared to a system without dams or for fish that have not been recently released from hatcheries.
58801	2	Lauri Dayton	N/A	Downstream migrant detection problems with Dam breaching. Pit tag detection, presently occurring at "pinch points" built into the Juvenile Bypass System at each Dam, will be rendered useless, if M03, breaching is implemented. No detection system currently exists (Widener, eta!) for spillway bypass routes-implying that the further uncertainties attending detection capability deployment for an earthworks breach will, at best, delay data acquisition further into the future. Meanwhile, without reliable data, information development is retarded and in turn, that of science-driven management tools, thus delaying and harming future stock recovery. Dam breaching will cause abandonment of existing data gathering infrastructure and impede understanding of migrant behavior. Further, since breaching is permanent, we would lose the ability to respond appropriately to new or unforeseen conditions and circumstances. I question the wisdom of such strategy, particularly in light of the known transitional habitat disruption attending breaching. It does not appear to be a sensible, prudent and reasonable strategy to permanently preclude further knowledge of downstream migrant attributes by providing an uncontrolled breach path past the dams. In short, the devil we know is preferable to a substantial probability of inflicting willful/ ignorance. Dam breaching appears to be a form of wagering our entire pile of anadromous chips-once-- "betting on the come." There appears to be little attention brought to the factors and notions above in the DEIS.	The co-lead agencies agree that MO3 would result in a major change in the region's ability to monitor fish passage and survival in the lower Snake River. The co-lead agencies would anticipate broad regional discussions on how to gather scientific information through the lower Snake River in the event the projects were breached.
58801	3	Lauri Dayton	N/A	ENERGY FACTORS The generation peaking and voltage support capability, are most important aspects of the electrical supply complex, and are supplied is virtually carbon free, by the LSRDs, according nicely with the Governor of Washington's vision of our energy future. Hydropower's most valuable attributes are it's storability and dispatchability --meaning it modulates automatically to match generation instantly (and efficiently) to changing demand conditions. Solar, while partially predictable on a daily basis, isn't available during dark hours. Wind is predictably available only during weather changes, usually not the more rigorous conditions associated with system peaking requirements. Having gained the reputation of "only generating when you don't need it," wind can supplement hydro generation, enhancing grid operations when available during fish flushes, allowing more bypass/spill. Supplementation is not replacement. Available "green" generating alternatives, beyond their inherent unsuitability for real-time supply-demand balance, are resource intensive. For example, for wind generation,(without getting into engineering weeds,) the simple formula for power,"I," current, x "V," voltage, requires 40 times the amount of copper to generate and deliver the same kilowatt to an identical "grid" port as does a typical Snake River hydro-generator, something ecology minded costing advocates should consider. Then there is the issue of wind turbines' shorter lifespans. Batteries don't generate any electricity, only store what is put into them. While complementarily useful for response purposes, they are scales of magnitude smaller and scales of magnitude more expensive. For example, if we assume 90% generator availability for the LSRD as a whole, no inflow at Lewiston (unrealistically conservative) and full pools, we could generate 3,135 MW for nearly 16 hours solely using LSRD reservoir capacity, for comparison with the largest utility scale battery installations, about 100 MW for 1 +hour. Supplementation is not replacement. This comment is offered to provide context to the economic and ecological issues of replacing LSRD energy /power by technologies often considered desirably "green."	The suggestion in the comment that hydropower is a reliable source of power that is important for grid stability and power reliability is consistent with the findings of the EIS (see Section 3.8). That hydropower can adjust generation to aid in grid stability and the integration of renewable power, as described by the comment, is also consistent with the descriptions and analysis of the EIS as described in the Bonneville Transmission System Reliability and Operations in Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS. Additionally, the EIS does find that a substantial amount of renewable replacement resources would need to be built or acquired to account for the reduction in hydropower due to the lower capacity factors of solar and wind. Of note, the EIS did not identify wind power as a cost-effective resource for the replacement resource portfolios and thus, did not evaluate the interconnection requirements of wind.
58801	4	Lauri Dayton	N/A	Opposition to use of "contingent" economics derived from the 2002 LSRD EIS: The current DEJS references the 2002 EIS contingency economics regarding recreation lines ~ 1733 to lines ~1785, pages 3-1215 to3-1218: "For the 2002 EIS, a contingent behavior survey was conducted to estimate how non-fishing ..... recreation use would change if the four lower Snake River dams were breached. Using results from this survey, visitation after dam breach was estimated to be 1.5 to 2.7 million annual recreation days after full recovery of the natural river system, ... " "Contingent" in the economic sense is not defined in the current DEIS, but was more fully identified in 2002 and has been construed to mean "indirect" or "non-use" values in later literature employing it relating to the LSRD removal issue. A major justification for it's inclusion in those documents is it's existence in the 2002 EIS. The 2020 DEIS appears to build on this shaky foundation . "Non-use" Values impa1t a degree of psychological wellbeing, satisfaction, or a sense of desirability in a respondent subject, and have been gaged by eliciting a response to the question: "What would you be (W)illing (T)o (P)ay for X?" The fundamental difficulty of including contingent/indirect/nonuse values into quantitative analysis is that they are not tangible. The worth afforded to values derived from a survey response, preference or opinion—requiring no tangible commitment of resources or expenditure-is limited. Contrastingly, tangible commitments and expenditures (including time) as evidenced by actual usage, are directly quantifiable. Exchange of tangibles for Usage constitutes a collective economic transaction. Since survey respondents know a- priori no actual resource expenditure will be required of them because no actual "other side" of the transaction (or exchange mechanism) exists, no quantifiable "contingent" market can be established. If the market does not exist then no substantiated expenditure can be adduced. Because there is no tangible constraint governing the respondents evaluation process, Non-Use value can be anything, nothing at all, or change without limit. —reducing the worth of the response to nothing more than a comment or opinion--which can be, and often is, much influenced by the phrasing of the question. The inherent unreliability and unsubstantial nature of que1y methods or surveys used to generate Non-use values should eliminate them from quantitative consideration. Local constituents unsurprisingly predominate present usage patterns, demonstrating the generally accepted inverse economic relationship between usage and decreasing proximity. Recurring warm season, multi-day visits characterized by home-away--from--home sensibilities complementary to farming and small-business responsibilities prevail. An economist would say that these recurring visits demonstrate a marginal utility of usage to these visitors far in excess of cost: repeated expenditure of time money and effort -or "significantly" in excess of cost. Why significantly? Because the "law of diminishing returns" applies to most discretionary expenditures, including leisure and recreation. This economic utility is "substantiated" by commitment of expenditure to usage, is therefore fully knowable and justified for inclusion into quantitative models. Further, if "Non-use Values" are to be admitted in any manner, the Non-use Value of the River in it's present condition for these more local visitors, and others, certainly exists because active behavior demonstrates an appreciation of desirability above and beyond the passive and unsubstantiated value associated with non-use as evaluated by survey, stated preference or query method. The foregoing	The recreation evaluation under MO3 described in Section 3.11.3.5 used a number of approaches. In the short-term, the evaluation used the current estimates of water- and land-based visitation at the four lower Snake River projects to estimate decreased visitation, social welfare, and regional economic effects from the dam breaching activity. In the long-term, there is considerable uncertainty in terms of recreational access and infrastructure development needed to facilitate river recreation, and the impacts on river-based visitation. The EIS describes a range in non-fishing visitation in the lower Snake River post dam breach based on the general recreation survey (contingent behavior survey) in the 2002 Juvenile Salmon Migration Feasibility Study and EIS. However, the EIS acknowledges that there were concerns regarding the survey methods and results. As a result, Section 3.11.3.5 adjusted the visitation from the survey results to provide a range in visitation. On the low end of the range, visitors from California were excluded. Visitation estimates in the lower Snake River (excluding anglers) would range from approximately 1.2 to 3.4 million annually, depending on whether the estimates were adjusted to current population levels, the extrapolation method used to apply sample results to the general population, and whether or not visitors from California were included. The social welfare values and regional economic effects associated with river recreation post dam breach were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The EIS relied on similar rivers in the region to provide an estimate of fishing visitation in the lower Snake River in the long-term; the 2002 Juvenile Salmon Migration Feasibility Study and EIS was not used. In addition, existing studies and literature were used to describe the angler visitation and economic contribution in the Snake River Basin in the Recreation Affected Environment and the No Action Alternative. The Fish Effects (Section 3.5.3.6) were used to describe how changes in fish abundance could affect angler trips in the long-term under MO3 and the other action alternatives. The EIS did not rely on the 2002 study results to quantify passive use value impacts of the CRSO alternatives. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Section 3.15.2.2 includes existing research on the passive use values for fish. This information is considered alongside the analysis of effects of the Multiple Objective alternatives on fish abundance (Sections 3.5 and 7.7.5). As described in Section 3.15.2.2, the economics literature includes research on passive use values for free-flowing rivers. These studies generally bundle the environmental changes associated with free-flowing rivers, including, for example, specifying effects on fish populations. Thus, passive use values for free-flowing rivers are not necessarily distinct from or additive with passive use values for the fish within these rivers.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				reveals the disparity of integrity between substantiated and unsubstantiated propositions relating to quantitative economic studies, the worth of the fanner and relative uselessness of the latter. The two do not belong in the same calculation, they are not fundamentally equivalent. But, by the mechanism of incorporating both sources of "dollars" into a common quantitative model, they are thereby (incorrectly) deemed equivalent and become fungible, or interchangeable for purposes of manipulation and evaluation. Therein lies the nexus of error; or dishonesty, depending on how characterized. Those homogenized "dollars" are then summed, discounted, multiplied and otherwise quantitatively processed, resulting in erroneous and misleading conclusions. The mischief of these economic mischaracterizations lie in the subsequent model processing where non-use/indirect/contingent estimates are multiplied (extended) by expanded (scaled) populations, then multiplied by multi-year discount factors to present immense benefits derived from compounded uncertainties, often to the extent of materially altering the conclusions of the quantitative analysis. If contingent values are to be admitted into the evaluation process they should be deeply attenuated to account for physical, political, economic, and cultural remoteness of the expanded population, as a matter of evaluative integrity. An example of incorrect application of the contingent/indirect/nonuse evaluative mechanism is shown by this example from the (Washington State) Governors "LSRD Stakeholder Engagement Report," intended to inform the Governor regarding his reasonable and prudent input to the 2020 LSRD DEIS. This report, funded to $750,000 by the Legislature, could not have been intended merely for the Governors personal edification: The stated question was essentially "How much extra would you pay per month to realize the ecological /recreational benefits (list inserted here) of LSR Dam removal and return the River to its natural state?" ie utility bills, taxes etc-was answered in dollars/month. The corollary question: "How much extra would you pay per month to continue realizing the ecological/recreational benefits (list inserted here) of the River retained in its present dammed state?" – clearly of importance to present visitors and the population cohort considered in the study—was not asked-ensuring a result of zero, thereby depriving the quantitative evaluation of the necessary and proper objective symmetry and automatically defaulting the net conclusion to be favorable to dam breaching. There was opposition in 2002 to the EIS to the contingent equivalence accorded Californians and others far afield from local county residents engaging in direct usage for precisely the same reasons as it is opposed here presently: the skewing of the analysis in a way that under-represents the interest of the more local cohort and the exaggeration of the worth to more remote cohorts. My recommendation is to eliminate the practice of contingency/indirect/nonuse valuation from the DEIS. This rather lengthly comment criticizing the appropriateness of recreation related contingent/indirect/nonuse valuation practices applied to quantitative economic analysis is intended to address the 2020 DEIS in the discussion occurring in or near lines~ 1733 to lines ~1785, pages 3-1215 to 3-1218.:	
58802	1	R. Kirk Schroeder	N/A	Summary In 2016 the U.S. District Court found that the Biological Opinion was inadequate for the 5th consecutive time, largely because it failed to address ongoing weaknesses in the approach despite a previous admonishment that "the situation literally cries out for a major overhaul [emphasis added]. I find that the approach in the present DEIS continues to be inadequate in addressing the protection of salmon and steelhead populations, much less their recovery. The Preferred Alternative (P A) in the 2020 DEIS offers only minor modifications to the failed status quo management that would further threaten the existence of Snake River wild salmon and steelhead populations, and falls far short of the 4% smolt to adult ratio (SAR) necessary for recovery. The P A fails as a "major overhaul" repeatedly called for by the courts. Rather than balance the river uses in the P A, it emphasizes unneeded hydropower production, subsidized barge transportation that has been declining for many years, and easily replaceable irrigation (out of one reservoir); all these replaceable uses are at the expense of unreplaceable wild salmon and steelhead populations. The P A, by its own admission ensures that wild salmon and steelhead will continue to decline, which will put them on the path to extinction. Thus, the DEIS fails to carry out the mandate of the court, and will almost certainly fail to recover salmon and steelhead populations. Recommendation As demonstrated by models results in the DEIS, the only option that ensures continued existence of salmon and steelhead and has the highest probability of recovering populations is M03 (dam breaching) that provides a free-flowing lower Snake River. This option combined with 125% spill at the lower Columbia River dams would prevent extinction and allow for recovery of populations. The dam breaching alternative is the only one that minimizes the risk of extinction for Snake River salmon and steelhead populations and it meets the survival criteria that is needed for recovery. A legal requirement of the DEIS is to minimize the risk of extinction for listed populations affected by dam operations. It is time to plan for dam breaching, the continuation of wild salmon and steelhead depends on this action.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Finally, the agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
58802	2	R. Kirk Schroeder	N/A	Specific Comments on Salmon and Steelhead Operation of the four Lower Snake River dams has been the major factor in the long-term decline of wild salmon and steelhead populations, and today many are near the brink of extinction. Snake River salmon and steelhead runs were listed as threatened or endangered under the Endangered Species Act (ESA) by the early 1990s. Since that time, a litany of approaches has been attempted to protect salmon and steelhead through replacement of wild fish with large hatchery programs or technological fixes such as barging juvenile fish, controlling predators (including native fishes), and countless attempts to safely pass juvenile fish at the dams. This DEIS proposes to continue the same failed course with an emphasis on a mechanistic approach rather than an ecological one. The effects of the four Snake River dams on passage of adult and juvenile salmon and steelhead has been well documented for decades. The DEIS does not adequately address ongoing passage problems. The assertion in the DEIS that juvenile passage at the dams is high is not backed up by scientific studies of the complete in-river survival, which include mortality at the dams plus predation and natural mortality. Another large source of mortality is delayed mortality that can occur in the river or can be expressed in early ocean mortality. All these mortality factors decrease the survival of juvenile salmon and steelhead in the estuary and ocean. SAR provides a more accurate measure of overall survival.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of those effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Latent mortality effects were considered and factor prominently in the decision on the Preferred Alternative, and those model results are presented in Section 3.5 and Chapter 7. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the Draft EIS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
58802	3	R. Kirk Schroeder	N/A	Studies and models estimate that SAR of 2-6% is necessary to provide ongoing continuation of salmon and steelhead populations. However, the SAR of the populations upstream of the lower Snake River dams has generally been much less than 2%. These low SARs have resulted in continued decreases in the wild populations. In contrast, salmon and steelhead populations in downstream watersheds that have to pass through fewer dams have higher SARs. Population recovery requires high survival to provide societal benefits of harvest by sport, commercial, and tribal fisheries; and that also provides ecological benefits such as prey for orcas and adequate spawners to "fertilize" watersheds. Scientists have identified an average SAR of 4% (range of2-6%) for a sustainable, harvestable population. The P A will not meet the regional SAR goal of 4% and at the lower end of the predicted range, the SAR is below 1%, which would lead to population decline and increase the risk of extinction. Fish survival under the PA is just slightly better than either the No Action Alternative or the M01 Alternative. In contrast, fish survival is higher under the dam breaching and 125% spill alternatives, which would ensure population stability with a higher probability of recovery than other alternatives.	Based on our analysis of the Preferred Alternative, it will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be minor because of benefits to salmon and steelhead. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the 4% average SAR target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. The co-lead agencies do not support comparisons of SARs between populations as evidence of latent mortality. The Independent Science Advisory Board has repeatedly questioned that line of evidence and has recommended that the CSS not conduct upstream/downstream comparative studies. For example, see ISAB/ISRP 2007-6 and ISAB 2020-1.
58802	4	R. Kirk Schroeder	N/A	The objective of the DEIS is apparently to prevent extinction of wild salmon and steelhead rather than to restore populations to levels of abundance that would provide for harvest (sport, commercial, tribal) and would provide adequate prey for orcas. Yet, even by this low standard, one of the models predicts the PA would negatively affect survival, thus the DEIS does not even meet the minimum requirement of preventing extinction. The P A continues a failed status quo management and is essentially an experiment that has a high risk of failing to recover salmon and steelhead populations that are in danger of extinction now. A model used to assess alternatives predicts the P A would result in a low SAR that would result in overall population decline, for populations that are already diminished. The P A basically represents a minor tweak to the status quo under the Flex Spill	Based on our analysis, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				agreement, which was designed as a temporary measure, not a long-term solution. Analysis of the juvenile passage under the P A is flawed because it uses an 80-year data set of flow presented as daily average flow and juvenile passage when flex spill operates on an hourly basis. This underestimates the higher percentage of juvenile passage through the powerhouse that would occur as a result of low spill levels in the evening and night when juvenile fish passage is higher than during the day.	The co-lead agencies do not agree that results are biased high due to hourly vs. daily time steps. These models will be used to assess relative changes so minor bias if present would not be enough to change relative magnitude of the effect. In practice, model estimates may not overestimate PITPH due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of nighttime spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and were analyzed for their effects on fish passage. These examples of adaptive management will continue during implementation of selected operations as described in Appendix R.
58802	5	R. Kirk Schroeder	N/A	The DEIS does not provide quantitative measures on the supposed benefits to the federally listed salmon and steelhead populations. Instead, the objective is qualitatively described in general terms as "improving juvenile salmon and improving adult salmon". This lack of quantitative measures is wholly inadequate for an EIS. The regional goal for SAR as laid out by the Northwest Power Planning Council and others is an average of 4% to provide for the recovery of these listed populations. The only alternative that would achieve this goal is M03 which calls for dam breaching. It is imperative that we begin to move rapidly toward this alternative to ensure the continued existence and recovery of these listed populations.	The co-lead agencies disagree that the Draft EIS does not provide quantitative measures on the benefits to ESA-listed species from implementation of the alternatives. Where current high quality information, resources, and models were available, the co-lead agencies were able to quantitatively assess benefits. Where this necessary data was not available for quantitative assessments, the agencies qualitatively assessed benefits using current high quality information. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils Fish and Wildlife Program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
58802	6	R. Kirk Schroeder	N/A	Despite professing to plan for the long term, the PA is extremely short-sighted with a one-year continuation of the existing Flex Spill agreement and an undefined process thereafter. The P A does not mandate operations over a long term and is therefore wholly inadequate in preventing the extinction of populations or in helping populations to recover. Instead, continuing this operation would harm salmon and steelhead populations as demonstrated by the poor performance of Flex Spill in 2019 under which the migration time and powerhouse entrainment .was unimproved from the spill operations of the 2018 BiOp and occasionally worse. Implementation of the PA would jeopardize wild salmon and steelhead populations, which analyses have shown would result in low SAR (1% or less) and put the populations at significant risk of possible extinction. These risks are even higher in light of changes to flow and water temperature from climate change, which the DEIS fails to adequately address or account for in the analyses of the alternatives.	The co-lead agencies do not feel that that short-term nature of this operation is an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies will provide additional clarifying text in Appendix R to make these points more clearly. After careful review of monitoring data from the 2019 flex spill operation, the flex spill signatory entities agreed that all biological, hydropower generation, and operational aspects of 2019 met all parties expectations. It is difficult, and not advisable, to take a single year of data from an operation, such as the single year of 2019, and make long term and long-range decisions based on a limited operation. That is why the parties to the agreement based their expected outcomes on multiple water conditions and potential outcomes. When considering benefits to fish, the flex spill parties used powerhouse encounter rate or PITPH as the primary metric, not in-river survival, or even Smolt-to-Adult (SAR) due to the variation in those metrics and the limited opportunity to evaluate and monitor based on a single year of data. Based on our analysis, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average SAR return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The EIS analyzes effects of the range of alternatives on greenhouse gas emissions and climate change in Section 3.8 and Chapters 4 and 7.
58802	7	R. Kirk Schroeder	N/A	P A does not assess effects of climate change on water quality, availability of water to meet spill goals, etc. that could lead to further declines in the populations. In fact, effects of a changing climate that will lead to warmer and drier conditions will make implementation of the P A difficult, if not impossible, which would likely result in greatly diminished wild populations and probable extinction. P A allows lowering reservoirs before spring which would increase the risk that there would not be enough water to provide spill during low snowpack years, which will become more likely under changing climatic conditions	Regarding climate change, the climate science community is still developing models at the resolution necessary to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to hydrology under the Preferred Alternative in Section 7.8.1 and anadromous fish in Section 7.8.4. The Preferred Alternative includes an adaptive management process as detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, tribal, and federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. If a changing climate has an impact on the co-lead agencies' ability to operate consistently with the Preferred Alternative, that impact will be discussed and addressed as described in the Adaptive Management Framework.
58802	8	R. Kirk Schroeder	N/A	The P A clearly favors hydropower production, barge transportation, and irrigation over the protection and recovery of the federally listed salmon and steelhead populations. It represents minor tweaks to the existing systems operations instead of the "major overhaul" called for by previous court rulings. Breaching the four lower Snake River dams is the only alternative presented in the DEIS that would have a high probability of not only ensuring the continued existence of the populations but also providing a chance for recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Regarding the Preferred Alternative, this alternative is not simply a minor change to operations and maintenance of the CRS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
58802	9	R. Kirk Schroeder	N/A	The DEIS has failed to be either balanced or adaptive. There is a long history of dam operations that have failed to either recover salmon and steelhead populations or even to stem their continued decline. Most of the alternatives in the DEIS would continue this course despite all the evidence showing this could lead to the extinction of populations. The only measures that have a high probability of success are to breach the lower Snake River dams and operating the lower Columbia River dams under spills of 125% TDG.	The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cummulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), and also meets most of all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions. It minimizing adverse impacts to communities and the economy. The Preferred Alternative is likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
58802	10	R. Kirk Schroeder	N/A	Data presented in the DEIS is sometimes disingenuous at best, and often appears to be included in order to mislead the public. As an example, Figure 3-111 (DEIS, p. 3-300) combines all species and all populations as a total count at Bonneville, which no management agency has used to convey status. This approach masks the status of individual species, much less that of the individual populations that are listed under the ESA. At a minimum, returns of the individual populations should be presented as well as their respective SARs. In addition, inclusion of hatchery returns confounds the overall status; wild populations should be shown separately. Finally, inclusion of all populations in the Bonneville Dam counts hides the poor return of salmon and steelhead to the Snake River and upper Columbia River and therefore provide no context for the effect of the lower four Snake River dams on the listed populations affected by the dams.	Hatchery programs have long been a part of the approach for salmon recovery. Figure 3-111 in the Draft EIS is an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. The commenter is correct – there are broad ecological effects concerning interactions of wild and hatchery fish, as well as harvest, throughout the basin. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in the CRSO Draft EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation and configuration of the CRS projects to the No Action Alternative. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. These consultations ensure the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					hatchery programs are not appreciably reducing the likelihood of ESA-listed species survival and recovery, or adversely modifying or destroying designated critical habitat. These consultations have resulted in many site-specific reforms to reduce effects of hatchery/wild fish interactions, such as decreasing the temporal and spatial overlap of wild and hatchery fish in integrated programs or transitioning to local broodstock in integrated programs, similar to the examples cited in the comment. The co-lead agencies used the most current, high-quality and scientifically accurate information, a multi-disciplinary team, and a science-based approach to analyze the alternatives in the EIS analysis. Federally funded hatcheries in the Columbia River basin are adaptively managed to minimize impacts on wild fish and the regulatory and action agencies use the best available science to establish best management practices for these programs. The co-lead agencies fund many ongoing research projects to better understand and minimize hatchery and wild fish interactions (i.e. evaluating the relative reproductive success of hatchery fish spawning in the wild from both segregated and integrated stocks, monitoring stray rates of hatchery and wild fish, understanding mechanisms that produce precocious maturation of male hatchery fish), including several referenced in your letter; however, information specifically focused on artificial propagation, while relevant to individual hatchery EISs and BiOps, is out of scope for the CRSO EIS. Consultations under Section 10 of the ESA also ensure that programs intended to be integrated recovery programs do indeed contribute to ESA-listed species. It is appropriate to claim beneficial effects from these hatchery programs. Based on the anadromous fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under the PA, hatchery and habitat programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. The PA proposes measures such as increased spill intended to improve survival of juvenile anadromous salmonids. Over time, the PA is anticipated to benefit both wild and hatchery fish.
58802	11	R. Kirk Schroeder	N/A	Economics The DEIS purports to provide a balance between uses of the dams and salmon and steelhead populations. This is disingenuous, at best. Even the analyses of costs and benefits of the alternatives is not balanced. For example, benefits of breaching the four lower Snake River dams are underestimated. The effects of declining salmon and steelhead populations on rural communities in the Northwest were not adequately assessed relative to the dam breaching alternative. Analyses did not include non-use or intrinsic values for assessing the benefits of restoring salmon and steelhead under the dam breaching alternative. These values are readily available, are acceptable for economic analyses, and were used by the U.S. Bureau of Reclamation in the study of dam removal on the Klamath River. In addition, the DEIS did not adequately assess the benefits of restoring 140 miles of the lower Snake River to a free-flowing condition. The DEIS instead emphasized potential, detrimental effects on the river ecosystem; effects such as long-term sedimentation that have not been observed in numerous studies of other dam removal projects including the recent removal of the Elwha Dam, which is much larger than the proposed dam breaching of the four lower Snake River dams.	The EIS (Section 3.15.2.2) describes the existing literature on passive use values for salmon, including the study of the Klamath dam referenced in this comment, and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each MO (as different fish are affected positively and negatively), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations.
58802	12	R. Kirk Schroeder	N/A	Power generation of lower Snake dams is overstated. Output of the dams is less than capacity because power generation is highest in spring and cannot operate at capacity during summer and fall. Low flow in winter and environmental requirements in summer means the four dams provide on average just 2% percent of the needs during the period of highest demand(winter and summer), and is often surplus to regional needs and sold to markets whose demands have shrunk over time.	The comment is correct that power generation at the lower Snake River projects (average about 1,000 aMW) is less than the installed capacity of these projects (3,033 MW). However, the models that are used in this EIS include the hydroelectric generation over the historic record and historic volume and shape of the flows including the high spring flows and do not assume that 3,033 MW of energy is produced. The EIS describes the operational characteristics of the four lower Snake River dams in Section 3.7.3.5 - Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). As described in that Section, although the dams are run-of-river, the projects do have 1 to 5 feet of operating range for their elevation plus there is upstream storage that is used to increase their firm capacity. This enables these projects to provide up to 2,000 MW of sustained peaking capacity at certain times of the year. In the Draft EIS, see Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907; and Table 3-160. The comment suggests that the four lower Snake River dams produce little energy in the winter. This is incorrect. These projects produce a substantial amount of power in the winter, which is currently the region's highest demand period. See Section 3.7.3.2, Table 3-122 in the Draft EIS. The four lower Snake River dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. The comments suggestion that the four lower Snake River dams only produce two percent of the needs for power is inconsistent with the findings of the EIS. The analysis for MO3 demonstrates that the capability of the Federal Columbia River Power System (FCRPS) would be reduced by up to 13 percent. In the Draft EIS, see Section 3.7.3.5, Changes in Power Generation, Table 3-159. The comment states that the output of the four lower Snake River dams is sold as surplus and to markets that have shrunk over time. This is incorrect. Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams is not exclusively sold as surplus, but rather is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. See Section 3.7.2.5, Bonneville Power and Transmission Customers in the Draft EIS.
58802	13	R. Kirk Schroeder	N/A	Costs of wind and solar power has continued to drop and could provide economical replacement power. One study estimated the increase in rates at $1.28 per month up to $1.3 8/month with additional greenhouse gas reduction policies. Costs would be lower if cost of wind and solar power further decrease. In addition, a study found that greenhouse gas emission would rise less than 1% under one scenario and decrease 2% under another scenario.	The statement that prices for renewable resources are declining is consistent with historical trends. The EIS also acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS relies on the best available cost information for the primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (page 13-5) and Mid-term Update. The 7th Power Plan was issued in February 2016, and the Mid-Term Update was issued in February 2019. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Council's 8th Power Plan is included as rate sensitivities in the final EIS. The final EIS also includes the de-escalating cost curves prepared by the National Renewable Energy Laboratory that will likely be used by the Council in its 8th Power Plan. The source of the cost statistics described in the comment may be a study commissioned by the Northwest Energy Coalition (NWEC) and the results are not consistent with the findings of the EIS. As described in the draft EIS in Section 3.7.3.5 and Appendix H, Power and Transmission, Section 2.4, page H-2-16, the EIS considered the NWEC study cited in the comment, but it is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. The EIS acknowledges past studies of breaching the four lower Snake River dams, but relies on more recent data and models, where appropriate.
58802	14	R. Kirk Schroeder	N/A	Costs are understated. Costs of operating and maintaining the dams has not been fully accounted in the DEIS, especially the high costs of turbine replacement and maintaining the aging infrastructure. One estimate showed that removing the dams and buying replacement power on the open market would cost $11 million/year, which is $38 million/year cheaper than estimated maintenance and operation costs of lower Snake dams. This estimate did not include benefits from reducing costs needed for juvenile fish passage and turbine replacement (a turbine replacement at McNary Dam was $46 million).	Turbine replacement and other capital requirements to maintain the four lower Snake River projects are included in the cost analysis for the appropriate alternatives, as described in Section 3.19 and Appendix Q.(see Section 4.2). Estimated costs for capital and O&M are $107 million annually for the four lower Snake River projects. Under MO3, the Lower Snake River Compensation Plan would no longer be funded, with a cost savings of $34 million. Bonneville's Fish and Wildlife Program costs are systemwide costs. Breaching the lower Snake River dams may result in changes to Bonneville's Fish and Wildlife Program. However, funding decisions for the Fish and Wildlife Program are not being made through the CRSO EIS process. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Additionally, the cost analysis estimates the capital and O&M costs savings that would occur under MO3 (see Table 4-1 and 5-1 in Appendix Q). The capital costs include additional construction and capital requirements that would be needed in the future to maintain the four lower Snake River dams. Considering hydropower costs and values, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
58802	15	R. Kirk Schroeder	N/A	The DEIS overstated the economic impact of dam breaching on barge transportation. Barge transportation is now heavily subsidized and have declined by 45% (grain) to 70% (freight) over the last 20 years, often in favor of shipping by rail. Locks will need extensive maintenance and rebuilding in the coming years because of their age.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true however, that barge movements on the Snake/Columbia river including grain and other commodities have declined over the past 20 years, but it also appears that the decline has stabilized over the past 10 years. The text of the EIS has be updated to describe how downriver shipment volumes have stabilized in recent years.
58802	16	R. Kirk Schroeder	N/A	Irrigation is not a priority use of the lower Snake River dams and costs of replacing the irrigation supplied by a single reservoir is low compared to benefits of breaching the dams. In some cases, this would merely require extending intake pipes to the river level.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis accordingly concludes that pumps are unable to deliver water to estimated at 48,000 acres.
58805	1	Marvin Dugger	N/A	In the early 1990's, our small group of Potlatch employeesin cooperation with members ofthe Lewiston and Clarkston Chambers of Commerce were researching environmental claims that the lower Snake River Dams were devastating salmon runs, when we learned about East Sand Island, a manmade island in the estuary of the Columbia River. The island was formed from dredging deposits in 1983 and by 1984, Caspian terns, cormorants and gulls had colonized the island and were feasting on salmon smelts. We thought "wow, this is an easy fix, tear out a manmade island and save millions of endangered fish." The environmentalists beat us to the punch. They filed in federal court to protect the island and the birds under the Migratory Bird Treaty Act of 1918. Now we have the largest nesting colony of these nonendangered birds in the world, on a manmade island. Every year these birds slaughter 20-30% of juvenile salmon entering the ocean. According to a study done by Oregon State University, between the years	The Proposed Action includes continuing management plans for Double crested cormorants and Caspian terns on East Sand Island. One point of correction, East Sand Island, while used in the past as a dredge material disposal site, is not man-made. The goal of the CATE management plan was to reduce habitat at East Sand Island to a minimum of 1.0 acre following the creation/enhancement of habitat at alternative sites outside of the Columbia River basin. Habitat creation/enhancement was completed and habitat at East Sand Island reduced to 1.0 acre preceding the 2015 breeding season. The number of breeding pairs nesting on East Sand Island was used as a proxy to assess predation rates, but the stated goal of the plan was defined as an acreage of habitat and not the number of pairs in the estuary which has been met. The one acre of habitat will continue to be maintained through the Corps Operations and Maintenance group and coordinated with the FPOM. The management goal of the DCCO plan was a reduction of the breeding colony at East Sand Island via lethal and non-lethal means to no more than 5,380 5,939 breeding pairs nesting. As described in the DCCO management plan, an average 3-year peak estimate of the breeding colony would be used to assess management objectives after implementation of Phase II activities (i.e. habitat modification). Actions would be considered successful when the average 3-year peak colony size estimate does not exceed 5,380 5,939 breeding pairs while no management activities are conducted. In coordination with USFWS, the Corps defines no management activities to mean non-lethal activities described in Chapter 5 of the FEIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				2000-2015, they killed about 200 million juvenile fish. Since the island was created, the birds have probably consumed somewhere between 3 and 4 hundred million smelts. After they leave the Columbia, studies show that about eighty-eight percent of the remaining fish die during their 2 or 3 years in the ocean from predators, adverse ocean conditions, and commercial fishing. The Frazier River in Canada is very similar to the Columbia River system, it and other streams along the west coast of the U.S. and Canada that have no dams, have the same fish problems as the Columbia River system. Bad ocean conditions equal bad fish runs. Each year for the last three decades, between the mouth of the Columbia river and Bonneville dam, about 40% of returning fish have been killed by thousands of nonendangered seals and sea lions. There are about 8000 of these animals now and only in the last several years has there been any meaningful effort to control their exploding numbers. The environmentalists have staunchly opposed any real effort to control these animals. Then, further upstream another 30% of the returning fish die from commercial and sport fishing, and Indian fisheries. If these fish are truly endangered, why do we keep killing them?	Specifically, Phase II activities are intended to consist of lower maintenance, non-lethal hazing and dissuasion actions that reduce the amount of human presence needs on East Sand Island to ensure colony size objectives are not exceeded. Hazing and dissuasion activities would be implemented as needed, and would continually transition to methods that are most effective, least impactful to non-target species, and require the least management effort and cost. Pending evaluation of the peak colony size during the 2020 breeding season, if the average 3-year breeding colony is less than 5,939 breeding pairs, management objectives will be met and actions will transition long-term operation and maintenance of the colony. The co-lead agencies have no authority to manage fisheries, and therefore there were no measures included in any of the alternatives on fisheries management.
58805	2	Marvin Dugger	N/A	Meanwhile, the same groups who are trying to destroy our dams are forcing the closure of coal fired power plants. Over the next 8 years, 12 coal fired plants across the west will be forced to close. A huge block of dependable energy will be lost, enough to power 3.8 million homes. The Northwest Power and Conservation Council was set up by congress to monitor situations like this. They continually run computerized scenarios for what they call Loss of Load Probability, the chance that our supply of power will not keep up with demand. A rating of 5% or less is acceptable. Their computer simulations are predicting 26-33% chance of loss by 2026. In other words, power blackouts, and that's not even considering the loss of our dams. We get 60% of our power from dams.	The statements that coal-fired power plants in the region are expected to retire and that the resulting Loss of Load Probability would be well above the Northwest Power and Conservation Councils target of 5 percent are consistent with the findings of the EIS. See Appendix H, Power and Transmission, Section 2.3 at H-2-8 15 in the Draft EIS. While the regional coal-fired generation is owned by investor-owned utilities, changes in their generation do affect the regional power supply and reliability, which in-turn affects the Columbia River System projects contributions to regional reliability. In the Draft EIS, see Section 3.7.3.2, No Action Alternative, 3-845-84, Table 3-123.
58806	1	rsjlmules@icloud.com	N/A	If theyre ever removed, it will cost many individuals their livelihood and will eventually change the geology of the areas in both sides of the river. Primarily removal would offset the geological stability associated with all roads that parallel the river. Resulting in the current highways being pushed towards the river should the dams be removed because of the removal of the current pressure provided by the stabilized geological pressures of the lakes formed below each of the dams. Dont take my word for it but consult with the Corps of Engineers they are well aware of this fact.	Reduction in slope stability associated with the exposure of saturated soils can arise when submerged shorelines experience a rapid reduction of the adjacent reservoir water level. More specifically, as the hydrostatic pressure exerted by the reservoir is reduced, the hydraulic pore-water pressure and internal stresses within the newly exposed soils are relatively higher until they gradually drain. During this draining period, saturated slopes are more susceptible to creep and failure and this risk can be exacerbated by additional stress such as: overland drainage, upslope surcharge loading or toe erosion.
58807	1	rhayden@portofpasco.org	Port of Pasco	The Tri-Cities in particular is heavily reliant on the power supplied by Ice Harbor Dam and would experience seasonal brownouts if the dam was removed. Our farmers and manufacturing businesses would not be viable without access to reliable power provided by the dams. Affordable and renewable hydroelectric power also supports other intermittent renewable energy sources such as wind and solar, providing reliable energy for our citizens and businesses when wind and solar cannot.	The suggestion that regional reliability would decline if Ice Harbor Dam ceased generation without replacement power resources and transmission reinforcement is consistent with the findings of the EIS as described in the Bonneville Transmission System Reliability and Operations subsection of Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs of the Draft EIS. Under Multiple Objective alternative 3, which includes the measure to breach the four Lower Snake river dams, the loss of generation at Ice Harbor would require that a transmission reinforcement project be in place prior to breaching of the dams. If the dams were breached prior to completion of the reinforcement, the Tri-Cities area would be vulnerable to a potential loss of load event. The commenter's additional suggestion that hydropower is valuable for balancing intermittent generation sources such as wind and solar is consistent with the findings of the EIS. This is described further in Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS.
58807	2	rhayden@portofpasco.org	Port of Pasco	Much of our nations grains, and the food we enjoy and depend on daily, is transported up and down the river system. The fuel and fertilizer needed to grow that food in our region is also transported on the river. In the Tri-Cities, at certain times of the year nearly half of the fuel used by farmers and consumers arrives by barge. Our economies are not prepared to function if barging on the Columbia and Snake rivers is eliminated. Our highway, rail, and grain elevator networks would need over $1.1 billion in capital investments to adapt. This includes hundreds of miles of shortline rail track that have been abandoned; new rail; major highway improvements; and retrofits for grain elevators that do not have rail-loading capabilities.	The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Section 3.10 of the Draft EIS provides an evaluation of the Columbia-Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, low air emissions relative to other transportation modes, potential regional economic effects, and other social effects that could occur under MO3. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs could occur. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5.
58807	3	rhayden@portofpasco.org	Port of Pasco	We are proud of the major improvements that have been made in fish runs through the Columbia/Snake River system. We all agree more needs to be done, but we need to consider the whole ecosystem affecting salmon and not limit our focus to just the Columbia/Snake dams. The investment in world-class fish passage infrastructure has improved to help over 95% of fish pass the dams on their journeys up and down river. The result is that fish populations on the Snake River have trended upward for the past 25 years. Breaching the dams would have marginal and uncertain improvements to fish populations and deprive our communities of the dams substantial and documented benefits.	The co-lead agencies have incorporated extensive improvements in structure and operation to mitigate for the effects of the CRS dams. Fish ladders have been shown to be effective in passing up high numbers of adult salmon and steelhead, while spill and barging operations have improved downstream survival and passage. In fact, the lower Snake River dams passed a record number of salmon and steelhead as recently as 2014, while also producing power, navigation, and recreation. Relative to breaching, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
58808	1	orcharding@yahoo.com	N/A	You need to have actual public meetings when the corona virus pandemic is over. Something as important as Saving the Salmon as well as all the other objectives needs to be fully heard, discussed, and thought aboutnot quickly decided while folks are distracted with the virus panic. Really, this is not acceptable. The agencies involved know better	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period. In response to COVID-19 concerns and public health requirements within the comment period, the agencies converted the six planned in-person regional public comment meetings to conference calls that provided an approach consistent with the format of the planned in-person comment meetings. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. These teleconference meetings were structured similarly to the previously scheduled in-person public comment meetings and provided speakers with the same amount of time to submit a verbal comment.
58815	1	afarmllc@embarqmail.com	N/A	The one thing that really bugs me is the talk about saving the Snake and Columbia Rivers salmon by removing the dams and or spilling water. What is little known, the original Snake River salmon were lost long before the dams were built and restocked with Alaska salmon in the early 1900s. Salmon would greatly benefit by cleaning up the rivers and sounds and having the Corp re-dredge the mouth of the Columbia River. If people really would study the problem and stop reacting to unverified information, they would see the true benefits of the dam system and correct the minor problems with the system.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. The items listed in this comment are beyond the scope of this EIS.
58819	1	chandra.ferrari@tu.org	Trout Unlimited	Trout Unlimited (TU) respectfully requests that the U.S. Army Corps of Engineers (Corps), Bureau of Reclamation (BOR) and Bonneville Power Administration (BPA) (collectively the Action Agencies) extend the public comment period on the Draft Environmental Impact Statement (DEIS) for the Columbia River System Operations (CSRO) to a minimum of 120 days. The current public comment period of 45 days is insufficient to allow meaningful public comment on such a complex and voluminous document; the DEIS is almost 8,000 pages including appendices. This request is consistent with the Action Agencies past practice. The scoping process for the CRSO, a much simpler step in the National Environmental Policy Act (NEPA) process, was afforded a 120-day public comment period. The issues addressed in the DEIS affect people, businesses, governments and communities throughout the Northwest and beyond. In order to ensure all interested individuals and entities are given an adequate opportunity to review, analyze, consider and comment on the DEIS, a minimum 120-day public comment period is required.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
58821	1	N/A	N/A	Without the Snake River locks, the 3.5 million tons of cargo, normally shipped by barge, would be shipped by train and truck. It is estimated that it would take more than 35,140 rail cars to carry this cargo, or more than 135,000 semi-trucks. The rail and infrastructure along the Columbia River are not prepared to function with the loss of barging on the Snake River. Northwest ports and navigation interests have always strongly supported robust salmon recovery efforts that preserve the multiple uses of the river system.	This information in this comment is largely consistent with the findings in Section 3.10 of the EIS.
58821	2	N/A	N/A	I believe, like most, that salmon runs have been affected by a variety of factors. A commitment to improving all four of the Hs of salmon recovery - hydro, habitat, harvest, and hatcheries - is necessary for listed species to recover. Extreme measures like dam breaching have been studied and rejected numerous times over the last twenty years. The dramatic increase in fish returns over the last ten years demonstrates the success of regional investments in fish passage, habitat, and other river improvements.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. The Draft EIS analyzes the effects of configuration, maintenance, and operation of the CRS projects in Chapter 3.4. The scope of the Draft EIS focuses on the area affected by the alternatives presented for operation and configuration of the CRS projects. We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
58823	1	N/A	N/A	Either breaching dams or increasing spillage will not save a significant additional percentage of fish and is untried wishful thinking. The 3% of fish that do not make it could easily be made up by a slight increase in hatchery output.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. MO3 (dam breaching) was not selected as the Preferred Alternative. Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternative, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as proposed under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed.
58823	2	N/A	N/A	One critical impact of removing dams that few seem to have considered, is the massive impact on river navigation and transportation. We certainly cannot go back to the hazardous and extremely dangerous river navigation methods of days gone by before our dams and locks were built. Loss of this resource would be extremely detrimental to our economy and greatly increase the amount of trucks on the roads. Not only would this greatly increase	The EIS found that under MO3, truck trips could increase, ranging from an additional 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions and add to traffic and congestion in the region. The EIS evaluates options for renewable energy sources to replace lost hydropower under MO3, the alternative that includes dam breach measures. However, assumptions regarding the potential use of electric trucks is not included in the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the amount of fossil fuel use for the foreseeable future, it would impact infrastructure maintenance costs and safety, jamming our roads with trucks. Even if it does become feasible to manufacture fully electric long-haul trucks in any quantity beyond experimental prototypes, the logistics of recharging them en-mass is a massive problem that will be extremely difficult to solve. People naively think that fast charging is going to solve that but they do not understand the immense electrical current required to do that at the low voltages of batteries, which also has its own problems of large copper conductor needs and its own dangers. If it were feasible to generate large amounts of power by solar methods, we would have to find a way to store it for night time use. Batteries are just not feasible in that capacity.	
58823	3	N/A	N/A	However, a method used in the UK might work by pumping water up to reservoirs during the day or off-peak times and generating hydroelectric power with it at night or peak usage times. This could do double duty for our water also by pumping it back behind the dams and reusing it, allowing for greater spillage to protect fish with no loss of hydro power of other or other valuable resources and making use of solar power at night. Its at least worth some thought.	The EIS did evaluate pumped storage as a potential replacement resource among other storage technologies. See, Section 3.7.3.5, at 3-909 in the Draft EIS. While there are several feasible sites in the region that could provide pumped storage capacity, those projects have additional costs, permitting and environmental concerns. There is also uncertainty that these resources would provide sufficient energy and capacity to provide a credible source of replacement resources. Further, the capability of these pumped storage sites would not be able to address the scope of replacement resource needs considered in the EIS. See draft EIS, section 3.7.3.5, at 3-909. Appendix H (Chapter 2) provides additional details on resource selection, including discussing pumped storage. Screening of these systems to minimize harm to fish was also a concern for these types of systems and may require additional mitigation if installed.
58826	1	robin.priddy@bentoncleanair.org	Benton Clear Air Agency	Benton Clean Air Agency in Benton County, Washington is concerned about the effects of additional truck and train shipping on air quality particularly in the lower part of the Columbia River Basin should dams be removed, or the management of the dams changed so that barge traffic can no longer pass down the Snake River as it does currently. Benton County is adjacent to Franklin and Walla Walla Counties at the confluence of the Snake and Columbia Rivers is the Lower Columbia Basin. The four snake river dams under consideration are upstream of this confluence. Currently, approximately two million tons of agricultural products move down the Snake River through these dams. This traffic is examined in detail in the EIS. Ozone is the specific pollutant of concern. The current Design Value for Kennewick is 69 ppb. The Federal Limit on the concentration of ozone as defined in the National Ambient Air Quality Standards (NAAQS) is 70 ppb. Beginning in 2015, ozone has been monitored in Kennewick and found to be consistently present in concentrations that approach the Federal limit in the NAAQS. Ozone is formed from a combination of four things: NOX which comes from combustion - IC engines VOC, also from IC engines and fuel Sunlight which we have in abundance, and Hot, still air the months of June, July, August especially A detailed study that was done by Washington State University and the University of Washington along with WA Department of Ecology in 2016 clearly identified that the ozone precursors NOX and VOCs are coming from vehicle traffic. Additional vehicle traffic that would be created by removing or changing management of the dams is a great concern. A Snake River Dams fact sheet showed that it would take 135,000 semis or 35,140 rail cars to replace barges, each year. This traffic would be moving during the time of year in which we are most likely to develop high levels of ozone (July September). Our region is very close to the Federal Limit. Exceeding that limit has a negative impact on public health and could result in restrictions on businesses and transportation development in the region. Please take ozone, and the specific conditions affecting ozone formation in the Tri-Cities into consideration in the Air Quality Analysis provided in the EIS.	While the EIS analysis includes the same estimate as this comment of approximately two million tons of freight moving on the lower Snake River, the EIS does not find that breaching the four lower Snake River dams would result in 135,000 semis or 35,140 rail cars to replace the barging along the river (please see Section 3.10.3.5 in the Draft EIS). The EIS estimates that rail ton-miles would increase from 819 million up to 1.5 billion and truck ton-miles from 463 million up to 855 million, depending on rail rate increases. Section 3.8 of the EIS (Air Quality and Greenhouse Gases) describes public health concerns and air quality standards related to ozone and emissions of ozone precursors. Section 3.8 also identifies the potential for changes in air pollutant emissions to affect air quality, in particular in areas that are not meeting current air quality standards (non-attainment areas) or have not met them in the recent past (maintenance areas). Because the area described in this study is neither a non-attainment nor a maintenance area, it was not specifically identified in the analysis. However, the EIS does find that Multiple Objective Alternative 3 would increase air pollutant emissions, including due to increased on-road vehicles, and make compliance with air quality standards more difficult in the area surrounding the dams. Specifically, Section 3.8.3.5 describes that the increase in truck freight transportation and truck related emissions is likely primarily in Washington (also see Section 3.10.3.5 and Appendix L for additional detail and maps of potential truck traffic). However, Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams was not identified as the Preferred Alternative in the Draft EIS.
58827	1	jonasseiler2@gmail.com	N/A	Obviously, the scope of the CRSO EIS is too narrow to solve the entire problem, which is also stated in the document itself.	The co-lead agencies respectfully disagree. The CRSO EIS has identified a reasonable range of alternatives that are capable of meeting the Purpose and Need Statement and to varying degrees the EIS objectives and the analysis is tailored to the area of effect for each affected resources.
58827	2	jonasseiler2@gmail.com	N/A	The Draft EIS relied on a qualitative, rather than quantitative, analysis to evaluate impacts despite the existence of several current studies on the economic contributions of outdoor recreation and sport fishing in states with salmon and steelhead. This is in contrast to water supply, irrigation, navigation, and hydropower generation, which were all evaluated quantitatively.	Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. The evaluations are clear, transparent, and repeatable based on the high quality information. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis.
58827	3	jonasseiler2@gmail.com	N/A	It is unacceptable that the Draft EIS did not use publicly-available data sources to quantify the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and the Pacific Northwest.	The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
58827	4	jonasseiler2@gmail.com	N/A	Attached is a screenshot of the qualitative vs quantitative approach for recreation and other uses. This slide is directly from the BPA presentation on the EIS given to Governor Little's Salmon Workgroup earlier this month. Many of the Workgroup members found it equally troubling. Highlighted is the conclusion that 'social welfare benefits may occur' for MO3. The fact that no quantitative analysis was done to accurately depict how important recreation is to Idaho's rural economy is embarrassing.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting tourism businesses. A range in visitation is described in the lower Snake River post dam breach based on the evaluation in the 2002 Juvenile Salmon Migration Feasibility Study and EIS. The social welfare values associated with river recreation post dam breach were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. In addition, the timeline of the EIS precluded an extensive survey of post dam breach recreation.
58839	1	N/A	N/A	One area of salmon enhancement that has had absolutely wonderful results has been the barging of smolts down the river.	The co-lead agencies have incorporated extensive improvements in structure and operation to mitigate for the effects of run of river dams on the Snake and Columbia Rivers. Fish ladders have been shown to be effective in passing up high numbers of adult salmon and steelhead, while spill and barging operations have improved downstream survival and passage. The co-lead agencies have proposed to continue the use of barge and truck transportation, albeit at lower rates than under previous spill operations. However, the majority of juvenile fish will migrate in-river. As the comment notes, transportation by barge or truck has been shown to provide a benefit that varies by species, by time of year, and by water condition. The juvenile salmon transportation program is managed by expected fish benefits as well as cost efficiency. SAR estimate for each week of the outmigrations, combined with other environmental and biological data, drive the decisions. Prior to these data being available, transportation began at the beginning of April; however, we learned that fish transported in early April performed very poorly. Transporting too early is not effective and does not justify the expense.
58839	2	N/A	N/A	We still face the fact that 1 in 4 smolts are consumed by the (NON NATIVE, INVASIVE) arctic tern colonies on the three sand islands (dredge spoils) in the lower Columbia River. Just the removal of these predators would instantly increase salmon and steelhead survival by 25%.	The co-lead agencies recognize the value in measures to reduce avian predation, including at native Caspian tern colonies in the Columbia River estuary and have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. While arctic terns do not nest in the Columbia River basin, the proposed alternative includes continued implementation of (1) dissuasion measures at the Corps' CRS facilities as described in the annual Fish Passage Plan and coordinated with the FPOM, (2) the Inland Avian Predation Management Plan (IAPMP), (3) Caspian tern management plan for reduction in habitat at East Sand Island, and (4) the Double-crested cormorant (DCCO) management plan at East Sand Island. Other entities in the region also have authorities and obligations to mitigate the impacts from predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. Depredation permits, including those for the removal of avian predators, are issued to alleviate some form of damage, not to achieve population control. As a result, depredation permits are issued only if the requested lethal take of birds is consistent with the conservation of the species (e.g., the species remains at a healthy and sustainable level). (From USFWS DCCO FAQ website: https://www.fws.gov/pacific/migratorybirds/pdf/DCCOQ_A_USFWS03212016.pdf)."
58839	3	N/A	N/A	The timid, half steps to eliminate marine mammal predators - seals and sea lions (which are ABUNDANT in population) in the Columbia below Bonneville dam should be greatly accelerated; many of the fish they kill are Snake River fish.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
58839	4	N/A	N/A	More than half the wheat exported comes down the river system to load ocean going vessels at the Portland docks. I cannot imagine the damage that 5-600 heavily loaded semi trucks daily would do to our freeway system, but I know it would be expensive. There is another cost to consider, I have never	The EIS found that under MO3, which includes breaching the four lower Snake River dams, truck trips could increase, ranging from an additional 14,000 to 79,000 truck trips per year (38 to 216 per day on average), which would increase air pollutant and greenhouse gas emissions and add to traffic and congestion in the region. The EIS also discusses in Section 3.10.3.1 that changes in transportation modes can also have implications for public safety. In particular, the EIS states that accident rates are generally higher for road travel than travel by either barge or rail. As such, shifts from barge to rail and truck would be anticipated to increase accident rates.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				heard of a death relating to shipping by barge; even with our really good professional drivers, with winter weather, spring and summer thunderstorms and dust storms, there is bound to be a number of FATAL accidents each and every year - an avoidable risk.	
58839	5	N/A	N/A	In irrigated farming, without abundant reasonably priced power, we are back to farming not the garden of Eden, but the desert - Where I live annual rainfall is a meager 8-9" annually	Thank you for your comment.
58839	6	N/A	N/A	A classic example is the nearby Fraser River, less than 200 miles to the north; this is an undammed river which has experienced WILD FLUCTUATIONS in each of the half dozen salmon and steelhead species in this river; within a few years runs of 4 million zoom to 24 million and then crash again. What can be learned from this? REMEMBER, there are no dams to blame....so the logical conclusion is inexcapable; IT IS OCEAN CONDITIONS driving the wide swings in populations. I think the latest BIOP reaches largely this same conclusion.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS.
58839	7	N/A	N/A	Take a look at GOOGLE EARTH, following the shoreline of Puget Sound. Tens of thousands of houses on the waterfront on septic, lots of impermeable surface run off and a lack of aggressive hatchery production have created the great chinook shortage in Puget Sound. That is the core area of the problem, until that is dealt with successfully, don't even look at my lower Snake River dams.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. According to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
58845	1	N/A	N/A	Gill netting seems to be more of an issue in my opinion	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including gill netting. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.

1.2.4 Form Letters Received

The agencies received 32 form letters (see Table 1-3 below). Form letters are defined as when a commenter sends an identical letter as other commenters. A form plus letter is when a commenter sends an identical letter but adds additional text (called variant text in this report). Note that a commenter can change the order of the form letter and delete sentences from their form letter submission. These changes would not be shown as variant added sentences. Table 1-3 also details the number of submissions the co-lead agencies received that were the form letter, and the number of submissions received that were the form letter with variant added sentences.

All form letter text and variant added sentences are shown in Table 1-4. If substantive comments were identified in the form letters, those comments were identified and the co-lead agencies provided a response. Form letter text is presented as submitted which may include spelling and other errors. This text has not been edited.

Form Letter #	Form Letter Text	Response
1	The Southern Resident killer whales and Snake River salmon and steelhead will not survive this EIS study process. As a first step, the federal agencies can and need to begin breaching the four lower Snake River dams this year. As a parallel step, the agencies can use this new EIS process to undertake future actions. The federal agencies can no longer afford to drag the process out with another EIS that will take years while the salmon and orca go extinct. We have tried expensive bypass systems and more spill, and still, 2019 was another year of costly efforts to recover Snake River salmon with no results. Federal agencies need to begin the breaching of the Snake River dams this year. **Variant Text** • There are 72 Southern Resident Killer Whales left. • Do something about this immediately, the Southern Resident killer whales and Snake River salmon and steelhead will not survive this EIS study process. • This is unacceptable. • As a first step, the federal agencies can and need to begin breaching the four lower Snake River dams this year, 2020. • The federal agencies can no longer afford to drag the process out with another EIS that will take years to while the salmon and orcas go extinct. • As a first step, the federal agencies can use this new EIS process to undertake future actions. • In addition, BPAs financial situation will worsen each year that money is lost on the dams. • We have tried expensive bypass systems and more spills, and still, 2019 was another year of costly efforts to recover Snake River salmon with no results • Governor Kate Brown came out in favor of breaching the four lower Snake River dams in February, stating that it is the best solution to breach these dams. • The Southerm Resident killer whales and Snake River salmon and steelhead will not survive this EIS study process. • Dear U.S. Army Corps of Engineers, Bureau of Reclamation, and Bonneville Power Administration, The southern resident killer whales and snake river salmon and steelhead will not survive this EIS process. • As a first step, the federal agencies can and need to begin breaching the four lower stake river dams this year. • Federal agencies need to begin the breaching of the snake river dams this year in 2020! • as a parallel stop the agencies can use this new eis process to undertake future actions.	The co-lead agencies analyzed the effects of the multiple objective alternatives on SRKW in Section 3.6. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and the Preferred Alternative is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states effects to SRKW would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases will come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. Moreover, NMFS concluded in its 2020 CRS Biological Opinion that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes. Bonneville has high investment grade credit ratings from all three rating agencies who rate Bonneville's ability to pay its debt obligations over many years. These ratings factor for revenue producing assets, market dynamics, financial metrics including cash reserves and future capital needs among other things. In light of all factors, Bonneville has a very strong investment grade credit. As described in the Draft EIS, Section 3.7.2.5, on pages 3-801-802; and, Section 3.7.3.1, on pages 3-842-843, upward rate pressure is an important factor in the competitiveness of Bonneville's rates. The EIS describes the upward rate pressure caused by each of the MOs, the largest range of which is associated with the breaching of the four lower Snake River dams in MO3. The analysis includes assumptions about future operations and maintenance (O&M) and capital investment in the four lower Snake River dams. See Section 3.7.3.5, Table 3-166 in the Draft EIS. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 in the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table.

Form Letter #	Form Letter Text	Response
		3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
2	There are only 72 Southern Resident Killer Whales left! They are starving to death, dying as the four lower Snake River dams cut off salmon runs and reduce their access to food. Campaigners are marching from Portland to Ice Harbor Dam, across the west coast of the USA, a journey that will take 22 days. On the day they reach the dam, a rally will be held. People will join in solidarity around the world. It's time to breach the dams! **Variant Text** • @cnnclimate there are 72 Southern Resident Killer Whales left. • Message @little.gypsea for more information. • We can be hundreds of people walking, but we need a bigger voice to make sure we are heard, or we're going to lose the orcas. • Come walk with us or even just share a tweet asking people to walk with us. • They are starving to death and we are marching 236-miles to put pressure on the governing bodies to finally take action. • There are 72 southern resident killer whales left. • There are only 72 Southern Resident killer whales. • People are marching from Portland to Ice Harbor Dams, a 236-mile march to put global pressure on @usacehq @bonnevillepower and @govinslee who are illegally violating the Endangered Species Act by ignoring the best action to save the orca and salmon, driving them from extinction. • We can still change this situation, but we need to take action NOW! Visit marchforthedams.com to learn more, or join the Facebook event We Are The Orca: March 4 The Dams. • We need everyone to join or we're going to lose the orcas. Go walk with them, for however long you can, we need thousands of people marching. If you can't come march with them, go to the protest held on March 22nd in Paris and London, or organize one in your city. We need the entire world asking for change.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not however require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet CRS purposes while minimizing effects to affected ESA-listed species and their designated critical habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and effect on ESA-listed species. Please see the co-lead agency response to Form Letter 1.
3	Dear Army Corps of Engineers, Bureau of Reclamation, and Bonneville Power Administration, As a person of faith, I care deeply about the health of the Columbia & Snake Rivers and the species and human communities that rely on them. People across the Northwest are calling for the restoration of abundant, harvestable salmon and steelhead populations, but the Columbia River System Operations Draft Environmental Impact Statement (DEIS) won't prevent extinction of our iconic salmon runs or the orcas that depend on them. The current limited scope of the DEIS prevents it from delivering real recommendations that move forward our region's urgent priorities: communities, energy, and salmon. The DEIS needs to recommend a comprehensive solution that addresses the needs of Snake River salmon and our communities by meeting these criteria: 1. Ensure the region meets its treaty obligations to Northwest Native tribes 2. Restore abundant, harvestable populations of salmon 3. Protect and invest in the economic vitality of local communities, especially farming and fishing communities 4. Continue the Northwest's legacy of providing reliable, affordable, clean energy I am calling on the federal agencies and our elected leaders to take bold action on the Snake River because we have a moral obligation to do so. An effective salmon recovery plan must bring all the different interests forward together. Policymakers must work with each other, Northwest tribes, farmers, fishermen, community leaders, and other river stakeholders to develop a salmon recovery plan that actually restores salmon and ensures a prosperous region for everyone. Sincerely,	While salmon recovery is not within the purview of the co-lead agencies, we recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.5 of the Preferred Alternative, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage.

Form Letter #	Form Letter Text	Response
		The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. The EIS also provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams, and outside the authority of the co-lead agencies. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The Preferred Alternative meets the Purpose and Need Statement and certain objectives identified in the EIS for operation of the Columbia River System. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums. In areas where the co-lead agencies have appropriate authority, we will continue to be strong regional partners. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision-making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The co-lead agencies are committed to fulfilling their treaty and trust obligations and providing early, open, transparent and meaningful consultation. See Sections 2.3 and 9.3.2. The co-lead agencies look forward to continuing to consult on the EIS, which covers changes to the water management of the existing 14 projects on the Columbia and lower Snake Rivers. The co-lead agencies recognize these obligations while also acknowledging that construction of the Federally authorized CRS projects directly affected many of the region's Tribal communities. Throughout this EIS process, the co-lead agencies have analyzed effects of the ongoing operation and maintenance of the CRS to treaty-reserved rights and associated resources. This analysis addresses how those rights would be affected by the potential alternatives—including how measures could affect fish abundance that may affect the U.S. v. Oregon Fishery Management Agreement, and the extent to which treaty rights and Tribal resources would be protected and enhanced. The Preferred Alternative includes actions to benefit ESA-listed fish as well as lamprey, and these actions also benefit Tribal interests and treaty resources. The MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely affected. The EIS describes the engineering solutions for irrigation (pipeline extensions, for example) in Section 3.12.3 Environmental Consequences, Region C under the MO3 alternative. The EIS describes that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative, it is assumed that pumps are unable to deliver water to an estimated 47,926 acres. Please also see the response to Form Letters 1 and 2.
4	Please accept these as my comments on the CRSO Draft Environmental Impact Statement (EIS) released on February 28, 2020, including my urgent call on our political leadership in the Pacific Northwest to support a new and much needed approach to comprehensively address the linked challenges facing the region's wild salmon, Tribes, endangered Southern Resident killer whales (SRKWs), fishing and farming communities, and energy system.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.

Form Letter #	Form Letter Text	Response
	First, I am deeply disappointment in the CRSO Draft EIS. Rather than embracing calls dating back to the 1990s for a "major overhaul" of said hydro-system operations in order to protect threatened and endangered salmon and steelhead, this "new" report recommends only minor adjustments to a status quo plan that will perpetuate many serious mistakes from years past. Flexible Spill Agreement (FSA) is the centerpiece of the governments Preferred Alternative. The best available science shows increased levels of spill can buy some additional time to put in place more effective actions for imperiled fish populations, it is not, by itself, a long-term survival strategy, let alone a recovery strategy. Indeed, the parties to the current, short-term FSA made this explicit. Most notably, respected regional scientists confirmed that the flexible spill included in the Preferred Alternative will NOT deliver salmon the survival benefits through the hydro-system they need. Instead, the changing climate will further erode any benefits of flexible spill and will only underscore the urgency for meaningful action. The wild sockeye, spring/summer chinook, fall chinook and steelhead within the Snake and Columbia Rivers face extinction today. This short-sighted alternative spells disaster to the irreplaceable benefits wild salmon and steelhead bring to communities, SRKWs, and the ecosystems working to sustain them. This recent CRSO Draft EIS report does not offer a new approach; rather it recommends minor tweaks to a 25-year federal approach that has cost billions of dollars, and has been invalidated five times consecutively in federal court. This inaction has not only brought salmon and steelhead to some of their lowest levels on record, and while increasing uncertainty for communities across the region, it has assisted in pushing the remaining 72 SRKWs to the edge of extinction. The clock is ticking. Second, I support restoring a free-flowing lower Snake River as an essential cornerstone for any effective strategy to protect and recover its endangered wild salmon and steelhead. The scientific support for restoring the lower Snake River and native fishes that use this basin through dam breaching is well established and documented. For over two decades, Tribal, federal, state and independent research has repeatedly corroborated this determination. The just-released 2020 Draft EIS also acknowledges that breaching will deliver greater benefits to endangered Snake River fish populations than any other option considered or analyzed. Restoring the lower Snake River should be included as a foundational element of the Preferred Alternative. Therefore, a dramatically new approach is urgently needed to develop the comprehensive plan the people of the Northwest and nation are asking for, require, and deserve. A new approach will: recover wild salmon abundance invest in fishing and farming communities to provide them a healthier future, and will support a reliable, affordable and increasingly decarbonized regional energy system In conclusion, the Draft EIS falls far short of what is needed to protect and recover endangered salmon and steelhead populations in the Columbia Basin. Science is well established in showing that restoration of the lower Snake River through dam breaching will be critical in protecting its imperiled native fishes from extinction and will recover them to abundant and harvestable levels. A new regionally-led approach is urgently needed with Northwest policymakers – governors and members of congress – working closely with the region's stakeholders, sovereigns and citizens to craft a lawful, science-based plan that recovers salmon, invests in vibrant fishing and farming communities and ensures a reliable and affordable energy system for current and future generations. Sincerely,	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on our analysis in the fish resources section of Chapter 7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and effect on ESA-listed species. As required by NEPA's implementing regulations, the co-lead agencies used high quality information in the analysis of the CRSO EIS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality waiver standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species but are generally minor relative to the No Action Alternative. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on today's conditions and environment. Technology is quickly changing, as is the region's dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. Factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused effects that have contributed to the decline of fish, and how the region should properly and effectively address those effects, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. Please also see response to Form Letters 1 and 3.
5	The Lower Snake River Dams Prevent Blackouts - The lower Snake River dams have already avoided blackouts in my area--the Tri-Cities. Thousands of new homes and businesses will be built here in the next few years. Our economy is growing. Because they can quickly increase energy production, all four lower Snake River Dams have never been more important to avoid blackouts with renewable, carbon-free hydroelectricity Higher Spill is Expensive and Unproven - I urge you to not consider the alternative with the highest spill levels. This approach could increase power rates by 40%, increase carbon emissions and potentially decrease fish survival according to one of the two fish survival models in the draft EIS. The Dams Make Wind and Solar Energy Possible - Without hydroelectricity to fill in the gaps, the grid cannot take the swings in generation caused by fluctuations in wind and sunshine. The Northwest's demand for electricity is highest in the winter when wind is less prevalent and the sun sets early. The Dams Meet Washington's Carbon-Free Goals - Washington state's Clean Energy Transformation Act (CETA) commits us to a path of no coal generation by 2025 and 100% clean energy by 2045. Zero carbon emissions are produced during hydropower generation.	The CRSO EIS describes the importance of the four lower Snake River dams, particularly Ice Harbor, for stability in the Tri-Cities area. See Section 3.7.3.5, Bonneville Transmission System Reliability and Operations. Although it is beyond the scope of the EIS to analyze the role of hydropower in achieving specific clean energy goals, the EIS does find that replacing the hydropower generation of the four lower Snake River dams would increase greenhouse gas emissions from power generation. See Section 3.8.3.5, pages 3-1009–3-1010 in the Draft EIS. The statements regarding the variability of other renewables and the importance of the four lower Snake River dams for integrating new renewables are consistent with the findings and discussions in the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907. The comment that replacing the four lower Snake River dams under Multiple Objective alternative 3 would drive up costs in the region is consistent with EIS findings In its analysis of effects, the Draft EIS used high quality data and best science, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs

Form Letter #	Form Letter Text	Response
	The Dams Provide Affordable Electricity - Several independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesn't consider the loss of coal generation which will also need to be replaced by carbon-free resources to reach CETA goals. A rise in energy costs would worsen our homeless crisis and mean greater hardships for people already struggling to make ends meet. The Dams Are Just One Factor in Salmon and Orca Survival - Salmon from the Snake River are only one part of an orca's diet. Salmon survival rates through these dams are as high as 97%. NOAA Fisheries' analysis shows Puget Sound Chinook salmon are most important for the Southern Resident Orcas. Cleaning the Puget Sound and reducing carbon output would be a better use of time and money in saving our treasured salmon and orca. The Dams Create Tourism, Recreation, Irrigation and Transportation - The lower Snake River dams provide industries, products, flood control and jobs to Northwest residents. **Variant Text** • I support the preferred alternative of the draft EIS. • The draft EIS is the most extensive study in the history of the Columbia River Basin. • I am pleased that the report recognizes the importance of the lower Snake River dams and does not recommend dam breaching. • I am also concerned that increased spill is under consideration. • I also hope the majority of the effort will be placed where the majority of the fish survival problems occur - in the ocean and Puget Sound. • Several independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. • It's a collaborative body of work that included significant input from federal agencies, Native American tribes and the states of Idaho, Montana, Oregon and Washington. • I am concerned that breaching the lower Snake River dams is an option under consideration but am pleased the preferred alternative does not include a recommendation to breach any of the dams. • Army Corp of Engineers, the Bureau of Reclamation and the Bonneville Power Administration: I appreciate your efforts in preparing the draft environmental impact statement for the 14 federal projects on the Columbia River System. • The lower Snake River dams provide industries, products, flood control, irrigation water to agricultural products, and jobs to Northwest residents. • I urge you to not consider the alternative with the highest spill levels. • NOAA Fisheries' analysis shows Puget Sound Chinook salmon are most important for the Southern Residents. • i also hope the majority of the effort will be placed where the majority of the fish survival problems occurin the ocean and puget sound.	associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas-related mortality of juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation and maintenance of the CRS dams, including toxics. The CRSO EIS is on the effects of the operations, maintenance, and configuration of the CRS and therefore, pollution in the Puget Sound outside the scope of this analysis. The Corps is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. However, research continues to evaluate the magnitude of these effects in the Sound. For more information see the NOAA website at: https://www.nwfsc.noaa.gov/research/index. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), as well as meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the DEIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Chapter 1, Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated flood risk for any of the alternatives.
6	Thank you for the opportunity to comment on the Columbia River System Operations Draft Environmental Impact Statement (DEIS). I am an employee of Midstate Electric Cooperative (MEC), a not-for-profit, member-owned electric cooperative headquartered in La Pine, Oregon. The cooperative purchases 100% of our power from the Bonneville Power Administration (BPA) to provide electric service to over 18,000 residents in four counties in Central Oregon. MEC agrees that Multiple Objective 3 (MO3) – breaching the four lower Snake River dams (LSRD) – would have an adverse impact on electric cooperative consumers, the reliability of the Northwest energy grid, and the global environment. The LSRD are an integral part of our electricity supply in the Pacific Northwest – powering 900,000 homes annually. We are pleased that the DEIS rejected the dam breaching option based on the conclusion that it "has the highest adverse impacts to other resources, especially social and economic effects." We are also pleased that the DEIS rejected Multiple Objective 4 (MO4), which significantly increases spill and dramatically decreases power production. MEC is serious about our mission of delivering clean, affordable, reliable electricity to our members. The DEIS concluded that breaching the LSRD would have long-term, major, adverse effects on power costs and rates, and the rate pressure could be up to 50% on wholesale power rates. Increased spill as envisioned by MO4 would also increase costs up to 41%. A 40-50% increase in BPAs rate could lead to an increase of several hundred dollars a year to our members. The most impacted by these rate increases will be our vulnerable populations senior citizens and those on fixed incomes who shouldnt have to choose between medicine, food or paying their electric bills. MEC also takes seriously our commitment to keep the lights on.	The comments that breaching the four lower Snake River dams would increase the frequency of power shortages unless and until replacement resources were built, and would result in increased costs in the region, are both consistent with EIS findings. See EIS, Section 3.7.3.5, Table 3-166 in the Draft EIS; and Appendix H, Table 2-1. The EIS also finds that Bonneville Power Administration (Bonneville) customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Draft EIS, Section 3.7.3.5, Residential Effects, page 3-929. The comment that replacing the four lower Snake River dams will drive up costs in the region is consistent with EIS findings. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. Although it is beyond the scope of the EIS to analyze the role of hydropower in achieving specific clean energy goals, the EIS does find that replacing the hydropower generation of the four lower Snake River dams would increase greenhouse gas emissions from power generation. See Section 3.8.3.5, pages 3-1009–3-1010 in the Draft EIS. The statement in the comment regarding the efficiency of fish passage at the lower Snake River dams is largely consistent with the EIS, see Section 3.5.

Form Letter #	Form Letter Text	Response
	The DEIS concludes the dam breaching alternative would more than double the regions risk of power shortages. MO4 creates an even higher risk of brownouts and blackouts in the Pacific Northwest, which again would harm our co-ops most vulnerable populations. Oregons electric cooperatives are proud of our clean energy profile, with a power supply that is consistently over 90% carbon-emission free. According to the DEIS, breaching the dams would create an additional 3.3 million metric tons (MMT) of CO2 - a staggering 10% increase in power-related emissions across the Northwest. MO4 shows similar carbon impacts. The DEIS clearly demonstrates that breaching the LSRD or spilling excessive amounts of water would be a step backward from decarbonization efforts in our region. The DEIS also noted that the co-lead agencies have made substantial improvements for fish passage at the LSRD and lower Columbia River dams. Our cooperative has helped fund this multi-billion-dollar effort to improve fish passage at the dams, which is meeting targets of 96% survival rates for migrating juvenile fish. We believe that it is important to build upon this successful fish passage program instead of taking the drastic measure envisioned in MO3 and MO4. Thank you, **Variant Text** • MEC is serious about their mission of delivering clean, affordable, reliable electricity to us, the members. • MEC also takes seriously their commitment to keep our lights on • A 40-50% increase in BPA's rate could lead to an increase of several hundred dollars a year to us, their members.	
7	To Whom It May Concern: Inland Power is the largest electric cooperative in the state, and we serve members in 13 counties in eastern Washington and northern Idaho. Many agricultural communities across the inland Northwest depend on the dams to provide access for low-carbon barging to get our products to market. The state currently exports $6.7 billion worth of agricultural products overseas. The loss of barging would directly raise costs for farms, reduce jobs, and cause air quality issues for Eastern Washington communities that already face an uphill battle with greenhouse gasses and smog. Washington state has 35,900 farms, 95% of which are small, family owned businesses, meaning they sell less than $250,000 each year. Removing the dams would have a severe negative impact on these family businesses. Inland Power, along with all other Washington utilities have been charged with becoming carbon-neutral by 2030 and 100 percent carbon-free by 2045. The lower Snake River dams are essential to reaching the Northwest's clean energy goals. They generate over 1,000 average megawatts of affordable, carbon-free electricity. That is enough energy to provide for more than 800,000 average U.S. homes. These dams also help us safely add intermittent renewables, like wind and solar power, to the grid. The hydroelectric turbines at the dams can very quickly fill in the gaps when the sun doesn't shine and the wind doesn't blow, keeping the grid balanced. The study considered a range of preferred alternatives, including breaching all four dams. In the draft conclusion, the agencies recommended a combination of the alternatives to help communities and fish & wildlife. They also found that dam breaching was not the best alternative for our region. I urge you to strongly consider the numerous negative results that would occur should these vital dams be removed. Our state would suffer greatly from an economic, energy, job, agricultural, trade and environmental standpoint. If we truly want to save salmon and orcas, and improve the health of our environment, we need to heal our oceans. If we genuinely want our clean energy future to include everyone, we need it to be affordable and reliable. To do both, the Northwest needs the lower Snake River dams. **Variant Text** • I serve on the Inland Power and Light's board of trustees. • Aside from my agricultural livelihood, I serve on the Inland Power and Light's board of trustees. • These dams provide the only source of irrigation for tens of thousands of acres in eastern Washington. • If we truly want to save salmon and improve the health of our environment, we need to heal our oceans.	The CRSO EIS recognizes the relevance of the Washington Clean Energy Transformation Act, among other regional emissions reductions targets, in the Section 3.7 Power and Transmission analysis and Section 3.8 Air Quality and Greenhouse Gas (GHG) emissions analysis. The analysis evaluates the extent to which the CRSO EIS alternatives influence the ability of the region to meet these objectives, finding that MO3 (including breaching of the four lower Snake River dams) would make these goals more difficult to meet. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the effect of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5. The MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely affected. The EIS describes the engineering solutions for irrigation (pipeline extensions, for example) in Section 3.12.3 Environmental Consequences, Region C under the MO3 alternative. The EIS describes that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative, it is assumed that pumps are unable to deliver water to an estimated 47,926 acres. Please also see the response to Form Letters 1 and 6.
8	-The Snake River Basin presents the greatest potential for wild fish recovery of any watershed in the Columbia Basin. Mile-for-mile it has the coldest, most undisturbed stream habitat and is predicted to contain the majority of coldwater habitat as the climate warms. -The science consistently supports removal of the four Lower Snake River dams as necessary to recover robust and fishable populations of salmon and steelhead in the Snake River basin. -The DEIS makes clear that removing the lower Snake River dams is the best option for Snake River salmon and steelhead, but substantially underestimates the level of benefit. -The DEIS preferred alternative does not even provide reasonable assurance that it will avoid extinction, let alone recover Snake River salmon and steelhead to abundant, harvestable levels. There is a good chance it will not meet the	The CRSO EIS documents the assessment of benefits and effects of changes to the operations of the 14 Federal projects of the CRS. Using a multi-disciplinary approach and with the coordination and consideration of cooperating agencies and Tribes, as well as public stakeholder input, and by using high-quality information, the co-lead agencies developed the Preferred Alternative. This alternative best meets the Purpose and Need Statement for the system operations in the region, as well as meets many objectives of the study in consideration of changing operations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species' survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. In this EIS, the Preferred Alternative meets most objectives of the EIS, including two objectives for ESA-

Form Letter #	Form Letter Text	Response
	requirements of the Endangered Species Act and will likely land everyone back in court starting yet another cycle of expensive litigation that keeps the region mired in uncertainty. -We are running out of time if we want populations of these iconic fish to persist for future generations. It is time for all stakeholders and elected officials to come to the table to build forward-looking and durable solutions that will recover Snake River salmon and steelhead while strengthening the regional economy. -Dam removal is a proven method to restore fish populations. While this might have been a radical idea at a point in our history, it is not any longer and its power to restore rivers is evident from Maine to the Olympic Peninsula of Washington State. -The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. Recovery of abundant, healthy and harvestable levels of Snake River salmon and steelhead is not achievable with the dams in place, as several decades of failed recovery efforts and billions of dollars have revealed. The agencies should call on Congress to make the necessary investments to replace the dams' benefits so we can both recover the fish and maintain a vibrant regional economy. **Variant Text** • Mile for mile it has the coldest most undisturbed stream habitat on the west coast and is predicted to contain the majority of coldwater habitat as climates change. • dam removal has been a tested and proven method to restore fish populations across the u • according to the science no other singular action can recover significant populations at the rate and in the time needed to avoid extinction • it is time for all stakeholders and elected officials to come to the table to build forward looking and durable solutions that will create opportunity across the pacific northwest and address challenges faced by other sectors such as agriculture transportation and energy. • the science consistently supports removal of the four lower snake river dams to recover robust and fishable populations of salmon and steelhead to idaho.	listed juvenile and adult anadromous. A full assessment of considerations of climate change and water temperatures are in Section 3.4 Water Quality, Chapter 4 Climate, and Chapter 7 of the Preferred Alternative of the analysis. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. Please also see response to Form Letter 2.
9	I am a farmer in Oregon, and I am writing to urge you to protect the operations of the Columbia system dams that Oregon farmers and ranchers rely on for irrigation water, barging our goods to market, and affordable power. Specifically, I urge you not to breach the lower Snake River dams, which would greatly disrupt agricultural shipping across the Northwest and make it much more expensive and difficult for Oregon farmers to get our products to market. I believe that healthy fish populations and healthy rural communities can exist, and maintenance of our dams is essential to our rural economies. Federal agencies have been proactive about installing fish passage and completing projects to help improve salmonid habitats. The health of salmon populations is critically tied to ocean conditions, which have been declining in the last several years, impacting salmonid and orca health. Breaching dams would not change these conditions. Hydropower helps reduce carbon generated electricity and helps ensure the Northwest is doing its part of combat climate change and reduce our carbon footprint. The Columbia system dams are critical for irrigation for farmers in Oregon and Washington, and our farming communities across Eastern Oregon rely on the dams to provide access for low-carbon barging to get our products to market. The loss of barging would directly raise costs for farms, reduce jobs, and create shipping bottlenecks for communities that are depend on agriculture for their economic and social well-being. I urge you to protect Oregon's farmers and ranchers by ensuring that the Columbia River System continue to support irrigation, barging and other services critical to Oregon's farmers and ranchers and that you do not allow the breaching of any dams on the system.	With the selection of the Preferred Alternative, it is not expected to be adverse effect to navigation, irrigation, or affordable power to Oregon farmers. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates, and the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. For those farming communities on the lower Snake River, the EIS acknowledges that rail rates may increase if the Lower Snake River dams are breached and evaluates three rate scenarios. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5. The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). On the Columbia River, there are no anticipated changes to water supply or irrigation, and therefore, adverse effect to those farming communities. The Draft EIS did not include the measure to breach the four lower Snake River dams in the identified Preferred Alternative.
10	I oppose the breaching of the four lower Snake River dams because that action would: Eliminate the pools behind these dams that will greatly reduce the only source of water for irrigation for nearly 50,000 acres of prime farmland in eastern Washington. Those farms, in turn, provide many diverse and under-served communities with agriculture work. Increase pumping costs that would result in lower net farm income across the region, which translates to farm households having less money to spend within the regional economy. Eliminate an essential component of the Northwest's supply of clean hydroelectric power and increase the regions power costs by $1 billion annually and raise residential utility bills by 25 percent or more. This is in comparison to the estimated rate increase of 2.5 percent	The EIS acknowledges that there is a physical limitation to delivering water to these lands in the absence of the four lower Snake River dams. The MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. The EIS describes the engineering solutions for irrigation (pipeline extensions, for example) in Section 3.12.3 Environmental Consequences, Region C under the MO3 alternative. The EIS describes that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative, it is assumed that pumps are unable to deliver water to an estimated 47,926 acres. Please see Section 3.12 and Appendix N for additional information.

Form Letter #	Form Letter Text	Response
	associated with increased spills for fish. Ignore the more than $2 billion investment to improve fish passage on the lower Snake and Columbia river dams since 2001. These investments have resulted in the highest adult salmon returns since the first Snake River dam was completed in 1961. Cost $457 million in social welfare as the result of lost irrigation and jobs for farm workers. Cost the U.S. $4 billion over the next 30 years due to the loss of barging. Drive up production costs associated with higher transportation costs for upriver movements (i.e., fertilizer, crops). Place additional demands on existing road and rail infrastructure as well as at barging facilities near the Tri-Cities, thereby increasing CO2 emissions by 17 percent. Remove the important flood mitigation that is currently provided to farmland and residential housing in multiple areas along the Snake River.	The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). Maintaining or improving flood risk management operations of the Columbia River System has informed both the alternative development and evaluation process. However the four lower Snake River dams are not authorized for flood risk mitigation and there is no elevated flood risk for any of the EIS alternatives. The Preferred Alternative identified in the Draft Environmental Impact Statement did not include the measure to breach the four lower Snake River dams.
11	Dear Co-Lead Agencies: I live in Ashton, Idaho and appreciate the opportunity to provide comments on the Draft Environmental Impact Statement (DEIS) for the Columbia River System Operations (CRSO). Thank you for the tremendous effort you made to assemble a vast amount of information from many regional stakeholder groups and countless individuals. The analysis has been vetted by industry experts and the final recommendation is thorough. I value all the aspects of the Columbia River and appreciate the consideration of all stakeholder's priorities including environmental stewardship, tribal treaties, irrigation and agriculture, flood control, economic growth and prosperity and affordable, reliable and carbon free hydroelectric generation. As an electric rate payer, I'm interested in preserving our access to a carbon free, reliable, and historically low-cost federal hydropower generation. I support the Preferred Alternative (PA) contained in the DEIS as a balanced approach that benefits the BSA-listed species, meets the multiple purposes of the federal projects, and minimizes adverse economic, environmental, and social impacts, although the PA comes at a cost to me as I pay for power as a member of Fall River Rural Electric Cooperative. My main concern with the PA is increased spill of up to 125% total dissolved gas (TDG) levels, resulting in higher power costs and possibly adverse effects to ESA-listed species. I support higher spill levels and the resulting higher power costs only if scientific analyses clearly show a meaningful benefit to ESA-listed species. Additionally, I urge you to include in the final Record of Decision (ROD) strengthened and expanded measures to mitigate the predation of tens of millions of ESA-listed juvenile fish each year, particularly in the lower Columbia River, by various birds and predatory fish. I also hope the federal agencies will take full advantage of the provisions of the Endangered Salmon Predation Prevention Act to strengthen and expand protections for returning adult fish and I would like to see a strong commitment to do so reflected in the final ROD. I'm concerned about making sure Fall River has a reliable source of power to meet our communities present and future needs at an affordable cost. Many in our community, include seniors and those on fixed or low incomes, are dependent on the electric service provided by Fall River to heat their homes, power appliances, provide hot water and even pump water from their well. I'm concerned about escalating power costs. While the preferred option and increased spill increases our costs, it is far better compared to other DEIS alternatives. Our electric Cooperative, Fall River Rural Electric Cooperative, is serious about their mission of delivering clean, affordable, reliable electricity to us, its members. The DEIS concluded that breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." A 50% increase in wholesale power costs would be financially devastating to our household. It is important to keep these financial impacts in perspective for rural communities like ours where incomes are below regional and state averages. These increases in power costs are not a simple shift from disposable and discretionary income to pay for essential services like electricity. Rather, they mean that some neighbors and family will be forced to make difficult choices about which essentials, like food, medicine, utilities, and such, they have to sacrifice. To conclude, I support the Preferred Alternative with certain caveats and concerns described previously. The PA provides a good blueprint for operating the Columbia River System and has been created and extensively reviewed by some of the best scientists and economists in the U.S. The Preferred Alternative proposes operating the Columbia River in a way which will benefit ESA-listed fish, meet the multiple purposes of the federal projects, and minimize adverse economic, environmental, and social impacts. Thank you for providing our region with a valuable resource of informed decisions on future Columbia River System Operations and for allowing me to participate in this important process.	The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the DEIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Total dissolved gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%.. The Preferred Alternative includes a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored. The co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation and adaptive management of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the effects from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing common metrics, identifying measures, and implementation of measures that will aid in the reduction of predation effects and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. The Preferred Alternative includes predation mitigation measures, including maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates, all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia River. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. The Preferred Alternative meets the objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. Please also see response to Form Letter 6.

	Variant Text • Subject: Comments on the Draft Columbia River System Operations Environmental Impact Statement Dear Co-Lead Agencies: I live in Rexburg, Idaho, and appreciate the opportunity to provide comments on the Draft Environmental Impact Statement (DEIS) for the Columbia River System Operations (CRSO). • Subject: Comments on the Draft Columbia River System Operations Environmental Impact Statement Dear Co-Lead Agencies: I live in Island Park, Idaho and appreciate the opportunity to provide comments on the Draft Environmental Impact Statement (DEIS) for the Columbia River System Operations (CRSO). • Subject: Comments on the Draft Columbia River System Operations Environmental Impact Statement Dear Co-Lead Agencies: I live in West Yellowstone, Montana and appreciate the opportunity to provide comments on the Draft Environmental Impact Statement (DEIS) for the Columbia River System Operations (CRSO). • they provide substantial energy operating reserves and ramping capability to help prevent blackouts and integrate other variable renewable generation like wind and solar. • they have also been built to facilitate fish passage with a spring juvenile survival rate of 96 which meets performance standards. • this reports conclusions on fish and wildlife are consistent with past findings which show the lower snake river dams do not jeopardize the existence of threatened and endangered salmon species that navigate past them • overall juvenile survival of salmon and steelhead through the columbia river system is 40 to 50 depending on the species which is comparable to freeflowing rivers such as the frasier river in canada. • these dams are a key source of lowcost carbon free power. • the dams on the columbia river act to some degree as an integrated battery which has been used to integrate variable wind and solar generation. • many in our area are particularly vulnerable to increased risks of blackouts and escalating power costs which makes the pa worthy of my support in terms of its lower risks in these areas compared to other deis alternatives. • in our area we are also dependent on electric service for our water from wells our electric heat electric water heaters wastewater and sewage treatment. • the lower snake river dams are some of the lowest cost generation marketed by bpa and are increasing in value as the region sets greenhouse gas ghg emission goals. • i am also concerned about the longterm cost of power. • i understand that some of the best scientists biologists and economists have been involved in the threeyear process which resulted in a proposed preferred alternative. • i encourage cooperation with environmental and tribal groups to work on plans which do bolster a sustainable salmon and steelhead population. • i appreciate the comprehensive evaluations and analysis which have taken place in the draft eis. • with regional efforts aimed at reducing carbon and moving to a carbon free generation portfolio having access to the carbon free reliable and flexible generation will be essential to ensure the regions power system reliability and will be essential in meeting the regions ghg goals. • specifically i support efforts to manage avian and other predation of salmon populations. • i support not removing the lower snake river dams as contained in the preferred alternative. • many of my friends and neighbors are seniors and have fixed or low incomes. • i also appreciate the multiple ways comments can be easily submitted for consideration. • im interested in preserving our access to a carbon free reliable and historically lowcost federal hydropower generation and therefore support the preferred alternative pa contained in the deis as a balanced approach that benefits the esalisted species meets the multiple purposes of the federal projects and minimizes adverse economic environmental and social impacts although the pa comes at a cost to me as an electric cooperative member.	
12	Thank you for the opportunity to provide comments. I write today expressing my support of the federal agencies' Preferred Alternative as presented in the Draft EIS for the Columbia River System. Idaho and the entire region benefit from the river system. As a farmer, I depend on the navigation system to get my crops to market outside of the state. Water management and power generation are also very important to me. Too much attention has been put on the discussion of dam breaching. I believe that salmon and dams can co-exist. I support the managed river system with dams, locks, and hydro-turbines that currently exist. I ask the federal agencies to finalize the EIS with the preferred alternative as presented in the Draft EIS.	Please see the response to Form Letter 9.

Form Letter #	Form Letter Text	Response
13	Thank you for the tremendous effort you made to assemble a vast amount of information from many regional stakeholder groups and countless individuals. The analysis has been vetted by industry experts and the final recommendation is thorough. I understand that some of the best scientists, biologists and economists have been involved in the three-year process which resulted in a proposed preferred alternative. I'm interested in preserving our access to a carbon free, reliable, and historically low-cost federal hydropower generation, and therefore support the Preferred Alternative (PA) contained in the DEIS as a balanced approach that benefits the ESA-listed species, meets the multiple purposes of the federal projects, and minimizes adverse economic, environmental, and social impacts, although the PA comes at a cost to me as an electric cooperative member. I appreciate and support he PA and would like to submit the following comments: 1. The Federal Columbia River Power System (FCRPS) provides significant value to the region and specifically to Fall River Electric Cooperative as our largest source of flexible, carbon free generation. The dams on the Columbia River act to some degree as an integrated battery which has been used to integrate variable wind and solar generation. 2. I support not removing the Lower Snake River Dams as contained in the Preferred Alternative. a. These dams are a key source of low-cost, carbon free power. b. Overall juvenile survival of salmon and steelhead through the Columbia River system is 40% to 50%, depending on the species, which is comparable to free-flowing rivers such as the Frasier River in Canada c. The Lower Snake River dams are some of the lowest cost generation marketed by BPA and are increasing in value as the region sets greenhouse gas (GHG) emission goals. d. They provide substantial energy, operating reserves and ramping capability to help prevent blackouts and integrate other variable renewable generation like wind and solar. They have also been built to facilitate fish passage with a spring juvenile survival rate of 96%, which meets performance standards. 3. This report's conclusions on fish and wildlife are consistent with past findings which show the lower Snake River dams do not jeopardize the existence of threatened and endangered salmon species that navigate past them. 4. I am concerned about global warming. With regional efforts aimed at reducing carbon and moving to a carbon free generation portfolio, having access to the carbon free, reliable and flexible generation will be essential to ensure the region's power system reliability and will be essential in meeting the regions GHG goals. 5. I encourage cooperation with environmental and Tribal groups to work on plans which do bolster a sustainable salmon and steelhead population. Specifically, I support efforts to manage avian and other predation of salmon populations. 6. I am also concerned about the long-term cost of power. Many of my friends and neighbors are seniors and have fixed or low incomes. In our area we are also dependent on electric service for our water from wells, our electric heat, electric water heaters, wastewater and sewage treatment. Many in our area are particularly vulnerable to increased risks of blackouts and escalating power costs, which makes the PA worthy of my support in terms of its lower risks in these areas compared to other DEIS alternatives. I appreciate the comprehensive evaluations and analysis which have taken place in the draft EIS. I also appreciate the multiple ways comments can be easily submitted for consideration. Sincerely, **Variant Text** • i appreciate and support he pa and would like to submit the following comments the federal columbia river power system fcrps provides significant value to the region and specifically to fall river electric cooperative as our largest source of flexible carbon free generation. • i appreciate the opportunity to provide comments on the draft environmental impact statement deis for the columbia river system operations crso. • i appreciate and support the pa and would like to submit the following comments 1. • the deis concluded that breaching the snake river dams would have longterm major adverse effects on power costs and rates and the rate pressure could be up to 50 on wholesale power rates. • our electric cooperative fall river rural electric cooperative is serious about their mission of delivering clean affordable reliable electricity to us its members. • a 50 increase in wholesale power costs would be financially devastating to our household. • we support not removing the lower snake river dams as contained in the preferred alternative • we understand that some of the best scientists biologists and economists have been involved in the threeyear process which resulted in a proposed preferred alternative. • we are concerned about global warming • we are also concerned about the longterm cost of power • we appreciate the comprehensive evaluations and analysis which have taken place in the draft eis	The co-lead agencies acknowledge that ocean conditions are a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies concur with the generalized survival rates through the CRS. The co-lead agencies advise caution when directly comparing survival rates between different populations of fish or from different geographical locations. See ISAB 2020-1 for discussion of comparing populations, even populations within the Columbia Basin. The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation and adaptive management of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the effects from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing common metrics, identifying measures, and implementation of measures that will aid in the reduction of predation effects and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies, many of the items listed are outside the co-lead agencies' authorities. The Preferred Alternative includes a large suite of predation mitigation measures. Some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operation will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. Please also see response to Form Letter 11.

15	To Whom it May Concern, I am writing to urge the US government agencies in the strongest terms possible to protect the anadramous and other native fishes of the Columbia and Snake River systems. As a life long Oregonian I have watched in horror as the salmonid species in particular, as well as the sturgeons and other fish, have experienced precipitous declines. The harm also extends to the resident Orca population of Puget Sound who feed in large part on salmonids that spawn in the Columbia and Snake systems. I have become aware that the four lower dams on the Snake River are not only out dated but also financially not self sustaining and dangerous to the water quality of the rivers themselves. In addition developments in modern technology with wind and solar power have obviated the need for the electrical generation from those dams on the Snake River. Any plan for salmon recovery on the Columbia and Snake Rivers must incorporate the following: --Removal of the 4 obsolete dams on the lower Snake River --Increase flow rates over Columbia River dams to lower water temperature --Updated salmon conservation and restoration strategies in line with guidelines following federal court five time rejection of previous agency strategies --Halt of unnecessary scapegoating of native wildlife for declines in salmon numbers --Inclusion of stakeholders in crafting inclusive, creative, proper solutions, including Indigenous peoples, environmental groups and communities along the river systems --Halt of sport and commercial fishing for salmon and sturgeon on the Columbia and Snake River systems by all but Indigenous peoples until fish recovery equals sustainable numbers The salmon, in particular, are a key species of the Columbia River and its tributaries. If they go extinct here, the ecosystems of all the Columbia drainage will suffer immeasurable devastation. It is incumbent upon us as a society to do all we can at this moment to save the salmon by saving our rivers. Thank you for your consideration on this incredibly vital issue. Sincerely,	From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. The comment suggests that the regional supply of power is sufficient without the output of the four lower Snake River dams, and even sufficient without replacing the output of the lower Snake River dams with other resources. Regional demands for power would not be met without the four lower Snake River dams during times of greater than average load or lower than average resource output. In those instances, power system emergencies or blackouts would occur. The EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council. See EIS Section 3.7.2.2; Appendix H Power and Transmission, at Section 2.1; Appendix I Hydroregulation, Section 2.4.4. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a blackout occurring in a year. See Appendix H Power and Transmission at Section 2.1. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one blackout in every 15 years. The EIS uses this LOLP level as the benchmark from which to gauge the other Multiple Objective alternatives. Under Multiple Objective alternative 3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one blackout every seven years. See EIS page 3-903; and Appendix H Power and Transmission, Table 2-1. Harvest certainly has an effect on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Please also see response to Form Letter 8.
16	I support restoring salmon, steelhead and other native aquatic species through the breaching of the 4 lower Snake River dams in eastern Washington. Unfortunately, the DEIS is incomplete, inadequate and inaccurate in terms of its analysis of the benefits of dam breaching. These benefits include not only restored fish runs, but also restored rural economies that depend on fishing and outdoor recreation, and restored cultures that have been interwoven with salmon and steelhead for millennia. The DEIS dismisses the overwhelming scientific research that shows restoring the lower Snake River to its free-flowing condition will provide salmon and steelhead with their best and likely only chance to recover, and it ignores the benefits of increasing salmon runs for critically endangered Southern Resident orcas. These orcas primarily eat Chinook salmon and forage for these fish from central California into the Salish Sea. The Columbia and Snake rivers have supported salmon runs that the orcas have relied on for centuries.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4 of the Preferred Alternative, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending

Form Letter #	Form Letter Text	Response
	Historically, nearly half of all the Chinook salmon returning to the Columbia Basin were bound for the Snake River. Scientists from the Fish Passage Center have stated that breaching the four lower Snake River dams would result in roughly one million adult Chinook salmon returning to the mouth of the Columbia River, providing a critical food source for endangered southern resident orcas. The DEIS presents a false choice between maintaining affordable utility bills and restoring healthy salmon and steelhead. It overstates the cost of replacing power from the lower Snake River dams with clean energy, and suggests replacing their power with fossil fuels, which is unnecessary. A report from the Northwest Energy Coalition shows that through strategic investments, the energy produced by these dams can be replaced at a marginal cost to ratepayers while also improving the reliability of the electrical grid. It is time to stop pitting salmon recovery against clean, affordable energy. The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices that have already been made by Native American tribes and other Northwest residents in terms of lost fishing opportunity, reduced jobs and incomes, impacts on cultural values, and other socio-economic effects. Further, the DEIS ignores the economic and community benefits of salmon recovery and the investments and jobs that river restoration activities will generate. As written, the DEIS does not provide a complete or accurate assessment of the feasible alternatives for the lower Snake River. An effective solution for Northwest salmon and people must move beyond historic conflicts and proactively address four urgent, connected issues. I support the development of long-term plan to: • Restore abundant, fishable salmon and steelhead populations in the Columbia Basin; • Protect and invest in the economic vitality of local farming and fishing communities; • Continue the region's legacy of providing reliable, affordable, clean energy; and • Honor our nation's treaty commitments to Native American tribes Thank you for taking my comments into consideration. Further, the DEIS ignores the economic and community benefits of salmon recovery and the investments and jobs that river restoration activities will generate. As written, the DEIS does not provide a complete or accurate assessment of the feasible alternatives for the lower Snake River. **Variant Text** • Thank you for the opportunity to comment on the Columbia River System Operations (CRSO) Draft Environmental Impact Statement (DEIS). • I am writing to express my support for recovering salmon and steelhead to abundant, self-sustaining levels, and for creating a more vibrant Northwest that is powered by clean energy and features healthy agricultural and fishing economies. • I support restoring salmon, steelhead and other native aquatic species through the breaching of Lower Granite, Little Goose, Lower Monumental and Ice Harbor dams on the lower Snake River in eastern Washington • i support the development of long term plan to restore abundant fishable salmon and steelhead populations in the columbia basin protect and invest in the economic vitality of local farming and fishing communities continue the regions • legacy of providing reliable affordable clean energy and honor our nations treaty commitments to native american tribes thank you for taking my comments into consideration.	point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. The EIS also provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams, and outside the authority of the co-lead agencies. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The Preferred Alternative meets the Purpose and Need Statement and certain objectives identified in the EIS for operation of the Columbia River System. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums. In areas where the co-lead agencies have appropriate authority, we will continue to be strong regional partners. The co-lead agencies are committed to fulfilling their treaty and trust obligations and providing early, open, transparent and meaningful consultation. See Sections 2.3 and 9.3.2. The co-lead agencies look forward to continuing to consult on the EIS, which covers changes to the water management of the existing 14 projects on the Columbia and lower Snake Rivers. The co-lead agencies recognize these obligations while also acknowledging that construction of the Federally authorized CRS projects directly affected many of the region's Tribal communities. Throughout this EIS process, the co-lead agencies have analyzed effects of the ongoing operation and maintenance of the CRS to treaty-reserved rights and associated resources. This analysis addresses how those rights would be affected by the potential alternatives—including how measures could affect fish abundance that may affect the U.S. v. Oregon Fishery Management Agreement, and the extent to which treaty rights and Tribal resources would be protected and enhanced. The Preferred Alternative includes actions to benefit ESA-listed fish as well as lamprey, and these actions also benefit Tribal interests and treaty resources. Please also see responses to Form Letters 1 and 15.
17	For twenty years, the US Army Corps of Engineers has failed to address the primary causes of salmon declines on the Columbia and Snake River Systems. Instead they have scapegoated fish-eating birds like cormorants and terns for doing what comes naturally. In fact, they have lost five times over the last twenty years in Federal Court over the insufficiency of their plans. It is long past time for real solutions, but the Corps has once again brought forward a plan that fails to address the dams. The Agencies preferred alternative perpetuates an approach that has pushed salmon, orca and other fish and wildlife populations to the edge of extinction, and led to the unnecessary scapegoating of native wildlife like Double Crested Cormorants	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes. The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation and adaptive management of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have

Form Letter #	Form Letter Text	Response
	The Agencies preferred alternative is a huge waste of public resources and perpetuates the status quo – which has been rejected 5 times by a federal court over the last 25 years. An Alternative Plan must focus on three things: -Removal of four obsolete Snake River Dams, increased flows over Columbia River Dams and habitat restoration -Persecution of native predator species must be eliminated from this plan -Real solutions for NW salmon, other wildlife and people will come from NW people – policymakers, sovereigns (states and tribes), stakeholders, and communities working urgently together to craft inclusive, creative solutions to our shared problems and bring all communities forward together. **Variant Text** • Additionally many people had trouble getting through on the phone hearings. • The comment period of 45-days was utterly inadequate to review this complex plan • The Agencies preferred alternative perpetuates an approach that has pushed salmon, orca, and other fish and wildlife populations to the edge of extinction. • The strategy put forth by the Agencies also led to the unnecessary scapegoating of native wildlife like Double Crested Cormorants. • Persecution of native predator species must be eliminated from this plan. • The comment period was insufficient • 45-days is woefully inadequate to review a plan of this complexity and many people had trouble getting through on the phone hearings. • An Alternative Plan must focus on three things: Removal of four obsolete Snake River Dams, increased flows over Columbia River Dams and habitat restoration 2. • Persecution of native predator species must be eliminated from this plan 3. • Real solutions for NW salmon, other wildlife and people will come from NW people – policymakers, sovereigns (states and tribes), stakeholders, and communities working urgently together to craft inclusive, creative solutions to our shared problems and bring all communities forward together.	authorities and obligations to mitigate the effects from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing common metrics, identifying measures, and implementation of measures that will aid in the reduction of predation effects and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies, many of the items listed are outside the co-lead agencies' authorities. The Preferred Alternative includes a large suite of predation mitigation measures. Some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. In addition, the co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period. In response to COVID-19 concerns and public health requirements within the comment period, the agencies converted the six planned in-person regional public comment meetings to conference calls that provided an approach consistent with the format of the planned in-person comment meetings. The agencies' announcements for the teleconferences included technical assistance instructions for callers who experienced difficulties joining or during a call. The agencies' technical team worked with the AT&T operators to track any concerns heard from anyone who encountered issues joining the calls; no related technical issues were reported. All comment methods were promoted alongside all teleconference information so those unable to participate in a call or who preferred other methods could refer to those comment options. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. These teleconference meetings were structured similarly to the previously scheduled in-person public comment meetings and provided speakers with the same amount of time to submit a verbal comment. Due to the format of these meetings, they were accessible to any public commenter, regardless of location. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone. Please also see response to Form Letters 4 and 16.
18	Breaching the lower four snake river dams immediately is the number one solution that will truly save Chinook Salmon and the Southern Resident Orcas from extinction. This is the only sustainable way to save two species from extinction. Immediately place a temporary moratorium on commercial salmon fishing. Absolutely no culling of the pinnipeds.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NOAA Fisheries website at: https://www.nwfsc.noaa.gov/research/index.cfm. However, the three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation and adaptive management of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Under the Preferred Alternative, actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with ESA as described in Section 7.6.4.1, Ongoing Programs, including ongoing measures to haze and monitor pinniped predators. Other entities in the region have authorities and obligations to mitigate the effects from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing common metrics, identifying measures, and implementation of measures that will aid in the reduction of predation effects and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies, many of the items listed are outside the co-lead agencies' authorities. The Preferred Alternative includes a large suite of predation mitigation measures. Some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile

		salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. Please also see response to Form Letter 8.
19	1) The Draft EIS is fatally flawed because it did not complete the analysis of the effects of climate change on river temperatures and salmon, 2) Dam breaching offers the best chance to save salmon and steelhead. 3) Breaching and restoring the lower Snake to a free flowing recreational mecca will provide enormous economic activity for struggling rural economies. The agencies must evaluate these benefits in the Final EIS. 4) The Final EIS must include a basin-wide review of flood risk management and how the 2024 expiration of the coordinated flood control operations under the U.S.-Canada Columbia River Treaty will impact storage and flows in the Columbia and Snake. 5) The Final EIS must consider the impacts of future irrigation withdrawals, from the lower Snake, which are likely to increase due to climate change. 6) The Final EIS must include consideration of fish passage and reintroduction above Grand Coulee and Chief Joseph dams to support tribal fishery restoration goals in the Upper Columbia. 7) The Final EIS must consider the proper context for addressing the benefits and costs of the Columbia-Snake hydropower system, which means properly addressing the enormous costs - past, present, and future - to the tribes within the basin from the loss and eventual extinction of salmon and steelhead.	1) Chapter 4 includes a discussion on the potential effects that future climate change may have on resources including water quality and quantity. The co-lead agencies agree that climate change is a concern. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the required resolution (river-scale vs. global- or regional-scale) at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and other water quality parameters (Section 4.2.3). Specific information in the Draft EIS on climate effects to hydrology and hydraulics can be found in Section 4.2.1, and how climate affects water supply can be found in Section 4.2.9 and Section 7.8.1 (hydrology and hydraulics) and 7.8.12 (water supply). 2) Please see response to Form Letter 4. 3) The potential benefits to recreation associated with Multiple Objective alternative 3 (MO3), which includes breaching the four lower Snake River dams, is described in Section 3.11.3.5. The EIS describes the potential for increased river recreation such as boating, rafting, and kayaking under MO3. There is some uncertainty in the figures; non-fishing recreation in the lower Snake River reach could range from 1.2 to 3.4 million visitors per year. Dworshak's summer drawdown would remain the same under MO3 as under the No Action Alternative because the cooling water in the lower Snake is needed under both alternatives. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Please also see response to Form Letter 16. 4) The current operations of the CRS, including current Treaty-related operations, are included in the EIS analysis. If Treaty-related operations change in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary. Section 2.5.10 of the Draft EIS explains why re-evaluating system flood risk management was screened out from further consideration in this EIS. Section 2.5.10 also explains that while the U.S. Entity Regional Recommendation stated support the pursuit of Congressional authorization and appropriations for a region-wide public process to assess potential changes to the current level of flood risk protection, no such authorization or appropriation was provided. As such, a study for this purpose was determined to be outside of the scope of this EIS. 5) Through ongoing regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. 6) Measures to reintroduce salmon above Chief Joseph and Grand Coulee Dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process.

Form Letter #	Form Letter Text	Response
		Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas. 7) Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision-making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and effects of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
20	I greatly appreciate the opportunity to comment on the Draft Environmental Impact Study. I am an elected Board Member of Peninsula Light Company, the 2nd largest electric cooperative in Washington State. We serve a membership comprised of 90% residential members and have proudly been providing reliable, affordable power for over 95 years. Almost half of Peninsula Light Companys members are on fixed incomes and 10% live below the poverty line. Any alternative that includes dam breaching would greatly impact rates and be a significant burden to more than 50% of our membership. The increased greenhouse gas emissions would serve to add significant upward pressure to electricity costs as we would pay a penalty for not providing 100% carbon free power. Peninsula Light Company strongly supports the D-EIS' Preferred Alternative option proposed by the co-lead agencies. It incorporates all of the critical objectives for sound river operations now and into the future; this is a delicate and complicated balancing act with huge consequences for our region. Peninsula Light Company supports the following public power positions: We must recognize the region's shared stake in fish recovery, financial health of BPA and equitably align cost responsibility; The economic, environmental, and operational benefits of the Federal Columbia River Power System as it exists today must be properly considered and accounted for; Hydropower is a clean, renewable, flexible resource, vital to meeting Washington State's carbon goals and enables the integration of variable resources like wind and solar; Federal Columbia River Power System projects are a significant part of providing low-cost power to the region In order to preserve our access to clean, affordable power, federal agencies and the Pacific Northwest region must recognize these fundamental tenets. Any alternative that contemplates breaching the four lower Snake river dams cannot be considered viable. Such an action would have decades-lasting, negative impacts on our consumers, the reliability of the Northwest power grid and the environment. I am deeply committed to all of these principles and resolute in my endeavor to make them a part of the legacy of Peninsula Light Company and the Pacific Northwest. Thank you again for this opportunity to comment.	The comment that power costs in the region would increase under MO3, which includes breaching of the four lower Snake River dams, is consistent with EIS findings. See Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers. The EIS also discusses the fact that Bonneville customers, such as cooperatives, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Section 3.7.3.5, Residential Effects, at page 3-929 in the Draft EIS, and Chapter 5 of Appendix H, Power and Transmission. The Environmental Justice analysis in Section 3.18.3, provides further detail on potential disproportionate effects to Tribal, low-income and minority populations from MO1, MO2, MO3 and MO4. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial effect of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control. The Preferred Alternative meets the objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System, as well as meeting the two objectives for ESA-listed juvenile and adult anadromous salmonids. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing effects to affected ESA species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and effect on ESA-listed species.
22	To save the endangered Snake River salmon, Southern Resident orcas and ratepayers money, the federal agencies need to address the Columbia River System in a two-tiered process. Tier one is an emergency response action for the immediate drawdown and breach of Lower Granite and Little Goose dam, followed by the remaining two dams in subsequent years. Tier two is addressing system operations and further mitigation activities in the rest of the Columbia River Basin using the new EIS, assuming that the four lower Snake River dams.	The Draft EIS evaluated under MO3 removal of the earthen embankment of the four lower Snake River dams (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the Columbia River System (CRS) and mitigation for effects to resources from implementing this alternative. If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous

Form Letter #	Form Letter Text	Response
		salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. Please also see response to Form Letters 1 and 2.
24	I'm writing to express my concerns about the Columbia River Systems Operations draft environmental impact statement (EIS) and to urge you to revise this plan to adequately protect salmon, the orcas that depend on them, and Native peoples' rights. Salmon populations in the Columbia Basin have dramatically declined since the four lower Snake River dams were built. Once-abundant species such as chinook salmon, which make up 80 percent of an orca's diet, are only returning at a small fraction of historic levels. Your draft EIS fails to adequately account for the impact that dwindling salmon populations in the Columbia and Snake rivers have on Southern Resident orca survival. There are only 72 of these majestic creatures left. Starving female orcas are experiencing high rates of pregnancy loss, a heartbreaking statistic that was starkly illustrated recently by a grieving mother who refused to let her dead newborn calf go. The draft EIS also fails to meet tribal cultural, health, and economic needs, or treaty trust obligations. For tens of thousands of years, Native peoples have lived with abundant salmon. Restoring plentiful salmon to the Columbia and Snake rivers is not just ecologically important, it is an environmental justice issue. The draft EIS's own analysis shows that, for salmon to recover, the four lower Snake dams must be breached and their energy replaced with zero carbon alternatives. Thank you. I hope to see you and your agency fulfill your responsibilities with a new and improved plan. **Variant Text** • i am writing to express my concerns about the columbia river systems operations draft environmental impact statement eis and to urge you to revise this plan to adequately protect salmon the orcas that depend on them and native peoples rights. • we hope to see you and your agency fulfill your responsibilities with a new and improved plan. • i urge you to revise this plan to adequately protect salmon the orcas that depend on them and native peoples rights. • starving female orcas are experiencing high rates of pregnancy loss • the draft eiss own analysis shows that for salmon to recover the four lower snake dams must be breached and their energy replaced with zerocarbon alternatives. • the draft eis fails to adequately account for the impact that dwindling salmon populations in the columbia and snake rivers have on southern resident orca survival. • the draft eiss own analysis shows that for salmon to recover the four lower snake dams must be breached • im writing to express my concerns about the columbia river systems operations draft environmental impact statement eis. • there are only 72 of these creatures left. • starving female orcas are experiencing high rates of pregnancy loss a statistic that was starkly illustrated recently by a grieving mother who refused to let her dead newborn calf go.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision-making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and effects of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would

	• onceabundant species such as chinook salmon which make up 80 percent of an orcas diet are returning at only a small fraction of historic levels. • i urge you to revise the columbia river systems operations draft environmental impact statement eis to adequately protect salmon the orcas that depend on them and native peoples rights. • your draft eis fails to account for the impact that dwindling salmon populations in the columbia and snake rivers have on southern resident orca survival. • i expect to see you and your agency fulfill your responsibilities with a new and improved plan.	not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. As discussed in Section 3.7.3.5 replacing the four lower Snake River dams hydropower with the least cost zero-carbon portfolio of 1,960 MW of solar plus 980 MW of storage is expected to cost $375 million per year, and 600 MWs of demand response would add an additional $29 million[1] per year (2019 dollars)[2]. The Preferred Alternative does not require the additional of any replacement resources for hydropower generation. The Preferred Alternative identified in the Draft EIS meets the objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System, as well as meeting the two objectives for ESA-listed juvenile and adult anadromous salmonids. Please also see response to Form Letters 1 and 2. [1] 400 MW of the assessed potential was assumed to be in Bonneville's service territory with the remainder assumed to be acquired in Portland, OR. Therefore, the rates analysis assumes ~$20 million for Bonneville rates regardless of financing, with the remaining ~$10 million included in the socioeconomic retail rate analysis in Portland General Electric's service territory. [2] These figures for solar power were calculated using data from the Council's midterm assessment to the 7th Power Plan for overnight capital costs and fixed O&M assuming public financing and a 30-year useful life for an eastside installation. Storage costs were sourced from the October 8, 2019 Generating Resources Advisory Committee presentation by the NW Council. The presentation relied on can be found at: https://www.nwcouncil.org/sites/default/files/2019_1015_p4.pdf. Demand response costs were also sourced from the 7th Power Plan. See page 14-10, Figure 14-2 of the 7th Power Plan, which shows the dollar cost of each cost bin which the NW Council staff developed; the transmission deferral benefit was sourced from DR Technical Appendix to the 7th Power Plan, Appendix J. See Pages J-3 through J-5, which present the discount and inflation rate assumptions used, the calculation formulas, and how a $26/kW-year transmission deferral credit was netted out of the real levelized implementation costs for DR. Because any benefits accruing to transmission are embedded in the transmission rate pressure analysis in this EIS, this deferral benefit was not assumed in power rate analysis.
25	I am writing to you on behalf of the Southern Resident orcas. These salmon-eating whales are starving to death due to the lack of Chinook salmon (80% of their diet). On August 6th, the Center for Whale Research pronounced three more deaths in the Southern Resident populations. One from each pod. L84- Nyssa K25- Scoter J17 - Princess Angeline 73. We have 73 Southern Residents left. Iftheir population drops below 70 then we have lost them for good. Their gene pool will not be able to recuperate after that. You cannot ignore this issue anymore. It is time to do something. Action is their only protection. Please use the 2002 EIS Alternative #4 and breach the lower four snake river dams! These dams kill 8 million young salmon per year. This drives the salmon and orcas closer to extinction. YOU can help change that. The immediate breach of the dams can change that. Breaching does not require congress. YOU have the power. YOU have 73 precious lives in your hands. The eyes of the world are on YOU. Extinction is forever. Please breach the dams.	The EIS acknowledges previous analyses of breaching the four lower Snake River dams. However, the Columbia River System Operations EIS relies on current information to evaluate the tradeoffs associated with dam breach under Multiple Objective alternative 3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. Please also see response to Form Letters 1 and 2.
26	Please use the 2002 EIS Alternative #4 and Breach the lower four snake river dams in 2019!	Please see response to form Letter 25.

Form Letter #	Form Letter Text	Response
27	The salmon, steelhead and orcas will not survive this EIS process. The first step the agencies need to breach the 4 lower Snake River dams THIS year. There is no more time for "studies" that delay action or small steps or other measures. Even though the Bureau of Reclamation, the Army Corp of Engineers and other agencies do not want to breach the dams - this is the needed step for this year 2020 if we want to save those species.	If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes. Please see responses to Form Letters 1 and 22.
28	Dear U.S. Army Corps of Engineers, Thank you for the opportunity to comment on the Columbia River System Operations (CRSO) Draft Environmental Impact Statement (DEIS). I am writing to express my support for restoring the Snake River, a major Columbia River tributary, which is critical if we are to save Columbia River salmon and steelhead from extinction. With 2019 salmon returns dropping to historic lows, we must rethink how we manage the lower Snake River, and the negative impacts of the Lower Snake River dams. Federal agencies have been tasked with developing a plan to save Snake River salmon from extinction. However, the most recent plan outlined in the DEIS written by U.S. Army Corps of Engineers is wholly inadequate and must be dramatically expanded. As proposed, it cannot recover salmon or provide our communities with economic security. Since the final construction of the dams in the 1970s, 28 distinct populations of salmon and steelhead have been listed as threatened or endangered under the Endangered Species Act. Despite decades of habitat recovery attempts at the cost more than $17 billion, salmon have not recovered. Instead of recognizing this expensive failure, the DEIS proposes only minor modification to ineffective and costly plans that have failed over the last 25 years. The Northwest needs smarter solutions based on real science. This DEIS downplays the best scientific information, which shows that restoring the lower Snake River will provide the biggest available boost to increase salmon and steelhead runs. We cannot continue to ignore the historic and current costs to fishing and rural communities and Tribes. They have shouldered the devastating impacts of job losses and reduced revenue from current river operations that have consistently failed to restore healthy fish runs. Because the DEIS is focused on the direct financial costs of restoring salmon and steelhead runs, it ignores the economic benefits of restored fish runs to rural communities and the investments and jobs that river restoration activities would generate for communities up and down the Snake and Columbia Rivers. People throughout the Northwest are calling for a plan that provides a comprehensive solution that addresses urgent and interconnected issues: restoring salmon runs, investing in the economic vitality of local communities and clean affordable energy. I urge federal agencies to revise the DEIS to deliver this plan. We need to restore the Columbia and Snake Rivers so that we have abundant salmon runs and vibrant communities throughout the Northwest. We need a plan that works for people, fish and wildlife alike. Thank you, **Variant Text** • we have options. • we have clean energy irrigation and transportation alternatives. • this deis is only a minor modification to ineffective and costly plans that have failed over the last 25 years. • the region is calling for a plan that includes a comprehensive solution that addresses urgent and interconnected issues restoring salmon runs investing in the economic vitality of local communities and clean affordable energy. • since the final construction of the dams in the 1970s 28 distinct populations of pacific salmon and steelhead have been listed as threatened or endangered under the endangered species act. • however for many populations of pacific northwest salmon that are barreling toward extinction we donatmt have a lot of time. • big policy changes are urgently needed to save iconic salmon runs and deliver real solutions for farmers fishermen ratepayers and northwest residents. • the deis also ignores future savings from eliminating capital operation and maintenance costs for the four lower snake river dams a savings that would total more than 1 billion. • i am calling on federal agencies to revise the deis to deliver what we need today a plan that aligns with what northwest communities need which is a healthy intact river ecosystem that works for people fish and wildlife alike.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative effects from fish modeling results are limited. The effects to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The cultural significance and effects of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries subsection and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries subsection of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Most Section of chapter 3 include a Tribal Interests Section at the end that attempts to summarize issues by topic. The costs to breach the dams and draw down the infrastructure are described in Section 3.19 and in Appendix Q (construction costs of the structural measures).Tables 4-1 and 5-1 in Appendix Q show the costs and cost savings under MO3. There would be approximately $107 million in annual capital and O&M cost savings under MO3 compared to the No Action Alternative for the four lower Snake River projects over the 50-year period of analysis. The cost of breaching the dams, as described in Section 3.19 and in Appendix Q, does not include changes to irrigation or rail infrastructure. The MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. The EIS describes the engineering solutions for irrigation (pipeline extensions, for example) in Section 3.12.3 Environmental Consequences, Region C under the MO3 alternative. The EIS describes that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative, it is assumed that pumps are unable to deliver water to an estimated 47,926 acres. Please see Section 3.12 and Appendix N for additional information. The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing alternative MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the effect of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary

Form Letter #	Form Letter Text	Response
	• i am writing to express my support for restoring the snake river which is a critical action to recover key salmon runs and the communities that depend on them. • despite decades of habitat recovery attempts at the cost more than 17 billion 2019 salmons returns remained perilously low forcing emergency fishing closures a and economic devastation a in washington and idaho fishing communities. • i support restoring the snake river a major columbia river tributary which is critical if we are to save columbia river salmon and steelhead from extinction.	throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The commenter's suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Act's anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation – Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the system's effects on anadromous fish). The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and COMPASS models predict that powerhouse encounters would be cut in half relative to the No-Action Alternative for Snake River spring/summer Chinook salmon. The uncertainty lies in the hypothesis that reduced powerhouse encounters will result in increased adult returns. To address this uncertainty, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Please also see responses to Form Letters 2, 4 and 22.
29	Please consider the following responses as part of my comments to the CRSO EIS The Columbia River and the Lower Snake River Dams are a reliable and economical source of renewable energy that must be retained to meet future challenges such as regional growth and reducing the carbon foot print. Clean, renewable hydropower will be required to adequately recharge the electric vehicles needed to meet current and future mandates. Also, according to the CRSO EIS estimates, the region's electric rates could jump as much as 50% due to breaching and I am opposed to that because I believe that would create an economic catastrophe. While wind and solar energy are an important newer energy source, I believe they will never replace hydroelectric power as an economical substitute. Also, these are unreliable sources of energy requiring a "battery" to offset periods when they are unable to generate power. Dams are the perfect battery since their output is continuously adjustable, thus they can quickly "fill in the blanks" that are caused by wind and solar. Several key dams on the Columbia and Snake Rivers are fitted with locks that allow barges and many other water craft to transit from the Pacific Ocean to as far upstream as Lewiston, Idaho. That barge traffic is critically important to the residents and economy of the Pacific Northwest. The roads and rail lines would be severely overloaded and require rebuilding if the Lower Snake River Dams were breached because the important barge traffic would cease. Public safety would also be degraded by the proliferation of trucks and trains required to offset the loss of barge transportation. The carbon foot print would be also enlarged with the added trucks and trains compared to the more efficient barges. Tens of thousands of acres became irrigated farmland when the Lower Snake River Dams were built. Breaching the dams will dry up those important farmlands. I am opposed to the loss of this irrigated farmland. The recovery of Salmon in Pacific Northwest is important, but the mitigation efforts that have been accomplished and future planned actions without breaching these Dams are the correct approach. There has been 16 billion dollars spent to mitigate the effects of the dams on the fish and habitat restoration. The high salmon survival percentages ·now being recorded at each dam is a testament to the effectiveness of these large investments. Recently the Lower Snake River Dams have been targeted as reducing the population of the Southern Resident Orcas which actually spend half their time in the Puget Sound. The EPA and other agencies have been studying the Puget Sound and its aquatic life for decades. There is a lot of science based data that shows that beside pollution in the Puget Sound, the lack of salmon there is also caused by the numerous blockages to streams which prevent them from spawning. These Puget Sound salmon are important to the Orcas because they are the major source of food for them. Cleaning up the Sound and opening the streams that empty into it which the salmon need to spawn in is the correct solution, not breaching major dams on the Columbia and Snake Rivers.	The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The comment that replacing the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations under MO3. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. The ability of hydropower to aid in grid stability and the integration of renewable power is described in the Bonneville Transmission System Reliability and Operations subsection of Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. Although it is beyond the scope of the EIS to analyze the role of hydropower in achieving specific clean energy goals, the EIS does find that replacing the hydropower generation of the four lower Snake River dams would increase greenhouse gas emissions from power generation. See Section 3.8.3.5, pages 3-1009-1010 in the Draft EIS. The statements regarding the variability of other renewables and the importance of the four lower Snake River dams for integrating new renewables are consistent with the findings and discussions in the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907. The Preferred Alternative identified in the Draft EIS meets the objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System, as well as most other objectives. The MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. The EIS describes the engineering solutions for irrigation (pipeline extensions, for example) in Section 3.12.3 Environmental Consequences, Region C under the MO3 alternative. The EIS describes that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative, it is assumed that pumps are unable to deliver water to an estimated 47,926 acres. Please see Section 3.12 and Appendix N for additional information. The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing alternative MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS evaluates potential effects on farmers

Form Letter #	Form Letter Text	Response
	The other half of the year, the Orcas travel close along the coast between California and South Eastern Alaska. Using satellite tracking tags on salmon, NOAA Fisheries recently made a startling discovery. It has been determined that the Upper Columbia and Snake River salmon after migrating to the ocean spend their time farther from the coast line than the Orcas do during their travels. It would be an unmitigated disaster to breach important power generating dams when the Orcas and the fish that are their supposed food source are not even in the same space. The Orcas number rose significantly in the 1980's and 90's when hatchery fish were reared and released in great numbers. As hatchery operations were scaled back, the Orcas numbers quickly declined. I believe that feeding the Orcas more hatchery fish, because it is a proven management tool makes more sense than crippling our electric grid through breaching. I believe it would be foolish and reckless to begin breaching Columbia or Snake River Dams after the years of work and billions of dollars invested that have brought great success to saving salmon in our region through mitigation and habitat restoration. Furthermore, blaming dams that have no effect on another species such as the Orcas is wrong and counterproductive when the problems exist elsewhere. I fully support the Preferred Alternative to save the Dams as presented in the CRSO EIS. Signed: Date: April 13, 2020	associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the effect of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5. The EIS evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).Under this scenario, up to $10 million in additional road wear-and-tear costs may occur. Actions in Puget Sound are outside the scope of this EIS, which focuses on CRS operations, maintenance and configuration. The US Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. Please also see response to Form Letters 1 and 8.
30	Thank you for the opportunity to comment on the Columbia River System Operations Draft Environmental Impact Statement (DEIS). I believe that breaching the four lower Snake River dams would have an adverse impact on electric cooperative consumers, the reliability of the Northwest power grid, and the environment. The Snake River dams are an integral part of our electricity supply in the Pacific Northwest, supplying power to 900,000 homes each year. The mission of Washington's electric cooperatives is to deliver clean, affordable, reliable electricity to our members. The DEIS concluded that breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." A 50% increase in the Bonneville Power Association's (BPA) rate would be a significant increase to electric cooperative consumers. The people most impacted by these rate increases will be our vulnerable populations---seniors, and those on fixed incomes. We shouldn't ask our members to choose between paying their electric bills or purchasing food and medicine. We also should reject any proposal that will lead to blackouts. The DEIS concludes the dam breaching alternative would "more than double the region's risk of power shortages." The Pacific Northwest has a legacy of clean energy, and according to the DEIS, breaching the dams would create a 10% increase in power-related emissions across the Northwest. The DEIS also noted that federal agencies have made substantial improvements for fish passage at the lower Snake River and lower Columbia River dams. BPA customers have helped fund this multi-billion-dollar effort to improve fish passage at the dams, which is meeting targets of 96% survival rates for migrating juvenile fish. I believe it is important to build upon this successful fish passage program, instead of taking drastic measures such as dam breaching. Thank you for the opportunity to comment on the DEIS.	The comment that replacing the hydropower generation from the four lower Snake River dams will drive up costs in the region is consistent with EIS findings. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. The commenter is correct that without replacement power, MO3, which includes the measure to breach the four lower Snake River dams, would increase the frequency of power shortages. If the lost capability of the four lower Snake River dams are replaced with natural gas, as assumed in least-cost conventional resource portfolios, emissions would increase. The EIS also considered replacing the lost capability of the four lower Snake River dams with a zero-carbon resource portfolio. The zero-carbon resource portfolio consists entirely of zero carbon resources: solar, wind, and storage technologies (i.e., batteries). However, even with new renewable resources, the EIS analysis finds that existing carbon-emitting resources would likely increase generation to integrate the large portfolio of renewable resources, resulting in a new increase in greenhouse gas emissions. This portfolio is described in Section 3.7.3.5, Potential Replacement Resources and Associated Costs, and emissions implications in Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation in the Draft EIS. The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the Preferred Alternative. However, because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability (LOLP) was essentially the same as that of the No Action Alternative. The co-lead agencies thoroughly analyzed the effects of the measure to breach the four lower Snake River dams, including effects to emissions, and did not include the measure to breach the four lower Snake River dams in the Preferred Alternative. The investments of Federal funds for fish passage has delivered the intended results when considered in the appropriate statutory context of the Northwest Power Act's anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation – Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the system's effects on anadromous fish). Please also see response to Form Letter 20.
32	I appreciate your efforts in preparing the draft environmental impact statement for the 14 federal projects on the Columbia River System. I am concerned that breaching the lower Snake River dams is an option under but am pleased that the increased preferred alternative does not include a recommendation to breach any of the dams. I am also concerned that increased spill is under consideration. The Lower Snake River Dams Prevent Blackouts - The lower Snake River dams have already avoided blackouts in my area - the Tri-Cities. Thousands of new homes and businesses will be built here in the next few years. Our economy is growing. Because they can quickly increase energy production, all four lower Snake River Dams have never been more important to avoid blackouts with renewable carbon-free hydroelectricity. Higher Spill is Expensive and Unproven - I urge you to not consider the alternative with the highest spill levels. This approach could increase power rates by 40%, increase carbon emissions and potentially decrease fish survival according to one of the two fish survival models in the draft EIS.	Please see the response to Form Letters 4, 5, and 6.

Form Letter #	Form Letter Text	Response
	The Dams Make Wind and Solar Energy Possible - Without hydroelectricity to fill in the gaps, the grid cannot take the swings in generation caused by fluctuations in wind and sunshine. The Northwest's demand for electricity is highest in the winter when wind is less prevalent and the sun sets early. The Dams Meet Washington's Carbon-Free Goals - Washington state's 2025 Clean Energy Transformation Zero Act carbon (CET A) commits us to a path no coal generation by 2025 and 100% clean energy by 2045. Zero carbon emissions are produced during hydropower generation. The Dams Provide Affordable Electricity -particularly independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesn't consider the loss of coal generation which will also need to be replaced by carbon-free resources to reach CETA goals. A rise in energy costs would worsen our homeless crisis and mean greater hardships for people already struggling to make end meet. The Dams are Just one factor in Salmon and Orca Survival - Salmon from the Snake River are only one part of an orca's diet. Salmon survival rates through these dams are as high as 97%. NOAA Fisheries' analysis shows Puget Sound Chinook salmon are most important for the Southern Resident Orcas. Cleaning the Puget Sound and reducing carbon output would be a better use of time and money in saving our treasured salmon and orca. The Dams Create Tourism, Recreation, Irrigation and Transportation - The lower Snake River dams provide industries, products, flood control and jobs to Northwest residents. The draft EIS is the most extensive study in the history of the Columbia River Basin. It's a collaborative body of work that included significant input form federal agencies, Native American tribes and the states of Idaho, Montana, Oregon and Washington. I am pleased that the report recognizes the importance of the lower Snake River dams and does not recommend dam breaching. I support the preferred alternative of the draft EIS. I also hope the majority of the effort will be placed where the majority of the fish survival problems occur - in the ocean and Puget Sound. **Variant Text** • a rise in energy costs would worsen our homeless crisis and mean greater hardships for people already struggling to make ends meet. • i am concerned that breaching the lower snake river dams is an option under consideration but am pleased the preferred alternative does not include a recommendation to breach any of the dams. • several independent studies indicate a shortage of electricity generation in the coming years particularly with the closure of coal plants • its a collaborative body of work that included significant input from federal agencies native american tribes and the states of idaho montana oregon and Washington. • i urge you to not consider the alternative with the highest spill levels. • the lower snake river dams provide industries products flood control irrigation water to agricultural products and jobs to northwest residents. • the dams provide affordable electricity several independent studies indicate a shortage of electricity generation in the coming years particularly with the closure of coal plants. • noaa fisheries analysis shows puget sound chinook salmon are most important for the southern residents • army corp of engineers the bureau of reclamation and the bonneville power administration i appreciate your efforts in preparing the draft environmental impact statement for the 14 federal projects on the columbia river system.	
	I am writing to give my support to save our dams. I feel it is important for our environment and for our economy. They do not appear to have any impact on salmon from the Snake and Columbia River dams. The dams are certainly important for the farmers and general economy and provide the cleanest transportation "highways" as compared to rail, trucking, pipe lines etc. The dams cannot be held responsible for what happens in the ocean before the fish arrive in the river or the gill netting by the Indians. I appreciate having our dams and the abundant clean electricity they provide. I cannot see where the protesters even have an argument. Washington state is already one of the most environmentally clean states in the union- perhaps it is the cleanest. Gas fired plants will never be as "clean" as dams. Wind power is so unreliable. I prefer to have electricity 100% of the time, not sporadically. I feel the "greenies" should "clean up their own backyard first". Most of the decreased salmon population is due to problems at the ocean and the gill netting in the rivers. The fish ladders on the Snake River are state of the art. Thank you for giving me an opportunity to give my opinion.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS estimates the costs to operate the CRSO dams, as well as the costs to the navigation and transportation industry that would be occur if the lower Snake River dams are breached under MO3 as part of this broad analysis that aims to balance the objectives of the agencies for the system. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options

Form Letter #	Form Letter Text	Response
		at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including gill netting. Research continues to evaluate the magnitude of these effects. For more information see the NOAA Fisheries website at: https://www.nwfsc.noaa.gov/research/index.cfm. Harvest certainly has an effect on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
34	Dear Bonneville Power Administration, U.S. Army Corps of Engineers, and Bureau of Reclamation, I'm writing to comment on the draft environmental impact statement for the Columbia River system and specifically in support of Alternative 3, which includes breaching all four lower Snake River dams. Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly one million adult Chinook salmon returning to the mouth of the Columbia River, providing significant relief for endangered Southern Resident orcas. As you know Chinook salmon are the orcas' primary food source from central California to the Salish Sea, and the Columbia Basin supports salmon runs that the orcas have relied on for centuries. Historically half of all the salmon returning to the Columbia Basin were bound for the Snake River. But after the river was dammed more than half a century ago, the wild salmon runs plummeted and left the orcas with fewer fish to eat. Despite the fish ladders and our current interim spill measures, dams continue to cause serious salmon declines by directly killing and preventing their migration. Breaching these dams will cut dam-caused mortality by at least 50%. What's more, these dams have flooded miles of spawning habitat, destroyed healthy riparian forests, and created lethal warm-water reservoirs. With climate change, the number of days where temperatures will reach deadly levels are expected to increase.By removing these dams, we'll also increase salmon access to more than 5,500 miles of free-flowing, climate-resilient, federally protected spawning habitat in northwest Oregon, southeast Washington and central Idaho. And doing so will deliver tremendous economic, ecological and cultural benefits to the region and nation. Removing the dams, of course, will require both state and federal governments to invest in infrastructure that eases the transition for farmers and communities that rely on these dams. But it's an essential endeavor. Investments in rail infrastructure, irrigation pipes and renewable energy will ensure a just transition for the region and help support salmon and orca recovery. There's not a moment to lose. Southern Resident orcas are among the most endangered mammals on the planet, and they're starving to death with only 72 individuals left in the wild. While the orcas also face threats from vessel noise and contamination, breaching the four lower Snake River dams is the most significant action the federal government can take right now to restore salmon runs and orcas' most valuable food source. Please breach the four lower Snake River dams. Sincerely, **Variant Text** • investments in rail infrastructure irrigation pipes and renewable energy will ensure a just transition for the region and help support salmon and orca recovery. • by removing these dams well also be increasing salmon access to more than 5500 miles of free flowing climateresilient federally protected spawning habitat in northwest oregon southeast washington and central idaho. • but its an essential endeavor. • as you know chinook salmon are the orcas primary food source from central california to the salish sea. • and the columbia basin supports salmon runs that the orcas have relied on for centuries • im writing to comment on the draft environmental impact statement for the columbia river system and specifically in support of alternative 3 which includes breaching all four lower snake river dams. • doing so will deliver tremendous economic ecological and cultural benefits to the region and nation • the columbia basin supports salmon runs that the orcas have relied on for centuries. • by removing these dams we will also be increasing salmon access to more than 5500 miles of free flowing climateresilient federally protected spawning habitat in northwest oregon southeast washington and central Idaho	Neither the modeling conducted for the CRSO EIS, nor Fish Passage Center modeling conducted outside the EIS process, indicates that breaching the four lower Snake River dams would result in 1 million adult Chinook salmon returning to the mouth of the Columbia River. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species' survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS concluded MO3 would result in greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. The CRSO EIS evaluated improvements to fish ladders in the Multiple Objective Alternatives. Fish ladders are proven effective at moving adult fish upstream at the dams that have them. The four lower Snake River and four lower Columbia River dams have fish ladders that safely and effectively pass millions of adult salmon upstream. Adult upstream passage success through these dams is relatively high, generally around 90% from Bonneville to Lower Granite dam. In addition to passing up to 60,000 salmon per day, some of these dams may pass upwards of 250,000 shad in a single day. As described in Section 7.6.2, the Preferred Alternatives includes the Bonneville Ladder Serpentine Weir Modification measure that is expected to reduce stress and delay for adult salmon, steelhead and bull trout and has the potential to increase adult salmon and steelhead survival by reducing upstream passage time at the dam. The Draft EIS does indicate that breaching dams would increase the Smolt-to-Adult ratio by approximately 10%, not the 1 million indicated in the comment. Breaching the dams and increasing the spill to 125% along the Lower Columbia is not possible and maintain the power generation load currently maintained by the CRO. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species' survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. It is well understood that the CRS dams have an effect on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS document. A system water quality model was developed to look at water temperature and TDG effects throughout the Columbia and Snake River system for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly, in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. However, the co-lead agencies do not currently have the authority to provide for those investments in rail or road infrastructure. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS

	• southern resident orcas are among the most endangered mammals on the planet and they are starving to death with only 72 individuals left in the wild. • there is not a moment to lose. • these dams have flooded miles of spawning habitat destroyed healthy riparian forests and created lethal warmwater reservoirs. • removing the dams will require both state and federal governments to invest in infrastructure that eases the transition for farmers and communities that rely on these dams. • but it is an essential endeavor. • chinook salmon are the orcas primary food source from central california to the salish sea. • with climate change the number of days where temperatures will reach deadly levels is expected to increase • scientists from the fish passage center have stated that breaching all four of these dams would result in roughly 1 million adult chinook salmon returning to the mouth of the columbia river. • after the river was dammed more than half a century ago the wild salmon runs plummeted and left the orcas with fewer fish to eat. • these dams kill up to 50 of juvenile salmon before they even reach the ocean and are roadblocks to adult salmon returning home to spawn. • as you know chinook salmon are the orcas primary food source from central california to the salish sea and the columbia basin supports salmon runs that the orcas have relied on for centuries. • removing the dams of course will require both state and federal governments to invest in infrastructure that eases the transition for farmers and communities that rely on these dams but its an essential endeavor. • furthermore these dams have flooded miles of spawning habitat destroyed healthy riparian forests and created lethal warmwater reservoirs. • federal tribal and independent scientists concluded years ago that removing these four dams is the best way to restore the areas wild salmon. • breaching the four lower snake river dams is the most significant action the federal government can take right now to restore salmon runs and orcas most valuable food source. • in addition these dams have flooded miles of spawning habitat destroyed healthy riparian forests and created lethal warmwater reservoirs. • while the orcas also face threats from vessel noise and contamination breaching the four lower snake river dams is the most significant action the federal government can take right now to restore salmon runs and orcas.	objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes. Please see response to Form Letter 1.
35	Dear U.S. Army Corps of Engineers, Bureau of Reclamation, and Bonneville Power Administration, Thank you for the opportunity to comment on the Columbia River System Operations (CRSO) Draft Environmental Impact Statement (DEIS). I am writing specifically out of concern for the endangered Southern Resident orca population, a unique community of fish-eating orcas that lives off the west coasts of the U.S. and Canada. The DEIS fails to adequately address the connection between Columbia and Snake River salmon and Southern Resident orcas, and the impact that declining salmon abundance has on their survival. As salmon specialists, the main component of the Southern Resident orcas diet is Chinook salmon, and they have depended on the regions historically abundant Chinook runs for millennia. [1] The Columbia Basin is still a significant source of food for Southern Resident orcas, particularly in the winter and early spring when the orcas are foraging in coastal waters. They are highly likely to be off the mouth of the Columbia River, recognized as a high use foraging area, when early spring Chinook are returning. Analysis of prey and fecal samples collected from the Southern Residents orcas in coastal waters indicate that over half of the Chinook consumed are from the Columbia River Basin. [2] As Chinook salmon abundance has declined throughout the Pacific Northwest and California, the orcas have suffered. Scientists have found a strong correlation between coastwide Chinook abundance and Southern Resident health indicators: declining Chinook abundance leads to reductions in growth rates, adult length, social cohesion, fecundity, and survival, as well as impaired body condition in Southern Resident orcas. [3] It is clear that the orcas do not have enough to eat, that nutritional stress has severe impacts on the population, and that recovery of Columbia Basin salmon is essential to ensure their survival. Independent salmon scientists, the National Oceanic and Atmospheric Administration, and this DEIS itself have all determined that breaching the Lower Snake River dams is the best way to recover sustainable wild runs of Snake River spring/summer Chinook salmon. [4] However, the Preferred Alternative offers only a minor adjustment to the status quo, which will not be enough to recover endangered salmon or orcas. Therefore, to support the recovery of the endangered Chinook salmon stocks that Southern Resident orcas rely on, the action agencies should implement measures that maximize salmon survival a combination of Alternative 3, breaching the Lower Snake River dams, and Alternative 4, implementing flexible spill levels up to 125% Total Dissolved Gas throughout the migration period for juvenile salmon. These measures are predicted to	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and MO4, individually each caused large LOLP results (e.g. increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest effect during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more

Form Letter #	Form Letter Text	Response
	result in the greatest improvements in salmon survival and have the highest likelihood of meeting recovery goals for endangered salmon, resulting in increased abundance available to Southern Resident orcas. This action must be accompanied by continued support and investment in salmon recovery and habitat protection and restoration throughout the range of the orcas. Efforts by state and federal leadership are needed to develop and implement a transition plan to support communities that currently rely on the Snake River dams, and to replace them with carbon-free energy alternatives. The Southern Resident orcas face a multitude of threats, but a lack of Chinook salmon is the primary limiting factor for their survival and recovery. They need abundant and available food high-fat and nutritious Chinook salmon year-round. Breaching the Lower Snake River dams is a vital step for restoring abundant salmon in the Pacific Northwest to support Southern Resident orcas, and rebuilding a healthy watershed to support regional ecosystems and communities.	than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire United States by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the effects of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability effects, and it is highly speculative that replacement resources could be sited, permitted and built to address these effects. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. Please see response to Form Letter 1.
36	Dear CRSO worker, Federally endangered Chinook Salmon & Southern Resident Orca whales will not survive this EIS process. Dam breaching, you've concluded in your own research, is a reliably effective way to restore salmon runs, as seen on the Elwha, Sandy & other rivers. Before dam construction in the 30s, anadromos (from ana-'up' + dromos 'running') fish runs on the Columbia, 'Great,' River were in the millions. Not only salmon (large & in the millions). But also lamprey, an eel easily harvested coming up small waterfalls. Steelhead. Sturgeon. All in numbers that sustained a thriving indigenous population, one of the wealthiest west of the Rockies. Today the Orcas are actually hungry. Today. Chinook salmon fishing on the lower Columbia has been completely shut down for 2 years because numbers are so low. I, as a resident of the (your river here) watershed, call upon the EIS team to breathe deep in this time of pandemic & think about the big picture. TODAY WE DON'T NEED A SEAPORT IN LEWISTON, IDAHO. The port today is rarely used. We should support piping projects for local agriculturists & farmers. The public is subsiding salmon passage (barging, trucking, ladders, maintaining bypass systems) while the power & transportation benefits the dams provide maintain an outdated status quo. The 4 LSR dams do not provide peaking power due to low flows & fish passage limitations, providing only 3.5% (or less) of Oregon's electricity, a number easily made in solar, wind, or mindful Christmas lighting.;) Wild spawning Chinook salmon are a millennia-old genetic stock. They used to come in as big as labradors, sustaining some of the wealthiest indigenous cultures, those of the Salish Sea & 'Nick'i-wana' Great River (Columbia). Please help keep them alive, for our grandchildren's grandchildren. In appreciation of your attention,	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads' numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. If MO3 were selected as the Preferred Alternative, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps' Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. Breaching of the four lower Snake River dams under Multiple Objective alternative 3 (MO3) would have a direct and substantial effect on the supply of Federal power to meet regional load requirements. These effects would reduce both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System. These dams provide over 1,000 aMW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage, with over 2,000 to approximately 2,300 MW of capability in certain months of the year. Table 3-160 of the Draft EIS presents the historical sustained ramping capability of the four lower Snake River dams, peaking that occurred within the normal operating range and without drawing the reservoir below MOP. Please see the response to Form Letter 1.
