5473	1	vicredding@sbcglobal.net	N/A	It does not appear that enough consideration has been given to the cost/benefit of removing the 4 Lower Snake River Dams, thus the DEIS is incomplete and not responsive. Rather than litigate this which is certainly the outcome if using this inadequate document, I request further study be completed.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level, which is a different charge than the referenced study. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making consistent with NEPA (see 40 C.F.R. 1502.23). Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
5495	1	N/A	N/A	Thriving shipping and recreation industries along the Columbia River at Umatilla, Irrigon and Boardman would be adversely affected by dam removal or river drawdowns in the inland Northwest. Regarding the impact on UECs residential members, our incomes are lower and poverty rates are higher than in urban areas. Many of our members have fixed or low incomes, and absolutely do not have the budget flexibility for rate increases of 25%.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects Section in Section 3.10.3.5. Information regarding expected effects from MO3 to recreation are discussed in Section 3.11. Additionally, the comment indicating increases in electricity costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 of the EIS) provides further detail on this as well as the potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment.
5495	2	N/A	N/A	Without the lower Snake River dams, the region would likely have no other alternative than to build fossil fuel combustion plants to replace the lost generating capacity and avoid blackouts. This would increase regional CO2 production at a time when state and federal regulators are cutting emissions through Renewable Portfolio Standards and other restrictions.	The EIS considers two scenarios for replacing power from the four lower Snake River dams. One scenario considers developing or acquiring natural gas resources to offset losses from the four lower Snake River dams. This results in a 3.3 MMT CO2 increase in greenhouse gas emissions under MO3 (a 8.9 percent increase in regional power sector emissions). Another scenario considers all renewable replacement resources (at a higher cost as discussed in Section 3.8). Under this scenario, the analysis finds a 2.7 percent increase in regional CO2 emissions relative to the No Action Alternative. The analysis finds that, under MO3, both replacement resource scenarios make emissions reductions targets more difficult to achieve.
5495	3	N/A	N/A	Regarding the Preferred Alternative, please note UECs ongoing concern about the efficacy of increased spill up to 125% of dissolved gas levels. The possible harmful effects and additional costs to ratepayers must be further analyzed.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia River Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
5512	1	kellshan@hotmail.com	N/A	During the call, I also was reminded of the lack of truth to the EIS report, specifically stating that our SRKW will be slightly impacted. This does not align at all to the research conducted by Dr. Giles and many other orca specialists. We know, specifically, our resident orca rely on WILD Chinook salmon, in fact, they rely on 547,500 wild Chinook salmon per year to survive, yet NOAA and the Pacific Salmon Commission have allocated ZERO to the SRKW. Cynically, one could say that it is due to false reporting and downplaying of the true impacts of functional extinction of of Wild chinook, such as the misreported impact in the EIS draft. In fact, the draft should state that the lack of fish is the NUBMER ONE impact that is impeding their survival is food! We know this, as our transient orca are thriving, in spite of the pollution, boat traffic, and all other topics where blame has been falsely misplaced. We know the number one issue is food security.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run,

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
5513	1	grooovyjake@gmail.com	N/A	The failure of this DEIS to meet legal requirements should be no surprise to anyone involved in drafting the document or even the most casual reader. Because the agencies fail to set goals for themselves commensurate with what is expected of a managing agency by the Endangered Species Act, even a perfect application of the preferred alternative would land the agencies back in court for a sixth time. Citizens of a nation that upholds the rule of law expect better from their government - they deserve better. The obvious shortcomings of the DEIS are not merely a threat to salmon and orca, they are a direct affront to the intelligence of the citizens of this nation. I am of course referring to the objectives that the agencies have set for themselves. By setting out to improve survival of salmon, lamprey, and resident fish, the agencies have started from a point of failure. Improvement is not recovery. It is the obligation of the agencies in compliance with the Endangered Species Act to recover endangered salmon and steelhead, not merely improve their chances of survival. The preferred alternative set forth in this DEIS draws heavily from the 2008 BiOp and establishes a survival goal of 96% for juvenile out migration at each dam in the Spring, and 93% juvenile survival at each dam in the summer. While that might sound like an impressive survival rate, when multiplied eight times to account for all eight dams that Snake Basin salmon and steelhead smolts must traverse, that figure becomes a 32 - 56 % mortality rate across the system. Allowing for that level of mortality at the projects themselves, not to mention the mortality that occurs at other points in the reservoir chain will never achieve the smolt to adult return rate (SAR) required for recovery in the Snake Basin. As a management plan, this leaves the door wide open for failure if any of the conditions outside of the agencies control lead to increased mortality elsewhere in either the ocean or tributaries. At best, this plan will result in a stabilization of the population at its current level. At worst it will lead to extinction.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, the survival through the dams estimates are put in context in the draft EIS on page 301: "To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CRS. Figure 3-112, shows recent estimates of survival at the eight lower CRS projects with fish passage. The dam survival estimates do not include systemwide or latent effects (see section 3.5.3.1). These estimates were developed to show progress towards meeting the individual dam survival goals developed during the 2008 Biological Opinion of 96 percent survival past each dam for yearling Chinook and steelhead, and 93 percent for Snake River sub-yearling fall Chinook." Later in this section (referenced in the quotations above) the Chapter 3 analysis discusses system survival rates, as well as latent mortality. The analysis of alternatives presented in-river system survival, which reflects the commenter's 'cumulative losses', and SARs (for those populations which could be modeled), among other metrics. The analysis of alternatives presents estimates of survival rates from Lower Granite to Bonneville dam (eight dams) for Snake River spring/summer Chinook and Snake River steelhead from two different models, with the estimates ranging from 40-60%. The mechanism and magnitude of latent mortality are not well understood, as presented in the discussion of Independent Scientific Review on Page 381.
5513	2	grooovyjake@gmail.com	N/A	In addition to the inadequacy of the 96% survival goal, this benchmark provides a convenient bit of misinformation in the halls of Congress and in the media as anti-salmon commentators and Congresspeople hold up the survival goal as if it were an SAR value. Congresswoman McMorris Rodgers has said several times on the record that salmon survival is at 96% when in fact the SAR is less than 2%. This misconception is not directly the responsibility of the agencies, but the failure of Reclamation and ACOE officials to clarify these terms when they are called to testify in Congressional hearings demonstrates either a shared misunderstanding of the facts, or an intention to propagate the spread of misinformation that justifies inaction on the part of the agencies.	The per-dam survival metric is both accurate and useful in measuring changes in near field survival at the dams due to structural modifications (e.g., surface passage routes) or operation changes (changes to spill levels or spill patterns). The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past 10 years has been shown to contribute to improvements in total in-river survival of smolts migrating through the CRS, especially for steelhead. These figures were used to provide context in the Affected Environment section. The focus of this EIS and the analysis presented throughout this EIS in Section 3.5 and Chapter 7 hinged around several metrics, including total in-river survival, travel time, powerhouse passage rates, and Smolt-to-Adult return (SAR) rates. It should be noted that the 2-6% SAR target referenced in this comment refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
5513	3	grooovyjake@gmail.com	N/A	Within the DEIS there is an alternative that--if implemented--could keep the agencies out of court. This is MO3 - the dam breaching alternative. Study of this alternative was the sole basis for restarting this process back in 2016, yet despite three years and plentiful publicly available data from decades of study by both government and private parties, the agencies failed to honestly consider this option and have not selected it as the prefered alternative. The data shows that which is perfectly obvious to observers of river recovery efforts around the globe: dam breaching provides great benefit to anadromous fish. Dam breaching results in the best SAR (4% or higher) because without the dams in place, the benefits of cold water being infused from the Clearwater and Salmon Rivers would be felt all the way down to Pasco, rather than merely cooling Lower Granite pool. I have observed the forebay temperatures on a daily basis at each of the Snake Dams. Summer release from Dworshak dam only affects the temperature of one of the four reservoirs. If that water was allowed to flow unimpeded, this cold water would spread much further and could even improve SARs in the Umatilla and Yakima Rivers. Yet this alternative was not selected, due to increased cost and potential instability of power production and transportation. These outcomes are the result of a mandate to replace both production and storage of power equivalent to the dams operating at their peak. This study was done assuming that the power storage that the dams provide by impounding water would need to be replaced with lithium battery storage--an extremely expensive method. I am not an expert on the energy front, so I will direct whoever is reading this to consult the comments of the NorthWest Energy Coalition and the 2018 study conducted by Energy Strategies.	The co-lead agencies disagree with the comment that the agencies failed to consider dam breaching in the analysis of alternatives. MO3, which includes breaching the four lower Snake River dams provides substantial potential benefits for Snake River salmon and steelhead than any other measure analyzed, and the effects of the various alternatives, including Smolt-to-Adult returns, are discussed in detail in Section 3.5. These benefits could contribute to recovery of these species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects. Thus, in the draft EIS, the co-lead agencies did not identify MO3 as Preferred Alternative, and instead identified an alternative that is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Although the EIS generally used resources identified by the Northwest Power and Conservation Council as primary resources in their 7th Power Plan, the EIS did look at battery storage because it is a rapidly evolving technology and will be considered a primary resource in the Council's 8th Power Plan. The Council has released draft pricing information for battery storage, and the EIS uses these prices in the final EIS. The comment cites the Northwest Energy Coalition (NWEC) report by Energy Strategies. As described in the draft EIS in Appendix H, Power and Transmission and Section 3.7.3.5, the EIS considered the NWEC study cited in the comment, but it is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. Further information on batteries, however, is available in the response to the comment from NWEC and in Appendix H, Section 2.2.
5513	4	grooovyjake@gmail.com	N/A	As for the transportation angle, the study conducted by ECONorthwest resulted in a much lower price tag for rail and truck replacement. The general public has been mislead by a few members of Congress and interest groups like Northwest River Partners to believe that replacing barge transportation would mean that a fleet of trucks would drive from Lewiston to Portland every day, when in fact truck traffic would not need to be any heavier than what is currently required to carry farm products to the river corridor. The fact that the trucks would be traveling to a rail loader instead of a port does not change the overall number of trips made. The operating budget of the barge system and the construction of expensive salmon and lamprey bypass systems, coupled with some funding from State and Federal governments and private contributions by railroad companies could easily cover the cost of that infrastructure that would be required to make a smooth transition away from river traffic.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.
5513	5	grooovyjake@gmail.com	N/A	What was not adequately considered when weighing the costs of dam breaching against the benefits of keeping the dams in place, was the fishing economy. Whole towns in Idaho like Orofino survive on the basis of a reliable steelhead fishing season bringing in tourists. Coastal towns from Astoria, OR to Sitka, AK are reliant on salmon fishing for an income and a way of life. Fishermen all along the west coast catch salmon from hatcheries in the Columbia-Snake Basin.	Chapter 7, Preferred Alternative, describes the process to select the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. Where possible, these effects were monetized or quantified. Consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Hatchery contributions are considered in the analysis. As described in chapter 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels." Although Bonneville's funding of the Lower Snake River Compensation Plan hatcheries would no longer be authorized, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
5513	6	grooovyjake@gmail.com	N/A	Causing the decline of steelhead to the point that members of the Nez Perce Tribe cannot catch a single fish, let alone enough to sustain themselves, is a violation of the Treaty of 1855 which was upheld as the supreme law in 1985 and again in 2018.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative
5513	7	grooovyjake@gmail.com	N/A	Any analysis that prefers the production of electricity and one form of transportation over the fishing economy and the legal and moral obligation that we have to the tribes is deeply flawed. Regardless of how the study is conducted as to the cost-benefit of hydropower, water supply, transportation, and fish survival, the fact that the agencies have engaged in a weighted process that does not hold species recovery as an absolute requirement of the final plan means that the plan will be ruled inadequate and illegal once again. The Endangered Species Act does not allow room for economic considerations to be weighed against species recovery. Unless the God Squad is invoked, the managing agencies are legally bound to pursue efforts to achieve recovery, not merely improved survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
5517	1	N/A	N/A	While the preferred alternative looks at spill, I dont think spill is a viable option. Spill causes turbulence which creates dissolved nitrogen in the water leading to nitrogen supersaturation. Too much nitrogen is lethal to fish as it causes gas bubble disease. Relying on an increase in spill for safe fish passage is not reasonable since it creates a new problem the fish must overcome.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
5533	1	Kristin Masteller	N/A	The electricity generated by the Snake River dams is mostly used by consumer-owned utilities like mine in rural communities. And the cost of replacing that power from the dams would hit my utility and customers disproportionately, as much as 25 percent is the projection. So basically, a senior citizen making $800 a month on Social Security who already struggles to pay their $200 power bill in January, would then have to contend with the decision to either pay another $50 a month to keep their lights on and stay warm or buy food and prescriptions.	The concern surrounding potential increases to electricity costs under MO3, which includes breaching the four lower Snake River dams, is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Table 3-166. The Environmental Justice analysis in Section 3.18.3 provides further detail on potential disproportionate effects to tribal, low-income, and minority populations under MO3. MO3 was not identified as the Preferred Alternative in the Draft EIS.
5538	1	Mark Busto	N/A	The DEIS, in our opinion, perpetuates an approach that has pushed salmon, orca, and other fish and wildlife populations to the edge of extinction. This approach has been extremely costly and it's been deemed illegal five different times. It has harmed fishing communities on the coast and inland, reducing fishing opportunity, fishing jobs and fishing income for both tribal and non-native peoples.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. This EIS has been developed in consultation with National Marine Fisheries Service and U.S. Fish and Wildlife Service to find an acceptable balance that allows the co-leads to meet the stated Purpose and Needs Statement while minimizing impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The Preferred Alternative is not simply a continuation of the status quo. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Regarding Southern Resident killer whales, the EIS determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. For additional information on the effects to Other Fish, see Sections 3.5 and 7.7.4; Wildlife effects, Recreation, see Section 7.7.13; and for Fisheries, see Section 7.7.17 in the EIS. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
5541	1	Dave Hagen	N/A	Clearwater serves some of the most remote and sparsely populated areas within Northern Idaho. The state of Idaho is one of the fastest growing states in the nation. Unfortunately, Clearwater Power has not enjoyed the same. In fact, over the last five years, Clearwater Power has added less than 100 new customers per year on average, and Clearwater weather-adjusted energy sales have declined approximately seven percent over the same period. Because of very slow account growth, declining sales, rising cost, including the wholesale cost of power from the Bonneville Power Administration, Clearwater has the highest retail residential rates in the state of Idaho. In 2019, the wholesale cost of power accounted for 43 percent of our members'	The comment expresses concerns regarding potential cost pressures to rural public utility customers of Bonneville. The EIS examined potential retail rate effects to both rural and urban end users, Chapter 5 of Appendix H describes this analysis in additional detail. In developing a Preferred Alternative, the co-lead agencies considered the need for an adequate, efficient, economic and reliable power supply, and to provide benefits to salmon, steelhead, and resident fish while meeting the EIS objectives for water management and water supply. The Preferred Alternative shows a rate impact relative to the No Action Alternative of 2.7 percent, which is among the smallest impacts to rates considered in the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				monthly power bill. As the single largest expense of providing safe, reliable, and affordable power to our member owners, the ability of the Federal Action Agencies to control their cost is imperative.	
5541	2	Dave Hagen	N/A	The four lower Snake River dams provide more than 2,000 megawatts of peaking capability and play an important role in maintaining reliability in the region. As some of the lowest cost carbon-free generation in the Northwest, their flexibility and dispatchability are valuable components of the FCRPS. Their removal would more than double the risk of regional blackouts and would have a tremendous social economic impact on the region.	The comment about the importance of the four lower Snake River dams for regional power reliability and the integration of renewable power are consistent with the EIS findings. Please see Draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907.
5542	1	Debra Ellers	N/A	Both scientists and the agencies know the lower Snake River dams are the major problem with restoring wild fish runs, not the other dams in the system. The lower Snake River dams and their stagnant reservoirs are cutting off salmon migration to and from the 5,500 miles of pristine spawning habitat above them. Including the other dams has been a waste of taxpayer time and agency resources.	The scope suggested by this comment would inappropriately narrow the examination of the broader operation of the Columbia River System. The co-lead agencies descriptions of the Purpose and Need Statement and scope of the project are in Sections 1.2 and 1.3 of the EIS. The co-lead agencies recognize that the maintenance and operation of dams in the CRS creates effects to salmon and steelhead populations in the Columbia River Basin. However, the co-lead agencies also recognize that there are many stressors to these fish populations from outside the CRS. These include, poor ocean conditions, harvest, and access to habitat. Current ocean conditions have limited adult returns up and down the west coast regardless of migration impediments. The commenters assertion that the four lower Snake River dams cut off salmon from thousands of miles of habitat is in error. All four dams have fish passage with high adult passage rates with conversion rates and juvenile survival rates in the mid to high 90 percent range. In the recent screening conference held in Walla Walla this past year, Washington, Oregon and Idaho reported that between 70 and 80 percent of tributary habitats in their states had access issues either from perched culverts, unscreened irrigation returns, or blockages. A study conducted on one stream in the Salmon River Basin reported that nearly all fish emigrating downstream were diverted in irrigation withdrawals. Thus, other passage barriers may be preventing access to these habitats.
5542	2	Debra Ellers	N/A	The DEIS is an even bigger fail on recovering the Southern Resident orcas. It uses outdated data and science dating back to 2008. It ignores the more recent scientific knowledge about the importance of Snake River Chinook to our starving Southern Resident orcas. These orcas rely on the nutritious salmon from the Snake River at key times of the year. Their numbers have been reduced to just 72. The best available science says that breaching the four lower Snake River dams gives these orcas a meaningful chance for recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of National Marine Fisheries Services (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKW), along with vessel traffic and noise, toxic contaminants. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Sections 3.6 and 7.7.8 discuss the effects to SRKW from the multiple objective alternatives, including the Preferred Alternative. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the effect from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
5542	3	Debra Ellers	N/A	Regarding power and transportation, the cost associated with the Snake River dams are exaggerated and the benefits understated. Billions of taxpayer dollars have been spent in the last few decades trying to improve fish patches, and it's been a big fail. It's time to admit we can't engineer salmon passage for the lower Snake River dams, and let Mother Nature do it with a free-flowing Snake River dam. With a free-flowing lower Snake River, we're talking about weighing the loss of irreplaceable species like salmon and Southern Resident orcas, while we have alternatives for barging and power. Improving railroads to give farmers increased flexibility for shipping their crops instead of keeping the highly taxpayer-subsidized barging would be a win-win for farmers — and the public. Improved trains would bolster our supply chain and transportation system.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Moreover, not all effects of dam breach are monetized in the EIS, but unquantified effects are nonetheless considered in decision making. The analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short-term. A description of the effects to navigation and transportation can be found in Section 3.10. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of National Marine Fisheries Services (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Based on the EIS analysis, the Preferred Alternative (PA) will make a substantial contribution to improving Snake River anadromous fish runs. The CSS model predicts that average Smolt-to-Adult return rates (SAR) would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the PA, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
5542	4	Debra Ellers	N/A	Finally, breaching the four lower Snake River dams, MO-3 provides the best option for honoring tribal rights and restoring cultural sites for native people. The lower Snake River dams were a gross violation of sovereign rights.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Chapter 7 provides the effects analysis on Cultural Resources and Indian Trust Assets, Tribal Perspectives, and Tribal Interests, in Sections 7.7.18 and 7.7.19 in the Draft EIS, respectively. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
5544	1	brianbrooks59@msn.com	N/A	We've been learning quite a lot over the last year about what we need for our fish to survive. And the key indicator of recovery is reaching a two to six percent smolt-to-adult return ratio, or SAR. A two percent SAR will keep the fish at a plateau, not recovering them, but just keeping them sustained at the same level. A four percent average is what is considered healthy and harvestable, an abundance that allows meaningful harvest for tribes, sportsmen, and the outfitting industry here in Idaho. The preferred alternative, unfortunately, fails on several fronts for Idaho anglers and outfitters and guides. By the acting agencies' own admittance, the smolt-to-adult return ratio for Idaho stocks under these preferred alternative, will only reach two percent, one out of every three years, ensuring we remain on extinction trajectory.	Based on the EIS analysis of the Preferred Alternative (PA), it will make a substantial contribution to improving Snake River anadromous fish runs. Broad recovery goals are beyond the scope of the EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used current, high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SAR) would increase for both Snake River spring Chinook and steelhead and would average above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the PA. The co-lead agencies disagree with the comment that a SAR rate of 2% will only maintain a population. A SAR rate of 2% can lead to significant population growth given adequate productivity and habitat quality.
5544	2	brianbrooks59@msn.com	N/A	Further, the DEIS did not even account for the economic impact of fishing in Idaho. In one good year, the town of Riggins made $40 million in primary and secondary spending from just one season of good returns. With steelhead season closure last year, Clearwater County lost $8 million a month just on steelhead. We have economic data; and it's omissions from the DEIS is, quite honestly, mind boggling. When that was presented to the Governor's Workgroup, it was pretty confusing why that was left out.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and Tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. The National Marine Fisheries Service (NMFS) estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million; $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 in Section 3.11.3.5 along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
5544	3	brianbrooks59@msn.com	N/A	By their own strategic plan, BPA has stated that they will reach their federal borrowing cap by 2023. And the only way they've extended it so long is by spreading the federal debt to private debtors totaling over $15 billion in debt. That does not sound like financial solvency. In fact, the impacts of their financial situation has already resulted in less money going towards fish mitigation projects in Idaho, when, arguably, we need more money for fish than ever. That has been clearly communicated to the Governor's Workgroup. BPA charges $36 per megawatt hour, while their competitors charge $22 per megawatt hour on the wholesale market. PUDs and other customers are leaving. One PUD in Idaho is investing in new transmission lines to leave BPA behind for another producer. Those who stay behind with BPA will be forced to incur the new cost for every PUD that leaves.	The comment incorrectly suggests that the wholesale spot-market price for power (here described as $22/MWh) is equivalent to the firm power provided under Bonneville's long-term power sales contracts for $36/MWh. The $22/MWh spot market purchase is for market energy purchases from the wholesale power market for surplus energy. It does not ensure availability nor deliverability, and is not suitable for load service, i.e., service to a load in any amount at all times. It is suitable only for buying and selling around firm load and resource forecast error, and for reducing system and fuel costs where more optimal and lower cost dispatch of energy resources is possible. Bonneville's long-term power sales are sold at a rate that is designed for firm load service; it ensures that what is needed is provided regardless of weather, hydrologic conditions, load, wind, market depth, or solar variability. Moreover, the carbon content of the Federal system, which is almost entirely carbon free, is not comparable to market purchases with the regional carbon mix, which contains a substantial amount of carbon-emitting resources (such as coal and natural gas). Regarding Bonneville's debt, Bonneville uses U.S. Treasury borrowing authority, non-Federal and other sources to fund Bonneville's ongoing capital program. Bonneville signaled in its Strategic Plan that, barring no changes, Bonneville would exhaust U.S. Treasury borrowing authority by 2023, so Bonneville's plan was to look at all available options to ensure U.S. Treasury borrowing would not be exhausted. For example, Bonneville recently made additional payments, through Transmission rates, to reduce the outstanding principal amount of bonds issued by Bonneville to the U. S. Treasury to help restore or preserve Bonneville's available capacity of its United States Treasury Borrowing. Paying additional debt is one action, but Bonneville is continuing to explore other options to assure sufficient borrowing authority on an ongoing basis. At the same time, it is also ensuring the amount of debt Bonneville incurs is also prudent. To that end, Bonneville instituted a leverage policy to ensure the amount of debt Bonneville incurs is prudent relative to the value of its revenue-producing assets that will repay that debt through future revenues. Bonneville's leverage ratio has declined over the past decade which is good (less debt relative to revenue producing assets), and the leverage policy ensures this will continue into the future resulting in less debt relative to the value of Bonneville's assets over time.
5546	1	tvstanger@gmail.com	N/A	Lincoln Electric believes that there needs to be a holistic view of the entire fish lifecycle, not just the impacts of the dams. The solutions need to include hydro, hatcheries, harvesting, and habitat, since they are all crucial to fish restoration efforts.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The co-lead agencies recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. The co-lead agencies analyzed the effects of the operation and configuration of the CRS projects on resources affected by the CRS, and they also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Moreover, research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm Harvest certainly has an impact on salmon and steelhead populations. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Improving survival of ESA-listed fish is one of several objectives of the Draft EIS and one of many resources analyzed. That said, the other areas mentioned by the commenter have been considered and included in mitigation measures as appropriate.
5546	2	tvstanger@gmail.com	N/A	Lincoln Electric believes the financial responsibility for fish restoration should be borne by everyone that benefit from the clean affordable energy provided by the Columbia River System, including special interest groups.	The financial responsibility for fish mitigation is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program, which is funded by Bonneville's electricity ratepayers as part of the rates that Bonneville sets to recover its costs. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
5547	1	Ron Gold	N/A	The salmon that go up the Fraser River is also a major source of food for the South Residency pod. And their runs are no better than the runs that come back up to the Snake River. There is no impairments on the Snake River dams, other than – excuse me –none on the Fraser River system. They had a bad landslide this past summer and it caused some problems with fisheries. But the true fact is, the resident's population of orcas on the west side of	The co-lead agencies recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm Harvest certainly has an impact on salmon and steelhead populations. A recent EIS addressing harvest was conducted by NMFS. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Vancouver Island's over 300. The biggest problem is over harvesting of the fish. The Puget Sound itself is a cesspool. Part of the problem the reason the Chinook are not doing as well is that their main food source, herring, in the Puget Sound, is over harvested.	Regarding impacts to orcas, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the CRS include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKW foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.5). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The US Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
5550	1	Rebecca Sayre	N/A	As I said, the dam removal is the best way to restore the salmon runs of the Columbia and Snake River systems. This option is appropriate action at a time of extinction crisis for the fish stock and the orca. Their condition is considered to be imminent if we don't act and act boldly. We must absolutely mitigate the impact to the communities who have to deal with the project changes.	Broad-sense recovery goals are beyond the scope of the EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. With respect to the Preferred Alternative, the anadromous fish analysis in Section 7.7.4 shows that the Preferred Alternative will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. Regarding impacts to orcas, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Mitigation for each of the alternatives is discussed in Chapter 5 and Chapter 7. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in this Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Records of Decision (ROD). Their inclusion in this Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure.
5553	1	David Doeringsfeld	N/A	Concerning transportation, the EIS does not reflect the total transportation cost increases if dams are breached. Short-line rail tracks are not adequate to handle increased grain exports. Unit train loading facilities are not adequate to handle increased grain exports. The cost to improve rail service will be made by private sector rail companies, and these private sector companies may choose not to make an investment of hundreds of millions of dollars. We would see rail rates skyrocket. The cost to improve road, bridge, and rail track and rail loading facilities could easily be ten times higher than the cost reflected in the EIS.	Rail rates are likely to increase under MO3, which includes a measure to breach the four lower Snake River dams. The impacts of rate increases are described in Section 3.10.3.5 of the EIS. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, price increases are unlikely to dramatically exceed estimates in the Draft EIS. The commenter is correct that some short-line rail tracks are currently inadequate to handle an increase in grain exports that would be anticipated and would require improvements. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS provides some estimates of these improvements in Section 3.10.3.5. The EIS finds that under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur. The EIS acknowledges that substantial uncertainty exists with regard to specific infrastructure costs that would be required.
5553	2	David Doeringsfeld	N/A	The preferred alternative increases the gas cap to 125 percent. We have concerns whether smolts can physically handle 125 percent gas gap. The preferred alternative does not provide the science to support 125 percent gas cap. We recommend an incremental approach to increasing the gas cap and to scientifically evaluate – – whether smolts can handle this increase.	Total Dissolved Gas (TDG) levels are regulated under the Federal Clean Water Act and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5554	1	Jean Murphy Ouellette	N/A	Another serious threat to the Columbia River Fishery is the proposed construction by the U.S. Army Corps of Engineers of Ice Harbor and three other dams on the lower Snake River between Pasco, Washington and Lewiston, Idaho, to provide flat water navigation and a relatively minor block of power. The development would remove part of the cost of waterborne shipping from the shipper and place it on the taxpayer, jeopardizing more than one half of the Columbia River salmon production in exchange for 148 miles of subsidized barging route. The transportation saver to the shipper would amount to $2 million annually, while salmon runs, having a wholesale value of $9 million, would be threatened with destruction.	The four lower Snake River projects have been operational for more than 30 years. Additional information about each project can be found at https://www.nww.usace.army.mil/Missions/Lower-Snake-River-Dams/. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative provides flexibility to adapt to changing conditions in the Columbia River Basin, ensures that human life and safety can be protected through flood risk management, protects valuable fish and wildlife resources, supplies water to farmers and cities, and ensures adequate, affordable, and reliable power. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. Impacts to navigation and transportation under MO3, which includes breaching the four lower Snake River dams, are provided in Section 3.10.
5556	1	Edwina Allen	N/A	After five rejections in court of the federal agency plans, to manage the Columbia River basin dams, the major objective of the current DEIS should be to produce a plan that will, in fact, meet legal requirements, recovery of salmon and steelhead in the Snake River.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, but the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
5557	1	dstempf@comcast.net	N/A	We've spent 17 billion on salmon restoration and haven't recovered a single run of our salmon, our salmon.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. The comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions, which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively; see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5559	1	Julia Reitan	N/A	I'm calling in to oppose the preferred alternative that fails to recover salmon and, by extension, also fails our orcas, and to speak in support of removing the four lower Snake River dams. That alternative was looked at, but rejected largely on the basis of a flawed economic analysis. The economic analysis of why breaching the Snake River dams is too expensive for us does not include at all, does not factor in the cost of maintaining the dams, the turbines, and the locks over the next 20 to 30 years. These costs are considerable because the dams and locks and turbines are now 40-some years old and maintenance has been delayed. The estimates are north of a billion dollars to keep the dams, turbines, and locks running. And the economic analysis also does not assign any value, any economic value to the recovery of salmon, and that is patently false.	Broad recovery goals are beyond the scope of the EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, the anadromous fish analysis in Section 7.7.4 shows that the Preferred Alternative will help contribute to broader recovery goals. Regarding impacts to orcas, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the measure to breach the four lower Snake River dams). The overall health and condition of the Southern Resident killer whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The cost analysis in the EIS does account for the costs of operating and maintaining the dams as well as capital costs (See Section 3.19 and Appendix Q). Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5561	1	yuiqwe1@gmail.com	N/A	It is time to remove the earthen portions of these dams. The material can be stockpiled. If after 20 years there's no improvement in fish populations, then rebuild the dams.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective 3 (MO3) which includes breaching the four lower Snake River dams. The PA also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The commenter's suggestion to stockpile and rebuild the dams if breaching did not result in meeting the anadromous fish objectives of the EIS would have to be studied and effects evaluated. Siting locations for materials of this amount for long-term storage and new construction costs to rebuild would be part of that analysis. The alternative suggested by the commenter would include the adverse effects of implementing MO3 and potentially irretrievable losses to communities and economy. Therefore, the co-lead agencies do not consider this to be a reasonable variation of MO3, which included breaching the four lower Snake River dams.
5562	1	Aviar Bhandari	N/A	A number of people who have testified in favor of DEIS have argued for keeping the dams because of the electricity they produce. But the simple truth is, we do not need the electricity from these dams to meet BPA energy contracts. The four lower Snake River dams produce only two to four percent of the electricity used in the Pacific Northwest. Not only are they not needed, but the power they produce just contributes to a surplus. In 2016, the Pacific Northwest had a surplus of 16 percent in energy. Currently, in the Northwest, we have two point times more energy from clean energy, wind and solar, than that produced by these dams.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. The four lower Snake River dams are among the most valuable projects in the FCRPS. These dams provide over 1,000 aMW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage, with over 2,000 to 2,300 MW of capability in certain months of the year. Table 3-160 of the Draft EIS presents the historical sustained ramping capability of the four lower Snake River dams. The power output for the four lower Snake River dams is not sold exclusively as surplus as the comment suggests. Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see EIS Section 3.7.2.5, Bonneville Power and Transmission Customers). While the regional power system does have surplus in some periods, most typically in the spring of high-water years, there are also periods when the region has very little or no surplus. For example during a winter cold snap demand for power may reach its annual peak. During a heat wave in summer when demand for power is high, river flows may be relatively low and several Federal and non-Federal hydropower projects are spilling water for juvenile fish passage. The EIS analysis for MO3, which includes breaching the four lower Snake River Dams, indicated that there is roughly a 14% chance of any given year having one or more power shortages (without factoring in the retirement of additional coal plants). See Section 3.7.3.5 of the EIS (Table 3-165 in the Draft EIS); and, Appendix J, Chapter 4, shows the seasonal variation of the loss-of-load events.
5562	2	Aviar Bhandari	N/A	Irrigation. Only the lowest or last of the four lower Snake River dams provides any irrigation water. Only about 14 farms and 40,000 acres are irrigated from this dam by pumping water from the reservoir. These farms could continue to irrigate by simply extending pump intakes, a longer straw.	The EIS discusses engineering solutions, including pipeline extensions. MO3 Region C discussion begins on page 3-1267, line 3244, in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
5562	3	Aviar Bhandari	N/A	Transportation of grain. Barge shipping is down 70 percent in the last 20 years. Grain volume has decreased 45 percent in favor of rail shipping. The Port Lewiston is heavily subsidized by taxpayers and is rarely profitable. Barge shipping is an unsustainable financial burden on the residents of the U.S.A. and Idaho. Taxpayers and ratepayers subsidize each and every barge shipment to the tune of about 20,000 per barge. Modern, affordable transportation alternatives exist for the transporting grain and other goods.	Access to barge transportation is the most cost effective means of accessing export markets for the majority of grain producers in the Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS analysis describes in Section 3.10. It is true that barge movements on the Snake and Columbia rivers have declined somewhat over the past 20 years. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5563	1	Al Jenkins	N/A	I support alternative number three, breach the lower four Snake River dams. And I know the Snake River dams are important to a lot of people. But we can come up with a plan that transitions and gives economic benefits to a lot of people and invest in other ways to transport product and other irrigation. You don't need dams to have irrigation. And the power generated is small. Just talking about dams, there's 60 dams on the whole Columbia Snake River system. Sixty. So we're talking about 4 out of 60. That's seven percent of the total and they generate less than seven percent of the Northwest power. So is 60 the right number? Is 64 the right number of dams? What's wrong with the number 56? That's still a lot of damn dams. So the salmon and steelhead and orcas and the people that depend on them, commercial fishers, tribal fishers, recreational fishers, professional guides that serve recreational fishermen, and businesses in small towns like Orofino, Idaho, depend on people coming back and supporting their economy. They've lost a lot of business over the last several years because the fish are not returning to Idaho and they're not returning to Eastern Washington in significant numbers. Talking about the seven percent of the dams, we also need to recognize that a, quote/unquote, balanced approach has led to a 95 percent reduction in wild salmon and steelhead that come back to the Columbia Snake River system. It used to be between 15 and 20 million salmon and steelhead came back every year and nobody had to do anything. They just showed up by the grace of God and creation and biology, and that's amazing. And so now we're talking about balancing out the last five percent. So I don't know why we can't lose seven percent of the dams, but we have to go ahead and lose 95-plus percent of the salmon.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. For example, the four lower Snake River dams produce upwards of 1,100 aMW of power, which is approximately 13 percent of the average power produced by the FCRPS. See EIS, section 3.7.3.5, Changes in Power Generation, Table 3-159 in the Draft EIS. This amount of lost power is equivalent to the amount of power used to serve 900,000 homes in the Pacific Northwest. See Section 3.7.3.5, Summary of Effects. The EIS also provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. Regarding the balancing of objectives, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex, and at times, conflicting legal requirements for a complex system.
5564	1	Dave Schneider	N/A	One hundred percent of our power is from the Bonneville Power Administration. Midstate Electric is relieved that the EIS rejected Multiple Objective 3, breaching the lower four Snake River dams and rejected increased spill as envisioned by the Multiple Objective 4. Both MOUs would have had major adverse effects on rates that could cause up to a 50 percent increase in wholesale power cost. The 50 percent increase in BPA's rate could lead to an increase of several hundred dollars a year for our members. Demographically, most of our members are senior citizens and many on fixed incomes. They should not have to choose between medicine, food, or paying their electric bill.	The comment that replacing the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. See Draft EIS, Section 3.7.3.5, Table 3-166. Multiple Objective alternative 4 (MO4) would also drive up costs. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects including to tribal, low-income and minority populations. The Preferred Alternative identified in the Draft EIS did not include either the measure to breach the four lower Snake River dams in MO3, or the measure to spill to 125% Total Dissolved Gas from MO4. The Preferred Alternative does meet the hydropower generation objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System.
5564	2	Dave Schneider	N/A	The DEIS concludes MO-3 and MO-4 creates a higher risk of brownouts and blackouts in the Pacific Northwest. It is not uncommon for temperatures to be well below zero in Midstate Electric service territory. Reliable base load generation is critical for the safety of our communities. Our resource needs can almost double overnight due do huge temperature swings that can last anywhere from a couple of hours to weeks. These are the times that Midstate Electric needs insurance against blackouts, which is exactly what the hydro system provides.	The comments about the impact of MO3 (which includes breaching the four lower Snake River dams) and MO4 on regional power reliability, unless and until replacement resources are added, is consistent with the EIS findings. See EIS, section 3.7.3.5, Effects on Power System Reliability, at 3-903; see also Appendix H, Table 2-1. The concern voiced by the comment towards health and safety effects is consistent with discussions in the EIS.
5564	3	Dave Schneider	N/A	Wind and solar implement and cannot alone meet the needs of the grid to have a precise balance of electricity production and consumption. Although battery storage is being developed to make wind and solar resources more reliable, they're a long way from being economical and having the needed storage capacity for our service territory with our cold weather extremes.	The suggestion that hydropower is a reliable source of power is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement, at pages 3-905-907. The findings of the power replacement resources indicated that more installed capacity for renewable resources (e.g., solar) would be needed due to the lower capacity factors of these resources, consistent with the comment. See Draft EIS, Section 3.7.3.1, Integration Services, at page 3-832. If lost hydropower were replaced largely by new variable, renewable energy sources, the existing dispatchable resources would need to provide integration services for these new resources.
5565	1	Dan Drase	N/A	I'm kind of surprised that you're not extending the comment period. My agency would likely have allowed an extended comment period for (indiscernible) scope and importance and controversy, even without a global pandemic interfering in the ability of the public and the tribes and the agencies to review and comment on it. I think it's generally unwise and inefficient not to take advantage of the input that you can get at this stage of the process to make a better final document, especially because you're on a extremely tight timeline and especially because you're going to get sued no matter what you do, you might as well make a bulletproof document and take advantage of what you're going to hear from people who are critical of it and fix those things now, because the flaws that are not raised and addressed now may well support successful appeals further on.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5566	1	Kim Jones	N/A	I am a concerned Washington citizen; extremely, extremely concerned about this whole ecosystem of Washington state. And it's basically in violation of the Endangered Species Act to blatantly fail to protect wild Chinook salmon as well as the Southern Resident orca.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The Preferred Alternative complies with the ESA (see Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information). The population dynamics of the Southern Resident killer whale (SRKW) are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by National Marine Fisheries Service (NMFS) in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the CRS directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the SRKW depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea. SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to SRKW would be minor. Thus, the co-lead agencies expect salmon and steelhead increases will come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
5567	1	Dallas Reed	N/A	And let's not overlook the disgusting cesspool that the Puget Sound is. So in regard to the Southern Residents and maybe some of the chemicals that are washed into the Puget Sound from Seattle and the greater Seattle area, birth control could very well be the number one reason for unsuccessful reproduction for the Southern Resident. Not to mention heroin and other opioids that are rinsed into the Puget Sound. So as far as the salmon supply from the Snake River, NOAA has found that 90 percent of the diet from the Chinook for the Southern Residents come from the Fraser River in British Columbia. And during the other half of the year, the orcas are so far out that scientists don't even know what the hell they eat. And if all that needs to be done is to help supplement fish for orcas, which is what hatcheries are, just a supplement, and I think they're supposed to produce somewhere around two percent of the salmon population for recreational needs and supplemental population needs, why don't we just increase the flow during times when juvenile salmon are out migrating.	Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
5569	1	Shiva Rajbhandari	N/A	The four lower Snake River dams are a financial burden to Idaho taxpayers and ratepayers, and that burden is likely to increase sharply in the near future as expensive repair costs are incurred. Today, taxpayers that support the operation and maintenance of these dams get back 17 cents for every dollar invested. The dams do not supply energy that is needed by Idahoans. They simply contribute to a surplus of energy. As much as 16 percent power	Breaching the dams and ending power generation would be a large loss for the regions electricity ratepayers as the value of the power produced by the dams is significantly more than the cost of maintaining them. The costs to operate and maintain (O&M), including needed capital investments, the lower Snake River dams are described in Appendix Q, Tables 4-1 and 5-1 in the Draft EIS. MO3 would result in a cost savings of $107 million in capital and O&M costs, annually. Capital cost estimates

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				surplus in the Pacific Northwest in 2016. If it is needed at all in the future, it can be supplied by less lethal generating sources. By preventing wild salmon from returning to their pristine Idaho habitat, these dams suppress an economic opportunity unique to the lower 48 -sport fishing in a wild pristine, incredibly beautiful natural setting. The dams keep the city of Lewiston stuck in a dream of the past, a booming inland seaport. This seaport is rarely profitable. Lewiston and Riggins is easily transitioned to a vastly more successful economy based upon a sport fishing economy that is valued at about $500 million annually.	are based on information from the Strategic Asset Management Plan, including investment needs over the long-term based on the hydropower engineering requirements and needs over the life of the asset, including replacement costs when assets are at the end of their use life. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. National Marine Fisheries Service (NMFS) estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million; $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The Multiple Objective alternatives (MOs) are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review 1/, the Headwater/Lower Snake Asset Class /2 is forecast to have a 50-year levelized cost of generation 3/ of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ The Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5570	1	grooovyjake@gmail.com	N/A	The stated objectives of the EIS are to operate the system in a way that, quote, improves fish survival. And you divide it into four parts here. But also to provide lost-cost electricity with minimal greenhouse gas emissions and reliable water supply. Failure to meet Endangered Species Act benchmarks for salmon recovery is what instigated this renewed process in the first place. Yet, your own objectives fall far short of what would be required to achieve that and stay out of the courtroom for the sixth time. If you only seek to improve fish survival rather than setting a more reasonable goal of achieving fish recovery, you will never develop a plan that means ESA requirements.	The purpose of the EIS is to evaluate options for the operation and configuration of the 14 dams in the CRS system. As required by NEPA, the co-lead agencies evaluated the effects of the Multiple Objective alternatives (MOs) on many resources, including effects to fish and wildlife. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies also contribute to the decline and recovery of fish, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, but the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), as well as meets the other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Additionally, the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
5570	2	grooovyjake@gmail.com	N/A	The preferred alternative draws heavily from the 2008 biological opinion that was ruled inadequate, which established the survival goal of 96 percent for juvenile migration at each dam in the spring and 93 percent at each dam in the summer. While that might sound like an impressive survival rate, when you multiply that over eight dams that Snake River salmon must traverse, you get a 32 to 56 percent die-off of juvenile fish across the system. And that's if you meet the goal that you set for yourselves.	The cited goals are not an objective of this Draft EIS. However, they were important in developing and accessing specific operational and configuration changes at the dams that did result in increased survival through the system, particularly for steelhead. Section 3.5 presents predicted system, or in-river survival, from either McNary or Lower Granite to Bonneville, for each modeled fish population. It is important to note that these goals account for all mortality within this reach. It should also be noted that juvenile salmon would die during the outmigration due to congenital problems, infectious disease, injuries, and predation. Welch et al. (2008) reported that cumulative mortality of yearly Chinook in the Snake and Columbia over 500 km of in-river migrating fish (~50%) is similar to that estimated for unregulated rivers of similar length (e.g., Fraser River (Welch et al. 2008)).
5570	3	grooovyjake@gmail.com	N/A	Continuing down the road of installing extremely expensive bypass systems rather than taking an honest look at the value of the projects themselves, makes neither biological nor fiscal sense. If the federal entities and, by extension, the tax and rate payers ever want to be free of the high cost of Endangered Species Act-mandated salmon mitigation, then they need to work with regional stakeholders, sovereigns, and legislators to fund replacement infrastructure for the four lower Snake River dams so that those dams can be removed.	The Preferred Alternative does not include any new bypass systems. It does included replacing the turbine intake screen material with a finer spacing to increase protections to juvenile lamprey. IFP turbines are not a bypass system, but is an increased investment over replacing in-kind. However, the extra design effort and increased construction costs yield a multitude of benefits including creating a much safer passage route for fish, while increasing the power production efficiency, decreasing the probability of petroleum leaks (fixed blade runners have no internal lubrication and adjustable blade units would have redundant seals), and lowering maintenance cost due to greatly reduced cavitation and petroleum leaks.
5571	1	Kurt Miller	Northwest River Partners	It's important to realize that juvenile sockeye salmon and the hydro system from Lower Granite Dam to Bonneville Dam survive at nearly the same rates, 46 percent, as salmon before they entered the hydro system from Redfish Lake to Lower Granite Dam at 48 percent. This is according to data from NOAA fisheries covering the period of 1997 to 2018. During that same time period, spring Chinook smolt survival from Lower Granite Dam to Bonneville Dam averaged 50 percent. A 2013 peer review study in the prestigious Proceedings of National Academy of Sciences showed that salmon pass through the lower Snake River and lower Columbia rivers as they do through the free-flowing Fraser River. Lastly, in 2014, the independent scientific advisory board found in its critique of the comparative survival study model, that increased spill levels have not proven to have a cause-and-effect relationship to adult salmon return rates because there are too many moving parts in the river and the ocean ecosystems.	The co-lead agencies recognize that there are many effects to salmon and steelhead populations outside the operation of the dams (see discussion of cumulative effects in Chapters 6 and 7 for more information). Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Underlying model assumptions for both CSS and NOAA based models were reviewed by independent experts as part of the Corps' IEPR process. The results of that review will be posted publicly. The primary models associated with this EIS process will also continue to undergo peer review as their development continues and as data associated with the Preferred Alternative is added to both modeling approaches.
5571	2	Kurt Miller	Northwest River Partners	On the other hand ---- it has been well documented that warming to a point in oceans may be causing salmon populations around the world to decline at a near synchronous rate. These declines have from been felt from Southern Oregon to Southeastern Alaska and include both rivers with and without dams. In 2019, the United Nations Intergovernmental Panel on Climate Change found that these conditions are being – MS. HABIBI: Your time has lapsed. KURT MILLER: -- caused by climate change.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead (Sections 3.4 and 7.7), as well as the many other factors that affect these fish, including factors outside of the influence of the Columbia River System projects, such as ocean conditions. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
5572	1	Jessica Zimmerle	Earth Ministry in Washington Interfaith Power and Light	Earth Ministry has been honored to partner with the Nez Perce group Niimiipuu for protecting the environment. And at their request, we have helped hold space for dialog that explores river management solutions that work for everyone. In the process of doing so, we've heard numerous tribal leaders share how their communities' livelihood and culture have been profoundly and adversely affected by the loss of Columbia and Snake River salmon. Treaty rights should not be treated as an afterthought. Sovereign nations are not just another stakeholder. The first peoples of this land have the inherent and treaty-protected right to fish in their usual and accustom places. It is unacceptable that five plans over 30 years have failed to meet salmon recovery goals, thereby violating this important treaty right.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery determinations are ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve more parties than just the co-lead agencies across the region that have an influence and impact on ESA-listed species. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5573	1	Cindy Hansen; Howard Garrett	Orca Network	We would like to express our disappointment that the draft EIS does not adequately represent the importance of Columbia basin salmon to the endangered Southern Resident orcas and it fails to recognize the biological need of Southern Residents to have continuous access to salmon from a variety of river systems throughout their range. The report states that Puget Sound Chinook salmon stocks are more important than Snake River stocks due to their availability for greater periods of the year. However, we know from a variety of research and data sources that Southern Resident orcas spend over half the year in coastal waters and that Columbia basin salmon make up over half of their outer coastal diet. We also know, as evidenced in 2018 and 2019, that Southern Residents will shift their patterns and feed off the coast during the summer when there is little to no salmon available in the Salish Sea, underscoring the importance of these coastal runs as Puget Sound and Fraser River stocks continue to decline or fail to improve. Of the alternatives presented in the draft EIS, MO-3, Snake River dam breaching plus increased spill over the Columbia River dams, represents the best chance of recovery for Snake River salmon and for Southern Resident orcas. The benefits of dam breaching were demonstrated in a recent whitepaper entitled Southern Resident Killer Whales and Columbia Snake River Chinook, A Review of the Available Scientific Evidence, which was written by five PhDs. We urge you to read it in its entirety. Our concern is that the preferred alternative is going to simply repeat the status quo and do little more than incorporate the interim agreement for increased spill. While this agreement is certainly a positive step for salmon, it is not enough to result in the salmon recovery needed for the survival of Southern Resident orcas and to restore salmon and cultural resources that were lost to local tribes.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5573	2	Cindy Hansen; Howard Garrett	Orca Network	The benefits of dam breaching were demonstrated in a recent whitepaper entitled Southern Resident Killer Whales and Columbia Snake River Chinook, A Review of the Available Scientific Evidence, which was written by five PhDs. We urge you to read it in its entirety.	Thank you for providing this reference. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
5573	3	Cindy Hansen; Howard Garrett	Orca Network	In 2018, Governor Inslee, Southern Resident Orca Task Force recommended a stakeholder process to discuss potential breaching or removal of he lower Snake River dams. This process was just completed. And while the final report is not perfect, we do not want to see this time and effort wasted. We would like to see some of this information incorporated into a dam removal plan and use to support stakeholders and make them whole as they transition to a free-flowing Snake River that can continue to meet their needs.	Thank you for your comment. We acknowledge this effort was occurring at the same time as the development of the CRSO EIS. As part of the NEPA process, we have coordinated with a number of stakeholders who participated in the report's process, state, tribal, and federal cooperating agencies, including the state of Washington. Their viewpoints have been considered in the development of the CRSO EIS and incorporated where appropriate.
5573	4	Cindy Hansen; Howard Garrett	Orca Network	Finally, we would like to request that you extend the current comment period.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
5575	1	Mark Hayden	N/A	The draft EIS also indicates that the cost of replacing clean energy benefits provided by the lower Snake River dams would add $1 billion annually to electricity costs. For millions of people across the Northwest, this would result in a 25 percent increase in their monthly energy bills.	The information provided in the comment regarding increased power-related costs under Multiple Objective alternative 3, which includes breaching the four lower Snake River dams, is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Table 3-166. The Preferred Alternative identified in the Draft EIS did not include the measure to breach the four lower Snake River dams that was analyzed in MO3. The Preferred Alternative does meet the hydropower generation objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System.
5576	1	Colleen Weiler	N/A	I would first like to say that the short time allowed for this comment period, particularly in the midst of a global crisis is insufficient for the public to review and provide much-needed input.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5576	2	Colleen Weiler	N/A	The timeline adopted by the agencies also limits their ability to fully consider the extensive ecosystem impacts of the CRSO and the DEIS is lacking information in several key areas, especially for the Southern Resident orcas. The primary threat to the survival of this unique population is a lack of their main food, Chinook salmon, throughout their range. Data increasingly shows that salmon from various river systems in the Pacific Northwest and California are important to Southern Resident orcas at different times of the year, and the movement of the orcas through their habitat is tied to the return of Chinook to these major river systems, including the Columbia. Research from the National Marine Fishery Service shows the Columbia River is a hotspot for the orcas and that more than half of the time they spend in coastal waters is in the area between the Columbia and Grays Harbor. Chinook salmon from the Columbia basin specifically comprise more than half of the Chinook consumed by the orcas when they are in coastal waters. However, the DEIS does not include any of this information in its review and, therefore, grossly under represents the importance of Columbia and Snake River salmon, the survival of the Southern Resident orcas.	The co-lead agencies were not able to extend the timeline to prepare the EIS. SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5576	3	Colleen Weiler	N/A	The preferred alternative is only a minor adjustment to status quo conditions which has not been sufficient to support the recovery of Columbia basin Chinook or of Southern Resident orcas. The DEIS does not offer the region-wide discussions or solutions that will be necessary to support this transition and will not be enough to support Northwest tribes and communities. A restored Snake River provides ecosystem-wide benefits that support a healthy river, habitat, and the communities. But the DEIS and federal agencies alone cannot accomplish this. This is a time for Northwest policymakers, stakeholders, leaders, and communities to work together to create inclusive, science-based, and supportive solutions for these region-wide issues.	There are many factors that affect salmonid populations, many of which are outside the control of the co-lead agencies. The Preferred Alternative (PA) carries forward certain mitigation measures that are known to provide benefits to ESA-listed species from the No Action Alternative. These actions by the co-lead agencies have resulted in a large percentage of fish being able to pass both upstream and downstream of the lower Snake River and lower Columbia River projects. See Section 3.5.2.3 Anadromous Fish for additional discussion. The co-lead agencies do not view the Preferred Alternative as a continuation of the status quo. The spill operation for juvenile fish passage in the PA is a significant departure from previous operations. See Section 7.6.3 Preferred Alternative Operational Measures for additional discussion. In addition, a large number of structural changes are included to benefits salmonid species and Pacific lamprey. See Section 7.6.2 Preferred Alternative Structural Measures for additional discussion. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, but the EIS is not intended or required to serve as an overall salmon recovery plan for the region.
5577	1	Stan Thayne	N/A	From a historical perspective, it is clear these four dams are controversial from the very beginning before they were authorized, precisely because of the negative impacts it would have on salmon and particularly in migrating juvenile salmon. And these concerns outweighed for many the potential benefits. There was intense opposition in the 1940s and '50s, and many agency directors and politicians were reluctant to repeat the errors and calamities that had already been perpetuated upon salmon in Europe, the East Coast, California, and the Columbia main Salmon tributaries. And even after Congress authorized these dams, actual construction was stalled for years because it was clear these dams would devastate salmon runs. Among the strategies that finally were pivotal in pushing through the opposition, one was an appeal to national beauty, an argument was made that Hanford would need more power. That's a moot point today, but I'd point out that we're still trying to clean up the mess that that effort has left us and these dams are not unlinked to that. The second was basically congressional maneuvering as this slid into a Civil Works Appropriation bill. And ironically, then it was two Democrats acting against Republican opposition to the dams. My point here is that these four dams went in against the better judgment and opposition of many agencies, citizens, scientists, and politicians, but they are not the status quo. And one point that's often made, currently, in defense of that status quo is the argument that power rates may increase for local users. I would like to suggest that there are other was that agency heads could work to flatten out increases by distributing that burden more broadly in the region among the power users. And as a power user, I would willingly pay more if that would help others pay less to shoulder this burden. I think we all throughout the region should do so. Another defense that is often raising the spectra of new coal plants to compensate for loss of power generation. I suggest that there are alternative routes we should pursue, including responsible energy conservation practices. And some economists have argued that taking out just these four dams, and my comments are specifically about these four dams, off the grid, would have negligible overall effects. And the DEIS is structured in such a way that it obscures the very context that brought it about. In 2016 and 2018, two court decisions ordered an outdated biop and EIS would take into account effects of climate change in considering the impacts of the Columbia and Snake River system operation on 13 species of — population of threatened and endangered steelhead and salmon. And I would add also lamprey and freshwater mussels and allother aspects of the threatened submerged and strangled native ecology. The DEIS itself makes clear that alternative three, breaching the four lower Snake River dams is the best choice for salmon, steelhead, lamprey, and all other native life in the Snake and Salmon River and tributaries.	We agree that the four lower Snake River projects have a long and complicated history. MO3 was not identified as the Preferred Alternative (PA) for reasons described in Sections 7.2, 7.3, and 7.4 of the EIS. The co-lead agencies expect that the alternative identified as the PA will allow them to meet the EIS intent as expressed in the Purpose and Need Statement and the EIS objectives, including those to benefit ESA-listed species. The PA also includes measures to benefit lamprey and seeks to balance the multiple purposes of the Federal projects, while complying with the applicable Federal environmental laws, including the ESA, regulations, and executive orders. Please see Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information. Regarding replacement resources, the CRSO EIS does not propose a new coal plan to replace the lost generation from the four lower Snake River dams. Instead, two portfolios were used to outline the potential resource options: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Section 3.7 in the Draft EIS. Finally, the EIS includes climate change analysis in Chapters 4 and 7.
5578	1	Jason Williams	N/A	It is very important to recognize that the CRSO draft EIS shows that losing the lower Snake River dams would double the risk of region-wide blackouts	The comments about the impact of breaching the four lower Snake River dams on regional power reliability is consistent with the EIS findings unless and until replacement resources are constructed. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and, Appendix H, Table 2-1.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5579	1	Scott Simms	Public Power Council PPC	Today, I'd like to focus on the matters of continued monitoring and adaptive management, with are aspects of the preferred alternative that commit federal co-agency resources to the review of action, some of which remain untested in this preferred alternative. First and foremost, Public Power's committed to mitigation efforts for impacts of federal projects operations. Our approach is that mitigation must scientific, cost-effective, and have a nexus with these operations. Improving survival, habitat, and conditions for these fish is important to the Northwest ecosystem, economy, and tribal way of life. PPC members pay substantial fish and wildlife costs through their wholesale power rate, on the order of 25 percent or more. These funds pay for fisheries that feed the ocean's food chain and feed people. The preferred alternative calls for an unprecedented level of spill and resultant TDZ in the Columbia River System. Specifically 125 percent TDZ is untested and creates significant biological uncertainty for the threatened endangered species the operation is, in fact, intended to benefit. We at PPC maintain that effective monitoring for unintended consequences from TDZ is essential, including ongoing transparency and public availability of information. This is in consideration that, first, the levels of TDZ in the preferred alternative exceed those recommended by the EPA and represent unchartered territory in Columbia River basin operation. In trying to help juvenile salmon, spill may result in compromising resident fish, other river organisms, and salmon via gas bubble trauma. And last, monitoring for gas level trauma and other side effects would be important to the adaptive management plan. And speaking of adaptive management, the federal co-lead agencies should consider the following in the final EIS: given the different predicted outcomes of the NOAA and CSS models are directly conflicting, the federal agencies need to establish a clear methodology to monitor and address the impacts of the final EIS on basin fish and wildlife and determine whether the measures help meet the defined objective. The co-lead agencies need --Thank you. The co-lead agencies need to be given the flexibility under the final EIS to execute the adapted management plan. Governance and decision making for these management plans need to reflect the broad range of stakeholders in the basin.	Total Dissolved Gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: make additional improvements for salmon and steelhead and maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunities to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences would be monitored and adjusted using current in-season management teams such as the Technical Management Team.
5581	1	Eloise Getton	N/A	With my respect, the EIS from 2014 has failed. You were already talking about immediate need action in your alternative with involvement (indiscernible) dragging at four location in the lower Snake River and lower Clearwater River in Washington and Idaho consist with the (indiscernible) long-term PSMP in concurrence with the PMSP's implementation. So we are now in 2020. Salmon population are further decline. For example, Snake River sockeye salmon were less endangered in November 1991, and their listing was reaffirmed in June 2005. So this list from 2005 includes five anadromous salmon population and three anadromous steelhead (indiscernible) population present in the LSRP. And nothing in your actual past EIS indicate the repercussion on the greater environment of the ocean, including orcas from the -- sorry --including the resident killer whale who are directly impacted by. And they are already on the list since 2005 for the endangered species. The federal agencies have spent nearly three decades fighting in court to (indiscernible). Five federal (indiscernible) have been declared illegal by three federal judge. The corps and Bonneville Power spend money on (indiscernible) and on repeated plans with no tangible results. The spending of this money could have been avoided. EPA documents show the four lower Snake River dams have been a problem since the beginning, by (indiscernible) Indentured Physicist Act, the Fish and Wildlife Coordination Act of 1958 and the Water Resource Development Act of 1976. How long this complaint can continue before you take the immediate and radical solution that is breaching the obsolete salmon-killing dams. How can it be true, the investigation led by the U.S. Army Corps of Engineers when all the EIS documents don't match with your actual Environmental Act?	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. See Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-leads to meet the stated Purpose and Needs Statement while minimizing impacts to affected ESA species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. See Chapters 6 and 7 for information on cumulative effects to ESA-listed species. Regarding Southern Resident killer whales (SRKW), the population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the CRS directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the SRKW depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. SRKW also are known to eat some steelhead, coho, and chum salmon, halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea. SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to SRKW would be minor. Thus, the co-lead agencies expect salmon and steelhead increases will come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
5582	1	Tim Stearns	N/A	The analysis demonstrates that removal of the four lower Snake dams has the highest likelihood to restore viable salmon and steelhead populations. Instead, the agencies crafted a preferred alternative with yet a new laundry list of techno-fixes and operational changes.	MO3 was not identified as the Preferred Alternative for reasons described in Sections 7.2, 7.3, and 7.4 of the EIS. The co-lead agencies expect that the Preferred Alternative (PA) will allow them to meet the EIS intent as expressed in the Purpose and Need Statement and the EIS objectives, including those to benefit ESA-listed species. The PA seeks to balance the multiple purposes of the Federal projects, while complying with the applicable Federal environmental laws, implementing regulations, and executive orders. See Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders. The PA carries forward certain mitigation measures that are known to provide benefits to ESA-listed species from the No Action Alternative. These actions by the co-lead agencies have resulted in a large percentage of fish being able to pass both upstream and downstream of the lower Snake River and lower Columbia River projects. See Section 3.5.2.3 Anadromous Fish for additional discussion. The co-lead agencies do not view the PA as a continuation of the status quo. The spill operation for juvenile fish passage in the PA is a significant departure from previous operations. See Section 7.6.3 Preferred Alternative Operational Measures for additional discussion. In addition, a large number of structural changes are included to benefit salmonid species and Pacific lamprey. See Section 7.6.2 Preferred Alternative Structural Measures for additional discussion.
5582	2	Tim Stearns	N/A	The document instead should have analyzed what investments could have been made to mitigate the impacts of dam removal. The region has 281 hydropower dams and 200 dams built for other purposes in the Columbia River basin, according to the Northwest Power Planning Council. We're not talking about removing the Columbia River hydro system, but we're talking about rebalancing it so that it works for the broad range of interests.	The EIS did evaluate the impacts of dam breaching on all resources and recommended mitigation for those effects. The description of these effects is within Chapter 3, organized by resource. Mitigation for impacts associated with dam breaching, included in MO3, is described in Chapter 5. Additionally, the EIS analyzes what resources would be needed to replace power loss from dam breach and included mitigation associated with breaching the four lower Snake River dams for certain resources. The analysis for MO3 demonstrates what types of resources would be needed to replace the key attributes of the four lower Snake River dams. Included in this analysis is a resource portfolio made up of alternative forms of energy (i.e., wind, solar, and batteries). As described in Section 3.7, and Chapter 7, the adverse reliability and upward rate pressure impacts from breaching the four lower Snake River dams support retaining these resources over other alternative forms of energy. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The PA also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
5583	1	kate@columbiariverkeeper.org	N/A	Water temperature is a major problem for salmon and steelhead. Between 1960 and 2015, water temperature in the Columbia and Snake River have increased by an average of 1.4 degrees Fahrenheit. Salmon are sensitive to water temperature at many stages of their lives. Warmer water can negatively affect fish, making it more difficult for them to swim upstream and making fish more susceptible to disease. In the lower Snake River, temperatures in the reservoirs exceed 68 degrees Fahrenheit for weeks or months at a time during the summer when many salmon migrate to or from the ocean. Temperatures above 68 degrees are very harmful to salmon. Salmon populations in the Snake River basin are increasingly threatened by warmer rivers, including significant warming from the reservoirs behind the four dams on the lower Snake River. The DEIS analysis is insufficient on several levels. In the analysis of climate change, the EIS should model water temperatures in the Columbia and Snake rivers under the climate conditions we expect to see in the next 20 to 50 years. In addressing the challenges that salmon face in the Columbia River and estuary, existing dams and worsening climate change are making the lower Columbia and estuaries too hot for fish. The DEIS does not explain this or provide any solution. The DEIS implies that lower Snake River dam removal would not significantly change water temperatures or improve conditions for salmon. This is not true. Summer and fall water temperature conditions in the lower Snake would be significantly better for salmon and steelhead with the dams gone.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the resolution required at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS (river vs. regional or global scale). In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Regarding water temperatures under the dam breach measure, the analysis of MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. The fish benefits of breaching the Snake River dams is discussed in the analyses of Snake River salmon and steelhead in the Draft EIS (see Section 3.5). Faster travel times, among other parameters such as temperature differences, under a breach scenario were incorporated into both models that were used to estimate juvenile survival and, as reported in the Draft EIS, both indicated higher juvenile survival than the No Action Alternative. For Snake River spring/summer Run Chinook Salmon, decreased travel time of 4.5 days and 5.5 days, respectively, were indicated by CSS and NMFS COMPASS models, compared to the No Action Alternative
5586	1	kairos42@earthlink.net	N/A	I'm a civil engineer. I spent 35 years with the Army Corps of Engineers and was a deputy district engineer in Walla Walla. I'm also a public utility commissioner here in the state of Washington. And I'm speaking as a citizen today, 'cause I'm just covering a lot of waterfront here. But I feel like I'm in a deja vu all over again, because I sat down in Walla Walla district when I was there and went over the feasibility EIS study at that point that we did 20 years ago on all this, and I'm seeing a lot of the same things but in a worse state, actually. What we saw back then or what happened back then was the cost of breaching was grossly over estimated in various means, and we've seen how to correct that and reduce that cost significantly. The other thing is the cost of the mitigation features, a couple hundred million dollars here and there to improve fish passage and so forth were grossly under estimated. And so what's happened in the last 20 years is those instead of $200 million price tag, we've got a billion dollar price tag on mitigational measures just on the dams. Now, that's ratepayer money that's paying for that. And my concern here is largely – well, what I'm telling you right now is for the ratepayers, because we're going to do this all over again. Even though the preferred alternative has stripped out most of the measures that you find on all the other multiple objectives, which doesn't make any sense, it's just basically then whitewashed to be a low-cost alternative to make it financially attractive versus the other alternatives, especially the breach alternative. And so my concern is, we're going to see these increases in cost on these measures go up and up and up. At the same time, another outlay just kind of feature of this thing is this claim that a billion dollars worth of value is attributed to the Snake	The Preferred Alternative (PA) carries forward certain mitigation measures that are known to provide benefits to ESA-listed species from the No Action Alternative. These actions by the co-lead agencies have resulted in a large percentage of fish being able to pass both upstream and downstream of the lower Snake River and lower Columbia River projects. See Section 3.5.2.3 Anadromous Fish for additional discussion. The spill operation for juvenile fish passage in the PA is a significant departure from previous operations. See Section 7.6.3 Preferred Alternative Operational Measures for additional discussion. In addition, a large number of structural changes are included to benefit salmonid speicies and Pacific lamprey. See Section 7.6.2 Preferred Alternative Structural Measures for additional discussion. Finally, cost information is provided in Chapter 7 and Appendix Q. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90% of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				River hydropower. Most of that value is attributed to the flexibility offered by ramping and sustained peaking power and reserve capability, none of which was identified 20 years ago. So somehow the dams have generated new value out of nowhere. So that again is just another exaggeration.	that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class2/ is forecast to have a 50-year levelized cost of generation3/ of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5588	1	Cassie Paumard	N/A	First, I'd like to state that the BPA is violating the Endangered Species Act by failing to protect wild Chinook salmon as well as the Southern Resident orcas.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. See Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-leads to meet the stated Purpose and Needs Statement while minimizing impacts to affected ESA species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. See Chapters 6 and 7 for information on cumulative effects to ESA-listed species. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
5588	2	Cassie Paumard	N/A	hese dams kill eight million smolt per year and we lost $100 million in 2019 because of them. I know there has been talk of supplementation from hatcheries. But artificial hatcheries will not help restore wild population. I want to bring light to a case study on captive salmon that I learned as a marine biology student at the time, and one that really stuck with me. In this study, the hatchery reared smaller egg sizes from 1996 to the year 2000. The scientific reason for this study is simply that hatcheries provide conditions that select for increased (indiscernible) at the cost of decreased egg size. This further caused wild populations once supplemented from hatcheries to decrease in egg size. This put wild populations of salmon at a deficit against predators. If we choose hatcheries, we choose less viable salmon for us and our starving Southern Resident orcas.	Hatchery programs have long been a part of the approach for salmon recovery. Based on the analysis of anadromous fish in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. The PA proposes measures such as increased spill intended to improve survival of anadromous salmonids. Figure 3-111 in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. Overtime, the PA is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin (CRS), and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The PA carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The PA has negligible effects to Southern Resident killer whales (SRKWs) as described in Section 7.7.8, in large part because hatchery production is consistent between the No Action Alternative and the PA. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent, congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation, and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
5591	1	David Dane	N/A	I would like to request an extension (indiscernible) written comment. The EIS is thousands of pages long and restrictions on activity due to COVID-19 limit opportunity to meet with colleagues efficiently and access older and other written materials in libraries that are not readily available online. More time is needed to provide well-reasoned comment.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5591	2	David Dane	N/A	Significant weakness in the DEIS is its consideration of impacts from endangered Southern Resident killer whale, Salish Sea's critical habitat, and part in migration of the Columbia River System Chinook salmon. Further, an instance proposed expanding critical habitat to include a much larger portion of the CRS Chinook salmon range along the Pacific Coast. The DEIS relies on an incomplete report on the importance of different river systems and providing food for SRKW. The authors noted many sources of bias; they do not have time for drafts. These biases lead to an underestimation of the importance of Columbia River Chinook. The DEIS relies on an inaccurate description of the distribution of SRKW. In fact, the majority of SRKW spend the majority of the year within the range of Columbia River Chinook. This portion of the range increases the Snake River Chinook rather than decline, indicating river runs are likely to be more important in the coming years than they were in the first 40 years of our study on resident killer -- The report failed to consider the effects of inbreeding on jeopardy to the DPS survival. Maintaining constant numbers will result in loss of genetic diversity and increased inbreeding, both of which reduce the likelihood of recovery. That is, a climate does not contribute or significantly increase in the Southern Resident killer whale numbers results in jeopardy. As early on, on the Maury Island Gravel Mine case, Judge Martinez noted that even small trucks to an already endangered population are likely to result in jeopardy. Thus, the DEIS should have concluded the preferred alternative is likely to adversely affect Southern Resident killer whales and results in jeopardy to the DPS survival. Alternative three, which calls for removal of the Snake River dams was for recovery of SRKWs, but was not seriously considered, to be combined with spill up to 125 percent total dissolved gas.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The determination for SRKW in regards to MO3 was based on the following facts: the population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.

					The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. Moreover, the commenter is asking for determinations made under the ESA and not impacts analysis as required under NEPA. For ESA, as described in the 2020 National Marine Fisheries Service (NMFS) BiOp, NMFS concluded the agencies are producing more hatchery fish than is needed to mitigate for their impacts to SRKW prey species, and thus, the agencies were not likely to adversely affect SRKWs. Both the benefits and adverse effects of MO3 and MO4 are included in the analysis. The impacts of both MO3 and MO4 are significant to several resources, but especially power generation and reliability. An alternative combining the two would exacerbate, not resolve, those power impacts. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g., increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023, per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching in MO3 would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. In developing the Preferred Alternatives, the agencies used the alternative analysis to optimize the combination of measures based on the measures' intent and performance minimize impacts and meet the Purpose and Need Statement and EIS objectives. See Chapter 7. In regards to moving barging facilities, these are not Federal facilities, and thus would be the responsibility of ports, private industry, regional or local entities. Relocation would not be a proposed alternative that the Federal agencies would propose. However, breaching the earthen embankment and the changes to regional economies related to changes in navigation is included in the analysis of MO3. It is anticipated these entities would not move, but that industry would change to a different transportation option, such as trucking or rail.
5591	3	David Dane	N/A	Failed to consider expanding rail capacity to replace barges. Failed to consider alternative means for (indiscernible) flows providing irrigation and water to farmers, ensuring the farms would remain viable without irrigation. Failed to consider continued hatchery operations as a conservation measure rather than as a mitigation measure. I'm rooting that congressional action may be required to reprioritize purposes of the lower Snake River dams — (indiscernible) elected offices to do just that.	The effects on transportation, including rail, and on irrigation and hatchery operations are described in Sections 7.7.12, 7.7.14, and 7.6.4.1, respectively. The co-lead agencies used current, high-quality information to evaluate the effects to transportation and irrigation. Hatchery operations are an ongoing action that is being carried forward from the No Action Alternative through existing authorities. A conservation measure is a term under the ESA and not NEPA, although the EIS does acknowledge certain conservation measures included in the associated CRS consultations for the ESA and the Fish and Wildlife Conservation Act.
5595	1	Julie Weichel	N/A	With respect to the real cost of time to mitigate the damage that the dams do to our salmon populations, BPA has spent between $15 and $17 billion in mitigation efforts.	Bonneville's mitigation investments have delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions, which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5597	1	kellshan@hotmail.com	N/A	Scientists agree that the most efficient and effective way to increase the wild salmon and steelhead populations is to restore the damaged ecosystem, and that is to breach the dams. The economic benefits of the dams and the regions have continued to decline and will continue to decline. The federal agencies have a responsibility to comply with the endangered species act and take the necessary actions to recover salmon, steelhead, and out Southern Resident killer whales.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses (see 40 C.F.R. 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS set forth eight objectives which, in tandem with the Purpose and Need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. However, the preferred alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NOAA and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with

					congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5597	2	kellshan@hotmail.com	N/A	Breaching the dam can be paid for by PBA (sic), and they'll at least cover the cost a way to accomplish fish mitigation under the 1980 Northwest Power and Conservation Act.	Bonneville does not have authority to breach dams. Commenters that mistakenly contend Bonneville has authority to fund the breach of dams typically suggest two statutory alternatives. The first is Bonneville's discretionary direct funding authority found at 16 U.S.C. 839d-l. Congress granted this authority as a means for Bonneville, the Corps, and Reclamation to proceed with funding additions, improvements, or replacements to the multiple purpose projects of the CRS without having to first wait for appropriations for the entire activity. Instead, Bonneville provides the power share directly so that the Corps and Reclamation need only seek appropriations to cover the non-power share; that is, the share attributed to the non-power purposes of the dam. Stated another way, Bonneville can provide direct funding to cover only hydropower costs, whereas costs attributable to or shared by other purposes of the dams would be joint projects and would require congressional appropriations to cover the non-hydropower share of the cost. The breach of a dam is not an addition, improvement, or replacement of a dams power features, so the direct funding authority does not apply to the breach of a dam. Moreover, even if for arguments sake it did, Bonneville could provide no more than the power share of the cost of breaching. Congress would still have to provide appropriations to the Corps for the non-power share. The use of Bonneville's discretionary direct funding authority therefore cannot provide a means of funding the breach of dams absent an act of Congress. The second statutory authority suggested for Bonneville to fund the breach of dams is the Northwest Power Act section 4(h)(10)(A) found at 16 U.S.C. 839(b)(h)(10)(A). The Bonneville Administrator must use the Bonneville Fund to protect, mitigate, and enhance fish and wildlife affected by the operation and development of the FCRPS in a manner consistent with the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program, the Councils Power Plan, and the purposes of the Act. Currently, dam breaching is not part of the current Council Fish and Wildlife Program, the Seventh Power Plan, or evident within the purposes of Act. For example, dam breaching is inconsistent with the statutory purpose of Section 2(6) of the Act, which says in relevant part that anadromous fish are dependent on environmental conditions substantially obtainable from operations and management of the Columbia River System and other hydropower facilities in the basin. Additionally, as Section 3.7 (Power Generation and Transmission) demonstrates, dam breaching is also inconsistent with another purpose of the Northwest Power Act, Section 2(2), which provides for assuring the Pacific Northwest an adequate, efficient, economical, and reliable power supply. Section 4(h)(10)(A) therefore does not mandate or confer authority on the Administrator to fund the breach of a dam.
5598	1	Deborah Giles	N/A	I'm a killer whale biologist with the University of Washington, Center for Conservation Biology, and the science and research director for a non-profit called Wild Orca. My research focuses on the endangered Southern Resident fish-eating killer whales, a distinct population of whales that number a mere 72 animals, down from 99 in 1995. This population of whales eats only fish, with as much as 90 percent of their diet being Chinook salmon. The Southern Residents co-evolved eating the once massive Chinook that historically spawned the Snake River watershed. Recovering the Snake River Salmonids to more historic numbers would significantly help the struggling Southern Residents. People in Puget Sound, Salish Sea like to claim the Southern Residents as their own. But even in the best salmon years, the whales only spend at most six months of the year in this part of the state. The rest of the year, fall through spring, the whales are utilizing the rest of their range, from northern Vancouver Island to Monterrey, California. And they spend a disproportionate amount of time in the early spring at the mouth of the Columbia River looking for returning lipid-rich Snake River Chinook salmon. In 2009, I started working for Dr. Sam Wasser, who pioneered the use of scat detection dogs to non-invasively sniff out killer whale floating feces on the water. Our first paper based on these samples was published in 2012, and it became evident that vessels are a problem, most significantly when the whales are not getting enough to eat. This realization was important because it turned my attention from being mostly focused on vessel effects to looking at the interactions between food-deprived whales and stress hormones. Our most recent paper was published in 2017, and that one showed that 69 percent of females are getting pregnant. Those that are getting pregnant are spontaneously miscarrying their calves. And these miscarriages are directly related to lack of nutrition in the would-be moms.	Thank you for your contribution to SRKW research. Many of the points you make in your comment have been incorporated into the SRKW analysis that is described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5598	2	Deborah Giles	N/A	Besides those comments, I would also like to respectfully request that he comment period be extended in light of this really amazing period of time that we're in, giving the public an opportunity to review the document with more time —- to consider – more consideration would be much appreciated.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
5598	3	Deborah Giles	N/A	Thank you very much for holding these webinars. I think that they've gone really well.	Thank you for your comment.
5599	1	Lori Gogitsch	N/A	Columbia River basin salmon have continued to drastically decline, even though $17 billion have been spent on salmon recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. Bonneville's mitigation investments have delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5599	2	Lori Gogitsch	N/A	Bold, proactive new actions need to be implemented to ensure an effective solution to declining salmon population. These actions need to address the following issues: One, restore abundant fishable salmon and steelhead populations in the Columbia River basin, which, in turn, will provide more food for the critically endangered Southern Resident killer whale; And two, honor our nation's treaty commitments to Native American tribes and culture.	Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS . Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the EIS objectives for resident fish, lamprey, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
5602	1	Lori Ody	N/A	If we want to see how the lower Snake River would perform if the dams were removed, we need only look at the Yakama River basin. Before the lower Snake River dams were built, the journey of smolt to the seas took about one week. Now it takes one month or more, if they survive at all. Smolts that survive may suffer from the journey only to die later. This is called delayed mortality. By contrast, in the Yakama River basin, fish have only four dams on the lower Columbia to pass. Yakama basin salmon are not impacted in the way that Idaho's wild fisheries have been impacted. The Yakama River populations demonstrate that the four lower Snake River dams are the problem, because, by comparison, Yakama River basin salmon populations remain viable while Snake River salmon are nearing extinction. Our salmon populations began their slide toward extinction after the lower Snake River dams were built. When both rivers populations only had four dams to navigate, both were healthy and viable. This point is further proven by the fact that historically the Snake River populations were much more viable and productive than the Yakama River populations. Today, the reverse is true.	The Draft EIS compares the effects of the No Action Alternative to the effects of each of the Multiple Objective alternatives. The CSS and National Marine Fisheries Services COMPASS/LCIM fish models allowed estimation of the effects of MO3 which includes the lower Snake River dam breaching measure as well as other measures such that the co-lead agencies were able to analyze the impacts to salmon and steelhead from breach of the four lower Snake River dams. Therefore, a comparison to another watershed or other species (i.e., species that return to the Yakama River basin) was not necessary.
5602	2	Lori Ody	N/A	Other dam removal projects undertaken in this country demonstrate how river restoration will restore salmon runs and many other benefits of free-flowing rivers: the Elwha, Kennebec, Rogue, (indiscernible) Salmon, and (indiscernible) rivers are prime examples.	The EIS studied breaching the four Lower Snake River Dams as a measure in MO3. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated under MO3. The Elwha dam in Washington State has little relevance to the lower Snake River dams. The Elwha dam had no fish passage and provided no economic benefits. In contrast, the four lower Snake River dams provide upstream and downstream fish passage, produce power, and provide navigation and recreation opportunities. The four lower Snake River dams would still have regulated flows due to the dams located upstream. For power, the four lower Snake River dams produce upwards of 1,000 aMW of power, which is approximately 11 percent of the average power produced by the Federal Columbia River Power System. See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 730,000 homes in the Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effect, at page 9-935, noting that loss of generation from the four lower Snake River Dams accounts for about 90% of the power loss in MO3.
5605	1	tim@timpalmer.org	N/A	Except for reports of entities paying for the reports that support keeping the dams intact and by agencies deeply invested in sustaining the status quo, the evidence of both biologists and economists say that we need to remove these dams to sustain our fish and to make our public agency solvent.	Based on the EIS analysis of fish in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The PA also meets most of the EIS, including those for resident fish, lamprey, hydropower, water management, and water supply, while minimizing adverse effects on communities and the economy. The EIS relies on high-quality information to evaluate the costs and benefits of the four lower Snake River dams. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90% of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix O, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix O, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class2/ is forecast to have a 50-year levelized cost of generation3/ of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5605	2	tim@timpalmer.org	N/A	I urge you to consider the full cost of these dams and a full accounting of the benefits in restoring our salmon and building a sustainable economy that is not predicated on the extinction of our salmon.	The EIS includes economic analysis of power and transmission (Section 3.7), costs to navigation and transportation (Section 3.10), and a cost analysis of the system implementation (Section 3.19) as well as mitigation, and cost analysis of the Preferred Alternative (Section 7.7). As analyzed in the Draft EIS, none of the alternatives would result in extinction of salmon. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					designated critical habitat. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS does not employ a cost-benefit framework for decision-making consistent with NEPA (40 C.F.R 1502.23). Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis.
5606	1	reputnam@gmail.com	N/A	We're both from Washington state and citizens, retired. A lot of time this last weekend reading a great deal about the EIS report, looking at the various alternatives. Then I got to Chapter 7 titled Preferred Alternative. Wait a minute. I thought, where is there some kind of analysis that takes all the pros and cons of the alternatives and evaluates them against the goals? How can you just jump to a solution, which is in Chapter 7, the preferred alternative, without considering the other choices, especially something this complicated?Where's the objective, numerical, quantitative, repeatable analysis? Well, there isn't one. There's no fair objective analysis. It's all subjective and intuitive. Okay. Well, let's see what it says. So I looked at Chapter 7.2. And I'm going to kind of quote things here, but for sake of brevity, I'm going to summarize a little bit, too. Chapter 7.2. The co-lead agencies determine that the no-action alternative and the other four alternatives that had nothing to do with dam removal allow for the operation of the projects, meaning dams, in furtherance of all of the congressionally authorized purposes, to varying degrees. Okay. There are some magic words in there. Alternative -- I'm still basically quoting. Alternative 3, which is the dam removal alternative, would not meet the congressionally authorized purposes of operating and maintaining the four lower Snake River dams. And again we see these magic words, congressionally authorized. So then it says, new congressional authority through new laws and associated funding would be required to implement dam breaching measures. So now I'm going to stop reading. And basically to summarize, these three agencies do one thing. They build and maintain dams - that's their life. That is their congressional authorization. Those are the magic words, congressional authorization. They say if you want to remove the dams, go get Congress to authorize that and get some money, because it will not happen with the local Corps of Engineers or BPA or Bureau of Reclamation. That's their story, but it's totally wrong. Those magic words, congressional authorization, are a smokescreen by the local lead agencies to make us believe that they can't take out the dams. In fact —- they could do that. They could do everything without additional congressional authorization. It doesn't take Congress to decommission a Navy ship, like it didn't take congressional action for the Portland Corps of Engineers to decommission the Willamette lock and dam in Portland. It's part of what they're responsible for.	The co-lead agencies are responsible for operating and maintaining the CRS to meet multiple requirements set forth by Congress as discussed in the EIS. The Purpose and Need Statement and eight objectives in the EIS were used to help identify a Preferred Alternative (PA). The four Multiple Objective alternatives (MOs) are evaluated throughout Chapters 3-6. The conclusions are represented in the discussion in Chapter 7, as the co-lead agencies used those evaluations to improve outcomes by building the PA based on lessons of the alternatives analysis. MO3 would only partially meet the objective for an adequate, efficient, economical, and reliable power supply due to the loss of hydropower generation, system flexibility and peaking capabilities at the four lower Snake River projects. MO3 is farther from meeting the objective to minimize greenhouse gas emissions because of the loss of hydropower and the loss of navigation on the Snake River compared to the PA. MO3 would also result in adverse effects on irrigation in the lower Snake River. Additionally, Snake River barge navigation would be eliminated. We are uncertain about the process the U.S. Navy uses to decommission ships. As to Willamette Falls Locks (this Corps' navigation project does not include a dam), the commenter is mistaken. The Corps has administrative discretion to (1) place the locks in a minimal maintenance caretaker status, on account of lack of funding associated with a decline in commercial tonnage through the locks, and (2) close the locks to vessel traffic, due to life safety concerns associated with unsafe physical conditions of the locks. The Corps lacks authority to deauthorize the project for its navigation purpose or dispose of the land and improvements prior to such deauthorization. Only Congress can deauthorize the project. The Corps has evaluated the feasibility of deauthorization and disposal, and understands that congressional committees are considering whether to include such a deauthorization in the next Water Resources Development Act (or WRDA). As such, the Corps administratively closing the locks to vessel traffic due to life safety concerns is quite different than Congress legislatively deauthorizing the project and directing disposal.
5608	1	Scott Levy	N/A	I liked what Deborah Giles said just a little while ago. She really showed what has got to happen with this EPA document. So she's an expert on the Salish Sea whales. Said, if I got the quote right, about LSR dam breaching, and then she goes, quote, could significantly help the recovery of Salish Sea orcas. Now, that rung counter to what the EIS says, has negligible effect. Let's see, page --Chapter 3, dash, 759, effects of MO-3, conclusion was minor effect for the orca with MO-3. The food available to Southern Resident killer whales and the lower Snake River population is only a smaller percentage of their overall diet. Change of food availability may change a whale's (indiscernible) behaviors sadly, but will not change their overall condition. The population dynamics in rep 3 is not likely to adversely affect the Southern Resident... So there you go right there. That's a point you guys can all get to work on right away, because you got no evidence that counters what Deborah Giles was saying and Ken Balcomb. Whoever's trying to say this, I suspect more fisheries, they don't have any science to back it up.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The overall health and condition of the Southern Resident killer whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKWs are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts. The final EIS, Vegetation, Wetlands, Wildlife, and Floodplains (Section 3..6.2.6 and Table 3-102) and Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
5610	1	Julian Matthews	N/A	I'm Nez Perce. Lived in Pullman, Washington, for 25 years, Nez Perce tribal member. And I'd like to say -- make a -- there's some Whitman County commissioner came on there earlier and I heard him say he represents all Whitman County residents and Columbia County. That's not true. He doesn't represent my viewpoints. And I'd just like to say that I mentioned this before, that I'm in favor of including the breaching of the Snake River dams, because, as many people have said, we have treaty rights to fish, to take salmon, and our ability to take salmon along the Columbia and the Snake were in place long before the U.S. became a country and before the state of Washington, Oregon, and Idaho. So I feel that's really important for the American people to stick up for that and ensure those treaty rights are enforceable. Right now -- and I will say also that the Nez Perce Tribal Government doesn't necessarily speak on my behalf. I don't support, necessarily, their plan. And I believe the spills are a part of -- I don't think -- I don't know for sure if the spills that they're talking about are part of our SRBA water, which I don't agree with at all, and I need to clarify that. When they talk about these spills off these two dams, I believe they're talking about taking that water from our settlement. That's the Snake River Basin Adjudication Settlement, which I don't agree with, and I need to clarify that.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
5612	1	Nina Sarmiento	N/A	I want to start off by saying I've heard a lot of power groups, PUD groups listening in who have a lot of fear in their hearts about what would happen to our power if the dams were breached. This fear has been instilled in them by misinformation from hydropower sales groups such as Northwest RiverPartners and the Public Power Council and the federal agencies I am speaking to right now. These fear tactics similar to the ones our current administration uses, is why people believe there will be blackouts and our rates will spike and they won't be able to pay their bills anymore. And propaganda by these federal agencies I'm speaking to are why people believe there's still 97 percent survival for fish through the dam. So this really has to stop. I don't blame these people. Until now, these have been the only groups giving them information about breaching. But that's changing because they cannot be counted on to tell the truth about these dams, the endangered salmon, or the endangered orca. I just looked up Appendix H, Figure 5.4, that one of the callers previous told us to look at. And MO-3 shows that rate -- there's a big map. It shows that rates in five counties will increase less than one percent with breaching, but in the preferred alternative, all of the counties in Washington, Oregon, Montana, and Idaho, will see an increase in utility rates upwards of one percent. So that is amazing, Appendix H, Figure 5.6, 5.4, just to show you that these fear tactics are making people believe their rates are going to increase by breaching, and that is false.	The co-lead agencies provided a rigorous analysis of the effects of various alternatives in the EIS. For MO3, which includes the measure to breach the four lower Snake River dams, the EIS finds that absent construction of a large fleet of new resources, the region would face more than a doubling of the risk of regional power shortages (loss-of-load instances, such as blackouts). See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and Appendix H, Table 2-1. With a large investment in new resources, the reliability of the power supply can be maintained at the current level of reliability. However, this will increase wholesale and retail electricity rates, especially for customers whose power is supplied by the Federal Columbia River Power System (FCRPS). The figure that the commenter cites, Appendix H, Figure 5-4, displays the data for Multiple Objective alternative 2, but was inadvertently mislabeled in the Draft EIS. Figure 3-186 in Chapter 3, Section 7, of the Draft EIS, shows the correct figure for MO3. The Tables in Appendix H, Chapter 5, correctly show rate increases for MO3. The error in the graphs in Appendix H should be correct in the Final EIS.
5612	2	Nina Sarmiento	N/A	So another propaganda thing that's been showing up everywhere and it's in the DEIS, is the peaking power capability of the dams, which is impossible based on the run of river configurations. The claim has no citations. It's not found in the appendices. It has never occurred in the history of —- the basin. So that needs to be addressed in the final.	Page 3-906 and 3-907 of the Draft EIS discuss how the ramping capability of the lower Snake River projects was calculated. The lower Snake River projects have the unique ability during certain times of the year to back down their generation to very low levels at night and then increase (ramp) the generation during the day to meet daytime peaks. This ability may be less obvious when looking at only heavy load and light load hour generation. To assess the ability of the lower Snake River projects to ramp, Bonneville looked at actual generation to derive a sustained peak value (6 peak hours per weekday for a month). This value is representative of the average of the super-peak hours when the highest generation is needed. This super-peak value is used to represent what can be sustained over a period of time as opposed to a single hour of generation. Once the super-peak value was derived from historic generation, it was then compared to the minimum generation required of those

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					projects, to derive how much the dams can ramp from minimum generation to a sustained peak. Depending on the time of the year, this can be over 2,000 MW. Also of significant importance is the ramping speed of hydro resources like the lower Snake River projects, which can change their output by hundreds of megawatts in just a few minutes. Table 3-160 presents the historical ramps for the lower Snake River projects with over 2,000 to 2,300 MW of capability in certain months of the year.
5612	3	Nina Sarmiento	N/A	The next critique I had was that Appendix M, page 1353, regional economic effects are forecasted with big numbers, large percentages of deficits. There's no analysis done to forecast benefits to regional economy. So in order to be able to make a clear decision on -- MS. HABIBI: Your time has lapsed. NINA SARMIENTO: -- rate alternatives, that needs to happen	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. Other economic beneficial and adverse effects are described in Section 3.10 (Transportation and Navigation), Section 3.11 (Recreation), Section 3.12 (Water Supply), and Section 3.15 (Fisheries). Additional information regarding the effects of the Preferred Alternative can be found in Chapter 7.
5614	1	N/A	N/A	So what I want to say is that your draft Environmental Impact Statement and the Environmental Impact Statement that will be done in September will drive the orcas and the salmon to extinction, unless you change it. The Southern Resident killer whales are starving; they are going extinct and the salmon are too. And ratepayers are losing money every year. And what are you doing? You're violating the Endangered Species Act and the National Environmental Policy Act.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5614	2	N/A	N/A	To save the endangered Snake River salmon, the Southern Resident orcas, and ratepayers money, the federal agencies need to address the Columbia River System in a two-tiered process. Tier 1 is an emergency response action for the immediate drawdown and breach of the Lower Granite and Little Goose Dam followed by the remaining two dams in subsequent years. Tier 2 is addressing system operations and further mitigation activities in the rest of the Columbia River basin using the new EIS, assuming that the four lower Snake River dams are breached.	The agencies would have to seek congressional authority for breaching the lower Snake River dams and could not immediately breach the dams. The ESA does not require the co-lead agencies to take affirmative actions to support recovery of ESA-listed species. The Draft EIS evaluated removal of the earthen embankment of the four lower Snake River dams (referenced as Tier 1 in the comment) under Multiple Objective alternative 3 including operations (referenced as Tier 2 in the comment) of the other ten Federal dams in the Columbia River System and mitigation for effects to resources from implementing this alternative.
5616	1	verandafay@gmail.com	N/A	For more than two decades, tribal,federal, state, and independent research has repeatedly confirmed that river restoration that includes dam removal will work. The DEIS itself recognizes that breaching the dams will deliver greater benefits to endangered Snake River fish populations, with greater certainty, than any other option. The draft EIS proposes a plan of action that does not offer a new approach; rather it recommends minor tweaks to a 25-year federal approach that has cost billions of dollars, brought salmon and steelhead today to some of their lowest levels on record, helped push orcas to the edge of extinction, increased uncertainty for communities across the region, and has been invalidated five times consecutively in federal court.	The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict that MO3 which includes the dam breaching measure is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The final EIS, Vegetation, Wetlands, Wildlife, and Floodplains (Section 3..6.2.6 and Table 3-102) and Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
5616	2	verandafay@gmail.com	N/A	Taxpayers and regional ratepayers have spent $17 billion on five insufficient Columbia Basin salmon plans over 25+ years, but failed to recover a single endangered population.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. The comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions, which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5616	3	verandafay@gmail.com	N/A	The proposed flexible spill plan is not sufficient to save salmon populations, especially because flex spill will not significantly reduce the transit time of juvenile fish, as shown from the implementation of a similar Flex Spill plan in 2019. One of the issues with flex spill is that it provides the Corps with the flexibility to spill when hydro needs are low, which is usually during the day, while salmon migrations are often highest at night, when spill is lower, reducing its beneficial effects.	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on fish analysis as described in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species. For example, the CSS and NMFS COMPASS models predict that power house encounters will be cut in half relative to the No Action Alternative for Snake River spring/summer Chinook salmon. The real uncertainty lies in the hypothesis that reduced powerhouse encounters would result in increased adult returns. To address this uncertainty, the PA includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas-related mortality of juvenile migrants. Please see Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information.
5616	4	verandafay@gmail.com	N/A	The DEIS says that breaching the dams would have a negligible effect for orca, but the orca scientists have repeatedly advocated for the breaching of the lower four Snake River dams to restore the salmon populations that the orca depend on as their main source of food.	MO3 was considered to have minor (not negligible) effect because of the following facts: The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
5616	5	verandafay@gmail.com	N/A	The Draft EIS fails to honor our treaty promises. Native tribes are more than simply river stakeholders as they have inherent rights as first people. Native nations also have treaties with the United States government which gives them sovereign status. Indigenous people gave up thousands of acres of their land for the right to hunt and fish in their usual and accustomed places, a promise which has not been kept by the government. Restoring salmon runs honors these agreements and the moral imperative for justice.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Moreover, the co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS. Tribal input was received during the development of this EIS and Tribal concerns, rights and interests, including treaty rights, were considered and incorporated throughout this EIS. Please see the treaty rights discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9, Coordination and Public Involvement Process. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
5626	1	N/A	N/A	The available science suggests removing lower Snake River dams and increasing the spill of other existing dams would significantly advance salmon recovery goals toward healthy levels, which, in turn, will greatly benefit endangered Southern Resident killer whales and other wildlife by increasing prey availability. This action should be coupled with others including establishing passage above blocked areas and aggressive habitat restoration. Timely action is paramount given the perilous state of salmon and killer whales, especially considering the increasing threats from climate change. With this draft EIS, the Action Agencies have failed to take the comprehensive approach that this region desperately needs to move forward. The result is a shortsighted analysis with inadequate conservation measures that doom wild salmon and wildlife. In moving forward, we urge you to work with the regions leaders to develop a comprehensive plan to restore salmon and steelhead for people and for killer whales, invest in fishing and farming communities, honor commitments to Native American tribes, and support the development of a clean, renewable energy system.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, Tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions on achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the draft CRSO EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS we choose as the Preferred Alternative, the decision would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. We look forward to participating in that discussion. Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the time frame of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas. In terms of this Draft EIS, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also most likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. The EIS analysis of the Preferred Alternative found the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. Socioeconomic effects were analyzed in the Draft EIS. Investing in fishing and farming communities, however, is outside the scope of this project and outside the authorities of the co-lead agencies. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The U.S. Government supports the development of alternative forms of energy through many different programs and policies. For example, the Bonneville Power Administration also has a robust conservation program, from which about 90 aMW in conservation are saved a year. Further, when acquiring long-term resources, the Bonneville Power Administration statutory directives give priority to conservation and renewable resources.
5651	1	john_twa@yahoo.com	N/A	It has been stated by BPA that the dams can produce 2650 MW of power for 10 hours per day in the event of a cold snap. This is false. Cold snaps occur in winter. The lower Snake River has low flows in winter. To run all the turbines needed to produce that much power, and still maintain water levels behind each dam to keep barges from grounding, the river would have to flow at 43,500 cfs. Flows in winter on the Snake are around 25,000 cfs. And during the spring fish passage season, dams are managed for fish passage, not power production. See attachment Peaking Power 4-9-2020-1.	Pages 3-906 and 3-907 of the Draft EIS discuss how the ramping capability of the four lower Snake River projects was calculated in the EIS. When flows are insufficient for all turbines to operate full time, the four lower Snake River projects generally operate at a lower generation level for most of the day, but are able to ramp up to provide higher generation levels to help meet demand during the highest-load hours. The dams provide over 2,000 to 2,300 MW of ramping capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160.
5651	3	john_twa@yahoo.com	N/A	Breaching costs have also been inflated. In this DEIS costs are close to $1 billion dollars. Hydraulic breaching could be done safely, effectively, and at a much lower cost ($400M). It has been used safely at other dams in the past. Instead, the Army Corps came up with their own extremely elaborate, overly inflated method to remove the dams. See attachment Summary 2016 Breach on Lower Granite Dam.	The method proposed for breaching the lower Snake River Dams is based on the extensive analysis of breaching completed for the 2002 Feasibility Study, but refined to reflect information learned from updated hydraulic modeling. The 2016 breaching methodology also reflects lessons regarding methods, sediment movement, and river recovery learned from other dam-breaching efforts undertaken in the United States. The methodology described in the Draft EIS is intended to minimize impacts on ESA-listed fish and other aquatic organisms, on the built environment, and to provide maximum protection to human health and safety. Regarding costs, for the purposes of this EIS, the 2002 cost estimates were adjusted to reflect the proposed plan (i.e., some features such as training walls and levees were removed as described in the updated methodology) and escalated to 2019 price levels to account for inflation. The co-lead agencies would continue to adhere to Federal standards for dam and levee safety and human life safety considerations. In the event that breaching of the lower Snake River dams is recommended for implementation, additional analysis would be conducted to refine methods and costs.
5651	4	john_twa@yahoo.com	N/A	he need for the power that the lower Snake River dams produce has also been inflated. If you look at BPA's 2018 FERC 714 filing, you will see that BPA exported 4 to 5 times as much power to California utilities as the lower Snake River dams produced that year. So why on God's green earth would BPA need to replace that power with nuclear plants, coal fired plants, or natural gas fired plants costing hundreds of millions of dollars? All they have to do is lower exports of power. Problem solved. Idaho's Snake River salmon should not be sacrificed to keep the lights on in California. See Part II, Schedule 5 in attached file FERC714 2018 Masterx.	The Federal Energy Regulatory Commission (FERC) Form 714 is not a measure of Bonneville's resource adequacy or load resource balance. Rather, Form 714 gathers utility operating and planning information for the purpose of evaluating utility mergers and dispositions, jurisdictional services, jurisdictional rates, energy market oversight, and wholesale market changes and competitive force. See Electronic Filing of FERC Form No. 714, 119 FERC 61,048 (April 19, 2007). As such, Form 714 gathers all loads and resources in the Bonneville control area, including non-Federal resources and non-Federal loads. Thus, any exports seen in the Form 714 are not directly attributed to any specific resource. The Form also omits Bonneville resources and Bonneville loads that are not in Bonneville's Balancing Authority Area, such as loads in Seattle, Tacoma, and parts of Oregon, and southeast Idaho, and Federal resources located in Idaho and Oregon. The EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the NW Power and Conservation Council (Council). See EIS Section 3.7.2.2; Appendix H Power and Transmission, at section 2.1; Appendix I Hydroregulation, section 2.4.4. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year having one or more blackouts. See Appendix H Power and Transmission at section 2.1. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to a year with one or more blackouts in every 15 years. The EIS uses this LOLP level as the benchmark from which to gauge the other Multi-Objective Alternatives. The EIS analysis focuses on primary technologies identified by the Council in their Seventh Power Plan (page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. Contrary to the comment, Bonneville did not include nuclear power or coal-fired power plants as potential replacement resources as they are not considered primary technologies by the Council. The analysis does consider natural gas as a potential conventional least-cost portfolio as this is considered a primary resource.
5651	5	john_twa@yahoo.com	N/A	And lastly, the effects on the farmers has been inflated. The DEIS states that loss of irrigation from Ice Harbor reservoir would cause hundreds of millions of dollars in losses. Independent studies have shown that irrigation could continue with an investment of $20 million in upgraded pumping equipment. There is no need for the farmers to suffer any loss of irrigation water. The Corps likes doing irrigation projects, so let them do this one. See attachment Irrigation Impacts LSR Dams The other inflated effect on farmers is the cost of transportation by rail. The DEIS states that shipping cost for farmers would rise 25 50% based on the opinion of some stakeholders. Without cost estimate modeling and supporting data, this is mere guessing. I have spoken to farmers in this region and asked about shipping costs during times that the lower Snake River locks were down for maintenance. Did they pay more for shipping during this time? No, they did not. Rail and truck can be competitive with barging.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3 Region C discussion begins on page 3-1267, line 3244, in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost-prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
5651	6	john_twa@yahoo.com	N/A	One thing not addressed in this DEIS are the methane emissions from the reservoirs created by these four dams. The Army Corps of Engineers has attempted many times to shrug off the methane emissions from these dams. There is new evidence showing that their assumption (with no analysis to back it up) that the reservoirs do not have the right conditions for methane generation have been wrong. It is time for them to acknowledge that methane emissions do occur, they have been measured at Lower Monumental Dam, and they could be an issue. See PNNL attachment Methane Emissions in Temperate Hydropower Reservoirs and Implications for US Policy on Greenhouse Gas Emissions.	Appendix G, Chapter 5, of the Draft EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River hydrosystem, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies will allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
5680	1	evansdavid@frontier.com	N/A	If people want to help the salmon runs then clean up Puget Sound, stop all commercial salmon fishing, and expand fish hatcheries and the funding for them.	Puget Sound, commercial fishing, and hatchery expansion are outside of the scope of this EIS. This EIS focuses on the operation, maintenance, and configuration of the Columbia River System federal dams.
5684	1	billwarthur@gmail.com	N/A	Taxpayers and ratepayers have invested over $16 Billion over the past thirty years to attempt to protect these remaining wild salmon and steelhead runs.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. Investments through fish and wildlife programs have delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation, Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5684	2	billwarthur@gmail.com	N/A	The DEIS serves as stark reminder that the federal agencies, if left to their own accord, will continue to imperil our fish, orca and communities and perpetuate the cycle of failure and litigation. That is why our region needs a new fresh approach that enables stakeholders, agencies, and political leaders to work together to forge a lasting durable solution that works for everyone.	The co-lead agencies must operate the Columbia River System for multiple, sometimes conflicting, purposes while complying with Section 7(a)(2) of the Endangered Species Act. There are many factors outside the control of the co-lead agencies that effect salmonid populations. Each of the dams on the lower Snake and lower Columbia rivers allow for a high percentage of adult and juvenile fish to bypass the dams. See Figure ES-4 in Executive Summary and a more detailed discussion in Section 3.5.2.3, Anadromous Fish, of the EIS. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums.
5684	3	billwarthur@gmail.com	N/A	The DEIS Alternatives and Analysis is Inadequate: The range of alternative is limited, inadequate, and fails to provide the hard look and meaningful comparison of the environmental consequences of all alternatives as intended by the National Environmental Policy Act. The federal agencies also made a decision in the statement of purpose and need to select and unreasonably narrow and inadequate goal for conservation of wild salmon and steelhead. The ESA defines conservation as returning a species to a self-supporting and sustainable condition in its native ecosystem. Yet the federal agencies arbitrarily decide to narrow their focus to only assuring their actions do notreduce appreciably the likelihood of both the survival and recovery of a listed species... NEPA does permit this kind of arbitrary limit to performing analysis on the effects of the alternatives to this narrow scope of the ESA	As stated in Chapter 2, the co-lead agencies developed the reasonable range of alternatives to meet the objectives and the Purpose and Need Statement. The purpose and need describes the congressionally authorized purposes of the system, which include hydropower generation, inland navigation, and irrigation, among others as well as the legal and institutional purposes the agencies evaluated the alternatives against. Sections 7.3 and 7.4 of the EIS provide a descriptive comparison of the alternatives evaluated. This information is also provided in Table 7-1, Evaluation of Alternatives in the Draft EIS and Table 7-55. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				without a fully rational explanation. However, the federal agencies do not provide any such rational explanation. So, once again, the federal agencies are selecting a goal that does not achieve recovery and very likely doesnt avoid extinction or jeopardy. Additionally, other statutes require even more of the agencies. Specifically, the Northwest Power and Conservation Act requires conservation and rebuilding of salmon and steelhead populations, e.g. adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat. To honor our treaties with Tribes of the Columbia Basin also requires healthy harvestable fish runs. The federal agencies never explain why these statutory and treaty requirements are not relevant to the purpose and need for the CRSO EIS or examine how or to what extent which of the alternatives they do consider would meet these requirements.	Wildlife Service (USFWS). This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, but the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The Pacific Northwest Electric Power and Conservation Act (Northwest Power Act) defines conservation, and it means any reduction in electric power consumption as a result of increases in the efficiency of energy use, production, or distribution. 16 U.S.C. 839a(3). The term conservation is not used in any provision of the Act to describe mandates regarding fish and wildlife. Similarly, the Act does not use the terms rebuild or rebuilding; they do not apply to the agencies statutory compliance. While the Northwest Power and Conservation Council and others use the terms conservation, rebuilding, and restoring when discussing fish and wildlife mitigation, the Northwest Power Acts legal mandates do not. Instead, the Act consistently uses the terms protect, mitigate and enhance when discussing fish and wildlife. 16 U.S.C. 839 b(h)(1), (2), (5), (10), and (11). For example, a purpose of the Act is to protect, mitigate and enhance the fish and wildlife, including related spawning grounds and habitat, of the Columbia River and its tributaries, particularly anadromous fish which are of significant importance to the social and economic well-being of the Pacific Northwest and the Nation and which are dependent on suitable environmental conditions substantially obtainable from the management and operation of Federal Columbia River Power System and other power generating facilities on the Columbia River and its tributaries. 16 U.S.C. 839(6). This language is also reflected in the Purpose and Need Statement for the EIS. Regarding treaties, treaty specific information is included in Section 3.17 as well as Chapter 7. As stated in that section, the treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Tribal input was received during the development of the EIS and Tribal concerns, rights and interests, including treaty rights, were considered and incorporated throughout the EIS. Please see treaty rights discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9.
5684	4	billwarthur@gmail.com	N/A	Of the alternatives identified only MO3 (Dam Removal) and MO4 (spill to 125%) have any real potential for recovering salmon and steelhead and meeting the requirements of law. The No Action Alternative which is used for baseline comparison was found inadequate and illegal by the Court in 2016. The alternatives, other the Preferred Alternative and MO3 and MO4, provide even lower benefits for salmon recovery.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the CRS. Using a multi-disciplinary approach and with the coordination and consideration of cooperating agencies and tribes, as well as public stakeholder input, and by using high-quality information, the co-lead agencies developed the Preferred Alternative (PA). The PA meets the Purpose and Need Statement for the system operations in the region, as well as most of the EIS objectives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The PA is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The PA also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
5684	5	billwarthur@gmail.com	N/A	The Preferred Alternative (PAA) is essentially the flex spill agreement that was agreed to by the states of Washington and Oregon, the Nez Perce Tribe, and BPA. At the time of the agreement it was put forward as an interim, short-term, measure not a long-term solution. We supported the flex spill agreement as a short-term action that provides some benefit to young fish migrating downstream. It was never intended to be a long-term solution and indeed it not sufficient to recovery our endangered salmon and steelhead. The CSS evaluation of the PAA demonstrated that the Smolt to Adult Returns (SARs) it would produce would be inadequate for recovery. The SARs are the consistent standard that must be used to evaluate the relative effectiveness between alternatives rather than selected metrics that only look at potential benefit for smolts passing from the forebay to the tailrace of the dams themselves. The Northwest Power and Conservation Council have selected SARs as the key metric for recovery and identified 4% SAR as the objective to achieve. A 2% SAR means we are simply at replacement level for our depleted and endangered runs of salmon and steelhead. The Chinook of the Snake River hover near 1% meaning a population decline over time with the risk of genetic and geographic extirpation. SARs of 4% and above demonstrate a trend toward recovery. Only MO3 (dam removal) showed an ability to achieve SARs of this level with any degree of consistency. MO4 (higher spill) also showed beneficial SARs but not as consistent or strong as dam removal. The PAA seldom achieved any consistent SARs within the magnitude of recovery. Not surprisingly the DEIS identified MO3 as providing the most benefit for recovering salmon and steelhead. Then chose not to select this option based on an inaccurate assessment of costs and benefits. However, the conclusion of MO3 (dam removal) is consistent, and builds on the abundant evidence, of prior analysis regarding the benefit for salmon recovery of dam removal. In 1998 The Plan for Analyzing and Testing Hypotheses (PATH), commissioned by the federal agencies, concluded that a natural river (breaching the dams) was the only option that would high probability for recovering salmon. This option had the greatest certainty for success and lowest risk of failure. In its 2000 Biological Opinion for operation of the dams on the Snake and Columbia Rivers, NOAA Fisheries also concluded that: breaching the four lower Snake River dams would provide more certainty of long-term survival and recovery than would other measures. Additional reports and studies in the intervening years have also pointed to the lethal impacts of the dams and slack water on the lower Snake River for salmon and steelhead. And, the Cumulative Survival Study repost (CSS) of 2019 predicts a two to three fold increase in salmon abundance with removal of the four lower Snake River dams. And, a potential for a four-fold increase if dam removal is combined with maximum spill over the lower Columbia River dams. A new alternative should be formulated and evaluated that is a combination of MO3 and MO4. The CSS 2017 Annual report looked at a combination of removing the four lower Snake River dams and spilling to 125% at the four lower Columbia River dams. This alternative was also presented to the CRSO-EIS Fish Technical Team on September 21, 2017 by the CSS Committee. The initial CSS analysis indicated that this combination of dam removal and spill produced the highest SARs leading to recovery yet the federal agencies did not consider it in the DEIS. This is a glaring failure and must be remedied.	The co-lead agencies understand that the 2019-2021 Spill Operation Agreement was not initially identified as a long-term solution at the time it was developed. After the alternatives were initially developed, the implementation of spring spill operations in 2018 and the development of the fish operations plan for 2019 led to new information regarding spill for juvenile fish passage to benefit downstream migration. With this information, the co-lead agencies modified the juvenile fish spill operation for the Preferred Alternative (PA) using the analysis from the range of spill levels evaluated in the MOs. The intent was to create an opportunity for a major potential benefit to salmon and steelhead through increased spill, as indicated by the CSS model, while avoiding many of the adverse effects to power generation and reliability associated with juvenile spill operations analyzed in Multiple Objective alternative 4 (MO4). The primary method to accomplish this in the PA is a spring juvenile fish passage spill operation that spills more for fish passage when power generation is less valuable and spills less when power generation is more valuable. The PA also acknowledges the range of potential outcomes predicted by the models used to estimate impacts to anadromous fish, and therefore includes a study to evaluate the potential benefits and unintended consequences of higher spill levels. The underlying principles and model of constructive collaboration established through the 2019-2021 Spill Operation Agreement have been carried forward in the PA. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the EIS analysis of the fish resources as described in Section 7.7.4, the co-lead agencies anticipate that the PA would provide substantial benefits to ESA-listed species. For example, the CSS and NMFS COMPASS models predict that powerhouse encounters will be cut in half relative to the No Action Alternative for Snake River spring/summer Chinook salmon. The real uncertainty lies in the hypothesis that reduced powerhouse encounters will result in increased adult returns. To address this uncertainty, the PA includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas-related mortality of juvenile migrants. The EIS concluded that MO3 would have greater improvement to certain salmonid species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the severity of the short-term effects, MO3 would likely have the most uncertainty. With respect to the PA, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Moreover, the agencies used current, high-quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over 20 years old and does not reflect current CRS operations. The commenter requests information about the potential benefits to salmonids from including an alternative that includes the dam breaching measure and spill up to 125% TDG at the four lower Columbia River projects. However, combining these measure would not be a reasonable alternative. Based on the power impacts under MO3 and Multiple Objective alternative 4 (MO4) discussed in Section 3.7, individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in every seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. For perspective, 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, this is not a reasonable alternative that the co-lead agencies analyzed in detailed study. The co-lead agencies expect that the suite of operational, maintenance, and structural measures included in the Preferred Alternative would allow them to meet the Purpose and Need Statement and the EIS objectives, including those to benefit ESA-listed species.
5684	6	billwarthur@gmail.com	N/A	The DEIS Fails to Adequately Evaluate Energy Replacement for Dam Removal The DEIS is woefully inadequate in evaluating the socio-economic aspects of dam removal and reasonably exploring and analyzing how to mitigate potential impacts. Mostly the DEIS identifies impacts, often with unreasonably high costs associated with them, and then fails to perform a serious (or in some cases any) analysis of how to effectively mitigate the impacts.	The EIS analyzed two resource portfolios to replace the power output of the four lower Snake River dams, both of which maintain regional power system reliability. The EIS finds that replacing the hydropower generation of the four lower Snake River dams with renewable resources would increase power costs. See Draft Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs.
5684	7	billwarthur@gmail.com	N/A	The DEIS also fails to evaluate the benefits of dam removal and a restored river and salmon runs to inland sport fishing communities and coastal fisheries. Thus it fails to provide a balanced approach to evaluating costs and benefits of dam breaching. A particularly glaring example of the failure to provide a reasonable analysis is the treatment of replacing the lost power if the lower Snake River dams are removed. The good news is that the federal agencies confirm that you can breach the dams and replace the power with clean energy and maintain electric system reliability. And, as previously stated, the DEIS also shows that dam removal provides the best opportunity for restoring our salmon and steelhead runs. However, the DEIS analysis of replacing the power from the dams is woefully inadequate, fails to meet industry standards, and results in costs that are hugely inflated and not realistic. The energy analysis does a huge disservice to the region and public in making reasoned decisions on the benefits of dam removal and the ability to replace the lost energy. Key elements contributing to this failure are: Decision to only look at solar and storage batteries as the replacement portfolio. There is no effort to look at the full range of clean energy options (energy efficiency, demand response, wind etc.) and identify a portfolio of least cost options. There is no effort to optimize the possible replacement resource portfolios. Selection of an arbitrary and unrealistic date of 2022 as the implementation date. Using a static, near-term, year rather than a multi-year analysis of the replacement portfolio needlessly drives up the costs. The NWPCC and utilities across the Northwest would perform an Integrated Resource Planning (IRP) approach and examine energy and capacity needs over a span of 20 years, explore demand requirements and assess resource options, then test and optimize combinations of possible replacement	The EIS recognizes the social and economic values associated with salmon although these values are not all expressed in monetary terms. Section 3.15 provides a discussion of the value of fisheries (commercial and subsistence) associated with salmon, as well as passive-use values that people hold for these fish. Section 3.11 describes recreational values associated with the fish. Given uncertainty associated with the specific effects of the alternatives on overall fish abundance, these values are described qualitatively. Additionally, Section 3.17 provides information on the cultural significance of the salmon to regional Tribes. The EIS used the most recent data from the Northwest Power and Conservation Council's (Council) Seventh Power plan and Mid-Term Update to analyze regional reliability, the need for replacement resources, and the potential for additional energy efficiency. The Councils Seventh Power Plan was issued in February 2016 and the Mid-Term Update was issued in February 2019. Draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821; and Appendix H, Power and Transmission, Section 2.2. Contrary to statements in the comment, the EIS replacement power analysis did not solely look at solar and storage as the replacement portfolio. The EIS examined the full range of resources defined as primary by the Council. See Draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821. This included solar, wind, natural gas, batteries, demand response and combinations of solar and wind. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at pages 3-904-905. For all portfolios, the most cost-effective was natural gas while the most cost-effective renewable option was solar. See Draft EIS, Section 3.7.3.5, Table 3-166. Wind was not selected because of its lower reliability benefit-to-cost ratio. However, wind was selected as an additional potential resource in the rate sensitivity analysis for replacing the capability of the four lower Snake River dams. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at pages 3-907-908. Based on responses to public comments, the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. See Appendix H, Section 2.2 in the Final EIS.

				resources. Costs chosen for clean energy resources are much higher than current prices as evidenced by recent responses to RFPs. This is further skewed by using the single year 2022 implementation date thus eliminating the ongoing decline in cost curves for renewable energy. The Northwest Energy Coalition (NWEC) in 2018 commissioned a study by Energy Strategies to determine the feasibility of replacing the power and services provided the by the lower Snake River dams with clean energy resources. The NWEC study using the same modeling tools as used by the regions power planners conducted a comparative analysis that the DEIS failed to do. Their analysis found that with a mix of efficiency, demand response, wind and solar power you could replace the energy from the dams without any loss in reliability and at less than one-third the cost suggested by the DEIS. The NWEC analysis did not optimize the resource portfolio but suggested that that such an evaluation be done. Performing such an optimization analysis along with the ongoing decline in the costs of renewable resources would undoubtedly result in even a lower cost replacement strategy. The failure of the DEIS to perform this kind of analysis and use a standard industry IRP approach is both puzzling and deeply disappointing. This should be rectified in order to provide the region and decision-makers valid information on the cost of power replacement.	The implementation date considered in the power analysis was selected for consistency with the implementation date used by the cost and implementation analysis (see Section 3.19 and Appendix Q). Actual replacement costs for the four lower Snake River dams would depend on the resource acquisition processes by Bonneville or other regional utilities to replace the lost capability. Those processes would review the same type of resources considered in the EIS, albeit in likely different combinations (e.g., natural gas paired with solar and battery). The EIS approach to resource selection was not designed to develop a single pinpoint, optimized resource portfolio. Instead, the EIS examined a broad range of resource options and established bookend options for replacing the power from the four lower Snake River dams. Those options included a least-cost resource portfolio (natural gas) and a zero-carbon option (solar with batteries). See Draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at pages 3-904-905. As described in Appendix H, Power and Transmission, Section 2.4, and Section 3.7.3.5 of the Draft EIS, the EIS considered the Northwest Energy Coalition study cited by the commenter, but that study is not directly comparable with the EIS. This is due to a variety of reasons including that the EIS has a broader scope and relies on more recent regional load and resource availability and cost data. The commenter suggests or questions why a competitive resource review, also known as an integrated resource plan (IRP), was not performed as part of the EIS analysis. An IRP is a resource planning tool that utilities use to plan for future resource builds and acquisitions to fulfill the utility's specific needs over a certain planning horizon, typically 20 years. Some utilities are required to conduct an IRP by their local or state utility commissions. Bonneville is not required to perform an IRP, but does perform resource planning to inform its decisions, including for this EIS. There are many different methods and tools that are used by utilities when performing an IRP. Furthermore, the output of an IRP is often driven by state energy policies, such as carbon emission requirements. Even if an IRP optimizes resource portfolios, the real costs of that portfolio are not known until a competitive request-for-proposal solicitation can be completed and evaluated. As explained in Draft EIS Chapter 3, Section 3.7.3.1, Base Case Methodology and Cost Sensitivities Analysis, the EIS analysis evaluates the power impacts of the Multiple Objective alternatives (MOs) on regional power system reliability, as measured through loss-of-load probability (LOLP). The regional scope of the EIS is necessary because the impacts of the MOs on power system reliability and costs transcend individual utilities and states. Thus, for example, the EIS addresses the cost impacts of replacement resources for each MO regardless of whether Bonneville pays for the replacement resources. If Bonneville does not replace the lost capability caused by an MO, regional reliability would still be worse than the No Action Alternative and above the Councils 5% standard, leaving other regional utilities to acquire the necessary resources. The EIS addressed the regional nature of the costs and resources needed to maintain power system reliability under the MOs. The EIS analysis looked at all potential resources as identified by the Northwest Power and Conservation Council. Specifically, the EIS used data from the resources in the Councils Seventh Power Plan (2016) and Mid-Term Update (2019) to develop various resource portfolios. The cost of batteries came from more recent utility IRP data from 2018 and 2019 instead of 2013 data used in the Councils Seventh Power Plan. Seven trial resource portfolios, one carbon and six carbon-free were produced for each MO and then ranked based on their ability to cost-effectively reduce the LOLP. From these portfolios, the EIS identified the two least-cost portfolios that reduced LOLP to the No Action Alternative levels. These least-cost portfolios include a (1) conventional resource (natural gas), and (2) a least-cost portfolio using zero-carbon resources (primarily solar). These resource portfolios represent a range of least-cost resources that could be available to restore regional reliability to the No Action Alternative level. Based on responses to public comments, the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. See Appendix H, Section 2.2 in the Final EIS. To further address concerns about potential reductions in resource costs, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the Final EIS. The Final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan.
5684	8	billwarthur@gmail.com	N/A	DEIS Does Not Evaluate the Alternatives and the Impacts of Climate Change. The DEIS has discussion of climate change in general (Chapter 4) and includes additional discussion in several other places. However, the DEIS does not analyze climate change and how it would impact the effectiveness of any of the alternatives. This is a serious and significant failure of the DEIS and, once again, leave reviewers in the dark about what the implications are for fish recovery in a climate change world. For example, the federal agencies acknowledge that a warming climate could cause moderate to severe declines in salmon and steelhead populations (DEIS 4-33). The federal agencies further acknowledge that a changing climate will most likely increase the adverse effects and lower the benefits from the alternatives. But there is no attempt to analyze these effects. There is no attempt to discern how much climate change may modify the projected results for improving the conditions for smolts and adult salmon and steelhead. Most important there is no effort to evaluate which of the alternatives may have the best ability to address salmon needs in a climate change world. There is reason to believe that removing the dams and restoring the Snake River will reduce water temperatures. Nor does the DEIS evaluate how the cool water that is delivered from Dworshak dam may change or diminish in benefit if the dams are or arent removed? How would removing the dams benefit the reduction in invasive predator fish that thrive in warm water? How much more damage to juvenile salmon and steelhead may occur if warmer waters from climate change increase populations of these non-native predator fish. A serious and substantive evaluation of the impacts of climate change on water temperature and how it will impact the projected results of the different alternatives is urgently needed and missing in whole from the DEIS.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
5684	9	billwarthur@gmail.com	N/A	DEIS Fails to Evaluate Impacts to Southern Resident Killer Whales. The leading scientists who work with Southern Resident Killer Whales (SRKW) are united in their opinion that removing the four lower Snake Rivers is essential to preventing the extinction of the orcas. Several letters were sent to Governor Inslee and Orca Recovery Task Force in 2018 making a strong case for removing the dams as an essential action to save starving orca. Extensive comment letters were also submitted to the federal agencies during the scoping process focused on the important connection between Columbia Basin salmon and SRKWs. Despite this extensive set of comments and record the federal agencies gave only a cursive look at orca and were quick to dismiss any potential benefit to orca from any of the alternatives without any valid citation. Indeed, without any citation, the DEIS claims that,[t]he food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whales foraging behavior patterns slightly but will not change their overall condition or population dynamics. This bold statement is not backed up with facts or evidence and is manifestly false and inaccurate. The DEIS falsely concludes that any increase in salmon, under any of the alternatives, would provide on a minor benefit to the orca. This is false for several reasons. First, the Snake River salmon are currently, and historically, important food forces for Southern Resident orca. Whale researchers, using both scat analysis and geo-tagging, have demonstrated that all three pods spend substantial time foraging for their primary prey (chinook salmon) off the west coast in late winter and spring. During this time they spend substantial time at the mouth of the Columbia River foraging for salmon as they return to spawn in the Columbia and Snake Rivers. Historically, the Snake River has produced just under 50% of all the chinook salmon from the Columbia Basin. In the pre-dam period when there were substantially more salmon these runs would have made up an even larger part of the orca diet. Two, the Snake River Chinook salmon are particularly important to Southern Residents because of their size and high nutritional (fat) content. These rich fatty fish are a high pay-off prey for the orca. The Snake River provides the single best opportunity to restore salmon abundance anywhere on the west coast. Restoring the Snake River salmon will provide more salmon to our starving orca than any other action we can take. Three, we must restore salmon to all parts of the Southern Resident orcas range to have successful recovery. The DEIS argues that salmon recovery should focus on the Salish Sea. The science clearly shows we must restore salmon throughout their range. Indeed, in the 2008 Recovery Plan for the Southern Resident Orcas, the National Marine Fisheries Service state that perhaps the singe greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. There is a serious disconnect between this statement and the attempt in the DEIS to dismiss the role and value of recovering Snake River chinook salmon for orca. The federal agencies must revise their analysis and evaluate the benefits of restored salmon, or failure to do so, for Southern Resident orcas.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The determination for SRKW in regards to MO3 was based on the following facts: The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.

5684	10	billwarthur@gmail.com	N/A	The final EIS must include a new option that includes removing the four lower Snake River dams and higher spill to 125% at the lower Columbia River dams. It should fully and fairly analyze relevant impacts and benefits of removing the dams. It must look at the ability for the different alternatives to deliver the projected results in a climate changing world.	Improving ESA-listed juvenile and adult anadromous salmonid conditions were two of the eight objectives of the CRSO EIS. The co-lead agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4) individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in every seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. For perspective, 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
5686	1	N/A	N/A	Ever since its origins in the 2016 lawsuit brought by the National Wildlife Federation, this new draft environmental impact statement has been about addressing the failures of the agencies managing the Columbia River System Operations in their obligation to protect fish listed under the Endangered Species Act. With the continuing decline of these fish species on the Columbia and Snake Rivers and their tributaries, it is clear that the action chosen by this draft environmental impact study must make restoring and maintaining these fish populations its top priority. Alternative 2 is the least effective of all the alternatives presented in the DEIS when it comes to the primary purpose of restoring and maintaining fish populations. This alternative prioritizes hydropower production, clearly giving fish a backseat, and was found to be less effective than all the other alternatives in meeting the objectives of improving juvenile salmon, improving adult salmon, and improving adult fish. The No Action Alternative entails continuing to manage the Columbia River System as it was managed under the EIS of September 2016. With fish populations continuing to decline between 2016 and the present day, this management plan clearly does not include measures to facilitate fish restoration, and therefore the No Action Alternative is also an unacceptable choice moving forward. The Preferred Alternative, while claiming to focus on improvements to salmon, also plans to maintain many management strategies carried over from the No Action Alternative, which has already been established as unacceptable for fish population restoration. The Preferred Alternatives focus on flexible spill is based on altering spill levels depending on hydropower generation needs. If hydropower generation is prioritized in this way, no spill measures will be significant enough to restore and maintain fish populations. Alternative 1 demonstrates significant improvements over all the other alternatives described above in terms of measures benefiting fish populations. Among these are the earlier start to juvenile fish barging, and the block spill plan because it includes periods of high spill. Alternative 1 falls short in a few key areas however: the target TDG in the tailrace during high spill is only 120 when research by the U.S. Fish and Wildlife Service and other agencies has found that only rates of 125 TDG will yield the target adult fish returns, and that fish can survive 125 TDG in the water. Additionally, the block spill plans fluctuation between these high spill blocks and periods of unspecified base operation leaves too much leeway for individual projects to prioritize hydropower generation over fish migration during the periods of base operation. Due to these shortcomings, Alternative 1 is insufficient for the restoration and maintenance of fish populations. Alternative 4 is the only alternative that does not include the breaching of the four lower Snake River dams that has the possibility to implement measures that would significantly contribute towards the restoration and maintenance of Columbia and Snake River fish populations. Primarily the inclusion of drawdown measures on the reservoirs of the lower Snake and Columbia Rivers and juvenile fish passage spill, up to 125 percent total dissolved gas levels 7 days a week, 24 hours a day from March 1 to August 31. These spill rates indicate a prioritization of fish populations over hydropower generation and make this an acceptable alternative, at least in the short term. Alternative 3 is the only alternative other than Alternative 4 that is acceptable for the purposes of restoration and maintenance of fish populations. This alternative includes the breaching of the four lower Snake River dams, thus it is by far the best alternative in terms of the benefits it provides to fish populations. However, the other operations that depend on the river (primarily hydropower generation and navigation) may not be immediately ready for the drastic change that will result from this alternative. If this is not the alternative chosen for this EIS, the agencies managing the Columbia River System must immediately begin to work on developing alternative sources of power generation and transportation to replace these functions of the four lower Snake River dams so that they can be breached in the near future.	The co-lead agencies understand your support for MO3 and MO4 with regard to benefits for salmonids on the lower Snake and Columbia rivers. However, the impacts to other affected resources under MO3 and MO4 were carefully evaluated by the co-lead agencies to develop the Preferred Alternative (PA). For example MO4 causes minor to major adverse effects on resident fish due to deep drafts of the upper basin storage projects. As you describe, MO3 and MO4 would not meet the objective to provide an adequate, efficient, economical and reliable power supply. For additional information on the impacts to the power system and reliability under MO3, see Section 3.7. Under MO4, for example, hydropower generation decreases by 1,300 aMW under average water conditions, and 870 aMW under low water conditions compared to the No Action Alternative, the largest impacts on hydropower generation of any of the alternatives. MO4 would also not meet the objective to minimize greenhouse gas emissions. The co-lead agencies expect that the PA would allow them to meet the EIS intent as expressed in the Purpose and Need Statement and most EIS objectives, including those to benefit ESA-listed species.
5693	1	N/A	N/A	This impact statement deserves a thorough hearing and to dismiss requests to extend the comment period is a grave disservice to all interested/impacted parties.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5695	1	annie4208m@gmail.com	N/A	The alternatives MO1, MO2 and MO4 are proposed to potentially improve adult salmon, juvenile salmon, and resident fish species. With the CRS being an important aspect for the lives of endangered species such as Chinook and steelhead, action should be taken to ensure the species increase in numbers rather than decrease. In each of the alternatives listed above, programs involving conservation hatcheries for ESA-listed fish and other hatcheries to mitigate for the construction and operation of the dams are used. However, peer reviewed science proves that hatcheries are more detrimental to wild fish populations than they are beneficial. Hatcheries dont work to recover the endangered and wild salmon and other fish species. Instead, the hatchery fish released negatively impact wild fish species by breeding with them, diluting the wild gene pool, competing for resources and so forth. Wild fish species are robust and resilient, but introducing hatchery fish to the wild species dilutes the genetic diversity and decreases their size advantage, making the offspring and the population as a whole more vulnerable.	The commenter is correct that hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives Multiple Objectives alternative 1 (MO1), Multiple Objective alternative 2 (MO2), and Multiple Objective alternative 4 (MO4), and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The PA proposes measures such as increased spill intended to improve survival of anadromous salmonids. Figure 3-111 in the Draft EIS illustrates that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. Over time, the PA is anticipated to benefit both wild and hatchery fish and the co-lead agencies continue to support information developed by the Hatchery Scientific Review Group and the Northwest Power and Conservation Council's Three-Step Review process.
5695	2	annie4208m@gmail.com	N/A	Not only are hatcheries harmful, but increasing spill over dams in order to aid juvenile migration downriver has yet to recover salmon runs. Few juvenile fish are able to make it through turbines in the dam during their migration, and spill operations are thought to be an effective way to allow juveniles over the dam. However, this system is also harmful to the juvenile fish. Impacts with spillway structures can result in physical injury, brain damage and death. The hydraulic forces associated with spill and the sudden depth changes are also potential hazards that are associated with this hydropower-related passage option.	The Draft EIS used currently available, high-quality data in the analysis, including peer-reviewed models. The commenter is correct that some juvenile fish are injured and killed as a result of passage through spillways and turbines. The Draft EIS analysis and modeling results included incorporation of empirical data on effects of dam passage, such as through spillways. Even with these effects, the CSS model predicts that Smolt-to-Adult return (SAR) rates would increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Council's recovery targets for the region) as a result of the Preferred Alternative.
5695	3	annie4208m@gmail.com	N/A	Barging, a procedure proposed in MO1, is also not beneficial for juvenile fish. This operation may seem effective, but it creates an unnatural environment and an unnatural migration pattern upon the return of fish inland. This decreases the survival rate of a fish as it begins to travel back upstream, since it doesnt have the system mapped out like it would if it migrated naturally downstream as a juvenile.	The juvenile salmon and steelhead transportation program has been an important mitigation tool to decrease travel times. The effectiveness has been monitored intensively, resulting in refined operations with confidence of benefiting the transported populations. Early migrating fish do not benefit from transporting, so they are not transported. However, for the most recent three years with complete returns (2015, 2016, and 2017), transporting bypassed wild Snake River spring Chinook from Lower Granite Dam averaged across these years a return of five times as many adults to Lower Granite Dam than the group returned to the river to out-migrate naturally. While fish that were transported as juveniles can experience higher straying and fallback behavior than fish that were not transported (Keefer et al. 2008), overall stray rates are relatively low for adult migrants (2.2% of spring/summer Chinook salmon, 4.2% of fall Chinook salmon, and 6.8% of steelhead strayed into non-natal tributaries overall; Keefer et al. 2005b). The magnitude of this adverse effect in most cases is far smaller than the increase in the Smolt-to-Adult return rate due to transportation.
5695	4	annie4208m@gmail.com	N/A	Sediment transfer is slightly discussed in the alternative MO3 and I believe it is worth being elaborated on. River sediment is full of rich nutrients that can be utilized for agricultural areas. In a river system, sediment is transported downstream and forms river banks and deltas. In the case of placement of dams, the blocked rivers result in a loss of riparian habitats along inundated reaches. In the case of the LSRD, there is also a loss of sediment transport to the Columbia delta. Without the flow of sediment, the delta cannot grow. The Columbia delta is important because it is a system that absorbs runoff from both floods and storms. It also acts to provide nurseries and spawning grounds for a large number of aquatic organisms. Sediment is no longer free-flowing down the CRS, rather its collecting in the upper reservoir of the dams. Pristine habitat for an abundance of aquatic and terrestrial species is impacted by this impeded flow.	Section 3.6 discussed sediment transfer in MO3 because it had an effect on vegetation establishment and some wildlife species. More detail regarding the sediment transfer system and potential effects are in Section 3.3 (River Mechanics) and Section 3.4 (Water quality). The EIS evaluated sediment transport in a dammed river for the No Action Alternative because that is the existing condition. The EIS compares the effect of the current Columbia River System as the No Action Alternative to each of the proposed alternatives.
5695	5	annie4208m@gmail.com	N/A	Another topic brought up in the MO3 alternative was the potential for an increase in the release of greenhouse gases. It was explained that with the loss of hydropower from the four lower dams, power would need to be replaced with natural gas. I understand that some cleaner options are less reliable, but solar and wind power combined with other clean alternatives is something that should be considered. Geothermal energy uses heat energy from the earth, and is capable of supplying renewable power around the clock that emits little to no greenhouse gases. It also requires a small environmental footprint to develop. Bioenergy is another power source that should be considered. This process utilizes biomass as an organic renewable energy source, including materials such as agriculture and forest residues, energy crops, and algae. The energy biomass produces can be converted into electricity, heat or biofuels.	As stated in the comment, the EIS considered a natural gas replacement portfolio as its conventional least-cost portfolio for replacing lost capability from the four lower Snake River dams under MO3. See Draft EIS, Section 3.7.3.5, at page 3-904. However, as suggested by the comment, the EIS also considered a zero-carbon replacement portfolio to replace lost generation from the four lower Snake River dams in MO3. See Draft EIS, Section 3.7.3.5, at pages 3-904-910. The zero carbon replacement portfolio included solar, wind, and storage technologies. See Draft EIS, Section 3.7.3.5, at pages 3-907-910. The commenter describes multiple technologies, both emerging and currently available, that may serve as potential replacement resources that would reduce the greenhouse gas emissions from new combustion turbines or offset hydropower. The energy sector is constantly undergoing transformation. With new technologies and practices being introduced all the time, the analysis in the EIS is unable to capture all potential permutations of resources. The EIS examined all potential resources identified in the Council's Seventh Power Plan and Mid-term Update, relying on these sources for resource information. The EIS acknowledges that technological improvements will likely bring other options. Appendix H provides additional details on resource selection.
5695	6	annie4208m@gmail.com	N/A	The report discusses species listed on the ESA such as salmon and steelhead, yet the requirements have yet to be met. The ESA requirements involve restoring listed species to all or a significant number of that range. The species listed on the ESA have yet to bounce back in numbers due to the lack of habitat, habitat they used to have access to, the negative impacts of hatcheries, the physical barriers of the dams, and so forth. With dwindling numbers	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				of fish species returning successfully, other species are greatly impacted, the Southern Resident Orcas in particular. Salmon constitute around 80% of the SR Orca diet, with an overwhelming majority of that fraction being Chinook. The CRS Operations is greatly reducing Chinook abundances, which contributes to Orca starvation and imperilment.	The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5704	1	clairecpodoll@gmail.com	N/A	A major proposed flaw of MO3 as described in the CRS-DEIS is its inability to minimize greenhouse gas emissions. However, the analysis leading to this conclusion is over presumptuous. Dams constructed for hydropower production cause the release of methane gas which is far more potent than carbon dioxide and contributes substantially to global warming. Methane has 72 times the global warming potential of carbon dioxide in the first year after emission and 21 times the global warming potential over the following 100 years according to Synapse Energy Economics. This form of energy production is not as green as it is made out to be.	Appendix G, Chapter 5, of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies will allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
5717	1	noelrk49@gmail.com	N/A	Hatchery Roles: Bonneville F&W program is presented throughout the DEIS as a funding source for a variety of hatchery programs. The DEIS does not address issues published in the comment period of the CRSO EIS planning phase. The discussions lack evaluations of past and current performance. Specific goals, objectives of the hatchery programs to enhance endangered species or other potentially affected species are not defined. Funding and oversight needs definition of the programs that implement and oversee the affected species. The DEIS should evaluate the performance of the specific hatcheries within the regions of the operations to denote what has and has not worked. With these determinations define the operations to be developed in existing and/or future hatcheries. Past hatchery operations have drawn criticism that they have negatively impacted wild runs of steel head and salmon. But recent literature regarding the river system Comments Columbia River System Operations DEIS indicates that well managed hatchery programs can make a significant difference to protect and and restore wild fish as well as improve returns and quality of fish released. The EIS needs to present current effects of well managed hatcheries within the overall rivers systems relative to the endangered species and apply those to specific goals, objectives and metrics for the future operations, i.e. Wild & Hatchery and broodstock programs.	Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The scope of this Draft EIS is the operation, maintenance, and configuration of CRS projects; a complete analysis of the maintenance and operations of all hatchery programs is beyond this scope. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
5717	2	noelrk49@gmail.com	N/A	Seal/Sea Lion Predation: Those of us in the Northwest and those that fish and recreate on the lower Columbia and tributaries have read of or seen first hand the impacts of these creatures. Many steelhead, salmon and sturgeon are lost to these predators especially at Bonneville. While the structural proposals to protect the ladders are protective measures, additional controls need to be evaluated and defined to enhance the returns. Experience within the system, i.e. Willamette returns, indicates that significant improvement in the number of returns can be had by eliminating this predation in areas immediately below. Because the co-lead agencies are responsible for Bonneville, they need to present the specific lead, e.g. the BPA F&W for funding and oversight. Evaluate the data learned in the Willamette and if applicable else where for potential applications to Bonneville. Develop and incorporate commitments into the preferred alternative with specific goals and metrics for application. The designated agency needs to be responsible to take the appropriate action to successfully implement and oversee this mitigation.	As described in the Preferred Alternative, the co-lead agencies propose several measures to reduce avian and marine mammal predation to mitigate adverse effects to listed species from CRS operations. The co-lead agencies utilized current high quality information regarding sea lion predation. Ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative. Sea lion management decisions at Bonneville Dam rely on input from the Sea Lion Management Working Group. This Working Group is a collaborative effort with NOAA, USFWS, various Tribes, and the co-lead agencies. The co-lead agencies works to minimize the effects of sea lions on salmon by implementing Best Management Practices specified in the NOAA Biological Opinion and by implementing recommendations developed by the Working Group. The co-lead agencies will continue to use this process to minimize the effects of sea lions on salmon within their authorities. The EIS discusses the Working Group and sea lion management in Section 3.5, 3.6 and Chapters 5 and 7. The co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam.
5717	3	noelrk49@gmail.com	N/A	Comments Columbia River System Operations DEIS Other Operating Dams: The other operating dams within the defined regions and outside these regions, i.e., Canada and within the USA, that can have an impact on the subject CRSO or maybe impacted by the preferred alternative, i.e. Priest Rapids. The EIS should define the controls and agreements that need to be taken with the other operating dams to ensure the desired outcomes. Define existing agreements and controls that are in place supporting the actions of the preferred alternative. Define agreements and/or controls the need negotiation and implementation to ensure outcomes of the EIS are met. Define any obligations that are committed or may be required if damage or deficiencies are found at any of the other dams. Describe negative impacts the respective impacts to the desired outcomes of this EIS.	For the EIS, the "controls and agreements" that are in place were assumed to be those that existed in 2016 when the EIS was initiated and included in the No Action Alternative. The co-lead agencies are not aware of any major agreements, other than the 2019-2021 Spill Operations Agreement, that have been implemented since that time. Any future agreements are outside the scope of this EIS, but that may affect the implementation of the Preferred Alternative in the future, will need to be evaluated when those agreements are being discussed. As the comment notes, the Draft EIS captures the effects to the CRS of storage in Canada that is coordinated with the United States under the Columbia River Treaty using the best available information in 2016, which included information from 2022-based studies and forecasts. Regarding the Power Supply and Replacement Resources chapter of Appendix H, the Columbia River Treaty requires the development of certain power studies in advance, and 2022 information from those studies, as well as other information described in the analysis, represented the best available information at the time of the CRSO Draft EIS. As aspects of the Columbia River Treaty regarding Canadian operations in 2024 and beyond remain the subject of an ongoing negotiation between the governments' of the United States and Canada, the co-lead agencies--including Bonneville and the Corps as members of the U.S. Entity--continue to use the best available information that was applied in the draft EIS to capture the effects of the Columbia River Treaty operations on the CRS in the final EIS.
5717	4	noelrk49@gmail.com	N/A	During the planning period for the CRSO EIS there was some comments that appeared to denigrate the tribes. The EIS should provide at least an overview of the agreements, of on going work and cooperation from the tribes related to harvest of steelhead, salmon and sturgeon within the subject regions.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 and details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource.

5717	5	noelrk49@gmail.com	N/A	Describe actions taken by other agencies that have impacted the endangered species of the DEIS. Define their impacts relative to the desired outcomes of the DEIS, i.e. the abandonment of the Columbia river agreements for commercial netting in the lower Columbia river.	Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Management of commercial fisheries is outside the jurisdiction of the three co-lead agencies. Specific discussion pertaining to commercial fishing is discussed in Section 3.15, Fisheries and Passive Use. Actions taken by other agencies are described in Chapter 6, Cumulative Effects, and Section 7.9, Cumulative Effects of the Preferred Alternative. Alternatives to include changes to harvest are not within the scope of this EIS. A recent EIS addressing harvest was conducted by NMFS. We cited this study in Chapter 3.15 as we used it's results to determine abundance considerations. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors.
5717	6	noelrk49@gmail.com	N/A	Lead Agency Uncertainties and Sensitivities: Analyses throughout the evaluations are based on data, modeling and assumptions. As a consequence the resulting conclusions and recommendations will have varying degrees of technical accuracy. Also implementation of selective actions are subject to line item and annual funding which may impact the implementation and thus effect the results. This would aid the effected/ interested members of the public and overseers the insights to influence and affect the desired results. Define the confidence level to the desired outcome of defined actions presented in the preferred alternative. Define the impacts to the defined actions for lack or loss of funding should that occur. Define the funded and unfunded actions of the preferred alternative as well as the lead agency responsible for the applicable sourcing. Co-lead Bonneville relies on non-capital funding for some significant operations in particular hatcheries. Define the potential impacts to the desired outcomes should funding shortcomings occur.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As the commenter notes, there are a variety of uncertainties in each resource analysis. The co-lead agencies have identified and described these uncertainties throughout the EIS. In addition, sections have been added to several of the technical appendices to further describe and clarify the uncertainties affecting analyses such as flood risk, navigation, recreation, and the cost analysis. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
5717	7	noelrk49@gmail.com	N/A	Other Agencies and Regulators: The DEIS addresses environmental characteristics, i.e. climate change, and current and potential power sources, i.e. solar and wind, that could impact the system. Other agencies have impact or potential impact on the subject endangered species that are presented in the DEIS. To understand the importance or significance of the agencies roles relative to the desired outcomes for the subject endangered species, these need to be presented in the EIS. Define the agencies with direct or indirect potential to impact the endangered species of the DEIS, i.e. agencies involved the with sport and commercial fishing.	Please see Chapter 6 for information about Reasonably Foreseeable Future Actions (RFFAs), and the agencies involved in each. These include RFFA 7 Fishery Management, RFFA 8 Bycatch and Incidental Take, RFFA 11 Resident Fisheries Management, and RFFA 13 Tribal, State and Local Fish and Wildlife improvement.
5754	1	aliciabuchter@gmail.com	N/A	The DEIS should consider an adaptation of MO3 that incorporates spill at the Columbia River dams to 125% TDG as MO4 suggests. Dam removal is crucial to improving fish populations, specifically smolt-to-adult returns, so removing the lower four Snake River Dams is the best option for ensuring that fish populations increase in size. However, fish populations can be improved more by increasing spill, and the most rigorous spill plan is outlined in MO4.	Improving ESA-listed juvenile and adult anadromous salmonid conditions was two of the eight objectives of the CRSO EIS. The co-lead agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and Multiple Objective alternative 4 (MO4) individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in every seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. For perspective, 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023, per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
5754	2	aliciabuchter@gmail.com	N/A	Multiple Objective Alternative 3 is preferred among the alternatives but more rigorous implementation of methods aiding fish travel should be added. Though MO3 is clearly the best option regarding the preservation and increase of fish populations, it is concerning that it does not meet the objective to minimize greenhouse gas emissions. Taking action to reduce the use of fossil fuels is likely the most important thing that can be done to prevent humanity's biggest threat. Due to the current climate change crisis and the western United States legislative and policy trend that is briefly described in the CRSO Executive Summary, it will be prudent to invest in renewable energy sources to replace the power generated by the removed Snake River dams. The least-carbon replacement portfolio outlines a plan that, when adopted, will still result in a 2.7 percent increase in greenhouse gas emissions across the region due to back-ups for renewables as well as another 53 percent increase from changes in transportation methods. It is crucial to consider, however, that globally, societies will inevitably be moving towards relying on renewable energy sources instead of disappearing fossil fuel reserves.	The scenario evaluated in the power and greenhouse gas (GHG) emissions analysis that assumes renewable resources are developed or acquired to replace hydropower under MO3 do still find an increase in power sector GHG emissions, as described in the comment. This is based on high-quality information on capacity and costs of future renewable resources and costs. This scenario is considered in the analysis because, as described in the comment, given policy and legislative decisions in Oregon and Washington targeting large reductions in GHG emissions, a future focus on integrating renewables is likely. The EIS considered replacing the lost capability of the four lower Snake River dams with a zero-carbon resource portfolio. This portfolio is entirely made up of zero carbon resources (solar, wind, and storage technologies, e.g., batteries). However, even with new renewable resources, the EIS analysis finds that existing carbon-emitting resources would likely increase generation to integrate the large portfolio of renewable resources, resulting in a new increase in GHG emissions. This portfolio is described in Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs, and emissions implications in Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation. As described in the Preferred Alternative, Section 7.6.3.13, the Early Start Transport measure allows the transport of juvenile salmon collected at Lower Granite, Little Goose, and Lower Monumental projects to begin as early as April 15, approximately two weeks earlier than current fish transport operations described in the No Action Alternative, if warranted based on transportation benefits or to facilitate transport research. Transport operations would end on September 30 at Lower Monumental and October 31 at Lower Granite and Little Goose. Collected juvenile fish would be transported to a location below Bonneville Dam via barge or truck on a daily or every-other-day schedule, depending on the numbers of fish collected at the collector projects.
5764	1	Sealiondefensebrigade@gmail.com	N/A	Dr. Gary Grossman Professor of Animal Ecology Warnell School of Forestry and Natural Resources University of Georgia Athens, Georgia said, I will speak about California central valley salmon, yet my comments apply to other habitats. Most predation occurs when young fish migrate downstream to their adult habitat the sea, Dr. Gary Grossman. According to fish experts Dr. Gary Grossman and fisheries expert, Mr. Doug Demko, predation on salmon occurs at its highest as baby salmon float down river towards their adult ocean habitat, so salmon smolt survival depends upon adequate FLOW of COLD water over the Dams which are controlled by the BPA. Moreover, current science shows that State, Federal and tribal agencies removing important native non- human animals from their ecosystems and the CRS erodes ancient and delicate ecological and biological relationships that promote ecological health, biodiversity and ecological productivity in the CRS and across the PNW bioregion. Unweaving a beautiful fabric of life for long term survival of the wild Chinook, steelhead, southern resident orcas and approximately, 120 other animals that rely on salmon for their very sustenance and survival not sport. Unfortunately the endangered salmon reside in a highly altered habitat difficult to establish a hierarchy on the cause effecting salmon mortality. Consequently assigning a value to potential increase in of salmon abundance that will be produced by predator control is problematical. When compared to increases potentially from other remediation of other negative influences such as degraded habitat, altered flow regime and contaminants. Dr. Gary Grossman Current peer reviewed science supports and Dr. Grossman conveys that BPA, State, federal and tribal agencies investing millions of dollars into predator removal programs no matter how expensive are not a worthy investment as a means to increase and protect populations of endangered salmon and steelhead because there will always be another predator species that will move in and fill the nitch of the targeted species. This is not a theory. It is well documented that although BPA funds expensive incentive programs such as the pike minnow removal program which has been successful in removing large numbers of pike minnow from the CRS. The pike minnow still outnumber wild salmon and steelhead populations in the CRS. At the same time BPA funding the removal of the pike minnow is assisting the ability of the small mouth bass and American shad populations to exponentially increase in the CRS. Bass and shad populations now dominate the CRS and outcompete with the wild native fish populations for food and habitat resources. As well, the small mouth bass, and other NIS species such as walleye, yellow perch, and channel catfish all predate heavily on Snake River- juvenile Chinook salmon	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped, pike minnow, and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. The Predator Disruption Operations measure in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Sea lions are protected under the Marine Mammal Protection Act. With the exception of continuation of the pikeminnow program, the co-agencies are not proposing additional predator management actions in the Preferred Alternative.
5764	2	Sealiondefensebrigade@gmail.com	N/A	Marine mammals especially sea lions help to strengthen the genetics of the wild salmon preserving their DNA and the sea lions help to aid the states in wild salmon recovery by weeding out the weak and genetically inferior hatchery and NIS fish. Sea Lions and other wildlife predate on the old, sick, injured, and dying fish freeing up habitat resources needed by the wild fish. It is well documented through history that it is only the human animal that predates on the biggest and strongest fish in the CRS and does it using all sorts of technology that enhances the humans ability to find and catch fish with a very unfair advantage. And it has been human hubris, greed and an out of proportion human sense of entitlement that has propelled all species on	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				planet earth one step closer towards EXTINCTION which is forever. Humans must learn to share fish and habitat in the CRS because they can not continue to operate the CRS as if all the fish in the CRS belong to sport and commercial fishermen and that the CRS exists merely to generate profits for humans and to get their products to market if we are serious about protecting and increasing populations of endangered salmon, steelhead and southern resident orca for future generations to come. Altogether to protect and increase wild salmon, steelhead and southern resident orca populations the BPA and US ACOE, State, Federal and Tribal agencies need to stop scapegoating and killing our native wildlife for merely being in the CRS and for eating fish. Peer reviewed science reports sea lions are important to maintaining the health and productivity of the Pacific Northwest ecology. Sea Lions known as ecosystem engineers because their gut and fecal flora are corner stone in the food chain for all life in our rivers and oceans. In addition to regulating species abundance, distribution and diversity, top non human animal predators provide essential food sources for scavengers and remove the sick and weak individuals from prey populations. Maybe its more accurate to describe pinniped poop as the near shore fertilizer equivalent to a gardeners Miracle-Gro because it promotes the well-being and lushness of phytoplankton populations, from giant kelp beds to microscopic marine algae, The volume of plant plankton has declined across much of the world over the past century, probably as a result of rising global temperatures. But the decline appears to have been been steepest where whales and seals have been most heavily hunted the fishermen who have insisted that predators such as seals and sea lions should be killed might have been reducing, not enhancing, their catch. Current science that shows that marine mammals are very important to the health and productivity of the Pacific Northwest ecology and that these four dams are not. We must remember the biological cost before the economical ones. We are a biological system on planet Earth and the laws of the ecology are not built on smoke and a mirrors like Wall Street is. Changes in vertebrate density and composition can have local and even global impacts: the decline of Pleistocene megafauna may have impacted methane production and thus atmospheric temperature. Comparisons of areas with and without keystone, apex and indicator species native non human animal predators show that apex predators provide greater biodiversity and higher densities of individuals, while areas without apex predators experience species absences	
5781	1	gbedirian@hotmail.com	N/A	Taxpayers and electricity ratepayers have spent$17 billion dollars on failed methods for fish recovery, yet these species continue to decline, and doing more of the same will not make any difference in fish and wildlife existence and numbers.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation, Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5781	2	gbedirian@hotmail.com	N/A	The draft environmental impact statement on the operation of the Columbia River Hydropower Systems and its effects on salmon and steelhead protected by the Endangered Species Act (ESA) notes that breaching the dams would cost about $955 million or about $35.4 million a year over 50 years but doesnt consider current operating losses, new construction costs and repairs of dams nor the taxpayer subsidies to the Port in Lewiston, barge companies and Portland Power and Electric. These last three are operating at a substantial loss. Breaching the dams would save the government nearly $79 million a year in dam maintenance costs and $32 million in capital costs and result in resurgent Salmon, Lamprey and Orca populations.	As noted in the comment, the cost analysis estimates the capital and O&M (expense) costs savings that would occur under MO3, see Table 4-1 and 5-1 in Appendix Q. The capital costs include additional construction and capital requirements that would be needed in the future for the lower Snake River dams. Regarding the profitability of power from the dams, the four lower Snake River dams are among the most valuable projects in Federal Columbia River Power System (FCRPS), as described in Section 3.7.3.5 of the EIS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of peaking capacity at certain times of the year. The dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage, with over 2,200 MW of capability in certain months of the year. The EIS in Section 3.10 discusses the potential effects of currently operating barge companies in a dam breach scenario. Impacts to the Port of Lewiston are addressed qualitatively. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Moreover, as described in the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and COMPASS models predict that power house encounters will be cut in half relative to the No-Action Alternative for Snake River spring/summer Chinook salmon. The Preferred Alternative also includes measures to improve lamprey passage.
5781	3	gbedirian@hotmail.com	N/A	The transportation costs are important to consider along with the livelihood of agriculture and fishing tourism. However, the costs of new construction of rail infrastructure and new energy sources are listed WITHOUT listing the operation losses of the existing power company and its outdated infrastructure, all subsidized by taxpayers. the report by the US. Army Corp of Engineers is lacking in critical data and analysis.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the FCRPS. Breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power and require replacement resources (either natural gas or renewables), placing upward pressure on power rates.
5791	1	memendes@hotmail.com	N/A	Of great importance is that once again, despite comments in the CSRO Preface to the Executive Summary noting the importance of salmon and the Snake River to the indigenous Tribes of the region, the co-lead agencies (the US Army Corp of Engineers, the Bureau of Reclamation, and the Bonneville Power Administration) continue to ignore the negative impact on the Tribes that it recognized on p. 3-1401: It is difficult to overstate the effect of each dams construction and operation has had to tribal cultures, lifeways, and traditions. They have shaken the very foundations of tribal identity and have either undermined or destroyed aspects of tribal culture central to the very concept of being an indigenous person in the Pacific Northwest. Appendix P, containing the comments of the Tribes, clearly indicates that most support breaching the lower four Snake River dams. It is beyond long overdue for the co-lead agencies to recognize that treaty rights, the U.S governments fiduciary obligations, and promises made to the Tribes supplant continuation of the status quo.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. The co-lead agencies accordingly included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. Moreover, tribal input was received during the development of the EIS and tribal concerns, rights and interests, including treaty rights, were considered and incorporated throughout the EIS. Please see treaty rights discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9.
5791	2	memendes@hotmail.com	N/A	I was not surprised, but still disappointed, that the Preferred Alternative described in the CSRO was simply the status quo with some additional spill water over the four lower Snake River dams. With 8,000 pages, several hearings, and much expert testimony, certainly it was clear that this approach has not worked in the past, is not working in the present, and will remain ineffective in the future. In short, the Preferred Alternative does not meet the first three stated CSRO objectives regarding fish survival, much less provide for restoring fish abundance. With regard to providing an . . . adequate, efficient, economical, and reliable power supply . . . it was clear once again that maintaining the status quo in this area was far more important than ensuring the survival of fish, or of developing alternative, less environmentally negative solutions.	There are many factors that affect salmonid populations, many of which are outside the control of the co-lead agencies. Past actions by the co-lead agencies have resulted in a large percentage of fish being able to pass both upstream and downstream of the lower Snake River and lower Columbia River projects. See Section 3.5.2.3, Anadromous Fish. Many measures have been included in the Preferred Alternative that will benefit ESA-listed species in both the upper and lower Columbia River. In addition, a large number of structural changes are included to benefit salmonid species and Pacific lamprey. See Section 7.6.2, Preferred Alternative Structural Measures. The spill operation for juvenile fish passage is a significant departure from previous operations (see Section 7.6.3 Preferred Alternative Operational Measures for additional discussion), so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and National Marine Fisheries Service COMPASS models predict that powerhouse encounters would be cut in half relative to the No Action Alternative for Snake River spring/summer Chinook salmon. The real uncertainty lies in the hypothesis that reduced powerhouse encounters would result in increased adult returns. To address this uncertainty, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas-related mortality of juvenile migrants. Please see Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component. Based on the evaluation described in Chapter 7, the Preferred Alternative meets the Purpose and Need Statement, and the EIS objectives for ESA-listed juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management and water supply while minimizing adverse effects to communities and the economy.
5825	2	charlesmccamy@gmail.com	N/A	I support the Preferred Alternative (PA) contained in the DEIS as a balanced approach that benefits the BSA-listed species, meets the multiple purposes of the federal projects, and minimizes adverse economic, environmental, and social impacts, although the PA comes at a cost to me as I pay for power as a member of Fall River Rural Electric Cooperative.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation.
5825	3	charlesmccamy@gmail.com	N/A	My main concern with the PA is increased spill of up to 125% total dissolved gas (TDG) levels, resulting in higher power costs and possibly adverse effects to ESA-listed species. I support higher spill levels and the resulting higher power costs only if scientific analyses clearly show a meaningful benefit to ESA-listed species.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin. Appendix R, Part 2 describes the principles for implementation of the flexible spill operations and guidance for adaptive management. One of the principles focuses on federal power system benefits, which will be as determined by Bonneville

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Power Administration. The understanding is that Bonneville must, at a minimum, be no worse financially compared to the 2018 spring fish passage spill operations ordered by the Court. This principle is directly related to Objective 5 of the CRSO EIS: Provide an adequate, efficient, economical and reliable power supply that supports the integrated CR Power System. The co-lead agencies have determined that the Preferred Alternative meets this Objective. In addition, the Preferred Alternative places additional rate pressure for wholesale power rates of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs it has significant control.
5825	4	charlesmccamy@gmail.com	N/A	Additionally, I urge you to include in the final Record of Decision (ROD) strengthened and expanded measures to mitigate the predation of tens of millions of ESA-listed juvenile fish each year, particularly in the lower Columbia River, by various birds and predatory fish. I also hope the federal agencies will take full advantage of the provisions of the Endangered Salmon Predation Prevention Act to strengthen and expand protections for returning adult fish and I would like to see a strong commitment to do so reflected in the final ROD.	As described in the Preferred Alternative, the co-lead agencies propose several measures to reduce avian and marine mammal predation to mitigate adverse effects to listed species from CRS operations. Ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam. The Preferred Alternative also includes the Predator Disruption Operation to discourage nesting within the John Day reservoir. The projects monitoring and adaptive management plan (Appendix R, part 1) includes monitoring to determine the measure effectiveness on reducing the avian predators nesting habitat. As analyzed in Section 7.7.7, the Predator Disruption Operations measure could delay in nesting waterbirds, forego nesting, or relocate to other areas. As discussed in Section 3.6.3.2, Caspian terns are highly mobile during the breeding season and move between breeding colonies in a given year and between years, demonstrating a willingness to nest away from the Columbia River while still foraging on juvenile salmonids (Corps 2014, 2018, 2019).
5825	5	charlesmccamy@gmail.com	N/A	Im concerned about making sure Fall River has a reliable source of power to meet our communities present and future needs at an affordable cost. Many in our community, include seniors and those on fixed or low incomes, are dependent on the electric service provided by Fall River to heat their homes, power appliances, provide hot water and even pump water from their well. Im concerned about escalating power costs. While the preferred option and increased spill increases our costs, it is far better compared to other DEIS alternatives. Our electric Cooperative, Fall River Rural Electric Cooperative, is serious about their mission of delivering clean, affordable, reliable electricity to us, its members. The DEIS concluded that breaching the Snake River dams would have long-term, major, adverse effects on power costs and rates, and the rate pressure could be up to 50% on wholesale power rates. A 50% increase in wholesale power costs would be financially devastating to our household. It is important to keep these financial impacts in perspective for rural communities like ours where incomes are below regional and state averages. These increases in power costs are not a simple shift from disposable and discretionary income to pay for essential services like electricity. Rather, they mean that some neighbors and family will be forced to make difficult choices about which essentials like food, medicine, utilities, and such they have to sacrifice.	The wholesale power rate effects described in the comment are consistent with the findings of the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Sections 3.18.3 and 7.7.20 of the EIS) provides further detail on this as well as the potential disproportionate effects to tribal, low-income and minority populations. The EIS also discusses that Bonneville customers, such as the cooperative mentioned in the comment, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Draft EIS, Section 3.7.3.5, Residential Effects page 3-929. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment. The Preferred Alternative does meet the hydropower generation objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System.
5825	6	charlesmccamy@gmail.com	N/A	To conclude, I support the Preferred Alternative with certain caveats and concerns described previously. The PA provides a good blueprint for operating the Columbia River System and has been created and extensively reviewed by some of the best scientists and economists in the U.S. The Preferred Alternative proposes operating the Columbia River in a way which will benefit ESA-listed fish, meet the multiple purposes of the federal projects, and minimize adverse economic, environmental, and social impacts.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation.
5855	1	N/A	N/A	We are also concerned that the climate change analysis in the DEIS looks at changes in air temperatures, streamflow, snowpack and precipitation, but not predicted changes in water temperature. The final EIS must have a more accurate assessment of how climate change will increase water temperatures in streams and reservoirs and how that will impact salmon survival, as well as how that would differ under the various management alternatives.	The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change. Unfortunately, there are not reliable models at this time due to the differences in needed resolution (river vs. global or regional scale). Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish in Section 4.2.3.
5863	1	N/A	N/A	I support keeping our dams. For many many reasons including power generation, agricultural and recreational. I would also support the addition of another dam on the upper snake for aquifer recharge and then release the cold water during low, warm flows to add flow and cool water for migrating fish.	Thank you for your comment and recommendations. The addition of another dam in the Upper Snake River basin is outside the scope of this EIS, which focuses on the operating, maintaining and configuring the Columbia River System.
5866	1	Howard Garrett	Orca Network	1. The DEIS is invalid because Peaking, Ramping, Balancing, and Reserve hydropower benefits of the LSRDs are widely inaccurate. The DEIS claims over 2,000 MW, which is inconsistent with the 15 MW claimed in the still operative 2002 EIS. Power Replacement Costs & Loss of Load Probability are vastly overstated. Least-cost power resource acquisition strategies are not modeled. The DEIS ignores surplus power i.e., power that goes to the interchange market. Most up to date costs and forecasts of wind and solar are not used for cost replacement, if replacement of power is needed. The DEIS claims that annual replacement value for the power lost to the LSRDs is almost a billion dollars a year, which is fictional, given the probability that little or no replacement power will be needed.	As explained in the Draft EIS Chapter 3, Section 3.7.3.1, Base Case Methodology and Cost Sensitivities Analysis, the EIS analysis evaluates the power impacts of the Multiple Objective alternatives (MOs) on regional power system reliability, as measured through loss-of-load probability (LOLP). The regional scope of the EIS is necessary because the impacts of the MOs on power system reliability and costs transcend individual utilities and states. Thus, for example, the EIS addresses the cost impacts of replacement resources for each MO regardless of whether Bonneville pays for the replacement resources. If Bonneville does not replace the lost capability caused by an MO, regional reliability would still be worse than the No Action Alternative and above the Northwest Power and Conservation Councils (Council) 5% standard, leaving other regional utilities to acquire the necessary resources. The EIS addressed the regional nature of the costs and resources needed to maintain power system reliability under the MOs. The EIS analysis looked at all potential resources as identified by the Council. Specifically, the EIS used data from the resources in the Councils Seventh Power Plan (2016) and Mid-Term Update (2019) to develop various resource portfolios. The cost of batteries came from more recent utility Integrated Resource Program data from 2018 and 2019 instead of 2013 data used in the Councils Seventh Power Plan. Seven trial resource portfolios, one carbon and six carbon-free, were produced for each MO and then ranked based on their ability to cost-effectively reduce the LOLP. From these portfolios, the EIS identified the two least-cost portfolios that reduced LOLP to the No Action Alternative levels. These least-cost portfolios include a: (1) conventional resources (natural gas); and (2) a least-cost portfolio using zero-carbon resources (primarily solar). These resource portfolios represent a range of least-cost resources that could be available to restore regional reliability to the No Action Alternative level. Based on responses to public comments, Appendix H, Section 2.2 in the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. Contrary to the information in the comment, the 2002 EIS identified the lower Snake River dams as 15%, rather than 15 MW, of the Federal Columbia River Power System (FCRPS) ramping capacity. The peaking capacity reported in the 2002 EIS is therefore slightly higher than reported in the CRSO EIS. Also contrary to statements in the comment, as explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of peaking capacity at certain times of the year. The dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage, with over 2,200 MW of capability in certain months of the year. To maintain regional reliability at the No Action Alternative levels, replacement resources would be needed, and contrary to the statements in the comment, the EIS considers a least-cost natural gas replacement portfolio and a carbon-free renewables portfolio. The cost of replacing the capability of the four lower Snake River dams is described in detail in the EIS in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. The EIS used the most recent data from the Council's Seventh Power plan and Mid-term Updates to analyze regional reliability, the need for replacement resources, and the potential for additional energy efficiency. The Councils Seventh Power Plan was issued in February 2016 and the Mid-Term Update was issued in February 2019.
5866	2	Howard Garrett	Orca Network	2. The DEIS is invalid because Snake River Chinook are considered insignificant prey source for Southern Resident Killer Whales (SRKW) ignoring NOAA's Northwest Fisheries Science Center data and other available science on SRKW historical and present day range and diet. The DEIS includes only three referenced sources on the Southern Residents, does not include the most recent population estimate from the Center for Whale Research and NMFS, and does not include any peer-reviewed studies from independent scientists or data from NMFS regarding the orcas presence in coastal habitat or the importance of Chinook salmon to the orcas survival. For some examples of NOAA providing faulty estimates while ignoring the best available science, and, see Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review Of The Available Scientific Evidence (http://www.orcanetwork.org/Main/PDF/Salmon_Orca_Scientist_White_Paper_02-20-20.pdf). The data compiled by NMFS from dedicated surveys, satellite-tagging, and passive acoustic monitoring indicate that the timing of the Southern Residents presence near the mouth of the Columbia River coincides with peak spring Chinook salmon returns. NMFS itself has noted this area to be a high use foraging area, and approximately 50% of the time spent by the orcas in coastal waters is between Grays Harbor and the Columbia River. The Co-Lead Agencies fail to consider the seasonal role of Columbia Basin Chinook in providing the Southern Residents with a key source of food and nutrition during the late winter and early spring. By ignoring key findings and scientific reports, the DEIS improperly diminishes the importance of Columbia/Snake River salmon as a critical prey resource for Southern Resident orcas.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5866	3	Howard Garrett	Orca Network	3. Transition from barge to rail assumes a rail rate increase of 25-50%. Use of rail line along lower Snake not mentioned.	The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID, to Ayer Junction, WA. The co-lead agencies' research suggests that elevator to river port movements via short-line rail are not currently occurring because in order to ship grain to river terminals on the Columbia, one must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers.
5866	4	Howard Garrett	Orca Network	4. Breach cost (without mitigation) is uncorrected from 2002 EIS despite multiple studies showing far lower costs. Error of approx. $600 million.	Corps' engineers and cost estimators reached out to dam breaching experts at Reclamation and considered techniques used at other facilities. The method proposed for breaching the four lower Snake River Dams is based on the extensive analysis of breaching completed for the 2002 Feasibility Study, but refined to reflect information learned from updated hydraulic modeling. The 2016 breaching methodology also reflects lessons regarding methods, sediment movement, and river recovery learned from other dam breaching efforts undertaken in the United States. The methodology described in the Draft EIS is intended to minimize impacts on ESA-listed fish and other aquatic organisms, on the built environment, and to provide maximum protection to human health and safety. Regarding costs, for the purposes of this EIS, the 2002 cost estimates were adjusted to reflect the proposed plan (i.e., some features such as training walls and levees were removed as described in the updated methodology) and escalated to 2019 price levels to account for inflation. The co-lead agencies would continue to adhere to Federal standards for dam and levee safety and human life safety considerations. In the event that breaching of the lower Snake River dams is recommended for implementation, additional analysis would be conducted to refine methods and costs.
5866	5	Howard Garrett	Orca Network	5. Breach alternative MO3 is obfuscated by conflating with construction and mitigation costs on other dams. This is the poison pill that makes LSRD breaching more expensive than the Preferred Alternative.	MO3 would include breaching the four lower Snake River dams and drawdown of the dam infrastructure (Annex A of Appendix Q). In addition, costs would be incurred to mitigate the adverse effects of MO3 (see Table 6-1 in Appendix Q, Draft EIS). However, there are additional benefits and costs across an array of resource areas associated with the Preferred Alternative and MO3, including potential effects at the national, regional and local level. The EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple objectives, for example, related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives.
5866	6	Howard Garrett	Orca Network	6. Irrigation mitigation of MO3 is based on devaluing irrigated land, 47,840 acres. Pipe extension and pump installation mitigation overlooked, with actual cost estimated at $20 million from Sampson, Rob 2018 A brief review of the impacts to irrigated farmland from breaching the four dams on Lower Snake River (LSR).	The EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267, line 3244, in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement, which concluded that modifying the existing pump system was cost-prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
5866	7	Howard Garrett	Orca Network	7. Salmon survival/mortality data are understated and insufficient. The DEIS does not assess latent mortality and reservoir mortality of smolts, which account for the vast majority of salmon mortalities, or the Smolt to Adult Ratio (SAR) values for recovery standards in each MO. The DEIS fails to acknowledge that out-migrating smolts not directly killed by the hydropower system may succumb to delayed mortality in the estuary and ocean due to accumulated, successive, hydropower system-related impacts.	The model results presented in Section 3.5 and Chapter 7 address latent mortality and reservoir mortality. Latent mortality is captured directly in the CSS model for Smolt-to-Adult return rates and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the National Marine Fisheries Service Lifecycle model results. Reservoir mortality is captured in the juvenile survival metrics presented in Chapter 3. Delayed mortality in the ocean due to Columbia River System dam passage is discussed throughout the Draft EIS.
5866	8	Howard Garrett	Orca Network	8. MO3 Anadromous fish mitigation cost is estimated at $78.1 million for additional hatchery salmon based on assumption that many would die during breaching. That cost is unnecessary if breaching occurs during winter when almost no fish are in the river. The 2002 EIS does not include that expense in its breach alternative for the same reason.	The timing of breaching in the current EIS evaluation is the same as the timing proposed in the 2002 EIS. The CRSO EIS evaluated the potential for impacts to water quality and river mechanics, and subsequently to fish and aquatics in an interim period of two-seven years, that were not provided in the 2002 EIS. This water quality and sediment evaluation in the CRSO EIS was used to identify the need for additional mitigation.
5866	9	Howard Garrett	Orca Network	9. Methane production of LSRDs is ignored under all MOs. Contrary to the DEIS, MO3 reduces greenhouse gas emissions as supported by US Department of Energy 2013 Evaluating greenhouse gas emissions from hydropower complexes on large rivers in Eastern Washington.	Appendix G, Chapter 5, of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. These sections include references to and discussion of Arntzen et al. (2013), research supported by the U.S. Department of Energy. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the four lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus, methane gas is generally not an issue. Additionally, in 2017, the Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies could allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
5866	10	Howard Garrett	Orca Network	10. Under the ESA, recovery means improvement in the status of listed species to the point at which listing is no longer appropriate. The Preferred Alternative and all alternatives except MO3 fail to improve any of the 13 distinct runs of salmon and steelhead evolutionarily significant units (ESUs), the Federal Caucus Agencies are tasked by the ESA and five successive Federal Court decisions to restore.	Based on the EIS analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species, including actions of the other Federal Caucus agencies.
5866	11	Howard Garrett	Orca Network	11. The DEIS is invalid because the Federal Caucus Agencies have failed to respond to opposing scientific viewpoints objectively and in good faith, as required by NEPA, including those of the governments own experts like NOAA's Northwest Fisheries Science Center and the Fish Passage Center.	The co-lead agencies are responding to comments from the public and other agencies on the Draft EIS as represented by Appendix T. The co-lead agencies implemented a multi-disciplinary approach, with the coordination and consideration of our cooperating agencies and Tribes, to complete the alternative analysis by using high-quality and current information. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The Comparative Survival Study model was run by the Fish Passage Center; and the NMFS COMPASS and Lifecycle models were run by NOAA's Northwest Fisheries Science Center for the co-lead agencies. The co-lead agencies sought an Independent External Peer Review on the technical analyses for scientific rigor. The review by this external panel of experts validated the use of both models in the co-lead agencies decision-making process. The panel highlighted the inherent uncertainties and risk that is always present when using complex ecological models and provided suggestions for continued development and improvement. Many suggestions by the expert panel are already accounted for and will be implemented through the adaptive implementation process detailed in Appendix R.
5866	12	Howard Garrett	Orca Network	12. The DEIS fails to acknowledge that Columbia River Basin hydropower development and ongoing operations have significantly altered and destroyed salmon habitat. The LSR dams have drastically reduced or eliminated access to historically accessible habitat, reduced natural river flow important for out-migrating smolts, flooded and covered spawning beds with sediment, increased water temperatures, and facilitated increased predation on salmon smolts. Additionally, turbines, bypass systems, and sluiceways directly kill both adult and juvenile salmon.	It is well understood that CRS dams have an impact on natural riverine processes, as well as anadromous fish migration. This is discussed throughout the EIS document. For example, a system water quality model was developed to examine water temperature and Total Dissolved Gas effects throughout the Columbia and Snake River systems for this EIS. Breaching the four lower Snake River dams would result in long-term benefits, including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. As a NEPA document, the effects of the alternatives are compared to the effects of the No Action Alternative. Effects of hydropower in a historical context are included in the description of the Affected Environment, and ongoing effects of the CRS projects that would continue to affect salmon and steelhead into the future are fully described and analyzed under the Environmental Consequences of the No Action Alternative.
5866	13	Howard Garrett	Orca Network	13. Congressional authorization assumption for MO3 incorrect and has been misrepresented for over two decades to dissuade and delay the necessary breaching alternative, be it Alt 4 in the 2002 FR/DEIS for the Snake River or this CRSO DEIS. The Corps HQ down to the Division needs to apply some true leadership to rectify this false whose got the power and authority excuse derivation. The Corps has the power and authority to manage, thus decommission and deconstruct, its water projects, as demonstrated by the failed bill to create such Congressional authority put before Congress by southeast and central Washington representatives to the House.	The co-lead agencies require congressional authority and appropriations to build dams and to deauthorize or breach dams. The agencies do not have the Federal authority or budgetary discretion to take actions affecting Federal resources without both authorization and appropriations from Congress. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2-100, Appendix G, Section III Post Authorization Changes.
5866	14	Howard Garrett	Orca Network	14. The DEIS fails to acknowledge that breaching the dams is the only biologically feasible mitigation to prevent the extinction of listed endangered species, including Southern Resident orcas.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3, which includes breaching the four lower Snake River dams. This conclusion is based on the fact that The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					behavior patterns slightly, but will not change their overall condition or population dynamics. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
5866	15	Howard Garrett	Orca Network	15. According to Earth Economics, the LSRDs have a combined Benefit-to-Cost ratio of 0.15. Whereas, if they breach, the BCR would be 4 to 1 and could be as high as 20 to 1. Why is this not revealed in the DEIS, and why is BPA not acting on this information?	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making, which is not a requirement of NEPA or the basis of alternative selection under NEPA (see 40 C.F.R. 1502.23). Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3, which includes breaching the four lower Snake River dams. However, the PA also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Regarding the Earth Economics study cited by the comment, the EIS considered this study among others that considered various approaches to valuing benefits. This discussion can be found in the EIS, Section 3.15.2.2, Benefit Transfer Studies.
5866	16	Howard Garrett	Orca Network	16. Expenses incurred by breaching can be written off as a fish mitigation credit. BPA would get a double win by removing costly projects and providing endangered salmon with a greater potential to recover. BPA is aware of this and yet continues to remain defensive of keeping the dams - why?	Under the Northwest Power Act, the Administrator must use the Bonneville Fund to protect, mitigate, and enhance fish and wildlife affected by the operation and development of the Federal Columbia River Power System (FCRPS) in a manner consistent with the Councils Fish and Wildlife Program, the Councils Power Plan, and the purposes of the Act. Section 4(h)(10)(A) (16 U.S.C. 839(b)(h)(10)(A)). The extent of mitigation Bonneville should fund is limited: A principle of the Act restates the longstanding appropriations and accounting principle that electric power consumers should bear the cost of mitigation designed to address the adverse impacts caused by development of FCRPS electric power facilities and programs only. 16 U.S.C. 839(b)(h)(8)(B). Because the FCRPS dams are multi-purpose projects, mitigation Bonneville funds using its section 4(h)(10)(A) authorities offset the adverse impacts of the non-power purposes as well as power purpose of the dams. To ensure electric power consumers pay only the power share of mitigation costs, Bonneville takes a fish credit from the U.S. Treasury to recoup non-power share of the mitigation funded on behalf the FCRPS. 16 U.S.C. 839(b)(h)(10)(C). As a recoupment owed ratepayers for funding non-power mitigation, the credit is not a gain or win as the comment suggests; it simply makes ratepayers whole. Moreover, the section 4(h)(10)(C) crediting mechanism is not available unless Bonneville funds the mitigation using its section 4(h)(10)(A) authority. Bonneville cannot use its section 4(h)(10)(A) mitigation authority under the Northwest Power Act to fund dam breach. Currently, dam breaching is not part of the Councils Fish and Wildlife Program, the Seventh Power Plan, or evident within the purposes of the Act. Dam breaching is inconsistent with the statutory purpose of section 2(6) of the Act, which says in relevant part that anadromous fish are dependent on environmental conditions substantially obtainable from operations and management of the CRS and other hydropower facilities in the basin. Additionally, as demonstrated in Section 3.7 (Power Generation and Transmission) of the EIS, dam breaching is also inconsistent with another purpose of the Northwest Power Act, section 2(2), which provides for assuring the Pacific Northwest an adequate, efficient, economical, and reliable power supply. Because the Northwest Power Act does not authorize Bonneville to fund dam breaching, there would be no mitigation credit available. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the FCRPS and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5866	17	Howard Garrett	Orca Network	17. According to Chris Penny, USACE, Walla Walla District Fishery Biologist (28 years 1991- 2018), Senior Subject Matter Expert on ESA-listed Salmon and Steelhead Passage through the Snake and Columbia river hydrosystems and lifecycle modeling for extinction risk and recovery determinations and management: The NOAA-constructed information for the best selection of a Preferred Alternative is there in the CRSO EIS and fully supports 4 LSR dam breaching in alternative MO3, but the information is well hidden in the complexity of the Appendices. By design of the co-leads this dissuades the reader from seeing the accurate information, to support their pre-determined and pre-selected status quo. The COMPASS-modeled reach survivals in the Appended Tables of Raw Data of Appendix E are very consistent with both NOAA NWFSC annual reporting of the PIT-tag detection modeling (50-70%s Snake River and 40-60% Columbia River reach survivals) and the PATH modeling statistical exercise for breach (Alt 4) in the 2002 FR/EIS for Snake River juvenile salmon migration (85-96% Snake River reach survivals, Columbia River variability stays near the same). These vital and critical reach survival statistics were not brought forth in any adequate way or manner by the co-lead authors, acting woefully and gravely to salmon and steelhead.	For the 2000 Biological Opinion (BiOp), National Marine Fisheries Service (NMFS) proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap and the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from the differences between these two trap-to-dam estimates. A 2004 NMFS memo updated the free-flowing survival estimate from the Salmon River trap using observations from 1993-2003. Expanding the mean 1993-2003 per-kilometer survival rate to an equivalent distance of the system from head of Lower Granite Reservoir to Bonneville tailrace (512 km) resulted in an imputed 78.6% (0.05 se) survival for yearling Chinook, and 82.0% (0.05se) for steelhead. For the CRSO Draft EIS, NMFS used a similar method of estimating free-flowing survival and travel times with the NMFS COMPASS model. PIT-based monitoring efforts have been added at a variety of additional hatchery and wild trap locations in the Snake and upper Columbia since the 2000 BiOp. The Salmon trap to Lower Granite reservoir free-flowing survival rate is used as a representative yearling Chinook population for the main text of the MO3 analysis. In the appendix, NMFS carries out a sensitivity analysis for the choice of upstream trap location by comparing free flowing survival rates estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent lower Snake River dam breach conditions under alternative MO3.
5866	18	Howard Garrett	Orca Network	A key question that is not addressed in the DEIS is the sum totals of federal funds or loan guarantees made available to BPA and the Federal Caucus annually. The answers are not easy to find except by deduction from publicized indications. One example that includes an ominous warning: April 23, 2019 - Congressman Mike Simpson (R - Idaho) at the 2019 Andrus Center conference: Energy, Salmon, Agriculture and Community: Can We Come Together? said: "Their ability to borrow money, 16 billion dollars in debt, I think it's 2023 or something like that, their ability to borrow runs out and	Regarding Bonneville's debt, Bonneville uses U.S. Treasury borrowing authority, non-Federal and other sources to fund Bonneville's ongoing capital program. Bonneville signaled in its strategic plan that, barring no changes, Bonneville would exhaust U.S. Treasury borrowing authority by 2023, so Bonneville's plan was to look at all available options to ensure U.S. Treasury borrowing would not be exhausted. One of the near-term actions Bonneville has taken was to pay an additional amount of U.S. Treasury debt in Transmission rates, doing so frees up U.S. Treasury borrowing authority, extending the timeline for when Bonneville expects it to be exhausted. Paying additional debt is one action, but Bonneville is continuing to explore other options to assure sufficient borrowing authority on an ongoing basis as well as ensuring the amount of debt Bonneville incurs is also prudent. To that end, Bonneville instituted a leverage policy, to ensure the amount of debt Bonneville incurs is

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Congress has to reauthorize that and I'm telling you, I don't know that Congress will reauthorize that. I have seen over my period of time more and more pressure in Congress to do away with power marketing administrations...selling off BPA transmission." Media reports indicate that BPA has spent over $900M in 10 years while adding billions to its federal debt obligations. BPA is one of, if not the most highly leveraged utilities in the country despite raising rates 30% over the same period. BPA isnt recovering its costs, because the Snake River dams generate little or no revenue and never have. According to Rocky Mountain Econometrics (February 18, 2020), the cost to maintain the LSRD by the Corps of Engineers: $49 M per year. The Fish and Wildlife Mitigation cost associated with the LSRD: $300 Million+ per year. According to the Walla Walla Union-Bulletin (https://www.union-bulletin.com/local/lower-monumental-dam-celebrates-half-century-mark/article_33dd909a-9831-11e9-8a14-c3b489c6f05d.html): About 50 Walla Walla District employees work at the [Lower Monumental dam] as electricians, lock operators, mechanics, welders, riggers, painters, utility workers, heavy equipment operators, biologists, park rangers, environmental resource specialists, administrative support staff, maintenance workers and engineers. It would be informative to estimate the total payroll for all those employees, including benefits, admin, travel budgets, etc., multiplied by four to account for all four dams, adjusting for each dam's circumstances, to arrive at the total payroll costs to the ACOE that would be eliminated or reassigned if the dams were breached. Then multiply that by the multiplier effect of their spending in Tri-Cities to Lewiston areas to estimate the total economic effects of the federal money spent in the region to keep the dams in place. In Recovering a Lost River, author Steven Hawley writes that between 2001 and 2011, NOAAs Northwest Fisheries Science Center, which is responsible for both endangered salmon in the Columbia-Snake River Basin and the endangered Southern Resident killer whales, received more than three-quarters of its budget from the Bonneville Power Administration and the Army Corps of Engineers. The proportion of those expenditures dedicated to studies of Snake River salmon or habitat issues is unclear.	prudent relative to the value of its revenue producing assets that will repay that debt through future revenues. Bonneville's leverage ratio has declined over the past decade which is good (less debt relative to revenue-producing assets), and the leverage policy ensures this will continue into the future, resulting in less debt relative to the value of Bonneville's assets over time. Bonneville's Fish and Wildlife Program has funded and continues to fund a wide range of entities including Federal agencies, states, Tribes, universities, non-governmental organizations and others to conduct projects to meet various statutory commitments, including under the Northwest Power Act (16 U.S.C. 839b(h)(10)(A)) and the Endangered Species Act (16 U.S.C. 1531 et seq.). Given their regional expertise and scientific knowledge, NOAAs Northwest Fisheries Science Center (NWFSC) is an important resource for the general public and Bonneville. Over the past two decades, NOAAs NWFSC has conducted critical work to support Bonneville's Fish and Wildlife Program objectives, informing such areas as: research and effectiveness of supplemental and safety-net artificial programs; Ocean Plume investigations; the effectiveness of habitat restoration efforts and importance of supporting ecosystem function such as food webs; evaluation of PIT-tagging techniques and improved monitoring and detection of PIT-tagged ESA-listed species. This work has been conducted across the Columbia and Snake River basins and is used in the development of management guidance for all Columbia and Snake River species. Specific Bonneville-funded NWFSC efforts to support Snake River salmon and steelhead include: management of the Lower Granite Dam adult trap; Snake River fall Chinook Salmon life history investigations; improving Snake River species survival estimates through the hydro system; and providing support and expertise on the management of Snake River spring Chinook and sockeye safety-net hatchery programs. Results from these studies are also typically reviewed by the independent science bodies associated with the Council: the Independent Scientific Advisory Board and the Independent Scientific Review Panel post their reviews on the Councils website: https://www.nwcouncil.org/reports. For additional information on these projects, including budgeting information, please see cbfish.org. The operating costs associated with the four lower Snake River projects are included in the operations and maintenance costs, as described in Table 5-1 in Appendix Q; these costs include the salaries of Corps' employees for operating and maintaining these projects. The regional economic benefits associated with operating the four lower Snake River projects are described in Section 3.19.3 and in Annex C in Appendix Q. Under MO3, the elimination of most of the operating costs for the four lower Snake River projects would result in reductions in jobs and income in the region. However, these are just a few of the trade-offs considered in the decision-making to identify the Preferred Alternative. The EIS evaluated benefits and adverse effects across an array of resource areas, including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple objectives, for example, related to improving fish passage and survival, providing reliable power generation, and minimizing greenhouse gas emissions. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of resource areas as well as the implementation costs of the alternatives. Section 7.3 and 7.4 provide additional discussion on the comparisons among the alternatives.
5878	1	mherke@mail.com	Yakima County Farm Bureau	First, it is a matter of necessity that our region and nation maintain a robust electrical generation capability. Western societies are becoming less dependent on fossil fuels due to the desire to reduce our carbon foot print and nuclear energy has been sidelined due to perceived safety concerns. This leaves hydropower, solar and wind generation as our exclusive electrical generating base in the near future. While there have been advancements in solar and wind generating technologies the YCFB believes that by the very nature of the natural resources they draw upon they are not trust worthy as a stand-alone energy source. In the case of solar, it can only generate power 50% of the time (at most) based on it needing sunlight. But the Sun is not available to its full extent due to cloud cover, thus it is available even less than half the time. Wind is available on its own schedule, not one when the power is needed the most. During the regions winters, a condition often occurs where long stretches of low temperature, stagnant air and solid cloud cover and/or fog which often lasts for weeks. The power needs are at their annual peaks due to heating and lighting needs during these periods. The net result is that when we have the most need for power, wind and solar is producing little or no electricity. Due to the variable and intermittent nature of wind and solar, to operate effectively, they require a large battery to help the grid through resource shortages (periods of no wind or sun). Manufactured battery technology such as Lithium Ion has been advancing but there are still considerable hurdles with respect to creating ones large enough for a wind or solar farm. These new batteries require a considerable investment to manufacture and are largely built overseas due to environmental regulations in the United States and are expensive enough that they are currently used only up to the size required to power compact automobiles for short distances. When these batteries expire they present both an environmental challenge and are expensive to safely dispose of. Replacement batteries would be required as the older ones fail, also at great expense. Traditional batteries containing lead which are less expensive would surely be a non-starter in the current legal environment. Hydropower dams are always able to generate power as they depend on (reliable) water and actually enhance both solar and wind production because of their ability to fill the gaps of production from these facilities. They work hand-in-hand with the power grid which ties all these production facilities together thus creating the perfect battery. Finally, the public does not have to build these facilities because they are already in operation.	The importance of renewable energy for reducing carbon emissions is consistent with the information and findings of the EIS, as described in Section 3.7, Power and Transmission, and Section 3.8, Air Quality and Greenhouse Gases. The variability of hydro, wind, and solar is modeled on an hourly basis in the reliability modeling. The EIS findings also indicated that more capacity for zero-carbon resources (e.g., solar) were needed to address lower capacity factors, consistent with the comment's concern regarding the variability of wind and solar resources. The EIS examined potential storage capabilities in resource replacement studies and found they were not selected due to the fact they had higher costs than other potential resources. However, they could provide various benefits, such as replacing lost capability and flexibility of the four lower Snake River projects when paired with solar power. As such, Multiple Objective Alternative 3 includes lithium ion batteries paired with solar power as described by cost estimates provided by the Northwest Power and Conservation Council. See draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs, at pages 3-904-905. The safe disposal of these batteries was not addressed in the EIS because when their disposal would be needed is speculative. The statement regarding the importance of hydropower for integrating renewable power and the dispatchability of hydropower is consistent with the findings of the EIS.
5878	2	mherke@mail.com	Yakima County Farm Bureau	Beyond the intermittent nature of solar and wind power generation, the overall cost of wind and solar equipment and operation is much higher. Our region would suffer from an overwhelming power rate shock if we began breaching any dams due the increased cost of the replacement solar and wind compared to retaining the existing hydropower facilities. While the Preferred Alternative of retaining the Lower Snake River dams and spilling more water for fish carries an estimated rate hike of 2.5%, the breaching alternative cost rises to about a 50% hike. The YCFB is opposed to any rate hike, the cost of breaching would be disastrous to agriculture, particularly with respect to irrigation rates. According to Washington State University, 1.8 million acres are irrigated in the State with 80% being irrigated by sprinkler, 5% by drip and 15% by surface methods. Irrigation is a very power dependent activity. Ground water (even more power intensive) accounts for 25% of with drawl leaving 75% by surface water sources. We must assume that with few exceptions 85% (80% by sprinkler plus 5% by drip) of the irrigated land or 1.53 million acres require power. Virtually all of that power in this region is by electricity. Of the other 300,000 acres irrigated by surface methods, a significant portion of that also requires power to deliver it. The Columbia Basin Project being a prime example. The fact is that irrigation power bills amount to a substantial impact to farms and ranches in Washington State. The YCFB believes that a substantial increase in electric rates would negatively impact agriculture and a rate increase of up to 50% as suggested in the CRSO EIS due to breaching would CRIPPLE our industry as well as many other supporting businesses and activities that agriculture is sustained by. When the Lower Snake River Dams were constructed, tens of thousands of acres of additional land became irrigated losing that agricultural production caused by breaching would be unacceptable. The YCFB believes that the promises offered to make the farm families whole due to a loss of their irrigation are hollow. Even if their loss were to be fully compensated, simple money does not reimburse for the loss of ones way of life. Also, the true cost of compensation would be staggering.	The statement that replacing the hydropower generation of the four lower Snake River dams with renewable resources would increase power costs is consistent with the findings of the EIS. See Section 3.7.3.5 and Table 3-166 of the Draft EIS, Potential Replacement Resources and Associated Costs.
5878	3	mherke@mail.com	Yakima County Farm Bureau	Interestingly, there are environmental consequences related to wind and solar production, some are known and some are surfacing over time. An example is the issue of birds being killed by wind turbines. Some of these species are in fact endangered or listed. The first generation of wind turbines were scrapped after generating power for a number of years because of their lethal nature to Bald Eagles and other birds. Imagine the cost of that reversal, first to develop the technology, implement it and then scuttle it? The current generation of turbines are claimed to have improved blades but the controversy continues and birds continue to die. Another issue with wind and solar farms is over the view scape. These installations typically occupy considerable amounts of real estate that are valued by many individuals for their scenic value. There have been instances of serious opposition and road blocks in the form of local zoning regulations adopted with the intent of barring new wind or solar projects. As a matter of economics, wind turbines can only be sited where the wind is fairly constant and there is enough speed to pay back the investment. As a matter of fact, they have already been built on the best locations and only upon less desirable sites later as the economics may or may not work out. There is a point of no return, where it simply does not pay to build on subsequently less favorable sites. Another requirement is that a substantive power line must be close enough to afford to connect a potential wind farm to the grid. So the net result is that wind turbines (and solar farms in the case of no close grid or little sunshine) just will not work everywhere. Further, wind turbines have a short life span compared to hydropower installations and that adds to the cost of power generation with them. We do not know what the lifespan of solar farm components are yet but due to the materials used to construct the generating panels, it certainly could not rival the lifespans of dams which are measured in centuries.	The EIS did not find wind power to be a cost-effective resource in the base analysis for the Multiple Objective alternatives (MOs). In Multiple Objective alternative 2 (MO2), the EIS analysis found that with the additional generation produced by the Federal Columbia River Power System (FCRPS), wind construction in Montana could be avoided. In the rate case sensitivity analysis for MO3, wind was included in the zero-carbon resource portfolio designed to replace the four lower Snake River dams capability. See Draft EIS, Section 3.7.3.5. Solar, Wind, and Batteries, pages 3-907-909. The EIS did analyze the potential amount of land required for large-scale solar power as well as the potential costs of transmission interconnections for new replacement resources. The EIS identified that a large amount of land would be required for potential new solar, consistent with the concern in the comment. For example, for MO3, the EIS found that to replace the four lower Snake River dams with solar would require at least 14,000 acres of land, or almost 22 square miles. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, page 3-904. If an alternative is selected that requires replacement resources, additional environmental review would be required. Appendix H, Section 2.2.4 in the Final EIS discusses the process for acquiring new resources.
5878	4	mherke@mail.com	Yakima County Farm Bureau	There is an argument that our region does not need more power or even as much generation capacity as it presently has. The YCFB strongly disagrees with that assertion. It is obvious that there will be continued long term economic growth in Washington and neighboring States which will demand more electricity. The recent leveling off in electrical demand has been created largely through conservation but one can only conserve to a point. Soon our regional load will increase due to economic growth however, the current total generating capability of wind and solar is far from substantial enough to satisfy our present needs. If Dams are allowed to be breached, emergency fossil or coal based power would have to bridge the gap and that would substantially add to carbon emissions. To reduce carbon emissions further, our electric demand will increase due to a continued move towards mobile electric transportation. While autos have led the way, both heavy and light rail transportation and city buses have a history of utilizing electricity and there are companies testing the feasibility of producing large and small electric freight and utility trucks. The move to electrify personal and freight transportation will certainly produce an increased load on power generation and ignoring the impact is foolish and dangerous.	The EIS findings regarding the regional power supply and the importance of hydropower for greenhouse gas emissions are consistent with the concern voiced in the comment. The EIS power analysis used the most recent load forecasts and power data from the Northwest Power and Conservation Council, but acknowledges that technical changes, including additional electric vehicles and economic growth, could affect the future power system and power demand as described by the comment. See Draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821. While the decarbonization of transportation was beyond the scope of the EIS, the analysis examined recent policy trends in Section 3.8, Air Quality and Greenhouse Gases.
5878	5	mherke@mail.com	Yakima County Farm Bureau	Another issue that has surfaced recently is that of a declining population of the Southern Resident Orcas. Advocates for breaching the LRSD blame a reduced salmon population due to losses because of them. The facts and history are illustrative because the Orca population is the same as it was before large scale fish hatchery operations began. The Orca count was about 66 individuals in the area of concern. Millions of salmon were reared and released from hatcheries for many years and the Orcas numbers increased to over 100. The hatcheries were closed or scaled back considerably and the Orcas now number .. 78. The YCFB believes that the Orcas rise in numbers and then their subsequent decline is significantly correlated to the rise and fall of artificial releases of hatchery reared fish. As the releases of hatchery salmon have declined, the Orcas finding fewer reared fish had to turn to the wild	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				salmon which then also declined because of the added pressure from the Orcas. If we need more Orcas, then it is obvious that we need to resume rearing and releasing more hatchery fish to feed them.	years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5878	6	mherke@mail.com	Yakima County Farm Bureau	Though there is disagreement within the environmental community about the genetic quality of hatchery fish, the YCFB believes that they are genetically one in the same as wild salmon, the difference being how they are reared. One study, from the Hood River, claims that first cross fish from eggs and sperm from wild salmon are only 87% as genetically fit as the wild parents. No one else has such a finding. YCFB agrees with the principle Native Nations on this issue. They are big proponents of hatchery fish, and they operate a number of rearing operations in the region and are also at the forefront on research on how to better breed and rear them with great success.	Hatchery programs are included as part of the No Action Alternative, and the Draft EIS does not propose changes to hatchery programs under the Preferred Alternative (PA). Figure 3-111 in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. Over time, the PA is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS.
5878	7	mherke@mail.com	Yakima County Farm Bureau	Understanding where the Southern Resident Orcas reside is also important since they range within the Puget Sound and the Salish Sea for more than half of the year. The EPA has been closely monitoring pollution levels in the Sound and adjoining Salish Sea for decades and they have been finding alarming levels of PCBs and PBDEs in the marine life there. The primary animals the agency is monitoring are the Pacific Herring and the Harbor Seal. Less often, the agency has retrieved samples from Orcas and one individual, a transient (mammal eating) Orca was found to have alarmingly high levels of these harmful pollutants. The resident (Salmon eating) Orcas tested are also showing heightened levels of a number of pollutants including PCBs and PBDEs. Shockingly, scientists in Canada are finding high estrogen levels in male salmon to an extent where some are producing eggs and female proteins. The estrogen is being dumped by humans into waste treatment systems. Scientists are finding similar trends in the Puget Sound. Cocaine is also among the numerous chemicals detected in salmon. The EPA banned PCBs in the 1980s and PBDEs by 2003. Continued monitoring has shown that PCB levels are declining and PBDE concentrations are leveling off. Unfortunately these pollutants are very persistent in the environment and have been shown to bio-accumulate with marine animals higher in the food chain such as with Orcas. It is to be noted that PCBs and PBDEs have been implicated with interfering with many critical life functions in animals. We also find it interesting that the highest levels of these onerous pollutants with in the Sound, on an order of magnitude (a few hundred units vs. nearly 4000) has been found right in the vicinity of Olympia. The YCFB believes that transposing a Puget Sound pollution issue into an advocacy to breach the Lower Snake River Dams is scapegoating, at best. Though a great amount of effort has been directed to fish passage around the Columbia River dams, the YCFB finds it very odd that relatively little has been accomplished with respect to passage around the many blockages of tributaries that empty into the Puget Sound. This is peculiar since this is the home space for the Orcas and if salmon, the prime food source for the resident Orcas, are not allowed to spawn in those tributaries, we ask the question: Is it any surprise that they (Orcas) are hungry? Further, Orcas while in the Sound are also threatened by humans conducting water travel by a multitude of surface and sub-surface ships and craft. These activities include commercial shipping, recreation and military. A point of fact is that even the commercial tour boats used to view the Orcas have been implicated in injuring them. The Orcas are said to be injured not only by the hull of the ships/boats but also by propeller strikes. A related controversy exists over the use of sonar by ships and other water craft. Orcas hunt, navigate and communicate with their own sonar and it is claimed that all these sonars working in a relatively confined space such as the Puget Sound is detrimental to the Orcas. One can count on Orca tour boats using a form of sonar when even the most basic outfitted fisherman in the Puget Sound is using the technology (fish finders). The sonar caused confusion could even add to the Orca/boat collisions. During the winter and spring, the South Resident Orcas range from Monterey Bay on the south to coastal South East Alaska on the north. NOAA has done some remarkable research utilizing satellite tracker tags on salmon and made several important discoveries. Interestingly, Columbia and Snake River salmon as a group do not all range in the same area when out in the ocean. They have found that salmon from the upper reaches of the Columbia River and the Snake River travel farther out into the Pacific Ocean before they begin traveling along the coast. This is incredibly significant because Orcas range more closely to the shore. Salmon from the lower Columbia tributaries such as those originating from rivers such as the Cowlitz and Deschutes among others travel closer to the shore precisely where the Orcas are during the winter and spring. The Snake River Salmon are farther from land than the Orcas looking for salmon. Breaching the LSRD expecting to get more salmon from the Snake River to feed the Orcas is foolish when in fact the Orcas rely upon salmon that arise from the lower tributaries of the Columbia and not those from the upper Columbia and Snake Rivers.	The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
5878	8	mherke@mail.com	Yakima County Farm Bureau	All of the Columbia and Snake River Salmon have relatively high return rates thanks to tremendous efforts and expense to improve habitat and passage in the entire basin. It is interesting that while these salmon have been increasingly successful it is found that runs in areas where NO dams exist are way down even in British Columbia and Alaska. Scientists studying this phenomenon are puzzled as to the reason but again there has been a great amount of land mark research and the likely problem stems from conditions in the Ocean. Predators are a suspected factor in reducing salmon populations. One researcher recently commented that they are having a difficult time finding other factors that could be impacting the salmon because his satellite tagged fish are getting eaten so quickly.	The majority of a salmon's life is spent in the ocean. Therefore, the habitat, food, and predator conditions in the ocean will have the largest influence on the proportion surviving to reproduce. When ocean conditions are good, the Columbia Basin enjoys large returns of salmon, such as in 2014, for example, when nearly every ESU had record returns. However, when conditions are poor, as has been the case for the past several years, the number of adult salmon are much smaller. In the context of the EIS, the ocean would not be affected by any of the alternatives, so it is treated as a constant among alternatives. Among the objectives are improving passage conditions and survival of both juvenile and adult, ESA-listed anadromous fish through the Columbia River System. The more healthy juvenile salmon that enter the ocean, whether the conditions there are good or poor, the greater the returns to the Columbia Basin can be. The greater the success adults have migrating up the Columbia and tributaries and spawning, the more juveniles can be produced for the next generation.
5878	9	mherke@mail.com	Yakima County Farm Bureau	The North Resident Orcas have been growing in numbers (about 200) to the extent that they are flourishing. One theory is that the South Resident Orcas are being out performed by their neighbors (the North Resident). Orcas are known to favor salmon greater than 25 inches long. The research points to a possible answer in that the increasing numbers of North Resident Orcas are harvesting the bigger fish before they can leave the Alaskan waters and travel south back to Washington State tributaries and thus denying the South Resident Orcas a chance to feed on them. The status of the South Resident Orcas and what needs to be accomplished to support a desired population of them is a complicated matter, the four Lower Snake River Dams are the least of their problems and focusing on the false hope that breaching affords will only allow their population to further decline since the real problems are being ignored.	The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5878	10	mherke@mail.com	Yakima County Farm Bureau	The dams of the Columbia and Snake Rivers also provide life and property saving flood mitigation. The floods of 1861 and 1894 occurred prior to the construction of any dams on the Columbia River and claimed many lives in 1861. The latter (1894) affected Portland Oregon and caused great damage. The water level reached 33.5 feet higher than low flow (a record) and many buildings had their ground floors entirely submerged across a 250 square block area. It was referred to as the dirty flood because raw sewage was routinely dumped into the river in that time and great numbers of flood killed livestock and then dead fish, further compounding the specter of serious water borne disease. The Van Port flood in 1948 also caused great loss and killed at least 15 people (but estimates ran as high as 50 lost). Only two major dams had been built by the time of the 1948 flood. Another serious flood also occurred in 1996 but the most unpredictable damages and danger to public safety was caused by flooding from the Willamette River. The Portland area has been fitted with other property and life-saving structures (levies etc.) in the intervening years but the role that the major dams on the Columbia River System serve in saving lives and property cannot be minimized. It should be noted that when the Columbia floods in the Portland area, those events are not historically short lived but have last from several days into weeks.	Maintaining or improving Flood Risk Management (FRM) operations of the CRS has informed both the alternatives development and evaluation process. As stated in the Purpose and Need Statement of the EIS in Section 1.2, one of the purposes of the EIS is to "Provide for a reliable level of FRM by operating the CRS to afford safeguards for public safety, infrastructure, and property." The FRM analysis evaluated flows and stages, both downstream of reservoirs and in reservoir pools, for each of the alternatives (No Action Alternative, Multiple Objective alternatives, and the Preferred Alternative). The FRM analysis and results are provided in Section 3.9, with additional details provided in Appendix K of the EIS. The four lower Snake River dams are not authorized for FRM.
5884	1	Kurt Reidinger	N/A	Chapter 3 briefly touches on portions of the aquatic ecosystem, such as noting which populations are listed under the ESA and the CRSO elements affecting those populations. But it leaves a good deal out. To give an example, in addition to the sockeye in the Snake River, there are two extant anadromous sockeye salmon populations in the mid-Columbia8 (Wenatchee and Okanogan), and a fledgling reintroduction in the upper Yakima system9. These too must cope with the CRS (and non-CRS) dams. These sockeye populations experience the effects of higher reservoir temperatures, passage delays, fallback, GBT, turbine mortality, predation by introduced fishes, and so on. These are real consequences of CRS operations and they are undoubtedly taking a toll10. There is little discussion, however, of CRSO effects on these populations other than to assume one can use Upper Columbia River spring-run Chinook as a surrogate species to account for some effects (Table 3-60 on p. 3-363). But these are very different animals, with different life histories, migration timing, and so on. The comparison is not credible. Similar comments apply to coho, not ESA-listed, in the mid-Columbia and the Snake River different races of Chinook salmon are used as surrogates. The same could also be said for summer and fall Chinook in the mid-Columbia which are not ESA-listed.	In the absence of a robust dataset that could support predictive population modeling, the Corps relied on "surrogates" in order to come to an informed, data driven framework for examining the likely effects on these populations. This process was also supported and informed by information supplied by experts from cooperating agencies working with the co-lead agencies on this EIS. An alternative to this approach would have relied on a qualitative analysis, which may not have been informative in the context of evaluating the effects of each alternative.
5884	2	Kurt Reidinger	N/A	The DEIS is also not forthcoming on the impacts to Pacific lamprey. Once highly abundant in the Columbia-Snake system, populations have taken a nosedive and many populations are at risk11. There is evidence that these anadromous animals use chemical cues different from salmonids in homing to natal rivers12: identification of lamprey spawning grounds is a function of actual lamprey presence (e.g., ammocoetes). So simply modifying CRSO passage structures is probably not enough to prevent further declines (e.g., Chapter 7, Preferred Alternative pp. 91-92).	The Affected Environment (Page 3-307 in Section 3.5.2.3) clearly describes the status of Pacific lamprey and discusses the factors that affect the species in a forthcoming manner. Ongoing effects from continued operation of the CRS projects into the future and ongoing existing mitigation programs that have been developed in response to those effects are detailed under the Effects of the No Action Alternative (Section 3.5.3.3, with Pacific lamprey beginning on page 3-400). As summarized, Key effects of the No Action Alternative on lamprey include continued effects to upstream migration of adults and downstream migration of juveniles in the form of passage delays, direct individual mortalities, and physical stress. The No Action Alternative also would continue effects on larval rearing via reservoir drawdowns and project maintenance dredging. The co-lead agencies plan to continue ongoing work in coordination with regional stakeholders through frameworks such as the Pacific Lamprey Conservation Initiative and the Tribal Pacific Lamprey Restoration Plan. The measures in the Draft EIS to meet the objective of improving conditions for Pacific lamprey were developed to address issues described in the Affected Environment and Effects of the No Action Alternative. These measures were designed to work in concert with the ongoing mitigation programs such as the habitat restoration, reintroduction and translocation, and other efforts and with recognition of the specific life history needs such as pheromone cues. The effects of implementing these measures as well as the effects of changes in other operations and configurations were analyzed for each alternative in the Environmental Consequences Sections in Chapter 3 for the multi-objective alternatives MO1, MO2, MO3, and MO4; and in Chapter 7 for the Preferred Alternative. The benefits and uncertainties regarding the effectiveness regarding structural modifications is recognized and discussed in these Sections.
5884	3	Kurt Reidinger	N/A	The DEIS largely focuses extant fish populations, but left unsaid are the CRSO impacts to populations that are now gone. The operation and configuration of the CRS have contributed to the decimation and reduction of what were once much larger and more robust fish populations. We bring this up not as a simple retrospective accounting of what was lost, but because it highlights a real CRSO impact. For example, chum salmon are struggling to survive in the Columbia River and contrary to the impression given by the BA, chum were undoubtedly much more abundant with runs extending above the site of Bonneville Dam and even upstream of Celilo. Hence the species has been affected by both federal CRS and local PUD projects14. The relevant point is that CRSO has confined chum to a relatively small portion of the historic range where the effects of climate change15 (and other factors) are likely render this restricted range less usable as time goes on. We see exclusion of these facts and ignoring the long-term threat as a deficiency in the current DEIS regarding this species and others.	The question of historical abundance and distribution is often confounded by negative conditions for fish that were ongoing at the time of a project's Congressional Authorization and construction. Though the CRS has undoubtedly changed the landscape of these species in some meaningful ways, the magnitude of that effect cannot be ascertained using historical information. One purpose of the analysis is to converge on solutions that do not preclude the possibility of recovery of ESA-listed fish populations. The historical status of salmon populations is important for context, but disentangling the historical project effect versus other effects (e.g., industrial, fishing) that were ongoing prior to the authorization of the project is outside the scope of the EIS. NEPA requires federal agencies to compare the effects of alternatives to a No Action Alternative. In this case, the No Action Alternative includes the baseline condition of 2016, when the EIS process began. An analysis of conditions prior to the construction of the dams is not required under NEPA.
5884	4	Kurt Reidinger	N/A	Flexible Spill Plan Because it is recognized the biological resources in the Snake River are at a crisis stage, one component of the Action Agencies proposal is essentially to continue operations as in the past with a modification termed Flexible Spill, an effort to improve juvenile survival (decrease turbine passage, increase bypass usage)16. But this would also increase Total Dissolved Gases (TDG), increase the probability of adult fallback, and likely degrade the tagging information system used to monitor survival17. Gosselin et. al. (2018, pp. 43-44) report studies showing higher TDG levels have adverse survival effects, particularly on run-of-river fish. We see this as evidence that the CRS is approaching limits in which to operate and still maintain threatened populations at survival levels, let alone contribute to their recovery. The proponents seem to acknowledge there doesnt appear to be a clear benefit to this operation18. As Gosselin et. al. (2018, p. 44) note: A non-linear relationship between percent spill and survival likely occurs, but determining the threshold at which spill changes from being a positive to a negative effect on survival has yet to be determined.. Even if researchers are able to carry out the tagging-spill experiments alluded to in the Gosselin et. al. (2018) paper and find operational optima, unpredictable real-world events (e.g., avian predation timing, snowpack, etc.) will likely limit the benefits of the operations.	The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill operations. The CSS model, which includes latent mortality effects, predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The commenter is correct that juvenile fish migrating in-river under the 125% TDG condition will be exposed to higher levels of dissolved gas than under the No Action Alternative. The Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants.
5884	5	Kurt Reidinger	N/A	We see the intense focus on survival/conversion rate analyses as myopic. The larger, more pertinent question is: how are the populations as a whole coping with the CRS? It is not necessarily what survival is measured at a given dam, or dams. If one looks at the figures in Section 6 of Gosselin et. al. (2018), one can see annual fluctuation that reflects in-river environmental and operational changes, but a striking feature is that survivals are often constrained to a relatively narrow band over a span of nearly two decades. One doesnt see dramatic changes. SARs may fluctuate to a greater degree. These, however, include uncontrollable ocean effects. Improving passage survival is a worthwhile goal, but as more and more populations have become suppressed by CRSO, now more than ever, its important to look holistically at the populations.	The per-dam survival metric is both accurate and useful in measuring changes in near-field survival at the dams due to structural modifications (e.g., surface passage routes) or operation changes (changes to spill levels or spill patterns). The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past 10 years has been shown to contribute to improvements in total in-river survival of smolts migrating through the CRS, especially for steelhead. These figures were used to provide context in the Affected Environment Section. The focus of the CRSO EIS and the analysis presented throughout this EIS in Section 3.5 and Chapter 7 utilized several metrics, including total in-river survival, travel time, powerhouse passage rates, and Smolt-to-Adult return rates.
5884	6	Kurt Reidinger	N/A	We think the Action Agencies need to analyze and consider whether alternative studies like the ECONorthwest study21 offers an appropriate economic perspective, not only with respect to the power market but the agriculture and transportation sectors as well.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. This is consistent with NEPA guidance, which describes that the EIS should not be a cost-benefit analysis if there are important tradeoffs that are not quantified. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3.
5884	7	Kurt Reidinger	N/A	In this particular EIS, we think the Action Agencies need to consider a wider range of alternatives. The Preferred Alternative is largely business as usual with relatively minor changes to the CRSO from an ecosystem perspective. From an economic perspective, the Action Agencies need to consider how more creative manipulation of the power market (e.g., shifting to alternative power sources) could deal with eventual removal of the lower Snake River dams. There is more work to be done in this area20.	The co-lead agencies presented a range of alternatives to continued operation and management of the CRS and evaluated the alternatives to inform decision making and the public. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Regarding the Preferred Alternative, this alternative is not simply a minor change to operations and maintenance of the CRS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects predicts that median Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The four lower Snake River dams are cost effective. Hydropower benefits exceed costs by $209M to $513M annually. The average annual costs to operate and maintain the four lower Snake River projects is $75M (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32M (Appendix Q, Table 4-1). The annual hydropower (Table 3-171) and navigation (Table 3-244 & Table 3-246) benefits alone for these projects are estimated at $284M to $588M in the base case analysis for MO3. These hydropower values include the effect of other measures in MO3, but the majority of this value stems from generation at the four lower Snake River dams. This estimate is derived from what the hydropower analysis called the base case and does not account for the full characteristics of the lower Snake River projects generation such as sustained peaking capability and fast ramping ability to integrate variable renewable energy sources. Fully replacing the generation capabilities of the four lower Snake River dams could roughly double estimated replacement resource costs (see Section 3.7.3.5).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Table 3-160. While the increase in solar and wind generation is consistent with the EIS discussion in 3.7.2.1 Power Generation, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under MO3. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5910	1	ross.holter@gmail.com	N/A	This leaves us with the Preferred Alternative which identified lamprey passage improvements plus adoption of a flexible spill program that would allow spill up to 125% TDG. We have very serious concerns about this operation which were identified directly in the Draft EIS. The Draft EIS acknowledges that this operation may actually reduce salmon survival by 7.5%! The loss of 160 aMW of generation on average while losing 300 aMW during low-water conditions does not represent an appropriate balancing of impacts for an operation that may end up killing more of the fish that it is intended to protect than the No-Action alternative. We have already seen a flexible spill operation in 2019 with spill up to 120% TDG that showed little benefit to fish with some evidence suggesting that survival was reduced.	The co-lead agencies used currently available, high-quality information in the analysis for the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative (PA), the CSS model predicts that average Smolt-to-Adult return (SAR) rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the PA increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
5920	1	dkellersjd@gmail.com	N/A	Procedurally, the co-agencies have ignored the fundamental precepts of NEPA, which requires the opportunity for full and fair public participation. This nearly 8,000 page DEIS is complicated to navigate, and not written in a manner that allows easy public review and understanding of the different alternatives, and how they were analyzed. The complexity of the DEIS, and the global emergency from the Corona Virus across the Pacific Northwest and country, call for an extension of the short 45 day comment period to provide adequate opportunity for public input. In addition to a lack of adequate review and response time, the limited mechanism used to collect comments through phone calls faced significant challenges, limiting participation in the public comment process, I do not feel that the public has had adequate opportunity to make their concerns fully heard. However, having known the co-agencies modus operandi of consistently ignoring public and scientific input ever since the four Lower Snake River Dams (LSRDs) were congressionally authorized in 1945 until the present, I am not surprised by their insistence on this truncated timeline.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5920	2	dkellersjd@gmail.com	N/A	The agencies appear to be actively defying Judge Simons directive to drastically overhaul their approach to CRSO operations, which currently rely on failed, artificial manipulations like smolt transport, elaborate bypass structures and flexible spill. The cynical view would be that the agencies are intentionally preparing a defective DEIS, so that the judge will invalidate it as strike 6 in the pending litigation, and remand it for more review. That would give the co-leads yet more time, more studies and more public resources expended, while salmon, steelhead and lamprey runs dwindle towards extinction. While re-doing a defective EIS is the usual remedy where agencies have prepared an inadequate one such as this, these are extraordinary times requiring extraordinary measures. Accordingly, the appropriate remedy is not for the co-leads to re-work this failed DEIS in its entirety. But rather, the co-leads should review their better 2002 EIS titled Lower Snake River Juvenile Salmon Migration Feasibility Study, and update MO3, LSRD breaching with the latest best available science.	The co-lead agencies take all legal and NEPA responsibilities very seriously and disagree with the comment. The CRSO EIS considered the 2002 EIS Lower Snake River Juvenile Salmon Migration Feasibility Study, incorporating still valid information where appropriate, and used current high-quality information where needed. The EIS evaluated the potential for impacts to water quality that were not provided in the 2002 EIS. This water quality evaluation in the EIS was used to identify the need for additional mitigation. There are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service (NMFS) website at: https://www.nwfsc.noaa.gov/research/index.cfm. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The PA also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the EIS analysis in Section 7.7.4, the co-lead agencies anticipate that the PA would provide substantial benefits to ESA-listed species. For example, the CSS and NMFS COMPASS models predict that powerhouse encounters will be cut in half relative to the No Action Alternative for Snake River spring/summer Chinook salmon. The Preferred Alternative is expected to make a substantial contribution to recovery.
5920	3	dkellersjd@gmail.com	N/A	Legally, the ESA and treaty rights trump economic concerns. Yet, the co-leads have elevated economic considerations over fulfilling their overriding legal obligations to save listed species and honor treaty rights. The Preferred Alternative is not based on ecological criteria to save listed fish, but simply to continue the flex spill agreement operating at BPAs dictate when market conditions permit it. The DEIS violates ESA and tribal treaty rights by failing to select the alternative that offers the most beneficial impact on them, M03. (See DEIS, Sections 3.5 and 3.6).	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative (PA). Treaty specific information can be found in Section 3.17. As stated in that section, the treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1, to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on this EIS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The PA complies with the ESA (see Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders, for more information). We disagree with the comment that we have elevated power generation over our legal obligations. The co-lead agencies used current, high-quality scientific information in the analysis for the EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The CSS model predicts that average Smolt-to-Adult return rates (SAR) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the PA (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Based on our analysis, the co-lead agencies anticipate that the PA would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS.
5920	4	dkellersjd@gmail.com	N/A	The DEIS also fails to fully address the significant impact that the dams along these river systems have on the critically endangered Southern Resident Orca population. The best available science indicates that restoring the lower Snake River would lead to stabilization of Chinook runs and provide critical food sources for the Southern Resident Orca.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3, which includes breaching the four lower Snake River dams. This conclusion is based on the fact that The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.
5920	5	dkellersjd@gmail.com	N/A	A) Alternative MO3 needs to include an accurate cost-benefit analysis of the four Lower Snake River dams impacts and the power they generate, such as the following items. Purchasing replacement power on the open market would cost $11 million/year. This is $38 million/year cheaper than estimated LSRD maintenance and operation expenses and does not include benefits from reduced fish and wildlife and turbine rehab costs. Turbine replacements and maintenance in the next decade at the four dams will cost tens of millions of dollars a year.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. As described in Tables 3-170 and 3-171 in Section 3.7.3 in the Draft EIS, hydropower replacement costs would range from approximately $140 million to $540 million annually. The socioeconomic analysis for power used two different approaches to evaluate the social welfare effects. The lower number, $140 million, assumes that replacement power would be purchased on the short-term wholesale power market. However, the short-term wholesale power market does not reliably have enough power available, and thus replacement resources would need to be built. The higher cost range ($270 million to $540 million) reflects the more realistic cost of acquiring new resources. Turbine replacement and other capital requirements to maintain the four lower Snake River projects are included in the cost analysis, as described in Section 3.19 and Appendix Q (see Section 4.2). Estimated costs for capital and O&M are $107 million annually for the four lower Snake River projects. Under MO3, the Lower Snake River Compensation Plan would no longer be funded, with a cost savings of $34 million. Bonneville's Fish and Wildlife Program costs are systemwide costs. Breaching the lower Snake River dams may result in changes to Bonneville's Fish and Wildlife Program. However, funding decisions for the Fish and Wildlife Program are not being made through the CRSO EIS process. Future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements.
5920	6	dkellersjd@gmail.com	N/A	Greenhouse Gas emissions such as methane from the reservoirs and as generated by the juvenile salmon transport system have been omitted from the analysis.	Appendix G, Chapter 5, of the EIS details the assessment of reservoir methane emissions from the Columbia River System projects. The findings are summarized in Section 3.8. The comment is correct that emissions from truck transport of fish would be reduced under Multiple Objective alternative 3; however, this reduction in emissions would be very minor compared with the changes in emissions from other sources, including from power resources and shifting from barge-based to road- and rail-based shipping.
5920	7	dkellersjd@gmail.com	N/A	B) The DEIS needs a more thorough economic analysis on the benefits of a restored Lower Snake River corridor. 140 river miles from Lewiston to Ice Harbor, about one-seventh of the entire Snake River, would be restored in the event of dam breaching. The jobs and economic benefits of a major restoration program removing riprap, planting native plants and restoring other damage from the 4 dam/reservoir system should be included as part of MO3. Likewise, the jobs and associated economic benefits from mitigation measures that will accompany breaching the 4 LSRDs, such as extending irrigation lines in the Ice Harbor vicinty, and improving railways along the lower Snake corridor should be included. The lower Snake restoration and improvement projects can employ many people to work in this job scarce portion of Eastern Washington. Small river towns like Kahlotus and Starbuck that are lacking in opportunities would significantly benefit, as well as regional population centers like Tri-Cities, Walla Walla and Lewiston-Clarkston. Opportunities for fishing, hunting, wildlife viewing, rafting, and general tourism would positively impact the local economy in this corridor. About 14,000 high value riparian acres would exist post-breaching, enabling opportunities for agriculture such as orchards, truck farms and viticulture, which were prevalent before the dams/reservoirs were constructed. Exercise of tribal rights, such as hunting, fishing, plant-gathering, and ceremonies at sacred sites would be restored in the 140 mile restored corridor. C) The DEIS MO3 analysis should include a comprehensive economic analysis upstream of the 4 LSRDs of the impact on Idahos salmon sportfishery and its potential in the event of restored abundant wild salmon and steelhead returns. In 2019 anglers spent $750 million dollars in Idaho. In the Clearwater region in 2003, during a decent return year, salmon and steelhead anglers spent $8.6 million a month. Salmon and steelhead fishing supports guides, outfitters, and businesses in river towns throughout the state. Chambers of commerce in towns such as Stanley, Riggins, Salmon and Kamiah support breaching the 4 LSRDs to save their local economies. Having experienced firsthand the importance of steelhead angling to these areas of Idaho in times other than the busy summer season, I understand that abundant fishing is literally a lifeline for these small communities.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Region C is described in Section 3.11.3.5, which would support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The jobs and income supported by the Multiple Objective alternatives' implementation and system expenditures are described in Section 3.19.3 and in Annex C of Appendix Q, including those jobs and income that would occur under the dam breaching of MO3.
5920	8	dkellersjd@gmail.com	N/A	D) The DEIS Findings and Conclusion on Sensitive Species Effects of MO3 Biological Assessment for South [sic] Resident Killer Whales Are Flawed, as They Rely On Erroneous and Outdated Data and Speculative Mitigation Measures, and Fail to Use Current and Best Available Science. The Southern Resident Killer Whales are an extended family of orcas, noted for their intelligence, bonds and importance of matriarchs. NOAA states The endangered Southern Resident is an icon of the Pacific Northwest and inspires widespread public interest, curiosity, and awe around the globe. (https://www.fisheries.noaa.gov/species/killer-whale#spotlight). Unfortunately, the DEIS fails to recognize the worldwide interest and irreplaceable value of these unique sea mammals, nor does it use current scientific data that is crucial to preserving this small, unique population. The CRSO-DEISs findings and conclusion about the impact of MO-3 on the Southern Resident Killer Whale (SRKW) DPS are incorrect. Table 3-106, Sensitive Species Analysis for MO3 (p. 3-759) states: Prey Availability: Minor effect. The Snake River spring/summer Chinook salmon is a negligible portion of their overall diet. These findings ignore the important nutritional role of Snake River chinook salmon runs during critical winter and spring feeding times for SRKWs, as discussed in more detail below. Similarly, the conclusion that MO3 would have a Minor effect on SRKWs is wrong. The CRSO-DEIS states as support for this conclusion: The food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whales foraging behavior patterns slightly but will not change their overall condition or population dynamics. That statement is inaccurate according to the best available science discussed further below. It fails to take into account how a substantially increased supply of Snake River chinook salmon is literally a matter of life and death for these starving, critically-endangered orcas. After reviewing the status, habitat and foraging of Southern Resident Killer Whales [SRKWs], the Biological Assessment (BA), (found at Appendix V, section 3.5.1.2, pgs. 3-598-3-600) concludes: Any remaining Chinook mortality attributable to the Proposed Action is only a subset of the total mortality from all sources within the mainstem migratory corridor. Therefore, the Action Agencies have determined that management of the CRS may affect, but is not likely to adversely affect, the SRKW species or designated critical habitat. This determination ignores the critically-endangered state of the SRKWS, their reliance on dwindling Chinook salmon runs and need for increased supply in their diet, especially wild Chinook, and the crucial foraging that the SRKWs engage in around the Columbia in winter and spring, which are particularly key time for their health and reproductive success. NOAA lists the SRKWs as one of its 9 species in the spotlight, which it defines as among the most at risk of extinction in the near future. https://www.fisheries.noaa.gov/topic/endangered-species-conservation#species-in-the-spotlight . Furthermore, NOAA states that for species in the spotlight such as SRKWs their populations are declining, and they are considered a recovery priority #1. A recovery priority #1 species is one whose extinction is almost certain in the immediate future because of rapid population decline or habitat destruction. SRKWs are starving. This starvation causes them to metabolize stored fat, which releases toxins into their system, impacting their own health, and also causing high rates of reproductive	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 which includes the measure to breach the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				failures. Chinook salmon are over 80% of their diet, and they arent getting enough to eat. Transient killer whales that are found in the same range as the SRKWs are healthy, enjoying great reproductive success and increasing their numbers because they have plenty of preyseals and other marine mammals. See e.g., Shields, Monika W., and Scott Veirs. 2019. Status and trends for West Coast Transient (Biggs) killer whales in the Salish Sea. Encyclopedia of Puget Sound. The BA fails to accurately assess the Proposed Actions impacts on the critically endangered SRKWs requiring a recovery priority #1. The BA contains several notable factual errors. One erroneous statement is that the SRKWs population is estimated at 73. (pg. 3-598). The BAs citation is to the Center for Whale Research (CWR) population data as of Sept. 6, 2019. However, well prior to the issuance of the DEIS on February 28, 2010, CWR reported on January 24, 2020 that L-41 Mega was missing from a sighting of his other family members, and was presumed dead. https://www.whaleresearch.com/2020-2 . In this critically-endangered SRKW population, the death of even one more member, especially a mature breeding male, is potentially devastating to further recovery. This key fact should have been reflected accurately in the BA, as their diminishing population is a key fact and compelling concern. At the time of their 2005 ESA listing, the SRKWs numbered 88. Fundamentally, an endangered listing means that the responsible agencies should be managing the species for recovery. In the SRKWs case, the responsible federal agency, NOAA, established a recovery goal for downlisting of 2.3% increase annually, based on historic growth rates from 1984-1996 for the species. (NOAA 2008 Recovery Plan, pg. IV-9, document available at https://repository.library.noaa.gov/view/noaa/15975). This 2.3%, recovery rate yields a projected increase of SRKWs at about 20+ per decade. Accordingly, based on NOAAs projections for recovery, there should be around 120 SRKWs by 2020. But instead of a healthy increase, the SRKWs have tragically decreased to just 72 now, with their prospects for recovery poor unless immediate, meaningful action is taken to save them. NOAAs recent findings recognize that the main obstacle to orca SRKW recovery is a severe shortage of their preferred food, Chinook salmon. See 84 Fed. Reg. at 49,215; National Marine Fisheries Service, West Coast Region, Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales, Draft Biological Report at 28 (Sept. 2019). The BA says that in the spring, summer, and fall, the SRKW are in the inland waters of Puget Sound, the Northwest Straights [sic] and southern Georgia Strait. [This area is commonly referred to as the Salish Sea]. But this broad assertion ignores both the historical evidence that SRKWs range over half the year away from the Salish Sea, and recent patterns where theyve been absent from the Salish Sea during summer months, likely due to not enough prey being available. Both of these topics are described in more detail below. Historically, as noted in a recent scientific report by a group of distinguished killer whale scientists, SOUTHERN RESIDENT KILLER WHALES & COLUMBIA/SNAKE RIVER CHINOOK: A REVIEW OF THE AVAILABLE SCIENTIFIC EVIDENCE FEBRUARY 2020, (Bain et al. Feb. 2020) (hereafter 2020 SKRW Scientists Report), the SRKWs geographic range is not confined to the Salish Sea for over half the year. See 2020 Scientists Report, pgs. 8-9 (citations omitted). Moreover, in the past few years, the SRKWs have not consistently been in their resident areas of the Salish Sea during the warmer months, but instead have been off the Pacific Coast. This pattern indicates that their foraging patterns are changing, likely due to the lack of chinook salmon in the Salish Sea. See Shields, Monika W., Jimmie Lindell, and Julie Woodruff. 2018. Declining spring usage of core habitat by endangered fish-eating killer whales reflects decreased availability of their primary prey. Pacific Conservation Biology https://doi.org/10.1071/PC17041 The BA also discounts the importance of chinook salmon runs from the Columbia/Snake Basins to the SRKWs, pointing instead to Puget Sound and Fraser River stocks. But to a starving creature, every meal is important, and the Columbia/Snake runs are particularly so. The 2020 Scientists Report provides a clear picture of the importance of Columbia/Snake River runs of chinook salmon to the SRKWs: The best available science indicates that the whales are likely to be especially reliant on the Columbia/Snake River watersheds early spring, nutrient-rich Chinook salmon runs. Indeed, the mouth of the Columbia Basin is one of the Southern Resident orcas favorite places to fish. Data compiled from tagged whales, dedicated surveys, and passive acoustic monitoring indicates the Southern Residents spend significant time in the winter and spring off the mouth of the Columbia and have been present there thirty-five times more often than would be expected by chance. Analysis of fish scale and Southern Resident fecal samples collected on the outer coast indicate that, as is the case in inland waters of the Salish Sea/Puget Sound, Chinook are the primary species consumed on the outer coast and that over half the Chinook consumed by the Southern Residents are from the Columbia River Basin. In partnership with the Washington Department of Fish and Wildlife (WDFW), NOAA created a preliminary priority list of West Coast Chinook salmon stocks important to the Southern Resident orcas recovery. Of the top fifteen priority stocks, seven are from the Columbia Basin, including both fall and spring Chinook. 2020 SKRW Scientists Report, pgs. 9-10, citations omitted. The link between the depleted Chinook salmon runs in the Columbia/Snake system and the depleted status of the SRKWs is clear: The current depleted level of adult Chinook returns to the Columbia is a critical component of the prey scarcity these whales face. This shortage is compounded by the fact that adult Chinook returns, especially hatchery stocks that comprise most of these returns, consist of an increasing number of younger and hence smaller fish than in the past. This fact means that these whales must expend far more energy today to obtain the same caloric value of prey with the net effect of less nourishment. The claim that maintaining the continued low adult salmon returns to the Columbia does not harm these critically endangered whales is not scientifically supported. 2020 SKRW Scientists Report, pg.11, citations omitted. The CROS-DEIS BA is relying on an outdated 2008 determination that found that the Columbia River system management was based on expected status improvements for prey originating from the Columbia as a result of three key factors: (1) previous modifications to system operations and configuration to benefit salmonids; (2) ongoing artificial production programs in the Columbia River Basis; and (3) implementation of the 2008 BiOps RPA actions, with further improvements to mainstem migration conditions, spawning and rearing habitat, predator management, and hatchery reforms. This determination was speculative in 2008, and with the benefit of hindsight, far too optimistic. The 2008 expected status improvements are not working for salmon or SKRWs, as shown by the alarming decrease in populations of these species. Moreover, as pointed out in the 2020 SRKW Scientists Report, hatchery fish are inferior to wild salmon to fulfill the SRKWs nutritional needs. Breaching the 4 Lower Snake River Dams, according to the CSS modeling, would result in an estimated 4 x the return of Chinook salmon with a few years. Consequently, independent SRKW scientists have concluded that breaching the 4 LSRDs is the best, and likely only, way to recover SRKWs. See e.g., 2020 SRKW Scientists Report at pg. 12: When all of this evidence is taken into account, we believe that, as a matter of scientific evidence, it is clear that lower Snake River restoration, including dam removal, is the single biggest and most effective step we can take to restore these two important species. The evidence of continued decline for both orcas and Snake River Chinook also highlights the great urgency to take this action as soon as possible. Accordingly, the co-leads should revise the BA to determine that the Proposed Action will adversely affect the SRKWs, and instead implement breaching the 4 LSRDs this year. Only breaching the 4 LSRDs, as described alternative MO3, offers an immediate, meaningful route to recover this critically-endangered species.	According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5920	9	dkellersjd@gmail.com	N/A	E) The DEISs Preferred Alternative Fails to Uphold Federal Treaty and Trust Obligations to the Tribes. I support the positions and comments of the Tribes who provided input, as set forth in CRSO-DEIS Appendix P, Tribal Perspectives. As the DEIS acknowledges on p, 3-1401, It is difficult to overstate the effect each dams construction and operation has had to tribal cultures, lifeways, and traditions. They have shaken the very foundations of tribal identity and have either undermined or destroyed aspects of tribal culture central to the very concept of being an indigenous person in the Pacific Northwest. MO3, which includes LSRD breaching, was specifically identified by several tribes as a preference relative to the range of alternatives analyzed in this EIS. Most tribes support breaching the four lower Snake River damsas it represents the only alternative that substantially attempts to restore the river to a more natural environment. (DEIS, p. 3-1414). Consequently, the co-agencies recognize the support for MO3 by a number of tribes. (DEIS, p. 1414). Despite this clear tribal support for breaching the 4 LSRDs as provided in MO3, the co-lead agencies have recommended their Preferred Alternative, which is essentially intended to extend the interim flex spill arrangement. The Preferred Alternative simply continues the failed status quo of artificial transport of smolts via barging and trucking, attempted technological fixes like adding bypass structures, and increasing spill at BPAs convenience for its economic returns, not based on ecological needs of the fish. The Nez Perce Tribe, one of the most adversely affected of all Tribes, has already provided a public statement that the underpinnings of the Preferred Alternative are not acceptable. See News Release, Nez Perce Tribe, February 28, 2020, published at https://indiancountrytoday.com/the-press-pool/nez-perce-tribe-calls-for-leadership-on-lower-snake-river-restoration-and-accurate-complete-and-transparent-information-on-impacts-of-four-lower-snake-river-dams-zkH0oasQHkKnAVxZ-jm5rw?fbclid=IwAR3EFCIg-Ep0JjO_G7DmcaxTMgSAg5IU77-t5TcMRIiRGMzaulcj8TLoQgc . Beyond supporting the stated positions of the various Tribes included in Appendix P and otherwise previously stated, I also support the rights of any other native peoples who may not have been expressly included in the DEIS, such as the rights of individual Native landowners, including Palouse Tribal members, who have been removed and displaced from their ancestral lands due to these dams. Their rights to fish, access cultural and sacred areas, and practice traditions would also best be honored by breaching the 4 LSRDs. Sadly, by recommending their economic-driven Preferred Alternative, the co-agencies have once again failed to honor treaty rights, the U.S. governments fiduciary obligation to native people, and related social and environmental justice imperatives. The Preferred Alternative will not recover salmon, steelhead, lamprey, native plants, or provide the Tribes access to their usual and accustomed fishing, hunting and gathering spots, cultural and sacred sites that existed for millennia along the free-flowing rivers pre-damming. Accordingly, breaching the 4 LSRDs as described in MO3 best protects the	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty rights are discussed in the Executive Summary, Section 3.16, Cultural Resources, and Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize Tribal issues by topic. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery determinations are ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve more parties than just the co-lead agencies across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the PA also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				rights of the Columbia Basin tribes, best fulfills the Co-agencies federal treaty and trust responsibilities, and best preserves the lands and natural and cultural resources native peoples have relied on in the Columbia Basin region for over 10,000 years.	
5926	1	sarahrwaldo@gmail.com	N/A	The increase in GHG emissions from replacing "carbon neutral" hydropower with other power sources has been listed among the top reasons for rejecting this proposal. In Chapter 3, section 3.8.2.2, the EIS authors discuss CH4 emissions from reservoirs, but end (page 3-980) by stating that they don't include any GHG emissions from the impounded waters of the Snake River in their analysis, citing insufficient data. I am commenting to request a reanalysis of the GHG footprint of the impounded waters of the Snake River, in light of relevant research including Miller et al., 2017, Environmental Management (attached).	Limited research exists regarding the methane emissions from the reservoirs created by the four dams on the Lower Snake River. Appendix G, Chapter 5, as well as Section 3.8 of the EIS, include references to these studies, including Miller et al. (2017) referenced in the comment. These studies generally conclude that there is substantial variability in methane emissions depending on site and management characteristics; however, based on a review of current, high-quality information, the Northwest Power and Conservation Council found in 2017 that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies will allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
5932	1	N/A	N/A	The federal agencies can and need to approach a two-tiered process. Tier one is an emergency response action for the immediate drawdown and breach of Lower Granite and Little Goose dam, followed by the remaining two dams in subsequent years. Tier two is addressing system operations and further mitigation activities in the rest of the Columbia River Basin using the new EIS, assuming that the four lower Snake River dams.	The agencies would have to seek congressional authority for breaching the lower Snake River dams and could not immediately breach the dams. The Endangered Species Act (ESA) does not require the co-lead agencies to take affirmative actions to support recovery of ESA-listed species. Additionally, recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of the EIS. Recovery of ESA-listed species is the purview of the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. The Draft EIS evaluated under Multiple Objective alternative 3 which includes the measure to breach the four lower Snake River dams (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the Columbia River System and mitigation for effects to resources from implementing this alternative. The Draft EIS evaluated a measure to breach the four lower Snake River dams, in Multiple Objective alternative 3, (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the Columbia River System and mitigation for effects to resources from implementing this alternative.
5936	1	yougoathead@gmail.com	N/A	There appears to be a misleading statement right off in the Introduction of the Executive Summary, the statement that annually 60 million tons of freight moves out of Lewiston Idaho down the river. Lewiston cannot take credit for the total operation of all of the dams. From your own facts on the USACE site, 1.1 million tons passed Lower Granite in 2015. Even that seems high given that there has not been container traffic for nearly 20 years, and the grain barges are half-loaded limited to 14 draft, due to dredging limitations when fighting the constant siltation. Then, 1.1 million tons of Little Gooses 1.3 million tons of freight is simply pass-through. Rivers work that way. Using your own percentage of the freight that is wheat on that 1.1 million ton figure, that services less than 100 farmers, figuring field rotations and the modern average size farm.	The commenter correctly pointed out a misleading statement in the Executive Summary. The system, not the Snake River, carries 50 to 60 million tons of cargo each year. This error has been corrected in the Final EIS.
5936	2	yougoathead@gmail.com	N/A	Your report should give a baseline of total grain exports from the region, showing what already moves other than on the river. There is infrastructure already in place. It is misleading to state that the Port of Lewiston gives Idaho farmers a vital shipping route. It gives the Camas Prairie and the Genesee/Moscow part of the Palouse an option. There is an active rail line down the Lower Snake River. The big part of Idaho does not come through Lewiston. Mostly it finds its way onto barges in the Lower Columbia. The Big Iron trucks arent even coming over the dangerous highway from Montana and the Dakotas to Lewiston like they used to in the heyday of the 1980s, with the consolidation of grain terminals in those regions into unit loaders along the rail mainline that happened in the 1990s. Grain produced north of and west of The Palouse, and south and west of Pomeroy also does not go out through the Lower Snake; it goes to the Lower Columbia via rail and truck to be loaded on barges there. And that is a huge region.	The various scenarios presented in Section 3.10.3.5 are derived from historic and current grain movements. Therefore, the total volume of grain and the routes where it is transported are reflective of current information. This is the case for movement through the Port of Lewiston. Regarding the WATCO short-line railroad that runs along the lower Snake River, based on the information that the shippers provided (and WSDOT), grain movements on the WATCO line no longer occurred due to their current operating agreement with Union Pacific. The WATCO line would need to substantially update their rail infrastructure to come into compliance with practices on Class I rail lines. For this reason, the WATCO line was not considered a viable option for grain movement in the case of a breach scenario. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers.
5936	3	yougoathead@gmail.com	N/A	The report does not mention what the Corps is collecting in Lock Fees for this commercial traffic. In my personal experience riding a small pleasure craft, the lock at Lower Granite was cycled for one 15 fishing boat, for free! If the traffic uses a multimillion dollar facility for free, no wonder water transportation is so economical. Part of the fee should be reparation to the public for commandeering the river.	There are no locking fees for these Federal projects, as they were constructed and are maintained by Federal tax dollars and generate national and regional economic benefits in excess of these costs to serve public good. The lower Columbia River and lower Snake River projects were authorized by Congress to serve navigation and other purposes and Congress annually appropriates funds for these operations.
5936	4	yougoathead@gmail.com	N/A	The report does not mention that the dams cannot now be removed because of the mess that has been made. The historical channel deep water is where the dredging spoils have been dumped for years. If let to free flow, this river would violate the Clean Water Act rules so badly for decades.	Section 3.3, River Mechanics, discusses the sediment movement under MO3. In Section 3.4, Water Quality, under MO3, the effects on water quality, including sediment quality, are analyzed. If MO3 were to be implemented, further studies and design would be required to breach the dams in a safe manner to minimize effects to resources. The co-lead agencies would coordinate and obtain any necessary permits to comply with applicable environmental laws. The co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others.
5936	5	yougoathead@gmail.com	N/A	The report fails to mention the replacement dams. When these dams were made they were publicized as 50 year infrastructure. They are proving to be 100 year structures. In reality they could well be 150 year structures. An Old Timer who worked concrete construction his whole life provided the local knowledge that concrete lasts about 150 years, then its life is over. All of this is nothing to geologic time, which the River runs on. If the dams are truly essential to Humanity for transportation of its food, where are the replacement dams? Where is that environmental Plan?	The cost analysis estimates the capital and operations and maintenance costs that would occur under the No Action Alternative (see Tables 4-1 and 5-1 in Appendix Q, in the Draft EIS). Capital cost estimates are based on information from the Strategic Asset Management Plan, including investment needs over the long-term based on the hydropower engineering requirements and needs over the life of the asset, including replacement costs when assets are at the end of their useful life.
5936	6	yougoathead@gmail.com	N/A	Commenting to the subject of the fish, the report should contain a documentary of all of the species that have already been expiated. That means made to come to an end, extinct. There should be information of how quickly the expiation occurred after completion of the subject dam.	The co-lead agencies prepared this Draft EIS in response to the need to review and update operations, maintenance, and configuration of the 14 Columbia River System dams. Analysis of construction of the dams and potential extinction is not in the scope of the EIS.
5938	1	dbhummon@msn.com	N/A	Removing the dams on the lower Snake is a good idea if..... A new rail line is built between Lewiston and the Tri Cities to move the grain at a reasonable cost to replace barges Water usage by Ag is provided for Subsidies for the tribes to make up for removing all nets from the snake and Columbia Allow the tribes to harvest the sea lions for profit as in Canada	The EIS evaluated the tradeoffs associated with the management of the system, which has multiple purposes. It was not an analysis that aimed to compare the benefits of navigation against the costs to salmon. The EIS estimates the costs to operate the Columbia River System dams, as well as the costs to the navigation and transportation industry, that would be occur if the four lower Snake River dams are breached under Multiple Objective alternative 3 as part of this broad analysis that seeks to balance the objectives of the agencies for the system.
5948	1	Dale Beasley	Columbia River Crab Fisherman's Assocation	CCF/CRCFA understands that the DEIS is limited in scope to just Columbia Basin operations. This however, is an incomplete analysis and does not offer enough help to restore salmon to the upper portions of the basin and without addressing a comprehensive SOLUTION BASED analysis will never solve the overall ESA listing of these precious salmon resources affected by ESA listings. Without addressing the total protection for over populated marine mammals in the MMPA along with impacts associated with MASSIVE avian predation which automatically put the dams under unjustified indictment and scrutiny for removal by a few vocal critics that always need a manufactured crisis to feed their own unguided ambitions at expense of benefits to all of society.	The scope of the EIS appropriately focuses on resources affected by CRS operations, maintenance and configuration. The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators, and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
5948	2	Dale Beasley	Columbia River Crab Fisherman's Assocation	Climate change Tug and Barge Transportation is cleaner and cheaper than truck or rail transportation by a large margin. losing the dam power would hurt the states goal of being carbon free by 2045, especially as the population grows and there is more demand for electrical cars that need to get their energy from our electrical grid that stretches into coal country.	Section 3.8 of the EIS evaluates how a shift in shipping modes under Multiple Objective alternative 3 from barge to road and rail would affect greenhouse gas emissions. Consistent with this comment, the analysis demonstrates that these changes in shipping would result in an increase in emissions of between 0.02 and 0.06 MMT CO_2.
5948	3	Dale Beasley	Columbia River Crab Fisherman's Assocation	In recent years NOAA fisheries has conducted offshore salmon smolt composition surveys and found that the majority of salmon smolts that survive to live in the ocean between Neah Bay WA and Newport OR are of 95% of hatchery origin these scientific study results shed light on the REALLY POOR SURVIVAL RATE of naturally spawned Wild salmon in our river systems overall; these surveys encompass all river systems, even those without dams from all over the NW. This is indicative of ALL Wild salmon found in the surveys from all coastal and inland rivers, many without any dams at all. This would lead any rational inquisitive scientist to conclude that there is an abundance of stressors on natural salmon populations other than just the Snake River Dams. Our nation MUST address this multitude or salmon stressors simultaneously if salmon are ever to get Dinner Plate Results.	The comment is correct, the effects of the four lower Snake River Dams, or even the entire CRS, are only a portion of the factors influencing the health and productivity of Columbia Basin salmon and steelhead. There are many effects on salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information, see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. Among the objectives of this EIS are improving passage conditions and survival of both juvenile and adult anadromous fish through the CRS. The more healthy juvenile salmon that enter the ocean, whether the conditions there are good or poor, the greater the returns to the Columbia Basin can be. The greater the success of adults migrating up the Columbia and tributaries and spawning, the more juveniles can be produced for the next generation.
5948	4	Dale Beasley	Columbia River Crab Fisherman's Assocation	The dams support vulnerable communities with fragile economies. The 10 counties most affected by a dam breaching scenario are primarily rural areas in which one in five people are already at or below the federal poverty level, and average wages are 25% below the national average.	As described in Section 3.7.3.5 of the EIS, the implications on the cost of electricity to end-users (such as residents and businesses) is upward rate pressure ranging from 1.6 to 3.6 percent relative to the No Action Alternative. The Environmental Justice analysis of the EIS (Section 3.18.3) describes that energy burdens in Region C are already likely unaffordable for all households with incomes below the Federal poverty level, and thus any upward rate pressure could impact low-income households for whom energy costs are a larger percentage of their income. The Environmental Justice section (Section 3.18.3.4) describes other effects to minority populations, low-income populations, or Indian tribes from MO3, which includes the dam breach measure. Regions C and D would lose commercial navigation and cruise ships. This could have an adverse effect on the economy which may lead to a minor adverse disproportionate effect on environmental justice population. Overall in Region C, long-term beneficial (e.g., riverine-oriented recreation) and adverse (e.g., lake or flatwater-oriented recreation) effects are anticipated. Basin-wide visitation could decrease by up to 21 percent (approximately 2.7 million visits and $25 million in annual social welfare benefits) in the short-term. The long-term river visitation estimates (land- and water-based) suggest that recreation values could range from 50 percent lower to 30 percent higher than under the No Action Alternative (1.5 to 3.4 million visitor days). Increased catch rates and angler visitation could occur over time as anadromous fish populations increase in Regions B, C, and D. Water supply effects on irrigated farmland in Region C would be the loss of 47,840 acres and 4,822 jobs. This could have an adverse effect on the economy which may lead to a minor adverse disproportionate effect on environmental justice populations. For Region D, an increase sediment would lead to an increase in maintenance costs. An increase in operational costs could lead to less labor being hired or the inability to stay in business. Hispanics make up 73% of farm workers in Region D. As discussed in Section 3.7, Power Generation and Transmission, Indian tribes could also be affected by changes in the Bonneville's Fish and Wildlife Program funding under MO3, which would decrease by approximately $34 million at least. Given that the lower Snake River dams would no longer be in place to operate, Bonneville's funding for the effects of construction and operation of these dams to the USFWS through the Lower Snake River Compensation Plan facilities would cease.
5948	5	Dale Beasley	Columbia River Crab Fisherman's Assocation	Breaching the Lower Snake River dams would cause diesel fuel consumption to increase by nearly 5 million gallons per year as barges are replaced by less efficient truck-to-rail shipments. At least 201 additional unit trains and 23.8 million miles 10 in additional trucking activity would be required annually, resulting in increases in CO_2 and other harmful emissions by over 1.2 million tons per year. The combined loss of clean power and fuel efficiency from the river system would result in equivalent carbon emissions generated by a Boardman coal-fired power plant every five to six years.	Section 3.8 of the EIS evaluates potential effects of MO3 on emissions due to shifts from use of barge-based shipping through the four lower Snake River dams to road and rail transportation. The analysis does find an increase in truck and rail transportation, and associated CO_2 emissions, under MO3 relative to the No Action Alternative. However, the EIS finds a lesser effect on truck and rail activity, amounting to an increase of 0.06 MMT CO_2 per year, about half the level described in this comment. The EIS does identify an adverse effect of MO3 on greenhouse gas emissions due both to the reduction in hydropower generation and the shifts from barge-based to road- and rail-based freight transportation.
5948	6	Dale Beasley	Columbia River Crab Fisherman's Assocation	See PDF of CRCFA PowerPoint below that shows clearly that the Snake River Dams are NOT as strongly correlated to the Orca demise as the highly significant reduction in Washington salmon hatchery production. Assailants on the dams never get this basic information to the public, it does not fit their bogus narrative or raise money for their errant cause from an uneducated public. As the state increased production in the 1980s the Orca populations responded with increased population that led to the highest Puget Sound Orca population ever, then as the state decreased salmon smolt	The EIS analysis found a minor effect to the Southern Resident killer whale (SRKW) would result from implementing Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams. This conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				production by 160 million smolts, the Orca population contracted accordingly Once the state stabilize the smolt production at a significantly reduced number the Orca population also stabilized at a significantly reduced number until very recently that is not graphed due to lack on additional updated information.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5952	1	N/A	N/A	First, upstream passage. While this has been a topic of conversation for many years and there have been many structural changes made to dams in the Columbia river basin, these alternatives do not address this important portion of fish passage well enough. Even if there are higher rates of downstream passage through increased spillway openings or additional structural improvements for downstream passage, what if these changes affect upstream passage? While the document does discuss upstream passage in the details of each alternative, it does not put enough weigh on keeping this metric as high as possible. If all this work is being done for downstream passage and only minimal monitoring for upstream passage is kept up, what happens when upstream passage starts to decline? These alternatives do not seem to account for this possibility well enough.	The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. Many of the considerations for structural changes proposed in the EIS would be to address downstream juvenile passage and survival and improvements for lamprey passage. Because structural changes to improve salmon and steelhead (e.g., spillway weirs) are in place at this point, there are few additional mechanistic fixes proposed in the Preferred Alternative (PA). Other changes, such as turbine replacements are not expected to have impacts to salmon and steelhead survival that are of a magnitude that would outweigh the modeled effects associated with the higher spill levels in the proposed action. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Monitoring will also be used to evaluate any potential impacts on adult upstream passage. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible.
5952	2	N/A	N/A	The second concern I have is over water temperature. There are many times throughout the document that water temperature is considered a large issue but not a driving factor in the decision-making. I feel that this is a short-sighted thought because water temperature controls so many other factors within a river system that it must be accounted for in the alternative determination. Climate change is real and is addressed in the EIS in depth in chapter four, but there does not seem to be enough insight into how to mitigate the effects of climate change on water temperature. It is noted that reservoir levels effect water temperature, but the final choices within each alternative do not seem to bear these effects in mind. Water temperature should be very closely monitored and regulated as much as possible, not only for fish, but also for water quality and safety.	Water temperature monitoring would continue under the Preferred Alternative, it is used for real-time decision-making regarding operation of the CRS dams. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS, as the commenter points out. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4).
5952	3	N/A	N/A	My final concern is of cultural sites and tribal input. Again, there seemed to be a lot of tribal input throughout the process and this is well documented in the EIS, but the preferred alternative does not seem to take very many of their requests into account. Every group and voice deserves to be heard in this decision making process in order to make this a document that everyone will buy into. I think that cultural sites deserve more recognition and should have more weight in the decision making process.	Cultural resources were addressed throughout the CRSO EIS NEPA process with input from many Tribes and cooperating agencies. The cultural resources impact analysis for Multiple Objective alternatives (MO), MO1 through MO4 in Sections 3.16.1-3.16.3.7, and for the Preferred Alternative (PA) in 7.7.18, provides the public and the co-lead agencies' decision-makers with a comparative analysis of impacts from all of the alternatives to cultural resource across the entire system. The co-lead agencies did not attempt to impose values on different resource types or effects for weighting purposes. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the PA. The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16, Cultural Resources, and Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests and Chapter 7, Preferred Alternative. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
5952	4	N/A	N/A	There are other ways to create renewable power without continuing to alter nature in such a significant way. Just a passing thought, although I know this is probably extremely cost prohibitive, could replacing these large dams with a series of lower head dams make a large enough impact on fish passage while still maintaining some flood regulation and energy production? This might allow there to be smaller reservoirs and less dangerous spillways throughout the Columbia River basin.	The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. Regarding the range of renewable technologies considered, the source of resource information used in the EIS is from the Northwest Power and Conservation Council's Seventh Power Plan and Mid-term Update. See Draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821; see also Appendix H, Power and Transmission, at Section 2.2. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their Seventh Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. The construction of additional dams is outside the scope of this EIS.
5952	5	N/A	N/A	This document is going to be in circulation and lead management decisions for many years to come and I think it is preposterous to ask for such a crucial document to be rushed by a year. There is so much more data that could be collected, surveys that could be run, and public comment that could be incorporated to create a much more far reaching and collaborative document if the proper amount of time had been granted to complete it.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5962	1	savpothier@gmail.com	N/A	One of the criticisms mentioned about breaching the dams is that jobs will be taken away and individuals will not be able to make money. When constructing the dams, this perspective was not shared when viewing how this would affect the Indigenous people. We took away their main source of food, salmon. They were given no voice and offered them no reconciliation for the damage and suffering that was caused. In the 1850s, a treaty was signed in order to ensure the right of taking fish. That treaty was not truly upheld. Continuing actions in the DEIS preferred alternative will result in the extinction in salmon. Taking away their resources of salmon is taking their rights guaranteed by the Treaty. The Indigenous people of these lands are so important. From the executive summary, their voices are still not being heard.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty-specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision-making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16, Cultural Resources, and Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests and Chapter 7, Preferred Alternative. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Under the ESA, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA-listed species is the purview of the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study.Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
5962	2	savpothier@gmail.com	N/A	Rivers provide habitat refuge through characteristics such as; sinuosity, large woody debris, and bank stabilization. These characteristics allow for salmon to have both a resting and spawning habitat. Reservoirs cannot offer that. They have no habitat complexity or sinuosity. Most of the trees have been clear-cut, and the area has been flooded from dam construction. Due to the lack of trees, leaf litter will also not be available for aquatic invertebrates which will then become food for salmon. The Preferred Alternative has not addressed these problems with solutions. There must be more effort in actually making the reservoir habitable if the goal is salmon survival. Within the written statement, mitigation for salmon cannot exist if these requirements for the survival of salmon are not actually addressed.	The Columbia River System projects, in most cases, do not affect spawning and rearing habitat for salmon and steelhead because they do not spawn in the mainstem Columbia and Snake Rivers; these are migratory corridors only. The exception is fall Chinook salmon. For all MOs, in the Columbia River, these habitats would be very similar to the No Action Alternative. The effects of Multiple Objective alternative 3, which includes breaching the four lower Snake River dams, in the Snake River on Snake River fall Chinook salmon includes qualitative discussion of habitat improvements. The Preferred Alternative, however, would also have similar habitat for fall Chinook salmon.
5962	3	savpothier@gmail.com	N/A	These dams are leading two species to extinction. Under the Endangered Species Act, it is required that any species endangered must be protected and recover those species and their habitats. Salmon cannot make it passed all four dams, and many of them just get killed in the turbines. The population is a fraction of what it once was, and the ESA must be complied with to prevent the complete biological extinction of salmon and as a result, the whales as well. The other law that must be considered is the Northwest Power Act. Fish have been given equal consideration as power acquisition. With the populations of salmon being reduced to less than 5%, they are not being considered equal.	Based on the EIS analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Because the effects of the Preferred Alternative would be negligible, the agencies determined that existing offsite mitigation efforts, including hatchery production, would be sufficient to address any potential impacts to prey availability (Chinook salmon) for Southern Resident Killer Whales (SRKW). The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. Regarding the Northwest Power Act, this comment appears to refer to the equitable treatment mandate of the Act. That provision requires [t]he Administrator and other Federal agencies responsible for managing, operating, or regulating Federal [] hydroelectric facilities located on the Columbia River or its tributaries to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects . . . in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated. 16 U.S.C. 839b(h)(11)(A)(i). The Ninth Circuit Court of Appeals has found it lawful for agencies to provide equitable treatment on a system-wide basis. See, Northwest Environmental Defense Center v. Bonneville, 117 F.3d 1520, 1533-34 (9th Cir. 1977). For example, the agencies may make some decisions that place power above fish, so long as on the whole, they treat fish on par with power. The comment suggests that salmon are not being considered equal based on the assertion that populations have been reduced to less than 5%, presumably of historic levels at an unspecified point in the past. The co-lead agencies understand the comment as alluding to the equitable treatment provision of the Act, requiring that the agencies management and operation of the CRS provide equitable treatment for fish and wildlife with the other authorized purposes for which the system is managed, such as flood risk management, hydropower generation, irrigation, navigation, and recreation. See 16 U.S.C. 839b(h)(11)(A)(i). The co-lead agencies provide fish and wildlife with equitable treatment on a system-wide basis. See NW. Envtl. Def. Ctr. v. Bonneville Power Admin., 117 F.3d 1520, 1533-34 (9th Cir. 1997) (While each power marketing action that affects the system implicates the equitable treatment provisions, Bonneville may properly exercise its obligation by insuring equitable treatment for fish on a systemwide basis.); Confederated Tribes of the Umatilla Indian Reservation v. Bonneville Power Admin., 342 F.3d 924, 931 (9th Cir. 2003) (The equitable mandate of [the Northwest Power Act] does not require every Bonneville decision to treat fish and wildlife equitably. For example, Bonneville may make some decisions that place power above fish, so long as on the while, it treats fish on par with power.). Through this EIS process, the co-lead agencies have considered management and operation of the CRS for its multiple authorized purposes. And, as noted above, CSS analysis of the Preferred Alternative predicts an increase in smolt-to-adult return rates as compared to the no action alternative. The co-lead agencies incorporation of measures specifically designed for improved benefits to fish and wildlife, as balanced against other authorized purposes of the system, reflects equitable treatment of fish and wildlife consistent with the Northwest Power Act. Additionally, the entire CRSO EIS process is an exercise in providing equitable treatment on a system-wide basis by using alternatives and analysis that treat fish and wildlife issues on par with the issues related to power, navigation, flood risk management, and the other authorized purposes of the CRS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. With MO3, for example, the EIS includes system configuration, management, and operations that would emphasize benefits to anadromous and resident fish. With the Preferred Alternative the agencies provide a reasonable balance of management and operation among all the authorized purposes. All of the alternatives include detailed analysis of impacts to fish and wildlife affected by the CRS as well as potential mitigation measures. In this way, the agencies are providing equitable treatment of fish and wildlife in this management planning process.
5962	4	savpothier@gmail.com	N/A	The true question is, will mitigation truly be enough to achieve the goal of ESA standards? The first option that is initially thought of is hatcheries. But are hatcheries really helpful to the wild salmon population? Studies prove they arent. Studies show that hatchery born salmon reduce the fitness of wild salmon, and cause a decrease in future abilities to adapt (Meyers, 2004). Salmon that are raised in a hatchery do not have the same ability to navigate and survive the wild. They breed with wild salmon, outcompete them, and spread disease. When wild salmon reproduce with hatchery fish, this causes a reduction in the fitness of the next generation of offspring. Hatchery salmon also outcompete wild salmon. Hatcheries actually cause more harm to wild salmon than actual benefits. A 25-year long study that was done on the Snake River. This study showed a negative correlation between the increase of hatchery fish being released and the survival of Chinook salmon (Levin & Zabel & Williams, 2001). This study suggested that hatchery fish being released into the waters actually impede the recovery process of salmon, and cause a negative impact.	Based on the analysis of fish in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well. The PA proposes measures such as increased spill intended to improve survival of anadromous salmonids. Figure 3-111 in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. Overtime, the PA is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS.
5962	6	savpothier@gmail.com	N/A	The mechanical system of hydropower is a clean method of converting energy, but the results of damming rivers into reservoirs causes an increase in both carbon dioxide and methane. The concentration of carbon dioxide within reservoirs tested have been found to have 2-3 times the amount of carbon dioxide in the atmosphere (Rudd & Hecky & Harry & Kelly, 1993). This increase is significant compared to normal lakes. The amount of greenhouse gases released by the process of hydroelectric are comparable to fossil fuels (Rosa & Schaeffer, 1994) Reservoirs in nature accumulate a large amount of sediment and nutrients. This causes algal blooms which causes a decrease in oxygen and an increase in carbon dioxide, also known as a dead zone.	This comment correctly identifies that hydropower reservoirs can act as a source of greenhouse gas (GHG) emissions. Appendix G, Chapter 5, of the EIS details the assessment of reservoir methane emissions from CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies will allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
5965	1	N/A	N/A	Almost half of Peninsula Light Companys members are on fixed incomes and 10% live below the poverty line. Any alternative that includes dam breaching would greatly impact rates and be a significant burden to more than 50% of our membership. The increased greenhouse gas emissions would serve to add significant upward pressure to electricity costs as we would pay a penalty for not providing 100% carbon free power.	The comment that electricity costs would increase under MO3, which includes breaching of the four lower Snake River dams, is consistent with the findings of the EIS. See Section 3.7.3.5, Table 3-166 in the Draft EIS. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. The comment about increased greenhouse gas emissions is also consistent with the findings of the MO3 greenhouse gas emissions analysis in Section 3.8.3.5, as well as the carbon compliance sensitivity presented in Table 3-166 in Section 3.7.3.5, in the Draft EIS.
5966	1	vern2dkv@gmail.com	N/A	Here's some specifics on how the DEIS fails: It ignores avoided costs and future savings by restoring the lower Snake River: The cost of maintaining the dams, and replacing turbines is significant. The DEIS ignores the anticipated savings of more than $1 billion by eliminating the rising capital, operations and maintenance costs for the four Snake River dams. It pits salmon recovery against clean, affordable energy: The DEIS presents a false choice between maintaining affordable utility bills and restoring healthy salmon and steelhead. It overstates the cost of replacing power from the Snake River dams with clean energy, and suggests replacing their power with fossil fuels, a step we know is unnecessary.	The EIS evaluated a No Action Alternative and five Multiple Objective alternatives (MOs), including the Preferred Alternative (PA), for tradeoffs associated with the management of the system, but did not quantitatively compare the benefits of the power system against the costs to salmon. The EIS estimates the costs to operate the CRS dams, as well as the costs to the power system that would occur if the four lower Snake River dams are breached under MO3. Contrary to the comment, the EIS considered the avoided operations and maintenance (O&M) and capital costs associated with dam breaching in the cost analysis and included these cost savings in power rates analysis. See Section 3.7.3.5, Bonneville's Fish And Wildlife Program And Lower Snake River Compensation Plan Costs, at page 3-913, in the Draft EIS. See also Section 3.7.3.5, Table 3-166 in the Draft EIS. Regarding the costs of replacing power, the EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative levels based on two potential portfolios: one based on renewable resources and another based on natural gas resources, which are generally the least-cost means to maintain reliability (see EIS at Section 3.7.3.5, Potential Replacement Resources and Associated Costs). The EIS uses high-quality resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources. The EIS does not suggest fossil fuels should be used to replace the power. The EIS evaluates a range of options, including a natural gas-based portfolio as well as a zero-carbon resource portfolios. See EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-820; see also Section 3.7.3.5, Potential Replacement Resources and Associated Costs, at page 3-904, in the Draft EIS. The purpose of providing the range of replacement resource options is to estimate a reasonable range in potential costs. The basis for developing both of these portfolios may be found in Section 3.7.3.1, Methodology.
5966	2	vern2dkv@gmail.com	N/A	It ignores salmon and orca science: The DEIS dismisses the overwhelming scientific research that restoring the lower Snake River will provide salmon and steelhead with their best chance to recover. It ignores the benefits of increasing those runs for critically endangered orcas and struggling fishing communities. (Yes, we know orca sit at the mouth of the Columbia and eat Snake River fish because of their poop!)	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The EIS analysis found a minor effect to the Southern Resident killer whale (SRKW) would result from implementing Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams. This conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5966	3	vern2dkv@gmail.com	N/A	It fails to protect salmon: The DEIS fails to acknowledge that its recommendation for flexible spill at the federal dams will not deliver sufficient survival benefits for endangered salmon and steelhead, and ignores the fact that any potential benefits will be eroded by climate impactssomething river restoration can help mitigate.	The co-lead agencies used current, high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The CSS model predicts that average Smolt-to-Adult return rates (SAR) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
5966	4	vern2dkv@gmail.com	N/A	It ignores the economic impact that has already been made on Native peoples: The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices already made by Tribes and rural communities in terms of lost fishing opportunity, reduced jobs and incomes, impacts on Tribal cultures and diets, and other socio-economic effects.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4. Additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS.
5966	5	vern2dkv@gmail.com	N/A	The DEIS ignores the economic and community benefits of salmon recovery and the investments and jobs that river restoration activities will generate. Many new jobs would be created with a free-flowing river. Fishing and recreation opportunities would improve, and about 4,000 acres of land currently flooded by the dams would become available for farming, recreation and would improve habitat.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Under MO3, Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.
5969	1	wkeefer516@gmail.com	N/A	What local agency would be willing to take responsibility for keeping a green space green when they cant access surface water to irrigate, like the Corps presently can? What happens when there is tremendously less surface water and everyone is fighting for their share, and the winners have to be those that supply surface water because ground water tables dropped when the reservoir disappeared? What this detailed series of questions is intended to convey is that under MO3, a solution is conceptualized, and because something/anything is proposed, suddenly in the mind of the authors, it is done. Simple. Easy. Like Harry Potter waived his magic wand. The reality is that each and every local government entity that mourns the loss of a valued recreational feature (and there are at least 26 in Lower Granite Pool alone that will be orphaned when the Corps no longer has responsibility) will need to undertake a feasibility process to determine whether or not they are willing to accept responsibility. Costs for capital investments, ongoing operations and maintenance costs, insurance for risks Look at Central Ferry in the next pool down from Lower Granite. No local entity would take over that recreational feature. So, its abandoned. Investments in restrooms and other facilities had to be torn down, or they would have been attractive nuisance. (Torn down at what cost to the public?) I think it's become a habitat unit because the Corps still remains responsibility for it presently under the M03 option. Consider: there will be no ownership of any recreational facilities by the Corps for a 140-mile stretch of the Snake river. Look at Lyons Ferry. Is the Port of Columbia going to be able to recover its features and make it useful after dam removal? Look at Granite Lake Park in Clarkston. I can tell you for 100% sure that the Port of Clarkston has no desire to own it because its built on a landfill, and the Port has no interest in taking on that liability. An important urban recreational venue will be permanently lost to the public. The recreational opportunities under MO3 will be decimated.	Section 3.11.3.5 describes the impacts to social welfare and regional economic effects in the short-term under MO3, when considerable reservoir recreational opportunities would no longer be available or accessible. Chapter 5 in the EIS describes the proposed mitigation measures under each of the Multiple Objective alternatives (MOs). Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. Consistent with the comment, no Federal mitigation is anticipated under MO3 to maintain access to the river as the Federal agencies would no longer operate the project lands for recreation as the projects are de-authorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. The lower Snake River projects currently support 2.6 million visitors and $24.5 million in social welfare value annually. Dam breach would have both beneficial and adverse effects on recreation. Dam breach would preclude reservoir recreation during and shortly after the breach, eliminating reservoir recreation; over time, and as recreation areas and access are redeveloped by others, long-term beneficial effects to river recreation, including angling, are anticipated. Sections 3.11 of the EIS describes that the visitation in the long-term in the lower Snake River would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses.
5969	2	wkeefer516@gmail.com	N/A	But lets go back to the Central Ferry example. The hardscape had to be removed. It was interfering with the natural environment, the purpose of a habitat management area, and frankly, it was an attractive nuisance. Are the concrete structures of the remaining parts of the dams that are dangerous to wildlife and people going to have to be removed, like at Central Ferry? If thats the case, two important things need to happen with the description of MO3: It has to describe dam REMOVAL not BREACHING, and it has to include the real costs of removing the concrete structures. Plus, the new riverine opportunities for recreation will be closed to the public for a longer period of time than projected, making the supposed comeback of recreation further	Breaching the embankments accomplishes the purpose of opening the river for unencumbered fish migration without delays at fish ladders. However, full removal is a larger and more costly construction project, including additional siting and disposal of materials. Full dam removal would be at a greater cost both in adverse environmental effects and Federal appropriations without any significant additional benefits. The EIS describes that visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the Multiple Objective alternatives as well as river recreation post dam-breach under Multiple Objective alternative 3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				out on the horizon. (Remember, no parties have yet adopted the orphaned recreational amenities or decided theyre affluent enough to create access.) The recreational benefits of fishing are wildly (pun intended) overstated. MO3--now re-written to be dam removal instead of breaching based on discussion above because thats the publicly responsible thing to do--does not bring back recreational fishing. The models that calculate fish returns including hatchery fish are tragically misleading and serve nothing other than a political purpose.	
5969	3	wkeefer516@gmail.com	N/A	Lastly, I want to discuss the challenges to health from MO3. As mentioned above, Im nearly 63. As I get older, chest congestion is more common; many like me in Asotin County suffer from asthma at higher levels than neighboring counties. I wont be able to wait for fugitive dust to settle and things to revegetate. I will need to move because I wont physically be able to handle the dust, which MO3 improperly mitigates for. (Hello, soil supplementation and then irrigation of plantingswhich wont occur because taking surface water by any party other than the Corps is not allowedare essential to some kind of dust abatement.)	Consistent with this comment, Section 3.8 of the EIS finds the potential for higher risk of adverse health effects from fugitive dust under MO3. MO3 was not identified as the Preferred Alternative.
5969	4	wkeefer516@gmail.com	N/A	I recommend re-writing every single element in the recreational component of the draft EIS. This means the executive summary, Chapter 3, and Appendix M. The EIS should more accurate reflect the loss of valued recreation assets, recovery of which is not going to occur within my lifetime. Remove guarantees of recreational fishing for hatchery fish in SAR models. Take out recreational fishingits wishful thinking. Maybe in 30 years or 40 or 50, things will have leveled out. Maybe then, access for still-water kayaking will have been carved out. I dont, however, expect to be around then.	There is considerable uncertainty on the timing of MO3, both the implementation and the resulting condition of the resource. However, the impacts to recreation have been described as short-term effects (during the dam breach and shortly thereafter) and in the long-term (when river conditions have been established). Section 3.11.3.5 Recreation describes the impacts in the short-term under MO3, when considerable reservoir recreational opportunities would no longer be available or accessible. Chapter 5 in the EIS describes the proposed mitigation measures under each of the Multiple Objective alternatives. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river as the Federal agencies would no longer operate the project lands for recreation as the projects are de-authorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. The potential for recreational fishing in the long-term is described in the EIS, Section 3.11.3.5. However, there is considerable uncertainty regarding the overall effects of MO3 on regional fish populations and the timing of those effects, and how such changes may affect the management of the fisheries, which limits the analysis of the specific impacts of each alternative on these recreational fishing values. Regarding the fish model, hatchery fish are one of many components that are aggregated into the forecasts from historically observed Smolt-to-Adult return rates. The models do not have inputs for the hatchery or harvest rates.
5972	2	dunnr@bentonpud.org	Benton PUD	Overall, Benton PUD supports the preferred alternative included in the DEIS; however, we have serious concerns regarding increased spill and the significant uncertainty as to whether any benefits or harm to salmon can be scientifically confirmed.	The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
5972	3	dunnr@bentonpud.org	Benton PUD	Like all utilities, Benton PUD is struggling to keep our rates low while being good stewards of the environment and keeping the lights on. Resource adequacy (RA) in the Pacific Northwest region has become increasingly concerning due to the thousands of megawatts of coal plant retirements planned over the next decade. The Northwest Power and Conservation Council (Council) updated its resource adequacy assessment in October 2019 and identified the urgent need for utilities to add capacity resources in the near term. The Council measures RA based on a loss of load probability (LOLP) with a threshold of 5% as the limit for what is considered an adequate level of power grid reliability. In their most recent RA assessment the Council indicated the regions LOLP could reach nearly 13% by 2024 and could rise to 26% by 2026. These are unacceptably high risks and regional utilities are scrambling to develop a path forward in an environment where legislative policies and public preferences for wind and solar power are chilling investments in proven and dispatchable power generation technologies. Removing the 3,033 MW of nameplate capacity provided by the Lower Snake River dams that account for nearly 25% of BPAs operating reserves and more than 2,000 MW of sustained winter peaking capabilities, would further increase the regions LOLP by 7.3% as indicated in the multiple objectives MO3 analysis. In contrast, the preferred alternative would have no additional impact to the LOLP. The DEIS analysis also showed that replacing the capacity value of the LSRDs would require 1,120 MW of natural gas or the combination of 2,550 MW of solar, 1,150 MW of battery storage, and 600 MW of demand response at a cost of $250 million and $420 million respectively. Benton PUD supports the preferred alternative as it does not further increase the LOLP and does not have additional replacement costs as compared to the no- action alternative.	The comments about the importance of the four lower Snake River dams for regional power reliability are consistent with the EIS findings. The EIS finds that, unless and until replacement resources are constructed, Multiple Objective Alternative3 would lead to a doubling of the risk of regional power shortages with the current fleet of other resources in the region. See draft EIS, Section 3.7.3.5, Table 3-166 and Appendix H, Table 2-1. With additional coal plants slated for retirement, the EIS finding is consistent with the comment and the Northwest Power and Conservation Councils findings of a high risk to regional resource adequacy. The resource capacities and costs are also consistent with the EIS. The replacement resource quantities and costs are updated in the final EIS, but the conclusions are fairly similar. The statement that the Preferred Alternative does not decrease regional reliability and thus, does not require replacement resources is consistent with the findings of the EIS. The replacement resource figures in the comment are also consistent with the findings of the EIS (see Section 3.7.3.5).
5972	4	dunnr@bentonpud.org	Benton PUD	Increased spill costs all consumers of BPA power and further erodes the flexibility of the regions most prolific carbon-free generation resources. The analysis of the preferred alternative shows a 300 aMW reduction of firm power, of which Benton PUDs share is about 8.5 aMW, or approximately 4% of our annual average load. This erosion of generating capability represents the impact on only 1 of 135 BPA customer utilities that will all see proportionate reductions in their baseload power supply resulting in additional costs for many utilities that must be passed on to retail customers.	The EIS recognizes the concern voiced in the comment regarding increasing power rates under the Preferred Alternative. The loss in hydropower generation quoted in the comment is consistent with the findings of the Draft EIS; in the Final EIS, an update in modeling resulted in a loss of 330 aMW. However, it is important to note these estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations or rates. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement, and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control. See Draft EIS, Section 3.7.3.1 page 3-817.
5972	5	dunnr@bentonpud.org	Benton PUD	In addition to the cost impacts, it has not been scientifically proven that spill levels up to 125% total dissolved gas (TDG) will improve salmon survival rates. Salmon survival depends on many factors including ocean conditions, predation, TDG levels, etc. Ocean conditions and predation can have significant impacts on the number of returning salmon and it will be difficult to conclude definitively that increased spill has a positive effect. Although it is not clear whether increased spill will have positive or negative impacts, Benton PUD appreciates the preferred alternative including the flex-spill operating protocol which allows a more balanced approach to accomplishing increased spill while still allowing for power generation during the highest demand and most valuable hours of the day.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin. Appendix R, Part 2 describes the principles for implementation of the flexible spill operations and guidance for adaptive management. One of the principles focuses on federal power system benefits, which will be as determined by Bonneville Power Administration. The understanding is that Bonneville must, at a minimum, be no worse financially compared to the 2018 spring fish passage spill operations ordered by the Court. This principle is directly related to Objective 5 of the CRSO EIS: Provide an adequate, efficient, economical and reliable power supply that supports the integrated CR Power System. The co-lead agencies have determined that the Preferred Alternative meets this Objective. In addition, the Preferred Alternative places additional rate pressure for wholesale power rates of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs it has significant control.
5972	6	dunnr@bentonpud.org	Benton PUD	Benton PUD also supports the preferred alternative because of the importance of the LSRDs to irrigation in the Tri-Cities. From a BPA wholesale rate impact perspective, the preferred alternative includes a modest increase of up to 2.7%; however, MO3 is estimated to result in a much larger increase of up to 10.7%. A larger increase like this would be significant not only to Benton PUDs low-income population, but also to our large agricultural irrigation customers which account for around 22% of our retail energy sales and 17% of our retail revenue. These irrigation customers conduct business in highly competitive, international markets and electricity for pumping water for crops is one of many inputs for which costs must be carefully controlled in order to maintain a competitive position.	The EIS recognizes the concern voiced in the comment regarding increasing power rates. The rate increases presented in the comment are consistent with the findings of the EIS for the Preferred Alternative and for the MO3 least-cost rate sensitivity. The EIS recognizes the concern stated in the comment and acknowledges the importance of electricity costs for regional businesses (see Draft EIS, footnote 15 page 3-812 and lines 28155 to 28158). The EIS also analyzed industrial retail rate effects, which included large agricultural businesses finding adverse effects under MO3 (see Draft EIS, Section 3.7.3.5). Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers and commercial and industrial rate effects. The Water Supply analysis (Section 3.12) also examined effects to agricultural irrigation identifying adverse socio-economic effects under MO3. The Preferred Alternative meets the hydropower generation objective to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System.
5972	7	dunnr@bentonpud.org	Benton PUD	In addition to cost impacts, the LSRDs are an integral part of the BPA transmission system that delivers electricity to the Tri-Cities area and supports wheeling of electricity from Montana. BPA already has concerns about power delivery into the Tri-Cities during peak summer months. In fact, under certain conditions Ice Harbor dam generation levels are critical to maintaining transmission system voltages and to providing essential power flow to mitigate operating contingencies that would require Tri-Cities area utilities to shed loads under certain scenarios in order to meet NERC reliability standards. Without the LSRDs, additional reliable and dispatchable generation would need to be constructed near the Tri-Cities in order to address these known contingencies.	The statements in the comment regarding the importance of the four lower Snake River dams, particularly Ice Harbor, for stability in the Tri-Cities area is consistent with the findings of the EIS (See Draft EIS, Section 3.7.3.5, Bonneville Transmission System Reliability and Operations). The loss of generation at Ice Harbor would require that a transmission reinforcement project be in place prior to breaching of the dams. If the dams were breached prior to completion of the reinforcements, the Tri-Cities area would be vulnerable to a potential loss of load event (i.e. power shortage or blackout).
5978	1	sixcases@msn.com	N/A	I do have concerns with the PAs option to increased spill and increase total dissolved gas (TDG) levels up to 125%. I hope testing on the net benefit of increased spill will be tracked to ensure the additional spill doesnt reduce the success rate of adult salmon returning to spawn and cause stress on juvenile salmon with increased TDG. Science should drive the decision on increasing spill and know it may take about three years to really know if increased spill help or harm salmon and steelhead. Scientific analyses must be done to clearly show a meaningful benefit to ESA-listed species and if not increased spill and TDG should be adjusted downward to appropriate levels.	Total dissolved gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Due to the disparity in the two fish models' forecasts for the Preferred Alternative (PA) and the uncertainty in the effects of TDG up to 125% on migrating salmon and steelhead, the PA will require a robust monitoring plan to help narrow the uncertainty between the two biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible.
5988	1	N/A	N/A	The more extreme alternatives, dam breaching in MO3 and the highest level of spill, flow augmentation and reservoir drawdowns in MO4, would cause great economic damage to rural communities in our service territory, as the DEIS concludes that breaching the Snake River dams would have long-term, major, adverse effects on power costs and rates, and the rate pressure could be up to 50% on wholesale power rates. The median household income in Washington County, in the Portland metro area, is about $78,000, compared to about $52,000 in our local Umatilla County (2018 census data). The poverty rate in our local counties is twice that of Washington County. Nearly half of our members struggle to pay their monthly utility bills, despite our retail rates being among the lowest in the nation. The alternatives MO3 and MO4 would negatively impact the technology, transportation, irrigation, food processing and energy development sectors that drive our economy in Northeast Oregon. Nearly 90% of our electrical sales go to these sectors. The working families in our communities, including sizable populations of Latino and Native American residents, depend on these industries for their livelihood. In turn, UEC depends on the financial viability of our members to successfully serve the core mission of a rural electric cooperative. The final EIS must fully examine the trade-offs inherent in managing the river system for multiple uses, from navigation to irrigation to power generation. I ask	The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The Environmental Justice analysis (Section 3.18.3 of the EIS) provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations. The EIS also discusses the fact that Bonneville customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville (see Section 3.7.3.5, Summary of Effects). Environmental and human health impacts associated with increased emissions to shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (3.8), and increase health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				that the economic and social impacts of these alternatives in rural communities be explored in greater depth in the final EIS. Regarding additional spill, UEC has expressed concerns in previous comments to the co-lead agencies. In summary, we have supported increased spill up to 125% total dissolved gas levels only if scientific evidence shows clear benefit to endangered species. It is encouraging to see the principles of the 2018 Flexible Spill Agreement are incorporated in the Preferred Alternative. With increased spill across eight dams on the lower Columbia and Snake rivers estimated to increase BPA wholesale rates by about 3% in the Preferred Alternative, please note our previously stated concern about negative economic impacts.	
5992	5	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	BDL recommends the USACE revise the draft CRSCO EIS to provide additional information pertinent to downtown Lewiston on two specific topics: 1. Mitigation of the impact of dam removal on our downtown economy; and, 2. Mitigation of the impact of dam removal on the physical spaces and infrastructure adjacent to and in downtown Lewiston .	Many of the infrastructure items listed in your comment are described within the relevant environmental consequences sections of the EIS. For example, changed infrastructure costs related to changing transportation modes are described in Infrastructure Costs subsection under Section 3.10.3.5. And additional information has been added regarding municipal and industrial waste water treatment facilities in the Water Quality Section (3.4). As described in Chapter 5 Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental impacts. If in a future analysis, breaching were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures.
5992	6	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	BDL also objects to the USACE proceeding with a 45-day comment period for this important study in light of a global pandemic. Our organization has prioritized public safety and avoided calling a large gathering to review this document with our constituents. While we feel we've adequately represented the concerns of downtown Lewiston, a longer review period during a time that the public ,can gather would result in more thorough public participation in this process. BDL urges the USACE to extend the comment period on this important document.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5992	7	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	Flood insurance 1. The draft CRSO EIS is unclear on if the existing levees separating the urban grid of downtown Lewiston from the Snake and Clearwater Rivers will remain in place or be demolished. As such, it's impossible to know the impact of dam removal on flood insurance rates for downtown property and business owners. The EIS should be revised to specifically recommend retention or removal of the levees. The EIS should also identify the negative impacts on flood control and flood insurance if the levees remain in place or are removed and identify equitable mitigation strategies.	As described in Chapter 5 Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental effects. If in a future analysis breaching were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project, including levee design and/or removal. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described, but rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures. If breaching were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project, as well as determine appropriate management and use of currently inundated areas and levees.
5992	8	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	River views 2. 3-747 22976 through 22978. "Approximately 3,000 acres of habitat management units that are currently irrigated under the No Action Alternative would no longer be irrigated, and these lands would transition to upland plant communities". Lewiston endured the loss of riverfront views and other amenities when slack water arrived. We were compensated by the installation of recreational amenities along the levee including irrigation. The recreational activities along the levee have become a significant amenity for community members living in downtown Lewiston. It also attracts visitors from throughout our region to walk, bike, and fish in the public recreation spaces. These visitors spill over into downtown businesses, creating a positive economic impact. The negative visual impact of the levee and waterfront along downtown Lewiston's recreational opportunities and sense of place must be evaluated and mitigated.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. Mitigation by the co-lead agencies is not anticipated under MO3 to maintain access to the river as the co-lead agencies would no longer operate the project lands for recreation as the projects are deauthorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. As described in Section 3.11.3.5, access to the river and its recreational opportunities will be paramount for the reestablishment of river visitation to the lower Snake River in the long-term. The EIS generally describes the recreation infrastructure needs (rec areas, parking lots, access roads, boat ramp extensions, etc.) post dam breach as well as some example costs to extend boat ramps and relocate recreation areas in the region. Post-dam breach, the Corps will not have a role in providing recreation facilities. However, other Federal, state, or local government agencies, or other entities could relocate existing recreation areas or extend boat ramps (from reservoir to river) so that water-based recreation for the river reach could occur in this region. If MO3 were selected as the Preferred Alternative, further studies and NEPA would be required to be understand and describe the land disposal/transfer process, real estate requirements, mitigation requirements, recreation effects, and other related topics.
5992	9	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	3. 3-1286 3896 through 3898. "The loss of the wide reservoirs would permanently expose portions of shoreline or reservoir bottom leading to temporary dust effects, erosion susceptibility, and rendering previous shoreline recreation obsolete". This outcome would negatively impact property values associated with water views, as well as the quality of life, air quality, and general sense of place of downtown Lewiston. The final EIS must include mitigation, up to and including reconstruction of the riverbed. The final EIS should also include a process through which community members and adjacent property owners can participate in the design of the reconstructed riverbed and shoreline.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. Mitigation by the co-lead agencies is not anticipated under MO3 to maintain access to the river as the co-lead agencies would no longer operate the project lands for recreation as the projects are deauthorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures. If MO3 were selected as the Preferred Alternative, further studies and NEPA would be required to be understand and describe the land disposal/transfer process, real estate requirements, mitigation requirements, recreation effects, and other related topics.
5992	10	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	4. 6-87. Under visual impacts, please include mention that what was once beautiful water views will become a barren brown edge along the river for years to come. As identified in BDL item 3 above, the possibility of creating a barren brown edge along the river for years to come is unacceptable for BDL and the constituents we represent. This potential outcome is one of BDL's strongest points in favor of retaining the dams. Any discussion of the removal of the dams and lowering of the water must include rapid mitigation of this outcome.	The visual impact analysis of MO3 finds that there would be a major effect from breaching the four lower Snake River dams. See Draft EIS pages 3-1286 to 3-1287. Mitigation for the breaching of the four lower Snake River dams has been identified, as described in Chapter 5, page 5-35, lines 1096-1099 in the Draft EIS. With this mitigation, the major effect on visual quality would diminish over time as the shoreline revegetates and blends into the surrounding landscape. The co-lead agencies have added language to Section 3.13 (Visual) to better describe this analysis in the Final EIS. MO3 and specifically the measure to breach the four lower Snake River dams was not identified as the Preferred Alternative in the Draft EIS.
5992	11	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	Loss of large passenger vessel traffic s. 3-1081 32115. Cruise ship passengers are listed as 18,000 in 2017. According to the Port of Clarkston's December 2018 Outlook, cruise ships generated an estimated 25,000 visits to the LC Valley. Please update the economic analysis with this new number. 6. 3-1214 1689 through 1691. "Lake or flat-water recreational activities, including water skiing, sailing, motor boating (in fiberglass boats), fishing for some warm-water species, and sightseeing in tour boats that cruise between Portland and Lewiston, would no longer be possible if breaching would occur". (Responding to 5 and 6) Large passenger vessel traffic represents an important and growing economic opportunity for small businesses in downtown Lewiston. These heritage tourists travel to our area for bespoke, sense-of-place experiences that can only be offered in a historic commercial core like downtown Lewiston. Loss of this passenger vessel traffic would negatively impact downtown Lewiston's businesses and cultural amenities, like the Lewis-Clark State College Center for Arts & History, the Nez Perce County Historical Society, and the First Territorial Capital. These businesses and nonprofits depend on the revenue generated from heritage tourists, and a negative economic impact ending large passenger vessel traffic must be mitigated. Loss of access from personal watercraft must be evaluated and mitigated. Watercraft recreation is an important part of Lewiston's economy, from boatbuilding to fueling boats to feeding people when they come off the river.	Cruise ship visitation is characterized in Section 3.10, and is characterized as growing over time, and providing important regional economic effects. Section 3.10.3.5 describes the contribution of cruise ships as providing demand for approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales).
5992	12	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	boating tourism and river recreation 7. 3-1463 9459 through 9466. Loss of visitors is described as costing the region $103 million, a decrease in 1,230 jobs and $39 million in labor income. This is a substantial loss for our community, and especially for downtown Lewiston, where businesses depend on discretionary spending by the locals to keep their businesses alive. BDL supports the City of Lewiston's request for direct financial payments until pre-project visitation, jobs and sales return. BDL recommends these funds be held in a community trust.	The Recreation Section 3.11.3.5 describes the social welfare, regional economic, and social effects associated with MO3, including a description of the major adverse effects that would occur to both water- and land-based recreation in the short-term in the region. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be required to implement the alternative. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures described. But rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures.
5992	13	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	8. M-2-10 373 through 376. "Without the federal reservoir project, the Corps will not have a role in providing recreational facilities; therefore, in order to re-establish recreation opportunities and water access in the region, there would likely be a cost impact on a government agency to provide recreational infrastructure and access roads" . It is ludicrous and beyond absurd that the USACE would not bear the cost and responsibility of restoring the riverbed and recreation access. If the obligation of restoring the river bed and recreational access is to be passed from the USACE to state or local government agencies, the USACE must establish a permanent endowment to offset local construction and maintenance costs to removed and maintain amenities now managed by the USACE as mitigation of the impact.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. Mitigation by the co-lead agencies is not anticipated under MO3 to maintain access to the river as the co-lead agencies would no longer operate the project lands for recreation as the projects are deauthorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. As described in Section 3.11.3.5, access to the river and its recreational opportunities will be paramount for the reestablishment of river visitation to the lower Snake River in the long-term. The EIS generally describes the recreation infrastructure needs (rec areas, parking lots, access roads, boat ramp extensions, etc.) post dam breach as well as some example costs to extend boat ramps and relocate recreation areas in the region. Post-dam breach, the Corps will not have a role in providing recreation facilities. However, other Federal, state, or local government agencies, or other entities could relocate existing recreation areas or extend boat ramps (from reservoir to river) so that water-based recreation for the river reach could occur in this region. If MO3 were selected as the Preferred Alternative, further studies and NEPA would be required to be understand and describe the land disposal/transfer process, real estate requirements, mitigation requirements, recreation effects, and other related topics.
5992	14	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	9. M-3-27 Table 3-10, M-3-28 Table 3-11. Provide no recreational counts for Snake River below Hell's Canyon dam. Most recreational usage of the Snake River from Lewis Clark Valley residents happens below Hells Canyon Dam. BDL reiterates the point made by the City of Lewiston that recreational usage	Section 3.11.2.2 describes gaps in the recreational visitation data. Data were not available for all sites, including along the Snake River below Hells Canyon Dam and above Lower Granite Lake. The 2016 report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho was considered for the EIS, but not relied upon directly due to the limited types of visitation data in the report, so it does not appear in the references. In addition, this region was not anticipated to be affected by changes in water surface elevations. However, additional information has been added to better describe fishing visitation in this region, its economic contribution to the communities along the Snake River and its tributaries, and the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				in this stretch of the river generates an estimated economic value of $22,810,512.1 This report was not included in the EIS reference section. Loss of this recreational access must be considered, evaluated, and mitigated.	potential impacts to fishing visitation under MO3 (Section 3.11). Estimates of power boating use from that study are broadly consistent with visitation data from Federal and state agencies used in the EIS where data is available. The expenditure data collected for that study cover power boating in Idaho, while the recreational expenditure data applied in the EIS covers the CRS basin and the broader range of activities reflected in the Federal and state visitation data. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities.
5992	15	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	10. M-6-4 line 1036 through 1039. "Pre-dam river stages under dam breaching would range from approximately 8 to 100 feet below current water surface elevations Existing water-based recreational facilities, such as boat ramps, swimming beaches, and moorage facilities, were designed to operate within very specific ranges of water elevations (generally within 5 feet of full pool). If dam breaching were to occur, none of these facilities could continue to be used without modification or relocation". The USACE must address this impact and recommend mitigation of that impact, including who will pay for the construction and maintenance of the mitigation solution, in the final CRSO EIS. 11. M-6-5 1052 through 1055. "Some (recreational) sites would simply cease to be used because the features that attracted people would be eliminated, while other sites would be abandoned because they would be so high above or far away from the river that access would be difficult and possibly dangerous". The impact of this outcome on nearby businesses build around these recreational sites is not addressed and mitigation is not recommended in the draft CRSO EIS. These issues must be resolved in the final draft. 12. M-6-71126 through 1127. "Visitation to the lower snake river would be limited by the availability of infrastructure to access river recreational opportunities". See comments under item 10 above. This impact is not mitigated.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No mitigation by the co-lead agencies is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to assess the requirements of the project and to potentially compensate for the changes in river conditions. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands after the projects are deauthorized.
5992	16	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	13. M-6-11Table 6-5 note 1, 1234 through 1237. "Social welfare effects presented for Regions C and D represent short-term effects. The long-term impacts to visitation is uncertain. Some adaptation is likely over time. To the extent that increases in anadromous fish populations draws additional fishing to the region, increases in regional economic expenditures and effects would increase in the long term" . The USACE must provide data proving the long-term impacts of visitation, as well as identifying short-term strategies to mitigate the negative impact on regional expenditures in the final CRSO EIS.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No mitigation by the co-lead agencies is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to implement that alternative. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands after the projects are deauthorized. In addition, the EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. Consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. There is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, which limits the analysis of the specific impacts of each alternative on these recreational fishing values. However, the EIS describes the visitation in the long-term in the lower Snake River under MO3 as a potential range based on previous studies and that it would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting tourism businesses. The potential for increases in recreational fishing in the lower Snake River and Snake River above Lewiston and in the tributaries is also described under MO3, which would support jobs, income, and social benefits in rural river communities.
5992	17	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	14. M -6-14 13 15-1317 . "As the river returns to natural conditions, river-based recreation would increase over time, given recreational access and infrastructure is developed". Who bears the burden of developing this recreational access and infrastructure is not identified in the draft CRSO EIS. The final CRSO EIS must identify the agencies involved in reconstructing recreational access and infrastructure and identify mitigation strategies to assist non-federal agencies with this burden.	As discussed in previous responses to this commenter, Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No mitigation by the co-lead agencies is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to implement that alternative. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands after the projects are deauthorized.
5992	18	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	15. M-6-15 1332 through 1338. Economic impacts and social welfare in the recreation category are estimated at $109 million, 1,420 jobs, $59 million in labor income and $189 million less in sales. The final CRSO EIS must identify mitigation strategies that offset these negative impacts, including direct financial support, investments in growth industries, and significant investments in local infrastructure. This negative economic impact must be mitigated until jobs, sales, and indicators recover to pre-project levels.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, Federal agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others If breaching were selected as the Preferred Alternative, further evaluation, studies, and NEPA analysis would be needed along with both congressional authorization and appropriations to assess the requirements of the project and to potentially compensate for the changes in river conditions. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands if the projects were de-authorized. Additionally, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region.
5992	19	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	16. 3-936 28236 through 28238. "The increased cost of electricity could increase the cost of living and doing business in the Pacific Northwest, resulting in regional economic impacts of $740 million in lost outputs (sales) and 4,900 jobs". Businesses in downtown Lewiston depend on ancillary and discretionary spending. The loss of $740 million in lost outputs must be mitigated for businesses of all sizes.	The information provided in the comment regarding the power-related regional economic impacts of MO3 (which includes breaching the four lower Snake River dams) is consistent with the findings of the EIS. If MO3 were selected, the co-lead agencies would use this EIS as a basis for the Corps to seek congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Bonneville would also need to consider its options for replacing the power from the four lower Snake River dams and evaluate potential changes to its transmission system. Additional economic analysis would be completed at that time, and then any appropriate mitigation would be proposed to address impacts from implementing breaching the four lower Snake River dams, subject to the co-lead agencies' authorities.
5992	20	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	17. 3-1147 Table 3-248. "Major adverse effects as the jobs and income provided by the four primary commercial navigation ports would be curtailed. Investment in infrastructure may be required, including upgrades to rail infrastructure, added shuttle rail capacity, and increased road maintenance costs. Adverse effects due to reductions in regional economic benefits to port cities where cruise line expenditures would have occurred". Why does the draft CRSO EIS fail to completely explore the efforts necessary to mitigate the loss of the commercial navigation through the four ports in the Lewiston area? These impacts must be evaluated and mitigated. Additionally, Idaho code prohibits the development of a Port district unless the port has access to international shipping. That's why the Port of Lewiston is "Idaho's only Seaport ." Loss of wat er-borne shipping status by the Port of Lewiston must be evaluated and mitigated, including physical and financial impacts, as well as state and federal policy development. Lewiston and the entire Lewis-Clark Valley has benefited from the Port of Lewiston's investment in critical "dark fiber" for high-speed internet services that connect our community to the increasingly global economy. If the Port of Lewiston is dissolved per state code as a result of the loss of water-borne shipping, how will the USACE mitigate the impact on the community's ability to invest in high-speed fiber?	Chapter 5 in the EIS describes the proposed mitigation measures considered under each of the MOs. Mitigation for port functions to include high speed internet was not evaluated in this EIS. If MO3 was selected and authorized by Congress, an implementation plan would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. The inclusion of mitigation measures that were considered in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures would not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure.
5992	21	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	18. 3-1462 9416 through 9418. "Under MO3, pumps and wells that supply municipal and industrial uses in the Lewiston area would no longer be operational once the dams were breached". This is a major impact on municipal and industrial users, especially Clearwater Paper, which employs 1,400 persons who in turn support 2,246 jobs, and have an economic value to the community of $152,699,602. (EMSI Q2 2019 Data Set). The cumulative effect of increasing transportation costs, modifying intakes, modifying discharges and the cost and lack of certainty in the ability to obtain a new discharge permit may be a fatal blow to the company. This impact has not been measured in the EIS nor mitigated. If necessary, mitigation should include USACE funding the design and construction of necessary retrofits.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. The MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3). NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks. See Chapter 5 for additional information on proposed mitigation.
5992	22	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	19. H-1-8 432 through 433. The increased cost of electricity may change household and business spending patterns on other regional goods and services, resulting in a reduction in annual regional economic output (sales) of $320 million to $740 million and cost 2,100 to 4,900 jobs. See comments under item 16. This impact must be mitigated. 20. N-4-19 1294 through 1297. "This decrease in household income ($5,849,112} has a negative effect on the regional economy". "These impacts were estimated as a loss of 55 jobs, $2,261,000 of labor income and $7,518,00 in output (sales) annually". These severe impacts need to be mitigated by USACE investments in infrastructure and facilities that make the Lewis-Clark Valley a competitive business environment on a national level. 21. Q-C-5. Table C-3 and Table C-4 go further to quantify the loss of jobs and their value as a low of $239.8 million to a high of $666.7 million. This significant adverse impact needs to be mitigated.	The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 of the EIS) provides further detail on this as well as the potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers mentioned in the comment. If MO3 were selected, the co-lead agencies would use this EIS as a basis for the Corps to see congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Bonneville would also need to consider its options for replacing the power from the four lower Snake River dams and evaluate potential changes to its transmission system. Additional economic analysis would be completed at that time, and then any appropriate mitigation would be proposed to address impacts from implementing breaching the four lower Snake River dams, subject to the co-lead agencies' authorities.
5992	23	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	Levees 22. 3-732 22518 through 225225. It is not clear how raising the allowable reservoir elevation would impact the Lewiston levee system. Please explain so that BDL and our constituents may appropriately comment.	The lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Chapter 1, Section 1.2. Section 3.9, Section 7.7.11, and Table 7-1 indicate that there is no elevated flood risk for any of the EIS alternatives. Unlike freely flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface. Under current operations or as modeled under the No Action Alternative, during high flows Lower Granite Reservoir is operated at a lower stage to increase conveyance and manage water surface elevations within the Lewiston vicinity. This practice of operating the Lower Granite Reservoir at a lower stage during high flows would continue thus ensuring the Lewiston levee system is not impacted.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5992	24	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	23. 5-31944 through 949. "The co-lead agencies do not have authorities for removing in-stream contaminated sediments, and have not identified a feasible way to avoid mobilization. To offset this impact and any associated impacts to bioaccumulation in fish and other aquatic species, other entities could remove or cap contaminated sediment "hot spots" in Lower Snake River prior to implementing the Breach Snake Embankment measures". It is unacceptable that the USACE would hand off responsibility for remediation of these hazardous materials to "other entities." The USACE dammed the rivers in the 1970s, causing the sediment and contaminants within the sediment to settle in the Lewis-Clark Valley. Failure to remove the contaminated sediment along the riverbed caused by the dams could result in the Lewis Clark Valley being identified as a Superfund site. Looking east towards Butte, Montana, we see how detrimental a Superfund designation is to a community' s future economic growth opportunities, not to mention existing property values. Leaving exposed, contaminated soils in the community, trash, and debris, may be a violation of Federal, state and local laws. This impact has been identified but no mitigation measures have been presented in the EIS.	If MO3 is identified as the selected alternative in the ROD, the co-lead agencies would study potential site-specific contamination issues in a NEPA process for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination that the commenter identified. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies will evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.
5992	25	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	24. K-1-14 Table 1-16. Changes in flood risk annual exceedance probabilities under MO 3 in region C. Region C gage location, action stage flood stages show no change from the no action alternative. According to the Corps "Lower Snake River Navigation Maintenance EIS, June 2005" page 4-10 "A drawdown/sediment flushing event would likely result in adverse impacts to the Lewiston Levee System. The Hydraulic modeling accomplished utilizing the "before and after drawdown conditions" supports this statement, showing a rise in the SPF water surface profiles after the 1992 drawdown event". The draft CRSO EIS is unclear on the impacts of this alternative on the reliability of the existing levee system for flood control. If the dams are removed, who is responsible for the levees? Who is responsible for repairing slope failures, landscaping, and flood control?	The lower Snake River dams are not authorized for flood risk management as stated in the EIS in Chapter 1, Section 1.2. Section 3.9, Section 7.7.11, and Table 7-1 indicate that there is no elevated flood risk for any of the EIS alternatives. The Walla Walla District constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. The breaching of the lower Snake River projects under MO3 would trigger the scour of legacy sediment deposits, which would eventually lower the base level to historical river elevations, and reduce flood risk (assuming the Lewiston levees still remain in place). If breaching were to be selected as the Preferred Alternative, additional, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project, as well as determine appropriate management and use of currently inundated areas. Under MO3, Dworshak has the same operational ruleset as in the No Action Alternative, and the breaching of the lower Snake River embankments under MO3 would generally reduce river stages from the draining of Lower Granite Reservoir, as noted in Appendix K.1.7.3. The three gages denoted in Table K-1-16 (Anatone, WA on the Snake, Spalding, ID on the Clearwater; and Orofino, ID on the Clearwater) are located outside of the Lewiston Levee extents and thus are not indicative of flood risk changes in the Lewiston confluence area. The breaching of the lower Snake River embankments under MO3 would trigger the scour of legacy sediment deposits, which would eventually lower the base level to historical river elevations, and reduce flood risk (assuming the Lewiston Levees still remain in place). This scenario is different than the 1992 drawdown event, and would not correlation with the SPF profiles noted by the commenter. Drawdown of Lower Granite Reservoir water surface elevations could have adverse effects on infrastructure adjacent to and crossing Lower Granite Reservoir as noted in the PSMP Section 4.5. Transportation infrastructure mitigation measures proposed for MO3 are described in Chapter 5.4.3.5.
5992	26	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	25. 3-1213 1643 through 1645. "Although it is uncertain who would own and manage the lands in the lower Snake River, recreational facilities, infrastructure and/or recreational access would need to be developed to facilitate river recreation visitation to the region". See comments under item 14.	As discussed in previous responses to this commenter, Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No mitigation by the co-lead agencies is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to implement that alternative. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands after the projects are deauthorized.
5992	27	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	26. Q-3-3. "Under the dam breaching measures of MO 3, it could be necessary to negotiate agreements with affected parties and property owners and enter into relocation contracts for the alteration or replacement of affected structures". BDL would like a specific listing of structures within one mile of city limits the agencies are expecting to need to relocate or replace so that we can ensure that private and public property owners are engaged in the process. Ownership and operation of the ponds at the west end of downtown Lewiston should be assigned to a public agency with the financial resources to manage them. If that means the USACE turns the ponds over to the City of Lewiston or Nez Perce County, the USACE should provide adequate financial support via a trust for the local government agency to complete the work.	If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be required along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. These further evaluations could include a more detailed evaluation of land transfer process, real estate requirements, recreation effects, and other related topics. Since the lower Snake River projects would be deauthorized, Federal agencies would no longer operate the projects or associated project lands. As described in Chapter 5, Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental impacts. Please refer to Chapter 5 for an overview of the type of mitgiation. As described in Section 5.1.1, Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures.
5992	28	courtney@beautifuldowntownlewiston.org	Beautiful Dawntown Lewiston	27. R-3-5 276 through 288. Areas of uncertainty in the analysis are acknowledged. Some of them: contamination of sediments, soil conditions in the surrounding landscape, planting success of mitigation actions, colonization by invasive species and contamination of groundwater are of great interest to Lewiston. Without answers to these questions, it's not possible for BDL to responsibly recommend the removal of the dams on the Snake River. All of these issues should be rigorously vetted and presented to the community to complete a comprehensive evaluation of the options.	If Multiple Objective alternative 3 is identified as the selected alternative in the ROD, the co-lead agencies would study potential site-specific contamination issues in a NEPA process for the implementation of that alternative. In addition, more detailed design and engineering would need to be implemented with this alternative, including development of planting and monitoring plans.
6006	1	brent.bischoff@cooscurryelectric.com	N/A	Use of the technical term Loss of Load Probability (LOLP) or the more generic power shortage within the report leaves readers without technical industry knowledge almost entirely unaware of the severity of what these terms describe. Loss of load or power shortage stated simply in lay terms means electrical blackout. The general public understands the term blackout and knows that large-scale blackouts are absolutely unacceptable being very costly in terms of public safety and economic loss. The DEIS does not describe in terms understandable to the lay person the extreme 2 societal impact caused by a significant increase in LOLP (ES, pg 25,30). The final EIS should include more detail and description of societal cost associated with significant increases in the probability of system-wide blackout. The probability of a large-scale blackout occurring one in seven years (ES, pg 25) or one in three years (ES, pg 30) is absolutely unacceptable by societal standards today. The final EIS should provide enough description and detail in lay terms so the reader is able to easily discern the severity of the increased risk stated.	The EIS defines the term loss of load and loss of load probability in both the Executive Summary and Chapter 3, as well as explaining the terminology in plain language. The EIS also includes a chart explaining, in summary form, the risk of blackouts for each Multiple Objective alternative (MO), without providing replacement resources. See Appendix H, Power and Transmission, Table 2-1, in the Draft EIS. Without being able to accurately forecast when a loss-of-load probability (LOLP) event would occur, it is too speculative to provide a detailed description of the societal costs, and would also be double-counting the effect, as replacement resources and their associated costs were calculated to bring each MO back to the reliability of the No Action Alternative. The comments about the importance of the four lower Snake River dams for regional power reliability are consistent with the EIS findings. The comment notes a concern for decreased power system reliability; the Preferred Alternative developed by the co-lead agencies has essentially the system reliability as the No Action Alternative, while Multiple Objective alternative 1, Multiple Objective alternative 3 and Multiple Objective alternative 4 did not meet the objective to maintain an adequate, efficient, economical and reliable power system.
6006	2	brent.bischoff@cooscurryelectric.com	N/A	MO3 and MO4: The loss of clean (carbon-free), renewable, low-cost, hydroelectric power proposed in MO3 (1100 aMW) and MO4 (1300 aMW) is unacceptable in the current societal environment focused on carbon-reduction and renewable energy sources to preserve the environment. Proposed replacement of lost hydro generation in MO3 and MO4 with natural gas turbines (ES, pg 25, 30), though potentially practical, is unlikely given the regional emphasis on carbon reduction. States in the region have passed, or are working toward legislation, to limit carbon emissions. For this reason, utilities are shutting down coal fired power plants in the region. The possibility to permit and construct new fossil fuel-fired generation is unlikely given present societal and political sentiment.	The comment that replacing hydropower lost under MO3 or Multiple Objective alternative 4 (MO4) would increase emissions is consistent with the EIS findings in Section 3.8, Air Quality and Greenhouse Gases. The EIS acknowledges that given recent changes to the energy policy landscape, the renewable replacement portfolio may better reflect future trends and that new fossil fuel-fired generation is not likely, as noted in the comment. See Section 3.7.3.1, Additional Power Rate Sensitivity Analysis And Other Regional Cost Pressure Analysis, at page 3-829 in the Draft EIS. The fossil fuel-based replacement portfolio provides a cost comparison and represents the lower end for the cost of replacement resources.
6006	3	brent.bischoff@cooscurryelectric.com	N/A	Proposed replacement of lost hydro generation in MO3 and MO4 with other renewable resources made up of solar and demand response may be long-term solutions (15 to 20 years or more) but are not practical in the short-term. The solar resource required to replace lost hydro (2550 MW for MO3 and 5000 MW for MO4) must be tremendously oversized to account for their variable nature. It is not clear in the DEIS if the cost to build transmission resources to service the new solar generation is included in the cost of construction. Transmission infrastructure is very costly and takes many years to permit and construct. Nor is the carbon emission to manufacture and construct these new solar resources mentioned in the study. Demand response pilot projects have been conducted in the region but development of demand response on the scale of 600 MW is theoretical in the region today; who knows how long it would take to develop this resource.	The findings in the EIS for the power replacement resources indicated that more capacity for zero-carbon resources (e.g., solar) were needed to address lower capacity factors, consistent with the commenter's concern that the amount of replacement resources would need to be much greater than the resources made unavailable in the Multiple Objective alternatives. The EIS evaluated and included the costs of transmission infrastructure needed to interconnect resources, including new solar generation, in the analysis under Bonneville Transmission System Interconnections, Reliability, and Operations in Sections 3.7.3.3 through 3.7.3.6. The developer of the resources would have to build additional transmission infrastructure to connect resources to the larger transmission network. The costs of the additional transmission infrastructure would vary depending on the geographical location of the resource with respect to the transmission network, size of the individual project, and other factors. In addition the EIS acknowledges the potential environmental concerns and permitting timelines from new solar and the associated transmission, such as the land required and potential effects on air quality and greenhouse gases from construction. Regarding demand response, the quantity evaluated in the EIS and noted in the comment is the Northwest Power and Conservation Council's target and given uncertainty that additional demand response capability could be added, no more than this target was included in the EIS analysis, consistent with the comment's concern.
6006	4	brent.bischoff@cooscurryelectric.com	N/A	The resulting rate increases, 50% for MO3 and 41% for MO4 (ES, pg 27, 30) and loss of reliability proposed by these alternatives are unbearable and unacceptable to the CCEC retail consumer. The marginal benefits and uncertain outcomes for fish provided by MO3 and MO4 nowhere near offset the loss of reliable and economical power supply suggested in these alternatives. For these reasons, MO3 and MO4 are not practical alternatives but extreme scenarios that realistically have only illustrative purpose in the context of the EIS. Additionally, if these were practical alternatives, it is unclear what entity/agency would be able to fund and construct the generation resources required to replace the lost hydro generation capability proposed by MO3 and MO4. Are any of the three colead agencies able to do so within their current Federal authority?	The information provided in the comment regarding the power rate impacts of Multiple Objective (MO) alternative 3, which includes breaching the four lower Snake River dams, and Multiple Objective alternative 4 is consistent with the findings of the EIS. Likewise, the reliability impacts of MO3 and MO4 unless and until replacement resources are acquired are consistent with the findings of the EIS. However, it should be noted that in contrast to the comment, these are not "extreme" scenarios but instead robust alternatives designed to enable an evaluation of the full scope of measures available for management of the CRS by the co-lead agencies. The EIS does not address what entities would take on the responsibility of building and financing the resources needed to return regional reliability from the MOs' levels to the No Action Alternative reliability level. Instead, the EIS presents two resource financing options: (1) Bonneville finances; and (2) region finances. These options are presented to describe the rate impacts of the identified resource portfolio on Bonneville rate customers and, if Bonneville is not involved in financing the construction, then to regional rate payers. Neither of these scenarios, however, is intended to determine whether Bonneville or regional utilities have the authority or ability to build the identified resource portfolio. As noted in the EIS, Bonneville has specific statutory requirements it must follow before acquiring a major resource. See EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-819-821.
6006	5	brent.bischoff@cooscurryelectric.com	N/A	Of concern, the Flexible Spill Agreement on which the Preferred Alternative is based calls for spill up to the 125% TDG level. Washington and Oregon have recently modified their TDG limits to allow spill up to 125% TDG. Absent current knowledge of how this higher level of dissolved gas will impact resident or migrating fish, CCEC urges a cautious and science-based approach to implementing this new higher TDG limit. Given that higher spill is intended to benefit juvenile fish migration downstream, this benefit must be demonstrated to offset the lost generation caused by the higher spill and without causing harm to resident and upstream migrating adult fish.	The co-lead agencies are aware of the concern regarding increasing the Total Dissolved Gas (TDG) cap to 125%, and plan to take a cautious approach, as the commenter suggests. There has been a long-standing program to monitor the effects of supersaturated TDG (dissolved gas levels >100%) on smolts migrating through the lower Snake and Columbia rivers. During high flow years, TDGs greater than 125% have occurred. The co-lead agencies do have monitoring data to suggest these conditions will be safe for fish. The co-lead agencies plan on continuing this monitoring program and adapting spill operations if in-season problems are seen. The Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migratory and resident fish. Please see Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information.
6007	1	patrick@3rivers-ashtanga.org	N/A	First, I urge additional time be given to receive comments regarding the DEIS. We note that public meetings have been cancelled due to COVID-19; this has limited the chance for groups and individuals to meet and prepare comments.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6007	2	patrick@3rivers-ashtanga.org	N/A	Flexible spill is the centerpiece of the governments Preferred Alternative. While the science shows that increased levels of spill can buy some additional time to put in place more effective actions for imperiled fish populations, it is not, by itself, a long-term survival strategy, let alone a recovery strategy. Indeed, the parties to the current, short-term Flexible Spill Agreement made this explicit; and respected regional scientists have confirmed that the flexible spill included in the Preferred Alternative will NOT deliver salmon the survival benefits through the hydrosystem they need. The changing climate will further erode any benefits of flexible spill as a long-term approach and only underscores the urgency for meaningful action. The draft plan includes little to address these intensifying impacts.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current, high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					region) as a result of the PA (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6009	1	N/A	N/A	I am VERY disappointed with the underrepresentation of importance of Columbia River Salmon for endangered Southern Resident killer whales (SRKW)! In NOAA's recovery plan for SRKW it states quite plainly "Perhaps the single greatest change in food availability for resident killer whales since the late 1800's has been the decline of salmon in the Columbia River Basin." The EIS does not adequately recognize that SRKW need a quality, abundant food supply throughout their entire range and throughout the entire year. The CAN NOT rely on just a few river systems in Puget Sound to keep them going. There is plenty of scientific data to represent the fact that SRKW spend over half their year in coastal waters (and increasing all the time due to the lack of abundance of salmon in the Fraser River watershed as well as other watersheds in the Salish Sea). We know that when SRKW are on the outer coast, Columbia River salmon make up over half of their diet (of which Spring Chinook are very important). Please consider SRKW more fully in the final EIS and the facts that would help their population to not only survive, but thrive.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
6011	1	kayhum@cableone.net	N/A	This draft EIS fails to fairly evaluate the minor amount of total electricity generated by the four lower Snake River dams, an amount that can be easily replaced from other sources, including the ever-growing contributions of conservation steps underway in the PNW region.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. Bonneville sells power from the FCRPS to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. See EIS Section 3.7.2.5, Bonneville Power and Transmission Customers. Under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the loss-of-load probability (LOLP) levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to a year with one or more blackouts every seven years. See Draft EIS at page 3-903; and Appendix H-Power and Transmission, at Table 2-1 in the Draft EIS. To determine resource replacement amounts, the EIS uses the LOLP metric utilized by the Northwest Power and Conservation Council. See EIS Section 3.7.2.2; Appendix H, Power and Transmission, at Section 2.1; Appendix I, Hydroregulation, Section 2.4.4. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a blackout occurring in a year. See Appendix H, Power and Transmission at Section 2.1. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one blackout every 15 years. The EIS uses this LOLP level as the benchmark of comparison for the other MOs. All cost-effective conservation identified by the Councils Seventh Power Plan is included in the load forecast. Under Washington and Oregon law, all cost-effective conservation must be acquired regardless of the status of the FCRPS. Therefore, conservation was not considered a potential resource replacement; it would be double-counting to allocate this conservation for replacing hydropower.
6011	2	kayhum@cableone.net	N/A	The DEIS omits the dire fiscal impacts and sure collapse of many central Idaho communities economies dependent on revenue from healthy sport Salmon and Steelhead fisheries This omission must be corrected or NEPA requirements will not be met. And these towns will die, as illustrated by the dire financial suffering experienced by residents and businesses when steelhead was closed in central Idaho last autumn.	The geographic scope of the EIS is the Columbia River and its major tributaries where the 14 federal projects of the Columbia River System are located. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
6015	1	N/A	N/A	Also that summer, there were road blocks everywhere in Lewiston and Clarkston because the roads had crumbled without the force of the water to hold them up. Without roads, we have no transportation for even semi-trucks to transport. During the mega-loads, a few years ago, there were groups picketing those transports because the mega-load runs were happening, clogging our highways, and damaging them. If we remove the dams that support the water flow for tug boats to ship goods to the surrounding areas, what will happen to the roads? If people picket a rare occurrence of a mega-load run, wont they picket the highways being crammed with more semi-trucks? And if these trucks become more abundant, wont the wear and tear on the roads become greater? In-turn, wont the cost to improve and repair them become more?	The EIS evaluates the level of anticipated increases in truck and rail traffic that would occur under MO3, which includes the measure to breach the four lower Snake River dams. The EIS finds that truck ton-miles may experience an increase of 19 to 84% under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutants and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86% (when rail rates are not assumed to increase) or decrease by 2% (when rail rates increase by 50 percent). The EIS acknowledges that depending on how rail rates respond to dam breach, short-line rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Environmental and human health impacts associated with increased emissions to shipping goods by rail or truck (or both) are evaluated and described in the Air Quality Section (3.8), and an increase of health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5).
6015	2	N/A	N/A	Along with being a resident, I am also in the real estate field and breaching dams would have a detrimental effect on the housing market, job market and livelihood of the entire valley with ripple effects wreaking havoc on the surrounding region for decades. Our area is growing right now, more	The potential economic impacts from breaching of the four lower Snake River dams are described throughout the EIS organized by resource area, including Power and Transmission in Section 3.7, Navigation and Transportation in Section 3.10, Water Supply in Section 3.12, and Recreation in Section 3.11.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				industry is trying to make its way to our green valley but if we have no rivers, dams, or reservoirs, we have no way to make industry come to stay and bring more jobs. The existing industry could crumble leaving thousands out of work; Clearwater Paper for example. At this time, the water flow level helps the mill retain low levels of chemicals in their holding ponds. Without the river, the mill would shut down. Thousands of workers would be out of jobs which would lead to loan defaults or moving out of the area to find work. Without the major financial support of Clearwater Paper, many would relocate. Without rivers for recreation, boat companiessome who have been contracted by large investors throughout the world and even for James Bond movieswould close their doors. Riverboats are also an enormous source of revenue from tourism and some relocating after a fun trip down the Columbia to the Snake River.	The lower Snake River projects currently support 2.6 million visitors and $24.5 million in social welfare value annually. Dam breaching would have both beneficial and adverse effects on recreation. Dam breaching would preclude reservoir recreation during and shortly after the breach, eliminating reservoir recreation in the short-term; over time, and as recreation areas and access are redeveloped by others, long-term beneficial effects to river recreation, including angling, are anticipated. Section 3.11 of the EIS describes that visitation in the long-term in the lower Snake River would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. Effects to communities and livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that are part of these assessments. As described in Section 3.7.3.5 of the EIS, the implications on the cost of electricity to end-users, such as residents and businesses, would be upward rate pressure ranging from 1.6% to 3.6% relative to the No Action Alternative. The Environmental Justice analysis of the EIS in Section 3.18.3 describes that energy burdens in Region C are already likely unaffordable for all households with incomes below the Federal poverty level, and that any upward rate pressure could impact low-income households for whom energy costs are a larger percentage of their income. The Navigation and Transportation Section 3.10.3.5 describes community concerns and potential impacts that would be anticipated in a dam breach scenario.
6018	1	N/A	N/A	POTENTIAL ALTERNATIVES - There are other consideration for improving salmon and steelhead populations that should be considered and implemented before removing dams these include - Addressing predatory Sea Lions in the lower Columbia river - Addressing predatory birds (terns, cormorants, pelicans, ...) - Returning funding to hatchery programs - Addressing fishing regulations (recreational, commercial, tribal) - Adjusting dam flow rates - New enhanced fish passage improvements at the dams - ... - These dams have operated for a significant number of years while maintaining salmon runs. During this time significant improvements and adjustments have been made to the dams and to their operating parameters that are continually improving fish passage. Meanwhile other impacting events, situations and circumstances have occurred which have had an adverse affect on salmon and steelhead populations. These include predatory animals, invasive species, reduction in hatchery production and changes in ocean temperatures and conditions, ... Time and efforts should be spent first on addressing these other variables before dismantling any of the snake river dams.	Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities, including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those mentioned in this comment. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service (NMFS) website at: https://www.nwfsc.noaa.gov/research/index.cfm. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators, and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Harvest certainly has an impact on salmon and steelhead populations. Alternatives to change harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
6018	2	N/A	N/A	Would removal of the dams enhance the spread some invasive animal or plant species? (shad, lamprey eels, insects, ...) - Does the increasing water temperature in the ocean have such an overriding affect on the fish populations that whatever happens to the dams will be insignificant?	As discussed in Section 3.6 of the EIS, breaching the four lower Snake River dams has the potential of causing colonization of invasive species within unvegetated areas along the shoreline. Any exposed sediment could encourage invasive plants to colonize the shorelines and expose sediment. Lamprey are native to the CRS (they are non-native to the Great Lakes) and shad are non-native to the CRS, but are not considered invasive. The co-lead agencies recognize that ocean conditions are a major driver in juvenile survival and adult returns. As such two of the biological fish models used in these analyses, National Marine Fisheries Service COMPASS and CSS Lifecycle models, use metrics of ocean productivity to predict adult returns. A number of metrics that monitor ocean temperature and productivity are reported annually and are used to predict salmon returns. These metrics can be seen at: https://www.nwfsc.noaa.gov/research/divisions/fe/estuarine/oeip/g-forecast.cfm.
6023	1	flyfishbum@sampsonsunvalley.com	N/A	It needs to address the Economic Impact on Idaho. Without the fish many small river towns in Idaho will hurt badly. Businesses in places like Riggins, White Bird, Salmon, Challis, Clayton, Stanley, Lewiston, Lenore, Peck, Orofino, Greer, Kamiah, Kooskia and others need to be considered.	The co-lead agencies used high-quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.
6028	1	mayor@clarkston-wa.com	N/A	The first major point of confusion is this: Will fish recover or not if the LSRD are breached? Your report says in Chapter 3, p. 548, lines 16557-16558: Currently, hatchery fish account for 80-90 percent of all juvenile Snake River fish passing CRS projects. [The fish] models [projecting increased returns] do not account for this potential major reduction in juvenile fish production. Yet, the Executive Summary and write-up on recreation explain benefits in the form of improved recreational or tribal fishing. Most people are aware that you cannot take endangered or threatened species. But if you get rid of the hatchery fish, what are people fishing for? (NOTE: LSRD ratepayers pay for hatchery operations and habitat improvements to mitigate for the dams. When the dams are gone, according to Birgit Koehler, Policy Lead for Power on the CRSO DEIS at Bonneville Power Administration (on Jan. 7), there will be no line item in BPAs future budgets for hatcheries and habitat improvements.) And if there was, the impact rolls out to local residents such that their power bills do not increase by 45% but by some other, higher number. If there will be fewer fish with LRSD removal, MO3 shouldnt even be under consideration.	The scope of the Draft EIS is to evaluate the effects of operations, maintenance, and configuration of the CRS projects. The analyses presented compares each alternative to the No Action Alternative. Overall, the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, even with certain hatchery programs no longer funded in the long term. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6028	2	mayor@clarkston-wa.com	N/A	There will be a concentration of impacts under MO3 in southeast Washington and north central Idaho. The impact will be even more significant in the turn-around point of the navigation channel, where more than 60,000 people live. Its the Lewis-Clark Valley consisting of these incorporated cities: Lewiston, ID, Clarkston, WA, and Asotin, WA plus the area immediately outside those boundaries in Nez Perce County, ID and Asotin County, WA. Farmers will choose to retire rather than operate at a loss (your analysis does not account for true increased costs of transportation). The land will not be productive. Neither farming land nor properties currently managed by the U.S. Army Corps of Engineers (hereinafter Corps) will be managed for dust control, erosion, noxious weeds, invasive species or upland habitat management. Cities (like the City of Asotin) will go bankrupt. Unfunded mandates, such as re-permitting and extending waste water treatment effluent lines from current locations to new locations will be expected from municipalities like the City of Clarkston at a time when property values will decrease because our reservoir disappears. Instead of the water being an asset, it will be a detriment with fugitive dust causing problems for asthmatics, loss of modulation of temperature during hot summer months and cold winter months from the reservoir, tremendous loss of water-based recreation (which is why people live here and not elsewhere), odor from decaying fish, loss of the cruise industry, loss of irrigation for key recreational facilities including access to the water and more. This area cannot afford and should not be forced to shoulder the impact of dam removal.	The EIS in Chapter 3 does include an evaluation of regional and social effects by regions for MO3 but does not address all the issues you have raised. If MO3 was selected and authorized by Congress, an implementation plan and associated National Environmental Policy Act (NEPA) analysis would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. In addition a table has been added to Section 7.4 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
6028	3	mayor@clarkston-wa.com	N/A	The City of Clarkston urges the action agencies to compile the impacts, stacking them one on top of another, to see what devastation MO3 will cause for our region. Then, we urge you to include mitigation so that our residents are not paying the steepest price.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A table added to Section 7.4 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. Chapter 5 in the EIS describes the proposed mitigation measures considered under each of the MOs. Mitigation for specific City of Clarkson impacts was not evaluated in this EIS. If MO3 was selected and authorized by Congress, an implementation plan would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. The inclusion of mitigation measures that were considered in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures would not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure.
6031	1	jlukas@3rivers.net	N/A	The Draft EIS does not describe or identify the likely fish community impacts that would result from Dam Breaching. The entire fish assemblage of the Lower Snake River would be affected. This would mean that populations of native and non-native species that have adapted and used the reservoirs of	The analyses of effects of breaching the four lower Snake River dams to Snake River resident fish communities is analyzed under Region C of the Draft EIS beginning on page 3-585. Generally speaking, there would be short-term adverse effects to the entire fish community due to breaching construction activities, and in the long-term the community would revert to a more native-dominated community than it is currently, due to the change from reservoir to riverine habitats. The shift in fish communities in the Snake River would not be expected to be displaced to the lower Columbia River, but rather just shift over time after the initial short-term adverse effects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the lower Snake River would likely be displaced into the lower Columbia River. Many of these species are aggressive smolt predators and there would be predation impacts modified and increased by this potential action. The Draft EIS should identify and consider these impacts.	
6031	2	jlukas@3rivers.net	N/A	The Draft EIS did identify impacts to long-standing mitigation programs as another impact of these alternatives and it should be high-lighted that hatchery production and funding would be impacted. With the breaching of Snake River Dams, there would no longer be the commitment to mitigate for those dams, so the hatchery programs funded by the Lower Snake River Compensation Plan would no longer produce smolts. These fish account for 80-90% of all juvenile Snake River fish passing CRS projects. This should be more directly identified as a negative consequence of dam-breaching.	The Draft EIS acknowledges that with breaching of the four lower Snake River dams under MO3, Bonneville would no longer be required to fund the U.S. Fish and Wildlife Service (USFWS) for operations and maintenance actions that are part of the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, and other mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs, and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. Under the Preferred Alternative, hatchery programs would continue as under the No Action Alternative. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the Columbia River System.
6031	3	jlukas@3rivers.net	N/A	The Draft EIS should also evaluate other impacts of lost power sales on the Direct Fish and Wildlife Program funded by BPA ratepayers. The lost sales of 1,100 aMW of energy and more than 2,000 MW of capacity from the lower Snake River Projects would be a massive shock to BPA Preference Customer Rights and result in many unintended consequences related to actions taken by preference customers to locate replacement power supply.	The statement in the comment that the loss of capacity and energy would adversely affect regional electricity costs and Bonneville customers is consistent with the findings of the EIS. As noted in the comment and stated in the EIS, the lost hydropower generation would require Bonneville or its customers to acquire replacement resources at considerable cost. See Draft EIS, Section 3.7.3.5, Table 3-166. Regarding the funding of Bonneville's Fish and Wildlife Program, funding decisions for the program are not being made as part of the CRSO EIS. A range of costs are included in Multiple Objective alternative 3 to inform the broader cost analysis, and any future budget adjustments would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums.
6031	4	jlukas@3rivers.net	N/A	This leaves us with the Preferred Alternative which identified lamprey passage improvements plus adoption of a flexible spill program that would allow spill up to 125% TDG. We have very serious concerns about this operation which were identified directly in the Draft EIS. The Draft EIS acknowledges that this operation may actually reduce salmon survival by 7.5%! The loss of 160 aMW of generation on average while losing 300 aMW during low-water conditions does not represent an appropriate balancing of impacts for an operation that may end up killing more of the fish that it is intended to protect than the No-Action alternative. We have already seen a flexible spill operation in 2019 with spill up to 120% TDG that showed little benefit to fish with some evidence suggesting that survival was reduced. Page 3 of 4 In our view the Juvenile Fish Passage Spill Operations (Section 7.6.3.10) of the Preferred Alternative fails to satisfy Objective 1 of the Draft EIS to: Improve ESA-listed anadromous salmonid juvenile fish rearing, passage and survival within the CRS project area through actions including but not limited to project configuration, flow management, spill operations and water quality management. The concerns below identify why this objective would not be satisfied. 1. The life-cycle modeling of the Draft EIS identifies a risk that the Preferred Alternative would reduce smolt to adult return rates. The DEIS analysis showed that: If latent mortality effects are not reduced the LCM predicts that SARs for Snake River spring Chinook would be lower than the No-Action Alternative (7.5% lower SARs) due to reduced transportation. Table 7-25 shows the potential for populations in the Middle Fork, South Fork and upper Salmon River to experience survival reductions of 9-25% under this operation of the Preferred Alternative! 2. In effect this element of the Preferred Alternative is a giant bet placed on the unverifiable CSS modeling assumptions related to latent mortality. In fact, one of the sole plausible mechanisms for latent mortality would be Gas Bubble Disease associated with spill up to 125% TDG. This shows what a risky proposition an alternative based on high levels of spill is as the Draft EIS itself predicts a sizable reduction in fish survival if the latent mortality assumptions are wrong. 3. This element of the Preferred Alternative is highly likely to have disproportionately negative impacts on steelhead which is one of the ESUs most in need of a different management regime given recent low returns and litigation over closure of fisheries. Steelhead travel in the upper portion of the water column exposing them to avian predation. Spill up to 125% is known to cause Gas Bubble Disease or Gas Bubble Trauma, one of the only defenses to this is depth compensation. This is why so many describe Gas Bubble Disease as similar to divers getting the bends. Fish like juvenile sockeye or Chinook that migrate deeper in the water column will be less susceptible to the impacts of High TDG levels. Steelhead that migrate closer to the surface will be more heavily and directly impacted. This will lead to higher levels of avian predation on fish compromised by Gas Bubble Disease. It is nearly certain that spill up to 125% TDG will negatively impact steelhead at a greater rate than other salmonid species. 4. It is also important to point out that the Draft EIS lacked comparative information for impacts of the Preferred Alternative on steelhead. Thus it appears that the Action Agencies relied only on the assumptions of the CSS (Table 7-27) for claims about steelhead survival noting that: There is no NMFS LCM model for Snake River Steelhead. 5. The Draft EIS claims that: The initial spring component of juvenile fish passage spill is a flexible spill operation over a 24-hour period to take advantage of peak and off-peak load hours for hydropower, while also providing high levels of spill intended to test the CRSO EIS modeled estimates of the benefits to downstream juvenile passage, while also ensuring operational feasibility for the Corps. The Draft EIS provides no information on this test other than a footnote claiming that: This measure will also allow the co-lead agencies to gather important scientific information on the relationship between the CRS and latent (delayed) mortality. With modeling within the Draft EIS showing a risk of a sizable reduction of survival related to this operation the Action Agencies should at least Page 4 of 4 identify what study will be conducted to confirm or refute their modeled estimates of reduced SARs under this risky and ill-advised operation. 6. Many of these concerns appear to be acknowledged yet ignored by the Draft EIS. We were only able to find one cryptic paragraph about this very important issue. Page 7-89 lists these concerns: Increase in gas bubble trauma can result in injury or even death of juvenile and adult salmonids if TDG exposure is of sufficient magnitude and duration. In addition, spill levels being proposed in the Preferred Alternative have been shown to delay adult migrants as they search for fishway entrances. Increased incidence of adult fish falling back over spillways would also be expected with the higher spill levels. Monitoring would be in place to help the co-lead agencies identify and remedy any of the potential adverse effects noted above. In the Final EIS the Action Agencies should provide much greater detail than a single sentence about monitoring and how this information about incidence and severity of Gas Bubble Disease (i.e. Gas Bubble Trauma) would be used to modify or reduce high levels of spill causing it.	The co-lead agencies used current, high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address the uncertainty due to the different model results, the Preferred Alternative (PA) includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. The PA includes a combination of measures that meet the Purpose and Need Statement and most objectives of the EIS, while balancing the authorized purposes of the 14 Federal dam and reservoir projects that make up the CRS, including providing an adequate, efficient, economical and reliable power supply. Gas Bubble Trauma (GBT) disease is a combination of exposure level and duration during both the current condition as well as past exposure. Severity is also a function of overall health as well as availability of depth compensation. In general, for fish without the ability for depth compensation, TDG levels greater than 110% can lead to higher mortality and shorter response time at higher TDG levels. Past studies regarding TDG effects on survival have been of short duration, thus high TDG exposure effects on smolt-to-adult survival remain unknown. In general, GBT disease tends to reduce overall fitness and thus can lead to reduced survivability. Over the past two years, the Corps has examined TDG exposure levels in the fish transport barge holds and collection raceways. Findings indicated transport barge aeration systems were successful at reducing TDG levels to less than 110% when the intake river water was 120% TDG. The results also indicated the raceway water supply at Little Goose Dam may need modifications to provide degassing when the water supply TDG is greater than 120%. Current adult returns have been related to poor ocean conditions rather than passage conditions in the CRS. Adult return rates over the next few years will be considered through adaptive management to inform any necessary alterations of operations in order to better benefit to Snake River salmon and steelhead. The EIS recognizes the concern voiced in the comment regarding lost generation, which leads to increasing power rates under the Preferred Alternative. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1, at page 3-817. Finally, the comment is correct that the Preferred Alternative would cause a potential reduction of 160 aMW of generation on average while losing 300 aMW during low-water conditions. However, because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability (LOLP) was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The Preferred Alternative does meet the EIS objectives for anadromous and resident fish, lamprey, hydropower, water management, and water supply, while minimizing adverse effects to communities and the economy.
6040	1	calla.hagle@burnspaiute-nsn.gov	Burns Paiute Tribe	The Burns Paiute Tribe appreciates the opportunity to offer formal comments to the Co-Lead Agencies regarding the DEIS for Columbia River System Operations. Please see the attached formal comment letter. For questions regarding this submission, please contact Calla Hagle (technical staff) at (541)573-8021 or email at calla.hagle@burnspaiute-nsn.gov	The co-lead agencies confirmed the Burns Paiute Tribe's comments were submitted by the Upper Snake River Tribes coded as Letter 6162. Please see responses to comments under Letter 6162.
6046	1	pmfinnegan@hotmail.com	N/A	The economic benefits provided by fishing to river communities in Idaho that depend on salmon and steelhead returns, such as Salmon, Challis, McCall, Riggins, White Bird, Grangeville, Orofino and Kamiah were not sufficiently evaluated in the draft EIS. While fishing is only one of many benefits of a free flowing Snake River, a 2005 study determined that salmon and steelhead fishing could bring Idaho over $544 million dollars annually.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.
6046	2	pmfinnegan@hotmail.com	N/A	The four LSR dams provide just 4-5% of the Northwests power supply. By 2013, wind energy in the Pacific Northwest produced 3.4 times as much electricity as all four LSR dams. Wind energy alone has thus already replaced the power generated by all four LSR dams more than three times over. The Pacific Northwest presently enjoys a 16% surplus of electricity. If the 4 LSR dams were removed today we would still enjoy an 11% electricity surplus. By relying on available hydropower from other dams in the Columbia River basin, grid stability at any point in time can readily be achieved. Analysis by the NW Energy Coalition and the RAND Corp. found that power from the LSR dams can be affordably replaced with proven carbon-free energy sources and efficiency upgrades. Like wind, hydropower output varies greatly. These two energy sources share similar efficiency ratings (production vs. nameplate capacity) on an annual basis. Further, hydropower produces its greatest volume of power during the spring, when the demand and price for that power are at their lowest levels. According to an analysis published by the NW Energy Coalition during 2015, power costs to Northwest ratepayers would increase by about $1 dollar per month if the LSR dams are breached.	To determine resource replacement amounts, the EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council. See Draft EIS Section 3.7.2.2; Appendix H, Power and Transmission, at Section 2.1; Appendix I, Hydroregulation, Section 2.4.4. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year having one or more blackouts. See Appendix H, Power and Transmission at Section 2.1. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to a year with one or more blackouts every 15 years. The EIS uses this LOLP level as the benchmark for comparison to the other Multiple Objective alternatives (MOs). Under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to a year with one or more blackouts every seven years. See Draft EIS at page 3-903; see also Appendix H-Power and Transmission, at Table 2-1. In addition, comparisons of wind to hydropower generation in this comment do not consider important factors about flexibility and dispatchability. For example, as described in the EIS, the four lower Snake River dams provide important ramping capability, the ability to generate energy quickly to match spikes in energy usage, with over 2,200 MW of capability in certain months of the year. See Draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907, Table 3-160. In other words, it is not enough to consider the average amount of generation from these dams in assessing their importance, but also to consider the timing and flexibility of that generation. The comment correctly states that hydropower generation and surplus is more likely in the spring while deficits are more likely in the winter. Furthermore, the amount of surplus or deficit varies considerably by water year. In addition, contrary to the comment, breaching the four lower Snake River dams decreased regional grid stability without replacement resources and transmission reinforcements.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Regarding the Northwest Energy Coalition (NWEC) study, Appendix H, Power and Transmission, and Section 3.7.3.5 describes how the EIS considered the NWEC study cited by the comment. As explained in the EIS, the NWEC study is not directly comparable with the analysis performed for the EIS. Most importantly, the EIS has a broader scope and relies on more recent regional load and resource availability and costs data.
6046	3	pmfinnegan@hotmail.com	N/A	Of the 4 LSR dams, only the Ice Harbor dam provides irrigation for farms. The relatively small amount of irrigated farmland along the LSR could be maintained by extending intake pipes to the free flowing river. Removal or breaching of the 4 LSR dams may actually take pressure off irrigators who otherwise would have to leave more water in the river to mitigate the effects of the dams.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267, line 3244, in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres.
6046	4	pmfinnegan@hotmail.com	N/A	The LSR is no longer necessary or viable for commercial freight. During the past fifteen years freight transport on the LSR has declined 69%, from a peak of 9.14 million tons in 1998 to 2.83 million tons in 2014. Freight volume in 2015 trended downward and has averaged over the past seven years 2.6 million tons per year. Of the twenty-one largest employers in the quad-cities of Lewiston, Clarkston, Moscow and Pullman, only one ships anything by water. That company is located about two miles from the Port of Lewiston (POL), produced 50% more tonnage of product than all the grain shipped through the POL, and yet in 2014 transported 99.5% of its product by truck and rail. A 2015 study conducted by Anthony M. Jones of the Boise economic consulting firm Rocky Mountain Econometrics found that farmers who use the river instead of rail save about 2.4 cents per ton, or about $7.6 million annually. But he said the Army Corps of Engineers spends $17.8 million per year to maintain the river transportation system and hundreds of millions each year to mitigate the harm dams cause to fish. He calculated that the dams provide a benefit of 21 cents for every dollar the Corps spends. Container shipping on the LSR has ceased, and the waterway has been all but abandoned by the lumber industry, along with paper, pulp, and petroleum. The LSR waterway is categorized by the Corps of Engineers as a waterway of negligible use. Removal of the LSR dams will reduce the river barge corridor by only 140 miles. Freight transportation can be accommodated by rail and truck. Investments in a modern rail system and improved highways is not only affordable, it will provide more benefits to the regions farmers, businesses and communities than the LSR barge system does.	Access to barge transportation is the most cost-effective means of accessing export markets for many of the grain producers in the Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS discusses in Section 3.10. It is true that barge movements on the Snake/Columbia rivers have declined somewhat over the past 20 years. The decline is mostly attributed to investments in shuttle rail terminals. The EIS finds that shifting traffic to road and rail would increase costs to shippers and would require infrastructure investments.
6046	5	pmfinnegan@hotmail.com	N/A	The LSR dams do not provide flood control. Instead, they create a flood risk. They are run-of-river dams, that dont store significant water volume. A growing flood threat exists to the cities of Clarkston and Lewiston because naturally occurring sediment accumulating at the confluence of the Clearwater and Snake Rivers is raising respective river levels. Proposed remedies, such as raising levees, dredging, and other measures will cost millions of dollars over the long term and pose threats to fish, wildlife and recreation opportunities. Lewiston community leaders are opposed to raising levees, which will cut the town off further from its rivers and disrupt popular biking and walking paths. The Corps admits that the volume of sediment is too vast for dredging to solve the problem.	The four lower Snake dams are not authorized for flood risk management and this is stated in the EIS in Chapter 1, Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the Lower Snake River reach for any of the EIS alternatives. Unlike freely flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface; under current operations or as modeled under the No Action Alternative, during high flows Lower Granite Reservoir is operated at a lower stage to increase conveyance and manage water surface elevations within the Lewiston vicinity. In 1992 and prior, to maintain channel conveyance, the most recent dredging in the Lewiston area has been to maintain a 14-foot depth in the Federal navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (PSMP). Channel capacity has been lost since the project was constructed, as early dredging efforts were not able to maintain the original capacity. However, provisional analyses described in the PSMP (Chapters 10-12) indicate that some segments of the channel in the upper reach of Lower Granite Reservoir are tending towards a state of relative morphological equilibrium under the prevailing sediment loads and discharges. Under the current flood control operations of Lower Granite Dam, during large flood flows, fluvial sediment transport processes were predicted to form an equilibrium channel that maintains the conveyance capacity of the upper reach of Lower Granite Reservoir. During sufficiently large flood flows, the hydraulic conditions are great enough that sediment erosion balances sediment deposition such that there is no net change in the equilibrium depth of the channel segment. At even higher velocities, if sediment loading remains constant, the rate of sediment erosion will exceed deposition and channel segments can tend to erode to reestablish a new deeper equilibrium depth. Under these conditions, sediment eroded from the confluence area was predicted to transport into the deeper reservoir reach downstream of Silcott Island where it has less effect on the flood stage at the Lewiston levees. According to the PSMP, levee capacity is predicted to remain adequate into the future. But modeling and monitoring of sediment accumulation were recommended for determining if/when channel conveyance dredging is required to maintain capacity, rather than attempting to maintain the original capacity, as was done during the early years of the project.
6046	6	pmfinnegan@hotmail.com	N/A	The 2015 study by Rocky Mountain Econometrics determined that the cost of maintaining the LSR dams and mitigating their impacts has been soaring while benefits are in steep decline. The economic benefit of shipping by barge out of the LSR Basin has plummeted from about $19.4 million per year to about $7.6 million in 2014. Meanwhile, direct costs for LSR dam operation and maintenance are at about $227 million per year and increasing about 4.5% annually. In addition to direct costs, fish related mitigation significantly increases the expense of LSR dam and navigation system operation and maintenance. In 2014 the Bonneville Power Administration (BPA) reported $782 million in mitigation costs for Columbia River Salmon and Steelhead. After subtracting hatchery operation costs of $35 million, if even one-fourth of annual mitigation costs are spent on the LSR dams, mitigation expenditures related to the lower Snake River total $187 million per year. Despite spending more than $1 billion for fish passage improvements on the LSR dams, survival of threatened and endangered salmon and steelhead has not improved since the 2002 LSR EIS was implemented. The economic benefits of dam breaching have been illustrated. In developing the 2002 LSR EIS, the Corps hired noted recreational economist John Loomis. Loomis pegged the economic gain via dam breaching at over $300 million. Temporary job growth to facilitate dam breaching, infrastructure modifications and restoration ecology would be significant. Improved commercial fisheries and recreation opportunities would generate long term economic growth. Improved aesthetics and quality of life associated with the enjoyment of a free flowing LSR would attract business and industry to the region. In spite of over $1 billion spent on fish passage improvements on the LSR dams, survival rates of endangered salmon and steelhead have not improved since the 2002 EIS was implemented.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Access to barge transportation continues to be the most cost-effective means of accessing export markets for the majority of grain producers in the Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia Rivers have declined somewhat over the past 20 years, but not by 70 percent. The EIS acknowledges that the decline is mostly attributed to investments in shuttle rail terminals. However, the EIS also acknowledges that shifting traffic to road and rail would increase costs to shippers and would require substantial infrastructure investments. While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As described in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams produce upwards of 1,000 aMW of power, which is approximately 11 percent of the average power produced by the FCRPS. See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. This is equivalent to the amount of power used to serve 730,000 homes in the Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effect, at page 9-935, noting that the loss of generation from the four lower Snake River dams accounts for about 90% of the power loss in MO3. The commenters suggestion that the loss of the four lower Snake River dams has already been replaced by wind and solar power is inconsistent with the findings in the EIS. The EIS analyzed the effects on regional reliability if the four lower Snake River dams were breached in MO3. To maintain regional power reliability at the No Action Alternative levels, the EIS found that additional replacement resources would be necessary. The EIS considered two resource portfolios to replace the power output of the four lower Snake River dams: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Draft EIS, Section 3.7.3.5, at pages 3-904-910. Under both of these replacement portfolios, however, regional power rate pressure increases considerably. The rate impacts of these replacement resources, which includes cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, pages 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operations and fish and wildlife mitigation costs, the net impact on power rates is in the range of between 13-50 percent (for zero-carbon resources replacements) and 4-10 percent (for natural gas/least cost replacements). The commenter also suggests that Bonneville's power is already in less demand due to California moving toward wind and solar. Demand for Bonneville power, both within the Northwest and outside of it, remains strong. This is primarily due to the flexibility and low carbon content of the FCRPS. Additionally, demand for services to integrate the new influx of wind and solar, as noted by the commenter, are expected to grow. The four lower Snake River dams are a key source of capacity for balancing reserves, the service used by Bonneville to balance variable resources such as wind and solar. See Draft EIS, Section 3.7.2.2, Meeting System Uncertainty With Generation Balancing Reserves, Dispatchable Resources, And Ramping Capability, and Section 3.7.3.5, Value of Lower Snake River Dam Flexibility, at pages 3-906-910. Breaching the four lower Snake River dams under MO3 would result in the loss of this integration capability.
6051	1	katiewhite1515@gmail.com	N/A	Without reliable baseload, we increase our risk of blackouts caused by power shortages during peak times. In fact, the DEIS estimates that breaching the Lower Snake River Dams would double our risk of regional blackouts we simply cant afford to do that. Especially in Montana where a blackout equates to more than just an inconvenience or an economical challenge it can lead to deaths at 20 degrees below zero.	The comments about the impact of breaching the four lower Snake River dams on regional power reliability is consistent with the EIS findings. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1. Should replacement resources not be built immediately to replace lost capacity, the concern voiced by the commenter towards health and safety effects is consistent with discussions in the EIS.
6065	1	N/A	N/A	The Columbia-Snake River system of dams and locks enables cost effective and fuel-efficient transportation of goodsconnecting the farthest inland port in the country to markets in the Northwest and abroad. One barge with tow can ship the equivalent goods of 1.4 100-unit freight trains, or 538 semi-trucks. These trains and trucks would congest our communities, increase greenhouse gas emissions, and decrease air quality if we lose the system of dams and locks that enable barge shipments.	Environmental and human health impacts associated with increased emissions to shipping goods by rail or truck (or both) are evaluated and described in the Section 3.8 Air Quality and Greenhouse Gas, and increased health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Section 3.10.3. 5 Navigation and Transportation for other social effects.
6065	2	N/A	N/A	In 2018, it would have taken 38,966 rail cars or 149,870 semi-trucks to move the 3.9 million tons of cargo shipped on the Snake River alone. Grain suppliers and shippers that our economies depend on will likely see an increase in transportation and storage costs by 50 to 100% if barging is lost as a transportation option. In an industry where $5.00 per bushel is the current break-even cost, the loss of barging could increase transportation and storage costs from $0.40 per bushel to up to $0.80 per bushel.	The EIS finds that under MO3, which includes breaching the four lower Snake River dams, average transportation costs for wheat farmers would increase 10 to 33%, but that individual farmers could experience increases that are double. Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, low air emissions relative to other transportation modes, potential regional economic, and other social effects that could occur under MO3.
6065	3	N/A	N/A	Breaching the Lower Snake River dams would cause diesel fuel consumption to increase by nearly 5 million gallons per year as barges are replaced by less efficient truck-to-rail shipments. At least 201 additional unit trains and 23.8 million miles in additional trucking activity would be required annually, resulting in increases in CO2 and other harmful emissions by over 1.2 million tons per year.	Section 3.10 of the EIS evaluates potential effects of MO3 on emissions due to shifts from use of barge-based shipping through the four lower Snake River dams to road and rail transportation. The analysis does find an increase in truck and rail transportation, and associated CO2 emissions, under MO3 relative to the No Action Alternative. MO3 was not identified as the Preferred Alternative in the Draft EIS.
6072	1	heartofidaho@moscow.com	N/A	The DEIS ignores the benefits and opportunities of salmon recovery for communities: The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices already made by Tribes and rural communities in terms of lost fishing opportunity, reduced jobs and incomes, impacts on Tribal cultures and diets, and other socio-economic effects.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For MO3, Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS. Section 3.11.3.7 describes the potential economic impacts to Tribes. Discussion of Tribal community concerns and Tribal treaty rights were considered and are discussed in a number of sections throughout this EIS. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are described in Section 3.15.4. Additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis in Section 3.11, including Tribal interests in Section 3.11.3.7. Many sections of Chapter 3 include a Tribal Interests sub-section at the end that attempts to summarize tribal issues by topic and Chapter 7 also includes additional information on the Preferred Alternative's impacts on these resources.
6077	1	bruce.a.connery@gmail.com	N/A	Ample information exists in numerous federal and stakeholder studies and previous documents (2002 EIS, USACE Walla Walla District, USACE Walla Walla District Snake River Production to Northwest Residential Use Negating Aug Sep 2015. , 1992 Reservoir Drawdown Test, etc.) to show that breaching (implementation plans, outreach, etc.) the four Lower Snake River Dams needs to start immediately.	The Corps does not have the authority to breach the four lower Snake River dams. If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments.
6079	1	scullyrjs@cableone.net	N/A	Recognizing that It would take several years for Congress to authorize decommissioning of the lower Snake River dams, planning and implementing programs to mitigate businesses affected by river restoration, and for dam removal to proceed, I recommend that the CRSO implement MO4 as an interim measure while the federal agencies prepare for MO3 implementation.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The comment is correct that implementation of MO3 would take years. Both MO3 and Multiple Objective alternative 4 (MO4), by contrast, have significant regional economic impacts and community effects as compared to the Preferred Alternative, and meet only a subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 or MO4, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6079	2	scullyrjs@cableone.net	N/A	The DEIS claims that the LSRDs are essential to ensure adequate power capacity in the Northwest. Between 2007 and 2018, BPA required LSRD power to meet preference customer demand on 2 hours. (Rocky Mtn Econometrics). That limited amount of power could have been purchased from the open market and saved hundreds of millions of dollars in M&O, channel dredging and fish and wildlife mitigation costs. When the LSRDs power is sold on the surplus market, it is almost always at less then the cost of production. Half the LSRDs power is produced during spring, when the Columbia system is awash in hydro-power and the price is lowest. The LSRDs are high cost/low value assets, are not needed and are killing salmon and steelhead! Solar and wind power production has increased significantly in the recent decade. California now has much less demand for BPA surplus power and the price for surplus power has decreased precipitously.	The commenters statements are inconsistent with the findings in the EIS. Specifically, the four lower Snake River dams produce roughly 1,000 aMW of power, which is approximately 11 percent of the average power produced by the Federal Columbia River Power System (FCRPS). See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. This amount of lost power is equivalent to the amount of power used to serve 730,000 homes in the Pacific Northwest. See EIS, Section 3.7.3.5, Summary of Effect, at page 9-935. To maintain regional reliability at the No Action Alternative levels, the EIS found that additional resources would be needed. See EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, at pages 3-904-910, noting that generation from the four lower Snake River dams is approximately 90 percent of the power loss in MO3. The commenter's suggestion that the four lower Snake River dams were only used to serve preference customer load for two hours is inaccurate. The power produced by these projects is not individually sold to any preference customer, but is melded with all other power produced by the FCRPS. See EIS Section 3.7.2.5, Bonneville Power and Transmission Customers. The commenter is correct that the largest power output from the four lower Snake River dam is produced during the spring. However, these projects produce power year-round. Using average water conditions, and an 80-year water data, the four lower Snake River dams produce between 460 aMW to upwards of 1,400 aMW of power during the winter months of December February, which are typically the most energy intensive months for Bonneville. They provide approximately 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. While the increase in solar and wind generation is consistent with the EIS discussion in 3.7.2.1 Power Generation, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under MO3. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, pages 3-903-910. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90% of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the FCRPS and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct-funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and O&M spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife Program, are not included in this metric.
6079	3	scullyrjs@cableone.net	N/A	The flex-spill experiment featured in the PA maximizes spill 16 hours per day to benefit smolt passage and maximizes flows through turbines 8 hours per day to maximize power production. BPA chooses the hours for spill reduction. If the most beneficial hours for smolt passage overlap with the most beneficial hours for power production, the benefit to smolt survival from flex-spill would be reduced. Fisheries experts should be allowed to select the hours for spill when most downstream movement of smolts is maximized. The flex-spill schedule should error toward the needs of the ESA listed species, not financial gain.	The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6079	4	scullyrjs@cableone.net	N/A	The DEIS dwells on the impacts that taking necessary steps to restore imperiled Snake River salmon and steelhead would have on industries and economies that did not even exist prior to the mid-1960s. At the same time the DEIS all but ignores the ecological, social and economic losses that occurred because of the construction and operation of the lower Snake River dams and the benefits that would result from restoring abundant, fishable and well distributed SRS&S .	The CRSO EIS focuses on evaluating the environmental, social and economics impacts to resources affected by Multiple Objective alternatives (MOs) to operations, maintenance and configuration. The MOs are compared against the No Action Alternative, which reflects operating rules in 2016, when the Notice of Intent to prepare the EIS was issued. Past effects are included in the Affected Environment for each respective affected resource in Chapter 3. Specifically to fish, the EIS includes an analysis of effects in Sections 3.5 and Section 7.7.5. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives.
6079	5	scullyrjs@cableone.net	N/A	Currently, there is a $7.6 million saving to grain shippers who use barge rather than rail because the federal government pays the cost of dam and lock operation and maintenance, channel dredging and fish and wildlife mitigation costs. In 2014, to move a ton of grain a mile on the lower Snake River, the farmer paid $0.039 and the U.S. Government paid $0.057, for a total of $0.096 per ton-mile. Compare that to the rail rate of $0.063 per ton-mile (Rocky Mtn econometrics). If the government was willing to subsidize the grain shippers to use rail as it is doing now with barge, the money could be used to build unit train depots and rail cars that could be managed cooperatively by the grain shippers.	The EIS analysis finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes. This change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. These effects are described in Section 3.10 and are considered in the context of the overall objectives of the EIS.
6083	1	marysteve@palouse.net	N/A	The draft document notes breaching the dams would cost about $955 million or about $35.4 million a year over 50 years but doesnt consider current operating losses, new construction costs and repairs of dams nor the taxpayer subsidies to the Port in Lewiston, barge companies and Portland Power and Electric. These last three are operating at a substantial loss. Breaching the dams would save the government nearly $79 million a year in dam maintenance costs and $32 million in capital costs and result in resurgent Salmon, Lamprey and Orca populations. As indicated by the Fish Passage Center, breaching the Lower Snake dams could lead to a fourfold increase in Snake River salmon and steelhead numbers. Comparing breaching with continuing the same failing strategy indicates that breaching operations and maintenance costs come to $477.5 million a year which is a DECREASE in expenditures of about $729,000 annually.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework (see 40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Moreover, the the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. Regarding the comment related to barge shipments, navigation benefits are estimated to range from $14 to $48 million annually (see Table 3-244 & Table 3-246). These benefits are estimated as increased transportation costs (decreased social welfare benefits) under MO3, based on barge traffic going away on the four lower Snake River dams and shifting to truck or rail transportation. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6083	2	marysteve@palouse.net	N/A	The transportation costs are important to consider along with the livelihood of agriculture and fishing tourism. However, the costs of new construction of rail infrastructure and new energy sources are listed WITHOUT listing the operation losses of the existing power company and its outdated infrastructure, all subsidized by taxpayers. the report by the US. Army Corp of Engineers is lacking in critical data and analysis.	Estimated costs to maintain the CRS are presented in Section 3.19 and Appendix Q. Increased infrastructure costs associated with increased rail demand in a dam breach scenario are described in Section 3.10.3.5, Navigation. Costs of replacement power resources that would be required to replace lost hydropower production are described in Section 3.8. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15).
6105	1	none provided none provided	Lewis Clark Valley MPO	The Lewis Clark Valley MPO has reviewed the CRSO Draft EIS and has submitted the attached document in response.	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
6106	1	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	One glaring deficiency in the DEIS is the absence of an accurate description of losses and effective mitigation in the Upper Columbia Basin. Although the area at and above Chief Joseph Dam generates nearly 50% of the power and has suffered more than 40% of documented fish and wildlifelossesin the entire FCRPS. it has been chronically undei:served by the Bonneville Power Administration's Fish and Wildlife Program. Fish and wildlife managers in the Upper Columbia Basin have called on the NorthwestPower and Conservation Council and federal action agencies for years to develop a Slrategy to address this power/loss inequity. but there is still no comprehensive mitigation plan in place. The DEIS did not take a hard look at these documented losses or the longstanding failure to eftectively mitigate them. Given that existing federal mitigation programs have not worked, the FEIS must identify with specify federal mitigation commitments to address significant adverse effects in 1he Upper Columbia Basin. These commitments should focus on improving ESA-listed resident fish survival and spawning success at CRSO projects through actions including, bul not limited to, project configuration, flow management. improving connectivity, project operations: and water quality management The DEIS and Preferred Alternative did not identify or provide. anything sub!)1antive to improve conditions for ESA-listed residen1 fish. The most critical omission was the failure to include Albeni falls Dam upstream fish passage as a structural measure. The U.S. Army Corps of Engineers has determined that this fishway Project. Final Post-Authorization Decision Document and Environmental Assessment. 178 pgs.) The Albeni Falls Dam upstream fishway should therefore be included as structural measure subject to any applicable funding constraints. Kalispel submits that the most straightfordward way to identify most necessary mitigation commitments in the Upper Columbia Basin is to incorporate conservation measures from existing fish accords into the Upper Columbia Mitigation Plan. This Plan, which should be described in the FEIS. would ensure that those actions that need to be performed in perpetuity are recognized as such, those actions that wilt be complete upon performance arc recognized as such, and that both categories of actions can be used to tm11sform future fish accords into mitigation agreement where funding is commensurate with the mitigation need and not inflated to encourage legal forbearance.	The scope of the CRSO EIS is to evaluate alternative operations, maintenance and configuration measures for the Columbia River System projects. Passage at Albeni Falls Dam was evaluated in the Albeni Falls Dam Fish Passage Projcet Post Authorization Decision Document & Environmental Assessment (PADD/EA) in June 2018, and is evaluated in the CRSO EIS under the Cumulative Effects analysis in Chapters 6 and 7. The co-lead agencies conduct mitigation actions in the Upper Columbia River basin with many project sponsors. Principles for future long-term mitigation agreements are beyond the scope of the EIS, but we agree that these discussions should continue.
6106	2	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Chapter J Pg.31 "Changes in reservoir elevation at Albeni Falls may result in reduced access to Bear Paw rock (sacred site), which may result in loss Tribal visitation. Comment A reduction in accessibility to 1his site by water navigation will occur under the McNary Flow Target. Such an impediment to the religious and cultural needs of the Kalispel Tribal membership is an ongoing impact that is further aggravated by our growing population and need to reconnection to places of cultural/spiritual importance.	As identified in the No Action Alternative, the co-lead agencies agree reservoir elevation changes result in some erosion impacts and accessibility to Bear Paw Rock; however, the landform surrounding Bear Paw Rock is dominated by bedrock and operation changes in reservoir elevation would not be likely to result in the loss of the landform through erosion effects. In addition, facilitation of short- or long-term access for Native American religious practitioners would not be problematic due to the exposed bedrock and erosion resistant location of the site. In Section 7.7.18 in the Draft EIS description of the Preferred Alternative, operational changes at Albeni Falls would be negligible as compared to the No Action Alternative and result in similar erosion and accessibility impacts.
6106	3	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Chapter 1 Pg.34 "Consistent with sacred sites identified for Chapter 3. the preferred Alternative evaluates effects to two sacred sites. Operational changes at Grand Coulee and Albeni Falls as described for the preferred alternative would he negligible when compared to the No Action Alternative." Comment "Negligible" but not diminished. Any ongoing or increase in impact is to a non-renewable resource and should be analyzed in that context. Once lost to erosion, flooding, or other operational impacts, these sites and their data are gone forever. The Kalispel Tribe of Indians and its sister sovereigns' resources continue to bear the weight of these types of decisions. Tribes within this Basin are deserving of their share of the environmental justice and ability to make use of the public benefit afforded by the Columbia River System.	As identified in the No Action Alternative in Section 3.16.3.3 in the Draft EIS, the co-lead agencies agree ongoing erosion processes would continue and result in loss of sediments that cover the landforms at Kettle Falls. However, because many of the features at Kettle Falls rest on bedrock, typical Lake Roosevelt operations would not likely result in the total loss of the underlying landforms. During deeper than average drawdowns of Lake Roosevelt, landforms such as Hayes Island would re-emerge, facilitating short-term access for Native American religious practitioners. Also identified in the No Action Alternative, the co-lead agencies agree reservoir elevation changes result in some erosion impacts and accessibility to Bear Paw Rock; however, the landform surrounding Bear Paw Rock is dominated by bedrock and operation changes in reservoir elevation would not be likely to result in the loss of the landform through erosion effects. In addition, facilitation of short- or long-term access for Native American religious practitioners would not be problematic due to the exposed bedrock and erosion resistant location of the site. In Section 7.7.18 of the Preferred Alternative in the Draft EIS, operational changes at Albeni Falls would be negligible as compared to the No Action Alternative and result in similar erosion and accessibility impacts.
6106	4	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Chapter 2 Pg. 2-68 "The McNary Flow Target" a minimum flow target for the Lower Columbia River, up to 2.0Mof of storage water from Hungry Horse, Libby, Albeni Falls, and Grand Coulee would be provided above that provided currently..." Comment The Upper Columbia River system continues to be called upon to subsidize the Lower Columbia River's benefits of river navigation, flood control, irrigation, and anodromous fish flows. It should be discussed that all anadromous fish were lost to the Upper Columbia River when Grand Coulee Dam was built. This public policy, as crafted in the DEIS, fails to examine the entirety of the system operations and how to maximize benefits throughout or at a minimum properly mitigate/compensate for the imbalance.	The McNary flow target referenced in this comment was analyzed as part of the alternative analysis, specifically MO4, but was not carried into the Preferred Alternative in part due to the impacts on upper basin resources. The co-lead agencies worked with sovereign parties from all parts of the Columbia Basin to seek balance and ensure that measures intended to benefit populations in one part of the basin did not have an adverse effect on populations in other parts of the basin.
6106	5	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Chapter 2 Pg. 2-68 "Then, Hungry Horse, Libby, and Albeni Falls reservoirs would be drafted to support augmented flow targets..." Comment These flow targets will accelerate archeological site decay in all three reservoirs.	The co-lead agencies agree that flow targets and operations of the Columbia River System result in archaeological site impacts. The co-lead agencies discuss impacts to archaeological resources of Multiple Objective alternative 4 in Section 3.16.3.7 in the Draft EIS. Tables 3-291 and 3-292 in the Draft EIS provide a summary of effects to archaeological resources across all of the cultural resources study area from the different Multiple Objective alternatives.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6106	6	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 3-237 Lines 5006-5016 "Albeni Falls Dam is located in northern Idaho on the Pend Oreille River about 28 miles downstream of Lake Pend Oreille. Although Lake Pend Oreille is a natural lake, Albeni Falls Dam regulates the upper 11.5 feet of the lake. Albeni Falls Dam has little ability to manage water temperatures in the Pend Oreille River, and water temperature changes in Lake Pend Oreille and the Pend Oreille River are mainly influenced by atmospheric conditions and weather patterns. Lake Pend Oreille is the fifth deepest lake in the United States and exhibits strong thermal stratification regardless of the runoff year. However, a shallow low-water outlet channel acts as a barrier to the transport of much colder deep water from Lake Pend Oreille into the Pend Oreille River resulting in warmer lake surface waters entering the river. The Pend Oreille River TMDL (2011 revised) addresses elevated water temperatures in the summer. Winter water temperatures can be in the low 30sF (0C to 2C) range, with some surface icing during colder winters." Comment: Albeni Falls Dam does have the ability to manage water temperatures in the Pend Oreille River downstream of Albeni Falls Dam. From 2011 to 2014, the Kalispel Tribe had been working with the US Army Corps of Engineers to investigate whether operational changes from Albeni Falls Dam (AFD) can be used to manage Pend Oreille River water temperatures post Labor Day (first week of September). This study was to evaluate whether operational releases at AFD could decrease downstream water temperature in support of bull trout and other aquatic species during the late summer. The relationship between AFD operations and POR temperatures was evaluated by using the two dimensional hydrodynamic and water quality model CE-QUA l, Vi2, The POR was modeled from the confluence with Lake Pend Oreille co Box Canyon Dam. Integrations of daily average. daily maximum, and 7 day moving average of daily maximum water temperatures were calculated for 11 river reaches as a means for comparing results from the simulations. There were 4 hypothetical and 1 operational sets of modeling completed. The central focus of these simulations was to characterize the in0ucnoe of alternative flow regimes at Albeni Falls Dam on the water temperature response throughout the Pend Oreille River from Lake Pend Oreille to Box Canyon Dam in late summer and early fall. Draft triggers were identified for executing a Temperc1.rure Mam1gcment Operation. They are as follows: During prominent cold weather conditions, decrease river flows to increase exposure time in the POR During hot weather conditions. increase river flows to reduce exposure lime in the POR When surface water temps in LPO are cooler than POR at AFD, increase flows to introduce cooler water downstream. The series of hypothetical Pend Oreille River water temperature simulations were conducted to explore the influence of flow regimes on water temperature characteristics. These hypothetical simulations were intended 10 provide insight on heat exchange and transport processes in the Pend Oreille River to help inform subsequent mode) simulations evaluating realistic water regulation alternatives subject to natural meteorological conditions and reservoir operations. The results of the hypothetical simulations indicated that operational strategies are possible to manage water temperatures in the river downstream of Albeni Falls Dam. Failure to modify project operations to improve water temperature results in a significant adverse: effect on native fish and water quality downstream of Albeni Falls Dam. This adverse effect must be considered and mitigated in the FEIS. The best mitigation for adverse effects of water temperature downstream of Albeni Falls Dam is 10 provide connectivity with the cold water refugia or Lake Pend Oreille.	A joint study was conducted in 2013 to investigate the ability to manage water temperatures downstream of Albeni Falls Dam. Although hypothetical modeling scenarios identified three operational triggers that showed potential for cooling the river, modeling performed under realistic meteorological and operational constraints showed little ability for Albeni Falls Dam operations to consistently cool the river over time and space. The river downstream of Albeni Falls Dam showed the greatest temperature differentials likely due to the shallow river conditions being more responsive to atmospheric thermal inputs. The main findings of the September 2013 model simulations of river hydrodynamics and water temperature during cold weather and warm weather events were as follows: 1) Increasing river flows in the Pend Oreille River during a prominent hot weather event in September 2013 resulted in both increases and decreases in water temperatures when compared to baseline conditions. The greater the flow increase, the greater the positive and negative temperature change. These temperature changes were transient in nature and were not uniform across the entire river; 2) There were no water temperature benefits to the Pend Oreille River of decreased flows during a cold weather event in September 2013. Decreased flows resulted in little to no temperature change in the river when compared to baseline conditions.
6106	7	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 3-334 & 335 Lines 8938-8985 Comment The Lake Pend Oreille subpopulation of bull trout is composed of migratory (fluvial and adfluvial) and also resident fish. It also states that it is "the largest known bull trout population in Idaho". The Salmon River drainage abundance estimates (387K) are much higher than the Clark Fork drainage (43K) (High et al. paper). It also states that "Redd monitoring In the 7 years following the 1999 listing suggests abundance has Increased and the population is stable or increasing", however in the previous section states that the population is "stable.	The co-lead agencies agree with these corrections. These changes would not change the outcome of the analysis of the multiple objective alternatives or of the Preferred Alternative.
6106	8	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 3-337 Lines 9048-9070 "Preliminary important environmental relationships for resident fish in this region that could be affected by MOs are as follows: Albeni Falls Dam outflow can affect entrainment rates through the dam. Entrainment can reduce populations of native fish such as bull tout, westslope cullthroat trout, kokanee, etc., in the lake as well as hastens the spread of non-native fish from the lake into the river downstream. Upstream fish passage at Albem Falls Dam may be implemented during the timeframe of the CRSO analysis period. Predation and competition between non-native and native fish can be unfluenced by operations that change outflows, temperature and reservoir levels. Flexible winter power operations result in changing lake elevations in the winter. A greater range of elevations can increase erosion rates and affect spawning success of kokanee and mountain whitefish. Comment: In terms of the Flexible Winter Operations. there is a potential for increased entrainment of sub-adult bull troul out-migrating from the Priest River system.	The first bullet "Albeni Falls Dam outflow can affect entrainment rates..." is a general statement intended to include any changes to outflow, including during flexible winter power operations. The idea in establishing these relationships in the Affected Environment Section is not to analyze effects of the alternatives, but rather set the stage by stating what important variables would be considered in the Environmental Consequences Section. The additional detail provided by the comment is included in Technical Appendix E in the notes column of the evaluation matrix in the row discussing flexible winter power operations. Further elaboration was not included in the body of the Draft EIS because no change was proposed under any of the alternatives. In other words, the matrix acknowledges the relationship under the No Action Alternative, but all of the action alternatives, including the Preferred Alternative, would be the same as the No Action.
6106	9	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Pages 3-406 Lines 11346-11354 "Bonneville's F&W Program also provides funding to the Kalispel Tribe to develop and implement a resident fish mitigation program for the impacts from Albeni Falls Dam. This work includes improving bull trout habitat within the basin. Additional priorities are to restore habitats for westslope cutthroat trout and maintain the suppression effort on non-native predator and competitive fish species within the Pend Oreille Basin. Finally, through the 2018 Northern Idaho Wildlife Agreement, Bonneville and the State of Idaho work to protect and enhance 1.378 acres to fully address operational impacts of Albeni Falls Dam on wildlife. Much of this work will focus on the Clark Fork Delta and restoration of riparian habitat and the reestablishment of wetland plant communities, which will also benefit resident fish species.: Comment: Bonneville's F&W Program provides funding to the Kalispel Tribe 10 develop and implement a resident fish mitigation program for the impacts from Albeni Falls Dam as well as an anadromous fish mitigation funding program due 10 the construction and operation of Grand Coulee and Chief Joseph dams.	Thank you for providing that clarification regarding the anadromous fish program.
6106	10	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 3-418 Lines 11823-11830 "An unknown number of bull trout are entrained through Albeni Falls Dam each year and are lost to the system, as there currently is no trap-and-haul program at Albeni Falls Dam to return them to the lake. However, a permanent trap and haul fishway may be completed during the period of analysis for the EIS that would allow these fish to return upstream. Entrainment is most common from March to June when flows are high (Corps 2018). Most populations of bull trout within Lake Pend Oreille are large enough that there are not likely to e major effects from entrainment. Entrainment is likely to continue under the No Action Alternative, with trap and haul reducing the number of fish lost in the future." Comment: Approximately 50% of the bull trout that are entrained through Albeni Falls Dam originate from weak stocks, thus the effects of entrainme11t can be significant to those weak populations.	Thank you for this information. For the purposes of this EIS, the specific populations that are subject to entrainment were not considered individually, but rather the bull trout population in the lake as a whole. While individual actions may be taken by the co-lead agencies in coordination with regional partners in an effort to focus on weak stocks in the area, in this instance, more specific detail would not change the overall outcome of alternative analyses of the multiple object alternatives nor the Preferred Alternative.
6106	11	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 3-420 Lines 11880 Downstream of Albeni Falls Dam, non-native Northern pike and walleye have expanded their populations and may consume bull trout there. Northern pike are the apex predator in this system and are experiencing exponential population growth (reference to be added prior to final). Suppression efforts started in 2012 in Box Canyon reservoir, the first reservoir downstream of Albeni Falls Dam, have resulted in a 90 percent reduction in northern pike (reference to be added prior to final). Suppression efforts have also started at Boundary Dam, which is downstream of Box Canyon Dam. However, suppression efforts would not eliminate northern pike from the river, and the remaining fish could prey on entrained bull trout. This predation would not affect bull trout populations as any entrained bull trout would not be able to return upstream of the dam to spawn and would not survive the high water temperatures in the summer. Walleye have also expanded their populations in both Box Canyon and Boundary Reservoirs, but their numbers are still relatively low. Predations by walleye would have the same effect on bull trout as for northern pike under the No Action Alternative." Comment: The statement that. .. "predation would not affect bull trout populations as any entrained bull trout would not be able to return upstream of the dam to spawn and would not survive the high water temperatures in the summer" is not a correct statement. Predation would have a negative effect on bull trout in several ways. As stated in this CRSO that upstream fish passage at Albeni Falls may be operational in this timeframe of the CRSO. The Kalispel Tribe will also be electrofishing to collect bull trout below Albeni Falls Dam for transport immediately upstream of the dam.	Concur. replaced "This predation would not affect bull trout populations as any entrained bull trout would not be able to return upstream of the dam to spawn and would not survive the high water temperatures in the summer." with "Under current conditions, some entrained bull trout would not be able to return upstream and would not survive the high water temperatures below Albeni Falls Dam in the summer. However, upstream fish passage facilities may be operational at Albeni Falls Dam during the timeframe of this EIS, and it is anticipated that the Kalispel Tribe will continue electrofishing and transporting bull trout upstream of the dam prior to completion of fish passage at the dam. Therefore this predation could reduce the survival of bull trout that would otherwise be passed upstream of Albeni Falls Dam."
6106	12	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Pg. 3-1370 "Even though the No Action Alternative is considered the baseline by which the MOs are evaluated, it is important to note that selection of the No Action alternative would continue to result in substantial degradation of archaeological resources. This was the conclusion of the System Operation Review (SOR) FEIS. Continuation of 2016 operations would result in the ongoing loss of archaeological resource integrity. Ongoing degradation of archaeological resources has been documented in the annual reports produced by the FCRPS Cultural Resource Program." Comment: AH considered changes in the system operations shall result in the "degradatjon of archaeological resources". The Killispel Tribe of Indians recommends the selection of an alternative that results in the least/slowest rate of impact to the affected resources. If this cannot be done. then we expect a robust mitigation package to be discussed as part of the selected alternative. Currently, funding and efforts to mitigate impact lags far behind the rate necessary to stave off the permanent loss to these non-renewable resources.	The co-lead agencies agree that system operations result in impacts to archaeological resources. In the Draft EIS Section 7.7.18, the co-lead agencies provide an archaeological resources impact analysis of the Preferred Alternative. In particular, Tables 7-47 through 7-50, in the Draft EIS provide the comparison of all alternatives to archaeological resources across the system. The co-lead agencies concluded the Preferred Alternative is the least impactful of all alternatives to archaeological resources. In Sections 5.2.1.6 and 7.6.4.2, the co-lead agencies discuss the existing program that addresses system operational impacts to cultural resources.
6106	13	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 3-1305 Lines 4508-4513 "In addition, the Kalispel Tribe of Indians, who fish for subsistence in the Box Canyon Reservoir, harvest fish placed there from the Kalispel Tribal Hatchery. The Tribe rears juvenile largemouth bass at the hatchery (Kalispel Tribe 2018d). Fishing access permits and hunting permits for fishing and hunting on the Reservation are sold by the Natural Resource Department to non-members (Kalispel Natural Resource Department 2018)." Comment: The Tribe rears triploid rainbow trout for out planting to a pond near Indian Creek.	The Draft EIS is consistent with the comment. At the time the Draft EIS was being developed, largemouth bass were being reared in the Kalispel Tribal Hatchery. In early 2018, the focal species shifted to triploid rainbow; this change is documented in cbfish.org as Budget Oversight Group (BOG) request #557 for Bonneville-funded project 1995-001-00. The Final EIS has removed the reference to the Kalispel Tribe of Indians raising largemouth bass.
6106	14	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 5-3 Lines 91-100 "5.1.3 Conservation Recommendations per Fish and Wildlife Coordination Act of 1934. In developing mitigation for the effects of the alternatives, the co-lead agencies also considered the conservation recommendations included in the U.S. Fish and Wildlife Service's (USFWS) Fish and Wildlife Coordination Act Report (CAR). The Fish and Wildlife Coordination Act (FWCA) of 1934, as amended (16 U.S.C. 661-667e) provides authority for USFWS and NMFS involvement in evaluating impacts to fish and wildlife from proposed water resource development projects and requires them to	The USFWS Final Coordination Act Report (CAR) has been received and is in Appendix U, Part 1. The co-lead agencies' responses to the Final CAR's conservation recommendations including the one mentioned in this comment can be found in Appendix U, Part 2. With regard to this particular invasive species recommendation, the co-lead agencies provide information about management of invasive species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				provide conservation recommendations for the project. The draft CAR is included in Appendix U and provides analysis of effects of the alternatives, landscape findings, and conservation recommendations. The USFWS will be preparing a final CAR with emphasis on the Preferred Alternative for inclusion in the final EIS. Coordination between the co-lead agencies and the USFWS is ongoing for the final CAR. Comment: The Fish and Wildlife Coordination Report on the CRSO states the following: "'In the interest of controlling invasive species, reducing their spread, and preventing, future invasions, the Service offers the following recommendations Reduce the impacts of non-Native fish in the study area and support northern pike removal program effort:; Provide support and resources for additional boat cleaning stations to prevent invasion and establishment of non-native species (e.g., aquatic invertebrates and plants) Coordinate with,, and implement prioritized actions identified by, interagency invasive species teams. The Aquatic Invasive Species Network and the Western Regional Panel con provide direction In ,.regard to aquatic invasive species. Each state in the study area (i.e .. Idaho. Montana, Oregon, and Washington) has an invasive species council that can also provide direction on focused action to eradicate and reduce the spread of invasive species". The Tribe urges the Action Agencies to include these measures in the CRSO.	
6106	15	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 5-5 Lines 164-177 "Under the No Action Alternative, mitigation currently being implemented would continue. With implementation of any of the proposed MOs there are nine mitigation programs that the co-lead agencies currently implement that would be incorporated, with certain modifications in the respective alternatives. These mitigation programs are the Bonneville Power Administration (Bonneville) Fish and Wildlife Program (F&W Program), the Lower Snake River Compensation Plan, the U.S. Army Corps of Engineers' (Corp) Columbia River Fish Mitigation Programs. U.S. Bureau of Reclamation's (Reclamation) Columbia River Tributary Habitat Program, the Federal Columbia River Power System Cultural Resources Program Predator Management, Invasive Species Management, Pest Management Programs, and Nutrient Supplementation Programs Outside of the specific mitigation measures that have been identified in the CRSO EIS changes to mitigation programs like the Bonneville F&W Program are not being made through this EIS process. Rather, for example, future program adjustments for the Bonneville F&W Programs would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements." Comment: BPA provides funding to Kalispel through a 2012 Memorandum of Agreement to develop and implement mitigation actions such as a resident fish mitigation program for the impacts from Albeni Falls Dam as well as an andromous fish mitigation program due to the construction and operation of Grand Coulee and Chief Joseph dams. As discussed in Kalispel's cover letter. these actions should be incorporated into an Upper Columbia Mitigation Program to ensure that they are fully performed in perpetuity and address the longstanding mitigation deficiency at and above Chief Joseph Dam. These mitigation measures include, but are not limited to, improving bull trout habitat within the basin. restoration of habitat for westlope cutthroal trout. and maintaining suppression of non-native predator and competitive fish species within the Pend Orille Basin. Although Kalispel's 2012 MOA contains similar forbearance language to other fish accords, we are the only non-litigant accord partner. We believe future fish accords should be more like ours where the financial consideration is commensurate with the work to be performed and not inflated to incentivize forbearance. Establishing an Upper Columbia .Mitigation Plan in the FEJS will encourage this transformation while addressing one of the causes of the Upper Basin's mitigation funding shortfall- namely, the enlargement of downstream fish accords not necessarily for mitigation work that is unnecessary but in amounts that exhaust BPA's ability to fund higher priority mitigation work in the Upper Basin.	The scope of the CRSO EIS is to evaluate alternative operations, maintenance and configuration measures for the Columbia River System projects. While the co-lead agencies do not have an Upper Columbia Mitigation Program mentioned by the commenter, the co-lead agencies conduct mitigation actions in the Upper Columbia River basin with many project sponsors, including under the 2012 Memorandum of Agreement with the Kalispel Tribe and also through Bonneville's Fish and Wildlife Program, which the comment observes is one of the mitigation programs incorporated into the Multiple Objective alternatives. Principles for future long-term mitigation agreements are beyond the scope of the EIS.
6106	16	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 5-8 Lines 269-272 Comment: The AAs describe existing mitigation actions for construction and inundation impacts would "...serve lo address the effects of reservoir operations on wildlife habitat to the extent that such operational impacts occur below full pool level " This simply is not factual and does not consider that operational impacts that occur below full pool can affect habitats above full pool. Erosional processes, altered floodplain interactions and reservoir elevation changes all impede. harm, remove., or otherwise alter wild lire habitat. This statement should be amended to reflect these unmitigated impacts of below pool Operational impacts to wildlife habitat .	The text referenced in the comment refers to the existing mitigation for construction of the CRS and subsequent loss of habitat due to inundation. The CRSO EIS analyzes the effects of operation, maintenance, and configuration and the effects of construction and inundation are not within the scope of this EIS. Under the Preferred Alternative, the River Mechanics analysis described a negligible (~0.1 feet) change to shoreline exposure at Grand Coulee and the Cultural Resources analysis found no change to shoreline erosion at Grand Coulee, both relative to the No Action Alternative.
6106	17	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 5-8 Lines 642-649 "Bonneville's F&W Program provides funding to the Kalispel Tribe to develop and implement a resident fish mitigation program for the impacts from Albeni Falls Dam. This work includes improving bull trout habitat within the basin. Additional priorities are to restore habitats for westslope cutthroat trout, and maintain the suppression effort on non-native predator and competitive fish species within the Pend Oreille Basin. Finally, through the 2018 Albeni Falls Dam Wildlife Mitigation Agreement, Bonneville and the State of Idaho to protect and enhance 1.378 acres to address operational impacts of Albeni Falls Dam on wildlife. Much of this work focuses on the Clark Fork Delta and restoration of riparian habitat and the reestablishment of wetland plant communities. which will also benefit resident fish species. Comment: Bonneville's F&W Program provides funding to the Kalispel Tribe to develop and implement a resident fish mitigation program for the impacts from Albeni Falls Dam as well as an anadromous fish mitigation funding due to the construction and operation of Grand Coulee and Chief Joseph dams.	The section of the Draft EIS cited in the comment was meant to provide examples of mitigation actions that Bonneville funds, but does not represent the complete list of projects or project purposes for mitigation funded through Bonneville's Fish and Wildlife Program or with the Kalispel Tribe in particular.
6106	18	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Chapter 5 All Alternatives, section NEW MITTIGATION ACTIONS under Vegetation ,Wildlife, Wetlands, and Floodplains: Comment: The AAs fail to describe the need to complete assessments for operational impacts in Region A. There is no mention of assessments or settlements to describe these impacts and allowance for a program to mitigate those impacts. Simply referring to a partial settlement to one agency (IDFG), does not reflect what full mitigation would be for Albeni Falls Dam,	The commenter is correct in its assertion that the agreement between Bonneville and the State of Idaho for mitigation of wildlife impacts from Albeni Falls Dam does not mitigate all operational impacts in Region A or even for Albeni Falls Dam. With respect to Albeni Falls Dams operational impacts to wildlife, that agreement addressed only those impacts occurring upriver of the dam. In addition, consistent with mitigation guidance in the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program, loss assessments and settlement agreements are both acceptable approaches for mitigating operational impacts. Therefore, while the comment suggests a need to complete operational impact assessments, that is only one of the available mitigation options; Bonneville may find it more appropriate to fulfill its Northwest Power Act mitigation responsibility to address remaining unmitigated wildlife impacts from Albeni Falls Dam or elsewhere through development of settlement agreements, consistent with Council Program guidance, in a manner similar to the approach taken in the Albeni Falls agreement between Bonneville and the State of Idaho. Edits have been made to the Final EIS to clarify that Bonneville continues to work with project sponsors to address any remaining, unmitigated operational impacts.
6106	19	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 5-20 Lines 705-710 Comment: The AAs indicate that the IDFG settlement "..,fully address operational impacts of Albeni Falls Dam on wildlife," This along with_ additional funding to address upriver impacts from AFD only mitigate IDFG and its identified priorities and impacts. This settlement does not fully mitigate Tribal impacts associated with operations at AFD. This paragraph should be amended to reflect that Operational mitigation is not fully addressed for AFD. This correction should occur in all sections of the DEIS that refer to Operational losses at AFD being fully addressed via the settlement agreement with IDFG.	The commenter is correct that Bonneville's settlement agreement with the State of Idaho does not mitigate Tribal impacts associated with operations at Albeni Falls Dam; nor does it mitigate Idahos impacts. Instead, it mitigates impacts to wildlife, consistent with the Northwest Power Acts (Act) mandate to protect, mitigate, and enhance fish and wildlife affected by development and operation of Federal Columbia River Power System dams, which include Columbia River System projects. The Act does not, however, require mitigation of particular entities. The settlement agreement between Bonneville and the State of Idaho reflects those parties agreement as to the adequacy of mitigation to fully address the upriver operational impacts of Albeni Falls Dam. The commenter is correct in its suggestions that the agreement with Idaho does not fully mitigate all operational impacts of Albeni Falls Dam because the scope of the agreement with Idaho does not extend to any impacts occurring below the dam. Edits clarifying this point have been made in the Final EIS.
6106	20	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 6-9 Lines 282-303 "RFFAIO - Ongoing and Future Habitat Improvement Actions for Bull Trout. A common goal among these actions is the improvement of aquatic habitat and water quality to benefit native salmonids, especially bull trout. Overlap varies but these actions are generally ongoing. A comprehensive list of activities that contribute to the recovery of bull trout in the Columbia River Recovery Unit and Lake Pend Oreille area is not available because of the multitude of federal state tribal and non-governmental organizations that conduct activities in the region. Some of the important Activities that are ongoing or have been recently completed within the region are as follows: Construction of upstream fish passage facility at Box Canyon Dam (construction began in 2016, facility expected to be operational in 2019: Pend Oreille Public Utility District) Loke trout removal In Lake Pend Oreille (Idaho Dept. of Fish and Game) t Tributary habitat restoration, enhancement, and passage Kalispel resident fish project (Kalispel Natural Resource Department) Non-native species suppression projects, such as the Kalispel Tribe Non-Native Fish Suppression Project in Pend Oreille River Road abandonment and bank stabilization (Kalispel Natural Resources Department) Bull trout research and monitoring Genetic Inventory of bull trout in the Pend Oreille River subbasin (Kalispel Natural Resources Department) Mainstream Pend Oreille River water quality Temperature total maximum daily load (TMDL) implementation for the Pend Oreille River (Washington Department of Ecology and stakeholders) t Water quality monitoring (Kalispel Natural Resources Department) Comment: Box Canyon Dam will be operational in 2021. Genetic inventory of bull trout in the Pend Oreille River subbasin was a project that was completed in 2007.	The final EIS has been updated based on your comments. The date Box Canyon fish passage facility is expected to be operational has been changed to 2021, and the bullet "Genetic inventory of bull trout in the Pend Oreille River subbasin..." has been removed from the list of cumulative scenarios because it was completed rather than ongoing or foreseeable in the future.
6106	21	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Pages 7-41 & 7-42 Table 7-5 Measures included In the Preferred Alternative to Benefit Endangered Species Act-listed Fish that are Being Carried Forward from Previous Committments by the Co-Lead Agencies Habitat Tributary Habitat Improvements for both Chinook salmon and steelhead Implementation of specified construction projects, research, monitoring and .evaluation (RM&E) actions, and species status and trend data collection on habitat and survival improvement. Page Hatcheries FCRPS Mitigation Hatcheries- Programmatic Continued support of hatcheries and adopt programmatic criteria for funding decisions on mitigation programs for the FCRPS that incorporate best management practices Predation Northern Pikeminnow Management Program (NPMP) Ongoing base program and general increase in northern pikeminnow Sport-reward fishery reward structure. Comment: Under "Habitat", tributary improvements should also be completed for bull trout and westslope cutthroat trout, not just for salmon and steelhead. Under the section "Predation", it only discusses the Northern Pikeminnow Management Program. In fact, the Preferred Alternative recommends an ongoing base program and a "general increase in the northern pikeminnow sport-reward fishery." The Kalispel Tribe recognizes that the FCRPS has created conditions that favor northern pikeminnow, but they are a native species. There are other non-native invasive fish species within the Columbia Basin that pose a more serious threat to the recovery of salmon, steelhead and bull trout. Northern Pike pose a serious risk throughout the Columbia Basin. Within the State of Washington., Northern Pike are classified as a Prohibited level 1 species under Washington Administrative Code 220-640-030. There are also 3 Revised Code of Washington statutes that pertain to Northern Pike as a Prohibited 1 species. This section should include actions to suppress and eradicate Northern Pike.	Re: Habitat – As described in Chapters 2 and 5, Bonneville works with states, Tribes, and watershed groups to protect, mitigate, and enhance spawning and rearing habitat, targeting factors that limit fish survival throughout the Columbia River Basin. Bonneville has funded hundreds of projects across the basin to restore natural stream channels, reconnect estuarine tidal channels, enhance flow volume and timing, and expand cold water refuges and open access to habitat (www.cbfish.org). These habitat improvement actions provide both near-term and long-term benefits to anadromous and resident species, including bull trout and westslope cutthroat, including those that will help address the effects of climate change. Actions that improve connectivity and streamflow will provide a buffer against the effects of climate change. In addition to habitat improvement actions, Bonneville works with willing landowners to protect land by putting it under permanent conservation easement to further support habitat and fish conservation in the short and long term. The co-lead agencies recognize that habitat actions targeted at salmon and steelhead have incidental benefits to bull trout in the targeted areas where bull trout and salmonid species coexist. When developing tributary habitat projects for salmon in areas where bull trout are present, the co-lead agencies, consistent with the BA, would engage with USFWS to leverage benefits for bull trout where feasible. In addition the Preferred Alternative includes actions identified to improve bull trout passage at Kootenai River tributaries. Changes to the ongoing fish and wildlife program other than directly related to mitigating for effects of the alternative compared to the No Action Alternative will be considered through the ongoing Northwest Power and Conservation Council's Fish and Wildlife Program. The co-lead agencies recognize the ongoing threat of downstream invasion of northern pike under the No Action Alternative and there would be a minor decrease in boat suppression efforts under the Preferred Alternative. The analyses showed there would be a minor effect (up to one week of boat ramp access impeded) in wet years only, and the resulting overall effect to the invasion of northern pike would be minor. The co-lead agencies recognize and appreciate the importance of northern pike invasion as a regional issue, but, in this EIS process, the co-lead agencies developed mitigation for moderate to major effects of the multiple purpose alternatives as compared to the No Action Alternative. Because the impact to northern pike was minor, mitigation was not appropriate for this effect.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6106	22	DOSTERMAN@KNRD.ORG	Kalispel Tribe of Indians	Page 7-128 Lines 3693-3698 "Hydrology modeling showed that Lake Pend Oreille elevations, inflows, and outflows would be similar to those found in the No Action Alternative. Biological relationships were dependent on these parameters, so the key effects of the Preferred Alternative for bull trout, fish habitat, and other fish species in the Pend Oreille basin would be the same as those described under the No Action Alternative. Comment: However, in Section 4.1.2.4, it states that "Albeni Falls Dam, reservoir outflow during the summer and fall could decrease due to potential reduced inflows." A decrease in outflow from Albeni Falls Dam during the summer and fall could have a negative impact on water temperature.	Changes to the Lake Pend Oreille inflows in the summer and fall are negligible from the Preferred Alternative as compared to the No Action Alternative. The statement from Section 4.1.2.4 implies that the changes would potentially be caused by climate change, and would be the same in both alternatives.
6108	1	dwayneparis@gmail.com	N/A	The city is close enough to bankruptcy that it is laughable the number of areas discussed in the CRSO DEIS MO3 alternative wherein the presumption that local entities will have resources to replace those that will disappear because the Corps will no longer have a project (i.e., Lower Granite Dam) and federal spending will cease. THESE UNFUNDED MANDATES WILL HAVE SEVERE CONSEQUENCES ON THE CITY OF ASOTIN. Mitigation dollars must be included in every line that is possibly going to the effect the City of Asotin, or policy makers will have an incomplete idea of what removal of the lower Snake River dams will actually cost. To do otherwise will put into jeopardy essential health, sanitation and safety, along with other public services, not just in Asotin but in the nine counties impacted in southeast Washington and north central Idaho.	Mitigation for each of the Multiple Objective alternatives (MOs) is described in Chapter 5, including MO3 which includes the measure to breach the four lower Snake River dams. Mitigation for the Preferred Alternative is described in Chapter 7. The Draft EIS does not identify MO3 as the Preferred Alternative. No Federal mitigation by the co-lead agencies is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, the co-lead agencies would likely no longer operate the project lands for recreation. After project lands have been transferred to other agencies, or entities, or individuals, recreational sites and associated facilities could be modified as determined by others. The purpose of the EIS is to provide information regarding potential effects to the natural and human environment. As part of this analysis costs associated with certain effects may be identified (navigation, transportation, power, water supply, etc.), but there is no presumption regarding who would pay to reduce or avoid potential effects. Further details about mitigation activities and requirements can be found in Chapter 5.
6108	2	dwayneparis@gmail.com	N/A	Cumulative effects: In its evaluation MO3the dam breaching alternative--the CRSO DEIS fails to consider the City of Asotins plea per its letter dated November 25, 2019 (copy attached) that cumulative effects on the Lewiston, ID, Clarkston, WA and Asotin, WA area be evaluated. The nine counties (in which the City of Asotin is included) most impacted by dam breaching are primarily rural where 1 in 5 people are already at or below the federal poverty level and average wages are 25% below the national average. Specifically, on 11-25-19, the City of Asotin (in follow-up to its scoping comments submitted 12-30-2016) listed the following impacts as examples of some of the impacts on non-federal agencies that should be evaluated and discussed under the cumulative effect of MO3: 1. Municipalities coping with loss of income because local property values will have diminished due to loss of economic vitality, unfavorable environmental conditions such as fugitive dust from areas formerly covered by water, lack of recreational access to the water, and more; 2. Municipalities, businesses, and private individuals on well water that must extend piping into a ground water supply, likely beefed up pumps to extract the water, and perhaps even pre-treating drinking water for contaminants because there will be a higher concentration of undesired chemicals in the water, since dilution is reduced with a lower water table. 3. Municipalities and businesses that must extend/repair effluent outfall piping from our wastewater treatment facilities (WWTF). 4. Municipalities and businesses that must pre-treating wastewater before it can be discharged in order to meet Water Quality Standards. 5. Municipalities or state agencies that must shore up or replace WWTF plants, roadways, railways and bridges along the shoreline because hydraulic support in the form of water in the Snake River will no longer be there to hold them in place. 6. Entities that must solving for methane gas releases from landfills along the river because water levels formerly keeping them from the atmosphere are gone. 7. Municipalities, non-profits and/or community organizations which expend capital and operating resources to restore and/or operate recreation facilities formerly operated by USACE, many of which draw water from the river for irrigation or provide access to the river. To that non-comprehensive list of cumulative effects, the City adds the following: 1. Electrical costs are expected to increase perhaps as much as 45% per NW RiverPartners for those living and doing business the Pacific Northwest if dams are breached. This adds stress to already over-burdened, fixed income taxpayers. 2. Municipalities that must monitor water quality at beaches to assure that swimmers do not access water that has a build-up of e coli. (This is a serious problem with the volume of water in the reservoir; it will be much more serious if water levels diminish to pre-dam levels.) This also means that human interaction in the rivers will be prohibited when summer temperatures are extreme and seeking out water is a survival technique. The weather pattern is such that near the confluence of Asotin Creek and the Snake River, at least 10 days per summer have temperatures that exceed 100 degrees. Has this been factored in to social welfare evaluation? 3. According to CRSO DEIS Chapter 3, p 585 Lines 17784 17796 migrating fish could experience barriers at tributaries due to reservoir drawdown. Asotin Creek is such a migrating stream that is likely to have new barriers from drawdown affect fish such that they may not be able to enter and spawn. If the City is expected to make investments to solve this problem, that too, must be included in cumulative effect. There is also no way to fully realize the impact removal of the dams will have on current fish populations with an increased and unknown sediment flow downstream along with current and flow changes.	The EIS describes the impacts associated with many of the items noted in this comment in the appropriate Chapter 3 resource section. Chapter 5 describes the adverse effects under the alternatives, including MO3, which includes the measure to breach the four lower Snake River dams, and mitigation that would be needed to reduce or minimize the adverse effects. Some mitigation is anticipated to be funded by the co-lead agencies, while other mitigation could by implemented by other agencies or the public. Chapter 6, Cumulative Effects, describes the cumulative effects associated with MO3 on Lewiston, Clarkston, Asotin, and other adjacent communities, considering multiple resource effects and mitigation measures. Many of the infrastructure items listed in your comment are described within the relevant environmental consequences sections within Chapter 3 of the EIS. Changes in infrastructure costs related to changing transportation modes are described in the Infrastructure Costs sub-section under Section 3.10.3.5. Additional information has been added regarding municipal and industrial wastewater treatment facilities in the Section 3.4 Water Quality. As described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described, but rather provide a list of potential mitigation needs, some of which could be implemented by other agencies or the public, which would potentially benefit from the mitigation measures. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, Federal agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies or entities, recreational sites and associated facilities could be modified as determined by others. Section 5.4.3.5 describes the mitigation measures associated with navigation, transportation, and transportation infrastructure, while Section 5.4.3.9 describes mitigation measures associated with public safety (modifying gas lines prior to breach). Some of these measures are anticipated to be Federally mitigated, such as armoring bridge piers and railroad and highway embankments as well as maintaining the remaining Federal navigation channel, while others, such as dredging local ports to access the Federal navigation channel after dam breach, would not be Corps-funded. If MO3 were selected as the Preferred Alternative, further evaluation and studies under NEPA would be required along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. These further evaluations could include a more detailed evaluation of municipal infrastructure modifications, land-transfer process, real estate requirements, recreation effects, and other related topics. Since the lower Snake River projects would be deauthorized, it is likely that the co-lead agencies would no longer operate the projects or associated project lands. Regarding water quality, while the co-lead agencies appreciate the concern with water quality at recreation areas, the change from reservoir to free-flowing river in MO3 does have water quality impacts, including changes to water temperature; but changes to specific recreation areas in relation to E. coli are highly uncertain. It is equally likely that free-flowing river reaches would be less likely to have E. coli water quality issues. Regarding power and transmission, the comment that MO3 would lead to increases in electricity costs and can adversely affect vulnerable groups is consistent with discussions in the EIS. The wholesale power rate effects described in the comment are consistent with the findings of the EIS. The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on this as well as the potential disproportionate effects to Tribal, low-income and minority populations. Appendix H, Power and Transmission, Table 6-1, in the Draft EIS, lists the retail rate impacts by county. Regarding air quality, consistent with this comment, Section 3.8.3.5 of the EIS evaluates the effects of MO3 on air quality from exposed riverbed that is no longer submerged under the reservoirs, describing the increased potential for erosion and suspension of dust by wind, generating particulate matter (PM) emissions. The EIS additionally describes that the risk of fugitive dust is likely short-term, declining over time as vegetation covers the exposed sediment and reduces the potentially erodible area. The potential air quality effects may be mitigated by planting of vegetation and restrictions on activities on exposed sediment. The potential of these types of short-term effects is dependent on weather (e.g., wind, precipitation levels) and mitigation efforts, thus the potential for property value impacts is uncertain.
6108	3	dwayneparis@gmail.com	N/A	Pumps and wells that supply municipal and industrial uses will not be operational under MO3. Of huge disappointment is that impacts to Lewiston, Clarkston, Asotin, Clearwater Paper, and more for modifying intakes, modifying discharges, and the cost and lack of certainty in the ability to obtain new discharge permits are described in the CRSO DEIS as minor. P. 3-1462 Lines 9416 9418 does discuss a loss of 55 jobs and $9.8 million in labor. Certainly, Clearwater Paper was deemed to continue to be viable given those very low estimates (See real impact of Clearwater Paper employment in Attachment 1).	This EIS discusses engineering solutions (pipeline extensions for example) in Chapter 3.12 section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative and in Appendix N. As described in the 'Summary of Effects' subsection of 3.12.3.4 Multiple Objective Alternative 3 (MO3), measures implemented under MO3 could affect delivery of current water supply in Region C and a loss of 48,000 acres of farmland. Similarly, There are M&I pumps in the Lewiston area that would likely be impacted by this measure, along with other small M&I uses along the river. The co-lead agencies identified a total of 16 points of diversion from surface water with a water rights purpose listed as M&I, which may use up to 9,230 acre-feet per year (USGS 2018a). As described in Section 3.12 of the EIS, effects to water supply from MO3 are expected to result in minor adverse effects to social welfare and major adverse effects to regional economics. Modifications to M&I systems would be required under MO3 increasing costs for supplying water to local communities and related industries. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. However, the co-lead agencies do not have authority to provide mitigation for the effects to infrastructure such as M&I systems.
6108	4	dwayneparis@gmail.com	N/A	There is a disconnect in municipal costs between 2002 analysis and the DEIS: At least, Improving Salmon Passage, Final Lower Snake River Juvenile Salmon Mitigation Feasibility Report/EIS February, 2002, Summary, p. 33, included recognition of the need to modify pumps owned by industrial and municipal parties and included cost estimates between $11 million and $55 millionin 2002. If these costs from 2002 are bumped up only by an inflation factor (which would fail to recognize new, more stringent environmental requirements), the new amount would bankrupt the three cities and put the viability of Clearwater Papers Lewiston operations into the realm of uncertainty. According to the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and EIS, the city of Lewiston, [Clearwater Paper], Atlas Sand and Rock, Lewiston Country Club & Golf Course and the Clarkston Golf & Country Club all have water supply intakes on the Clearwater or Snake Rivers. So, too, does the Corps for keeping the greenbelt trail along the Clearwater Snake National Recreation Trail. The action agencies need to recognize mitigation to rebuild or relocate all intakes to function in riverine conditions.	This EIS discusses engineering solutions (pipeline extensions for example) in Chapter 3.12 section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative and in Appendix N. As described in the 'Summary of Effects' subsection of 3.12.3.4 Multiple Objective Alternative 3 (MO3), measures implemented under MO3 could affect delivery of current water supply in Region C and a loss of 48,000 acres of farmland. Similarly, There are M&I pumps in the Lewiston area that would likely be impacted by this measure, along with other small M&I uses along the river. The co-lead agencies identified a total of 16 points of diversion from surface water with a water rights purpose listed as M&I, which may use up to 9,230 acre-feet per year (USGS 2018a). As described in Section 3.12 of the EIS, effects to water supply from MO3 are expected to result in minor adverse effects to social welfare and major adverse effects to regional economics. As described in Section 3.12.3.4 Multiple Objective Alternative 3, Municipal and Industrial water supply intakes in the Lewiston, ID area would likely be impacted by a dam breach scenario. Modifications to M&I systems would be required under MO3 increaing costs for supplying water to local communities and related industries like golf courses. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. However, the co-lead agencies do not have authority to provide mitigation for the effects to infrastructure such as M&I systems.
6108	5	dwayneparis@gmail.com	N/A	Land conveyance from the Corps to local entities is a nightmare. Chapter 5, page 30 states Deauthorized project lands are transferred to new ownership. The City was successful in having included in the 2014 Water Resources & Reform Development Act (WRRDA) legislation authorizing conveyance of some of the land managed by the U.S. Army Corps of Engineers. The progress to date on land conveyance, however, has been a nightmare. As the city of Kennewick will testify, land conveyance from federal to other entities is not an easy process. Caught up in the bureaucracy, a municipality pays a lot of resources for the Corps to work through the red tape. Kennewick has been involved in the process of conveyance on a single authorization for a period exceeding 20 years. Lines 907-909 contain a vast understatement, deauthorized project lands[being] transferred to new ownership[involve] real estate transactions [which] would require their own review and are outside the scope of this EIS. Land conveyances currently are requiring a NEPA process and may or may not also require an EIS of their own. The expense for a single transaction involving ownership for the federal side alone can exceed $1 million per transaction; some may require EIS. The onerous, expensive, time-consuming process of transferring federal property to new ownership is not realistically conveyed in the CRSO DEIS. More analysis is required, so that proper expectations can be set.	Real estate costs were included in the costs analysis under MO3 and described in Appendix Q Section 3.1.2.2. Under the dam breaching measures of MO3, it could be necessary to negotiate agreements with affected parties and property owners and enter into relocation contracts for the alteration or replacement of affected structures. Real estate administrative costs were developed for renegotiating contracts, leases, agreements, rights-of entry, etc. Given the uncertainty in the design and specifics of MO3 at this point, the real estate evaluation used the approach from the Lower Snake River Juvenile Salmon Migration Final Feasibility Report and Environmental Impact Statement (2002) and updated the data and costs as needed (Corps Walla Walla District Real Estate Division, 2019). If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments.
6108	6	dwayneparis@gmail.com	N/A	MO3 will destroy strategies to jumpstart the economy within City limits: Obtaining title to the land was part of an overall strategy with an expectation that changes would result in economic growth. The City conceived a plan to restore its boat basin and had the potential to attract companies that provide guided jet boat tours up Hells Canyon National Recreation Area to locate within city limits. This would have brought people to town to shop, eat, get fuel and more before or after the Hells Canyon experience. Businesses could start-up or reopen. Sales tax would then grow and be used by the City for essential services. The company most interested currently has the contracts for all of the cruise line passengers electing the Hells Canyon option. As you are probably aware, the cruise boat industry is an important component of the local economy. Passenger counts on the Columbia and Snake Rivers now exceed that on the Mississippi (3-1081, Lines 32120 32122). If MO3 occurs, there will be no boat basin to restore. There will be no access to the river for Asotin residents and other visitors. The City may have to dissolve. We cannot stress enough what the negative ramifications to the City of Asotin would be if MO3 suddenly becomes the preferred alternative.	The statements and information presented in this comment regarding impacts to the cruise boat industry near Asotin from dam breaching in MO3 are consistent with the findings of the EIS. Cruise ship visitation is characterized in Section 3.10, and is characterized as providing important regional economic effects, particularly in the Lewis-Clark Valley where Asotin is located. Section 3.10.3.5 describes the contribution of cruise ships as providing demand for approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). The potential for loss of this growing industry, as well as the potential regional economic and other social effects associated with dam breach in that area is described in section 3.10.3.5. Other effects to recreation from MO3 are described in Section 3.11.3.5.The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
6108	7	dwayneparis@gmail.com	N/A	Mitigation for revegetation is insufficient and fails to recognize the need for soil supplementation and regular watering to assure that plantings take. Fugitive dust in blowing wind will make air quality in Asotin untenable. There was a promise of grass seed in the DEIS. The seed itself is insufficient. Soil conditions where water has been for decades, is not conducive to desirable plant growth. It will need supplementation. Seed wont take or seedlings wont survive in summer conditions in Asotin without regular irrigation. More must be done to mitigate impact from fugitive dust under MO3. Page 3-1013 discusses, Over time, the risk of fugitive dust likely declines as vegetation covers the exposed sediment, reducing the potentially erodible area. Re-vegetation can only occur under the right conditions. Further, the agencies should note that Asotin County (in which the City is located) has an occurrence of asthma higher than neighboring counties (Innovia Foundation. A Region-Wide Community Needs and Opportunity Assessment, January 2020, Appendix F).	If Multiple Objective alternative 3 is identified as the Preferred Alternative, the co-lead agencies would conduct further design and engineering to implement this alternative and would develop a more detailed mitigation plan including air quality and vegetation mitigation measures.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6110	1	ttrue@earthjustice.org	Earthjustice	There is indisputable evidence that the current SARs for Snake River spring/summer Chinook are at or below 1%, barely half of the minimum 2% SAR level the Northwest Power and Conservation Council has identified as necessary for maintaining existing populations, and only one quarter or less of the 4% to 6% SAR level that must be achieved and sustained for this population to rebuild and recover (CSS 2016 Annual Report, Chapter 7, Petrosky et al. in press). This evidence is at odds with the DEISs claim of increased salmon abundance in recent years (DEIS Chapter 3 pages 299-300; Figure 3-111-Combined Annual Salmon and Steelhead Returns (all species) to Bonneville Dam from 1938-2019.). Moreover, this unacceptably low SAR has been consistent for many years, indicating that the extensive and expensive efforts so far to rebuild Snake River spring/summer Chinook populations have not been successful. NOAAs publications confirm this point -- that wild Snake River spring/summer Chinook returns to the uppermost Snake River dam have declined by at least 60% since the late 1960s when the lower Snake River dams were built (from an average of 47,615 fish to just 18,774). NOAA FAQs (2018) -graph at bottom of page 2). The DEISs claim that spring/summer Chinook abundance has increased relies entirely on the fact that over this same period, Snake River spring/summer Chinook hatchery returns to the uppermost dam have increased by at least 15-fold (from 4,933 fish to 73,487), an increase that actually reflects increased hatchery production to mitigate for losses of salmon due to the FCRPS, rather than improved survival from restoration measures. The point here is not to criticize the role of hatcheries, but to highlight the extent to which the DEISs claim of increased Chinook abundance relies on increased hatchery production, not increased survival rates and subsequent wild/natural returns. 6 It is also important to remember that wild Snake River spring/summer Chinook are protected by the ESA and ultimately must recover and rebuild to sustain the species health.	The most recent ESA status review reported that the Snake River spring/summer Chinook population trends in total spawner abundance were positive over the period 1999 to 2014 for 23 of the 26 population natural origin abundance series, but the relative rates of increase for each population were lower than estimates of trends for the prior review period (Table 15). Northwest Fisheries Science Center, 2015. Status review update for Pacific salmon and steelhead listed under the Endangered Species Act: Pacific Northwest. However, return rates have been low over the three years this EIS has been in process. In addition, the Snake River spring/summer Chinook ESU includes spring/summer Chinook salmon from 11 hatchery programs. The co-lead agencies used high quality information and best science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. A SAR rate of 2% can lead to significant population growth given adequate productivity and habitat quality. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6110	2	ttrue@earthjustice.org	Earthjustice	1. Restoration of the Lower Snake River Through Dam Removal Would Provide More Certainty of Long-Term Survival and Recovery for Snake River Chinook than Any Other Measure. In its 2000 Biological Opinion for operation of hydroelectric dams on the Columbia and Snake Rivers, NOAA Fisheries concluded: breaching the four lower Snake River dams would provide more certainty of long-term survival and recovery than would other measures (BIOP 2000). That conclusion was supported by extensive evidence from a peer-reviewed, interagency process, the Plan for Analyzing and Testing Hypotheses (PATH), which summarized available empirical evidence, retrospectively analyzed patterns of survival in the various life stages and across the life cycle, and performed prospective analyses using a wide range of assumptions (Marmorek et al. 1998, Deriso et al. 2001, Marmorek and Peters 2001).PATH analyses showed that dam breaching options were the most likely to recover Snake River salmon and steelhead with the lowest risk under a wide range of assumptions. A weight of evidence accumulated since the PATH process has continued to consistently demonstrate major adverse impacts from the Snake and Columbia River dams (the FCRPS) on 7 salmon and steelhead (Schaller and Petrosky 2007, Petrosky and Schaller 2010, Buchannan et al. 2011, Marmorek et al. 2011, Haeseker et al. 2012, Schaller et al. 2014). This evidence, from multiple data sets and analytical approaches, has repeatedly demonstrated that survival of Snake River spring/summer Chinook in the smolt-to-adult stage, in the ocean, and across the life cycle is lower than that of similar downriver populations that experience fewer dams. There also is considerable evidence that Snake River stream-type Chinook experience substantial delayed mortality in the marine environment as a result of their outmigration experience through the FCRPS (Williams et al. 2005; Schaller and Petrosky 2007; Marmorek et al. 2011; Schaller et al. 2014). This outmigration experience results in an accumulation of injuries, multiple stress events, and alteration of estuary arrival timing: mechanisms that may explain levels of delayed mortality (Budy et al. 2002; Muir et al. 2006; Scheuerell et al. 2009; Rechisky et al. 2012). Decreased water velocity and increased number of powerhouse passages have been related to large increases in the time required for juveniles to migrate to sea and reductions in life cycle survival, smolt to adult returns, and marine survival rates for Snake River Chinook Salmon (Schaller et al. 2007, Petrosky and Schaller 2010, Haeseker et al. 2012, Schaller et al. 2014). This large body of scientific evidence and analyses identifies a significant level of hydrosystem delayed mortality (latent mortality) for Snake River Chinook populations. As explained further below, the recent paper by Faulkner et al. (2019) discussing smolt size does not weaken the weight of evidence for hydrosystem delayed mortality, because of the serious scientific flaws in that paper identified by the Fish Passage Center in their review of it (CSS 2019 Appendix G; 2019 FPC Memorandum 49-19 reviewing Faulkner et al. 2019). In sum, the best currently available scientific information continues to strongly support NOAAs conclusion regarding dam removal from the 2000 biological opinion. In its 2017 8 Annual Report on the Comparative Survival Study (CSS), the Fish Passage Center evaluated the effects of various levels of voluntary spring spill, as well as removal of the four lower Snake River dams, on smolt-to-adult return rates (SARs) (2017 CSS Annual Report, Chapter 2 & Appendix K) for Snake River spring/summer Chinook. Using more than twenty years of empirical data on dam passage survival and SARs, the CSS Report concluded that dam removal on the lower Snake, together with any reasonable level of voluntary spill at the lower Columbia River dams, would lead to significantly higher SARs. It also concluded that dam removal plus spill at 120% Total Dissolved Gas (TDG) or more would lead to SARs at or above the levels identified by the Northwest Power Planning and Conservation Council (NWPPC) as necessary to rebuild salmon populations to healthy levels (NPCC 2014). The CSS Report reached this conclusion taking into account other variables including ocean conditions (CSS 2017, Chapter 2 & Appendix K). In addition, the CSS Report compared SARs for salmon stocks that migrate past only three or four lower Columbia River dams to Snake River stocks and noted that SARs for these downstream stocks, which negotiate four or fewer reservoirs and dams, are now consistently more robust than SARs for Snake River stocks, further supporting the conclusion that lower Snake River restoration would be likely to substantially improve the conditions of Snake River fish (CSS 2017, Chapter 2 & Appendix K). Because breaching the four Snake River dams with higher spill (to 125% TDG) at the four lower river dams is the only option that can reduce the high levels of mortality for Snake River Chinook, the best currently available science affirms that dam breaching is the most probable option for achieving recovery and rebuilding goals for these populations. Given strong evidence of climate change effects (Lijing et al. 2019), these measures will need to be taken sooner, rather than later, to ensure persistence of these populations. 9 Two recent letters from a number of independent scientists rely on the CSS analysis as well as considerable other evidence to conclude that lower Snake River restoration is necessary to allow Snake River salmon and steelhead populations to not just avoid extinction, but also to begin rebuilding to a sustainable abundance (Letter to Gov. Inslee & Orca Task Force (Oct. 15, 2018); Letter to Northwest Policy Makers re River Temperatures (Oct. 22, 2019). The most recent of these letters focuses particularly on the role of the lower Snake River dams in increasing water temperatures and the survival benefits that will accrue from reducing these temperatures as a result of removing these dams. These scientists further emphasize the importance of these benefits to salmon survival and recovery as the climate warms in the years ahead (Letter re River Temperatures, Oct.22, 2019). Despite this compelling evidence, the DEIS downplays the benefits of dam removal by stating that Snake River Chinook abundance has increased in recent years, by focusing narrowly on juvenile survival through the lower Snake River only, and by dismissing as unknowable the precise extent of the delayed effects on salmon survival of hydrosystem passage (called delayed or latent mortality). The DEIS also relies on an analysis by its Fisheries Science Center that suggests smolt size has more to do with juvenile survival than the route a smolt takes past dams (Faulkner et al. 2019), to dismiss empirical evidence linked to SAR levels in the CSS modeling results (DEIS Chapter 3 pages 361-362 and DEIS Appendix V section 3 on Latent Mortality). This smolt size study is scientifically flawed and draws erroneous conclusions for informing management decisions as explained further below (CSS 2019, Appendix G). The DEIS also fails to rationally address the above scientific evidence, discuss its significance for the choice among the alternatives it presents, or explain why the DEIS discounts and disregards this evidence. Instead, as noted above, the DEIS focuses almost all of its analysis 10 on a comparison of alternatives to a no-action alternative that would continue to implement a plan rejected by the courts in 2016.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective 3 (MO3) which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase – Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to breaching the four lower Snake River dams, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2%). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the better CRSO EIS alternative for salmon and steelhead. One model predicts adult return increases an order of magnitude higher than the other. With respect to the Preferred Alternative, the CSS model predicts that average SAR rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Moreover, the agencies used current, high-quality modeling information consistent with the National Environmental Policy Act and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over 20-years-old and does not reflect current Columbia River System operations.
6110	3	ttrue@earthjustice.org	Earthjustice	2. The Benefits of Lower River Restoration and Dam Removal for Imperiled Snake River Salmon Would Be Substantial. The DEIS takes the position that juvenile salmon survival is already high through the lower Snake River and that restoring the river and removing its dams would not change this survival dramatically. The basis for this claim that juvenile survival through the four lower Snake River dams and their reservoirs is already 75% to 80% is unclear and suspect. What we do know is that the lower Snake River dams are only four of eight dams that Snake River juveniles must pass on their migration to the sea, and that the effects of dam passage compound as the number of dams and reservoirs increase. This compounding effect for Snake River Chinook is reflected in downstream juvenile survival rates past all eight dams, which CSS 2019 Appendix Table 1 estimates as only 54% on average from above the upper-most Snake River dam to below Bonneville dam over the period 1994-2019. Table A4 in this Appendix estimates juvenile survival as only 48% on average for Snake River steelhead over the same years. The CSS Study has also concluded that for each powerhouse encounter a juvenile salmon experiences, its risk of mortality increases by about 12% (CSS 2016 Annual Report, Chapter 7). Importantly, this CSS analysis underestimates hydrosystem-caused mortality, as it does not account for direct and delayed mortality through powerhouse passage or due to reservoirs, which slow fish migration and expose juvenile migrants to warmer water, disease, and increased predation pressure. This analysis is a relative measure that reflects the additional mortality that arises later from the delayed effects of passage through bypass systems compared to other routes (CSS 2016 Annual Report, Chapter 7). Ultimately, the DEIS concludes that there is some level of scientific uncertainty about exactly how much juvenile survival and SARs would improve 11 without the dams. But NOAA has also never disclaimed its long-standing conclusion that breaching the four lower Snake River dams would provide more certainty of long-term survival and recovery than would other measures and the DEIS reaches a similar conclusion regarding	The co-lead agencies do not agree with the characterizations made in this comment regarding current survival through the four lower Snake River dams. The 75% to 80% current survival rate referenced by the commenter does not appear to be tied or referenced to the Draft EIS and it is not tied to a specific species, river condition, or conveyance mode. The co-lead agencies agree that the analysis shows that Multiple Objective 3, which includes the measure to breach the four lower Snake River dams, would provide the most benefits to anadromous Snake River fish. The co-lead agencies have presented in the EIS analysis the highest quality, current information on juvenile fish passage survival. The in-river survival referenced in this comment was generated by the CSS (as well as by NMFS), but note that the CSS reports cited in this comment prior to 2019 do not reflect the measures considered in this EIS analysis. Estimates provided by the CSS Lifecycle models for the purposes of this EIS evaluate changes in metrics such as juvenile travel time, and powerhouse encounter rates. Smolt-to-Adult return rates predicted by the CSS models encompass any delayed or latent mortality associated with those factors.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				alternative MO3, despite components of that alternative that might tend to degrade salmon survival through the hydrosystem. The best currently available scientific evidence continues to support this conclusion. Any remaining uncertainty about just how dramatic juvenile survival improvements would be without the lower Snake River dams must be viewed from this perspective.	
6110	4	ttrue@earthjustice.org	Earthjustice	3. The Benefits of Lower Snake River Restoration and Dam Removal Are Not Affected by the Difficulty of Precisely Quantifying Latent (or Delayed) Hydrosystem Mortality. Calculating the precise extent of latent or delayed mortality as a result of dam passage is not actually relevant to concluding that lower Snake River restoration and dam removal would improve Snake River Chinook returns by a very large amount, and more than any other available measure. Moreover, as noted above, there is a substantial weight of evidence, from multiple data sets, analytical approaches and scientific publications that consistently demonstrate high levels of latent (i.e., delayed hydrosystem) mortality due to the FCRPS over varying ocean conditions (Schaller and Petrosky 2007). The DEIS attempts to cloud these beneficial effects because the precise extent of latent or delayed mortality is difficult to determine (DEIS chapter 3 pages 361 362; DEIS Appendix V section 3 on Latent Mortality). First, whatever the precise nature and extent of these effects, they are captured and reflected in the current unsustainably low SARs 1% or less for Snake River spring/summer Chinook (CSS 2019 Annual Report, Chapter 4). These Chinook are simply not surviving at rates sufficient to avoid extinction, let alone at rates sufficient to allow them to rebuild and recover. CSS analyses indicate that these low return rates would be improved very substantially by lower 12 Snake River dam removal and continued adequate spill levels at the lower Columbia River dams (2017 CSS Annual Report, Chapter 2). And again, NOAA itself has said that dam removal will do more than any other available measure to support increased population growth for this species. The DEIS also concludes that dam removal should be discounted and set aside because it will require congressional action and take some years to improve salmon survival. This suggestion begs the central question: is there an alternative action with benefits of a similar magnitude for salmon survival that we could take more quickly? NOAAs longstanding answer is no: breaching the four lower Snake River dams would provide more certainty of long-term survival and recovery than would other measures. And extensive scientific evidence and analyses, much of it summarized above, continues to support this conclusion. The most effective near-term measure that could be taken (until breaching of the lower Snake River dams could be fully implemented) would be to operate all dams with spill to 125% TDG, similar to actions described in MO4. NOAAs Fisheries Science Center recently released a new analysis which questions the conclusion that the number of powerhouse (dam) encounters experienced by juvenile salmon has a significant negative impact on survival. This new paper asserts that it is smolt size, not the number of dam encounters, that is most significant in determining survival (Faulkner et al. 2019). The analysis in this new paper, however, does not support NOAAs claim. First, there is no dispute that, as compared to other passage routes (e.g. spill), fish that pass through powerhouses have lower SARs (CSS 2016 Annual Report, Chapter 7, Buchanan et al. 2011). One of the DEISs claims is that these lower SARs are driven by fish size, not powerhouse passage, because more smaller fish pass through powerhouses and smaller fish suffer higher 13 mortality in the ocean (Faulkner et al.2019) (DEIS Chapter 3 pages 361-362; DEIS Appendix V sections 3 on Latent Mortality). What the Faulkner analysis does not show is whether SARs for larger fish that pass through the powerhouses are nonetheless still lower than larger fish that pass via spill. Without this critical comparison, the Faulkner analysis cannot support its conclusion about the role of fish size in dam passage survival. A recent review of this paper by the Fish Passage Center found many shortcomings with it, including: 1) study fish all experienced at least two dam bypasses and additional handling; 2) the Faulkner analytical approach didnt incorporate spill and flow, which are major factors determining collection efficiency and bypass probability; 3) the analysis ignores the fact that smolts from the John Day River which are similar (or smaller than Snake smolts) and migrate at the same time as Snake River fish and which pass fewer dams, have much higher SARs (CSS 2019, Appendix G). In sum, the DEIS fails to fully or objectively describe the above relevant history and evidence or discuss its significance for the choice among the alternatives it presents, choosing instead to focus almost all of its analysis on a comparison of alternatives to a no-action alternative that the agencies apparently assume they could continue to implement even though it is largely a continuation of a plan rejected by the courts in 2016 as inadequate to even avoid jeopardy under the ESA. This comparison fails to provide the public or decisionmakers with relevant context that is crucial to understanding the choice among the alternatives presented in the DEIS or a rational basis for selecting and alternative and so fails to comply with the fundamental informational purposes of NEPA.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on our fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The co-lead agencies disagree that latent mortality is irrelevant to identifying the extent to which the dam breach measure would improve anadromous fish returns. If the latent mortality hypothesis proves unfounded, for example, certain predicted benefits of breaching of the four lower Snake River dams would decrease. The co-lead agencies nevertheless agree, as the Draft EIS analysis shows, that Multiple Objective (MO3) provides the greatest benefits to Snake River anadromous fish. The co-lead agencies also disagree that the Draft EIS attempts "to cloud" effects. The analysis describes the high quality, current information on likely effects of different actions and related uncertainties. The co-lead agencies appreciate the commenters perspective on Faulkner et al. 2019. The analysis presents this and other available information to establish a range of possible effects. The EIS does not purport to resolve ongoing scientific disagreements. Consistent with the National Environmental Policy Act and its implementing regulations, the Draft EIS analysis identifies status quo Columbia River System operations as the No Action Alternative in evaluation of this ongoing action.
6110	5	ttrue@earthjustice.org	Earthjustice	III. THE STATEMENT OF PURPOSE AND NEED IN THE DEIS IS UNREASONABLY NARROW AND LACKS ANY ADEQUATE BASIS IN LAW OR FACT In describing the purpose and need for the CRSO EIS, the agencies acknowledge that conservation of wild salmon and steelhead is a goal of the CRSO. E.g. DEIS 1-3, 1-4. The ESA defines conservation as returning a species to a self-supporting and sustainable condition in its native ecosystem. 16 U.S.C. 1631(3) (to the point at which the measures provided pursuant to this Act are no longer necessary). But the agencies later set aside consideration of the extent to which the alternatives would achieve these purposes in favor of a narrow focus on a only a portion of their responsibilities under ESA section 7(a)(2). From DEIS 7-4: While federal agencies must ensure their actions do not reduce appreciably the likelihood of both the survival and recovery of a listed species [citing 50 C.F.R. 402.02], the co-lead agencies are not, however, obliged under Section 7(a)(2) to contribute affirmatively toward recovery achievement. Recovery is an important, but distinct, public policy objective that is furthered through a separate planning process governed by ESA Section 4(f) to guide societal actions by both federal and non-federal actors. Nothing in NEPA permits them to limit their analysis to the effects of the alternatives to this narrow scope under the ESA without some rational explanation. Nor do the agencies adequately explain why any other aspect of the ESA is not relevant to the scope of the CRSO EIS.1 Even if the agencies are correct that recovery can be addressed through a separate ESA provision, that does not make consideration of the effects of the alternatives on conservation or recovery irrelevant to the purpose and need for the CRSO EIS. Further, the agencies do not explain the relationship between their improve objective (whatever that means) for comparing the effects 1 The DEIS also cites in passing to the ESAs command to ensure that actions are not likely to destroy or adversely modify critical habitat. 16 U.S.C. 1632(a)(2). The statutes definition of critical habitat expressly includes conservation, defined by the statute to incorporate a goal of recovery. See, text, supra. 15 of the alternatives to the no action alternative even for the narrow aspect of the ESAs requirements they do recognize. In addition, other statutes require more of the agencies in terms of conservation and environmental protection than the ESA. Specifically, the Northwest Power Act requires conservation and rebuilding of salmon and steelhead populations. 16 USC 839b(h)(11)(A)(i) (adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat). And nothing prevents the agencies from considering broader public goals and obligations like the restoration of abundant salmon, meeting obligations to Native American Tribes to restore healthy, harvestable fish runs, or to meeting the population rebuilding and conservation goals of the Columbia Basin Partnership. The agencies never explain why these requirements are not relevant to the purpose and need for the CRSO EIS or examine how or the extent to which the alternatives they do consider would meet this requirements. While the agencies may have wide discretion to articulate the purpose and need for the CRSO EIS, they cannot arbitrarily and without explanation disregard relevant legal requirements and public needs in order to adopt an unreasonably narrow statement of purpose and need. See National Parks & Conservation Ass'n v. Bureau of Land Management, 606 F.3d 1058, 1072 (9th Cir. 2010) (finding that an unreasonably narrow purpose and need statement resulted in the agency necessarily consider[ing] an unreasonably narrow range of alternatives.). As the court overseeing this remand recognized, a comprehensive EIS that fully and fairly examines all reasonable alternatives is necessary if the agencies are to break through any logjam that simply maintains the precarious status quo. Natl Wildlife Fed., 184 F.Supp.3d at 876. Moreover, as soon as the agencies shift to describing the objectives of the alternatives they consider in light of their statement of purpose and need, they change their goal from even 16 narrow compliance with one aspect of the ESA to merely improving conditions for salmon to some unstated degree as compared to the no action alternative. DEIS 2-3. They do not define improvement in terms of any statutory requirement or explain how it relates to these requirements. An amorphous objective of improve[ment] is incompatible with the fixed legal standards the agencies are required to meet. Even were their legal obligations limited to the ESA requirement to avoid jeopardy, the agencies fail to describe how their objective of improve[ment] will meet this command. Their failure to rationally explain how their chosen metric meets relevant statutory requirements, even limited to the jeopardy standard under the ESA, has also been an aspect of past failed dam operation plans. As the Court in NWF v. NMFS most recently ruled, An increasing population . . . does not necessarily equate to a no jeopardy finding[.] Natl Wildlife Fed., 184 F.Supp.3d at 888 (rejecting NMFSs application of its trending towards recovery standard from the 2014 biological opinion). As the courts have noted, allowing a species to hover on the brink of extinction at low population numbers for long periods, even with minor improvements, increases the risk of extinction from chance events. Id. at 888 (observing that a population that remains dangerously low in abundance . . . [can] remain[] dangerously low despite the increase); see also Aluminum Co. of Am. v. Bonneville Power Admin, 175 F.3d 1156, 1162 n.6 (9th Cir. 1999) (noting that NMFS correctly viewed incremental improvements as insufficient to avoid jeopardy in light of the already vulnerable status of the listed species)in sum, the improvement metric the agencies actually use in the DEIS to evaluate the effects of their alternatives on salmon and steelhead is contrary to applicable legal requirements and the agencies fail to explain how it satisfies their legal responsibilities. In addition, the agencies statement of purpose and need with respect to salmon 17 and steelhead disregards relevant legal requirements and is arbitrarily narrow without explanation.	The co-lead agencies disagree that the Purpose and Need Statement is lacking. Among other things, the Purpose and Need Statement identified broad purposes related to the co-lead agencies varied legal obligations, including under the ESA and Northwest Power Act. The restoration of abundant salmon is not within the legal obligation or authority of the co-lead agencies. The comment is therefore mistaken to equate these broader public goals with requirements the agencies are obligated to explain. The comment also mistakenly redefines the anadromous fish conservation element of the Purpose and Need Statement to mean recovery of ESA-listed species, and misconstrues the description of the agencies' legal obligations under Section 7(a)(2) of the ESA as a description of the effects analysis. To determine whether the Preferred Alternative complies with Section 7(a)(2), the co-lead agencies consulted with the respective Services. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA and Northwest Power Act.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6110	6	ttrue@earthjustice.org	Earthjustice	A. The DEIS does not actually rely on, or address rationally, recognized population performance metrics to reach or support its conclusions. Regional fish experts agree that smolt-to-adult returns (SARs) must be at least 2% for populations to stabilize, and at least 4% for populations to increase towards abundant, harvestable levels. The NPCC (2014) Fish and Wildlife Program objectives include supporting tribal and non-tribal harvest and achieving SARs averaging 4% and ranging from 2%-6% on a sustained basis for listed Snake and upper Columbia salmon and steelhead. Recognizing that SARs will vary from year-to-year for a variety of reasons, experts consider sustained SARs of 2%-6% necessary to rebuild salmon abundance. Recent CSS (2017 Chapter 5) analyses further support the rationale of the NPCC 2%-6% SAR objectives. SARs measured at Lower Granite Dam (LGR) are most relevant to escapement objectives and ESA population abundance criteria. Snake River population abundances are far below carrying capacity and ESA Minimum Abundance thresholds. Wild Snake River spring/summer Chinook SARs (measured at LGR) averaged only 0.8% from 1994-2017; wild steelhead SARs have averaged 1.4% (CSS 2019). SARs less than 1% have consistently resulted in population decline from one generation to the next for Snake River spring/summer Chinook and steelhead in recent years (CSS 2017). These populations began to show some increase from low abundance 18 in the few years within this time period when SARs were greater than 2% (CSS 2017). Low abundance and the perpetuation of low SARs (low productivity), due in large part to FCRPS operations, pose high genetic and demographic risks to salmon and steelhead populations (ICTRT 2007; Petrosky et al. in press), which result in high probabilities of population extirpation (and ultimately extinction). Pre-harvest SARs (measured at the Columbia River mouth) are most relevant to regional goals of healthy, harvestable salmon populations (CSS 2017). Petrosky et al. (in press) also compared historical life cycle productivity (Schaller et al. 2014) with pre-harvest SARs. Results indicate that pre-harvest SARs in the range of 4%-6% are associated with 1950s-1960s levels of productivity for Snake River spring/summer Chinook, when populations were healthy and harvestable. The DEIS does not use this or any other population-level performance metric in a rational way to assess the extent to which the alternatives will provide population growth that can achieve the established regional metrics or other appropriate goals although this information is readily available. Instead, the DEIS arbitrarily picks and chooses to report some limited aspects of the CSS results for SARs for the alternatives the DEIS considers but omit significant aspects of these results like the probabilities associated with the reported CSS results. They then rely on their conclusions regarding a vague and unexplained standard of improvement as discussed above. They also attempt to describe a dispute about methodology between two analyses, the CSS work and modeling using the Life Cycle or LCM model. For the reasons set out below, omission of the probabilities associated with the CSS analysis is not reasonable or rational and the dispute regarding the CSS results and the LCM model is based on a mischaracterization of the CSS model and is arbitrary in light of the available evidence.	The co-lead agencies used high-quality, current data and modeling in evaluating effects to resources from the alternatives. Specifically, the co-lead agencies used juvenile survival, fish travel time, and Smolt-to-Adult return (SAR) rates to evaluate the effects of alternatives to salmon and steelhead. These metrics are regionally accepted and regularly used to evaluate operational changes to the CRS. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils targets are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. In addition, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS/National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Regarding the commenter's assertion that productivity in the 1950s and 1960s provides a reasonable target, the co-lead agencies note the highest returns of salmon and steelhead to Bonneville Dam occurred between 2010 and 2015 when the number of salmon and steelhead returning to the mouth of the Columbia River more than doubled the time period of reference. As noted by the ISAB in their review of the CSS model results generated for this EIS (ISAB 2020-1), changing climate conditions should be carefully assessed when considering potential impacts to salmon and steelhead, but the co-lead agencies note the concerns raised by the ISAB regarding the CSS's quartile range analysis and the likelihood or probabilities of SARs falling below 1 percent. The co-lead agencies will evaluate that analysis as it evolves but are not relying on the probability analysis at this time.
6110	7	ttrue@earthjustice.org	Earthjustice	There were several important findings from the CSS analyses of the alternatives in the DEIS. For both CSS models, among the federal alternatives, MO3 (the four dam breach alternative with spill to the 120% tailrace TDG at the lower Columbia River dams) resulted in the highest SARs and in-river survivals, followed by MO4 (the spill to the 125% tailrace TDG alternative). These two alternatives, among the federal alternatives, resulted in the highest likelihood of meeting the 4% average SAR regional goal. The vast majority of the predicted SAR range for MO3 was also above 1% for both Chinook (85%) and steelhead (88%) but, for MO4, only 64-61% of the predictions were above 1%, indicating a greater risk of further 21 population decline than occurred under MO3. The other federal alternatives (NAA, MO1, MO2, and the PA) did not meet the regional 4% SAR goal and a considerable percentage of predicted SARs under those alternatives were well below 1%, indicating a much greater risk of further population decline under each of these alternatives. For all fish survival metrics, the PA resulted in only slightly better performance than the NAA and MO1, and had much lower performance than both MO3 and MO4. Because the modeled datasets provided by the federal agencies used daily averages, the CSS results for the PA likely overestimate the SARs it will produce. The following graph (from the Chapter 2 CSS analyses and March 3, 2020 presentation of the CSS analyses to the Pacific Fishery Management Council Habitat Committee on the CRSO-EIS) summarizes and qualifies the risk associated with each operational alternative. The graph shows that the PA results in an SAR less than 1% 36 to39% of the time for yearling Chinook and steelhead, while the breach option (MO3) results in an SAR less than 1% only 12 to 19% of the time. SAR survivals less than 1% are considered to have a significant risk of continued population decline. Nearly 40% of the preferred alternative simulations produce survival estimates in this very low SAR range that will allow further decline of the endangered populations. Conversely, the MO3 option provides SARs greater than 2%. SARs of this level are expected to allow modest population increases and will do so nearly twice as often as the PA (57 to 68% vs. 35 to 37%). The DEIS also failed to analyze all available and reasonable alternatives. In the 2017 CSS Annual Report, the concept of breaching the lower Snake Dams, and spilling to 125% at the lower Columbia Projects was introduced and analyzed. The alternative of combining the breaching of the Lower Snake River Dams with spill to the 125% gas cap was also presented to the CRSO-EIS Fish Technical Team on September 21, 2017 by the CSS Committee. Questions 22 from that meeting were addressed in a subsequent memo from the Fish Passage Center dated October 5, 2017. Although initial CSS analyses indicated that the combination of breach and spill at the lower Columbia River projects to 125% produced the highest SARs, the federal agencies did not consider in the DEIS an alternative that incorporated this operation. Consequently, the range of alternatives considered in the DEIS does not examine a reasonable and available alternative for dam operations that would actually produce the highest survival rates for Snake River salmon and steelhead (and other species given the higher spill levels at the lower Columbia River dams). The CSS 2019 Annual Report (FPC Memo to Eric Merrill, February 28, 2020) built on the 2017 concept by incorporating elements included in DEIS alternatives MO3 and MO4 to develop an available dam operation termed MO34. The MO34 option included breach of the four Lower Snake River dams, which means there was no spill operation at these projects. Since MO34 involved breach of the Lower Snake projects, there is no transportation under this scenario either. The spring spill operation at all four lower Columbia River dams was spill to the 125% TDG levels. The MO34 option also includes the addition of fish friendly turbines at John Day Dam and the installation of Powerhouse Surface Passage routes (PSPs) at McNary and John Day dams. MO34 also carried over several measures from alternatives MO3 and MO4 that affect flows and water travel time (WTT) potentially decreasing survival estimates. These measures included: 1) changes in the drafting of high-head reservoir projects that could potentially lead to decreases in flows in the Mid-Columbia River increasing fish travel time, 2) operating John Day Dam within full reservoir operating range, which may lead to increases in WTT and subsequent increases in fish travel times, and 3) operating turbines within and above the 1% peak efficiency 23 during the spill season, which may result in higher powerhouse capacities forcing more fish to pass through turbine units. Even with these measures that may decrease fish survival, the above described MO34 alternative demonstrated the greatest expected improvements across all biological response metrics, compared to all of the federal CRSO-EIS alternatives. On average, the MO34 alternative exceeded the 4% average SAR regional goal. The predicted SARs for MO34 were above 1% for both Chinook (SAR>1% for 85% of simulations) and steelhead (SAR>1% for 92% of simulations) indicating that MO34 had the highest likelihood of avoiding further population declines and supporting population rebuilding. Quantifying risks and desired outcomes SARs < 1% associated with population declines SARs > 2% associated with population increases (also NPCC minimum SAR goal) PA: 36-39% of SARs < 1% MO34: 8-15% of SARs < 1% Fig. Probabilities of SARs less than 1% (top panel) and probabilities of SARs greater than 2% (bottom panel) for yearling spring/summer Chinook salmon (grey bars) and steelhead (blue bars) for each of the alternatives. The conclusions of the CSS Analysis showed that alternative MO2 consistently resulted in poor biological performance, worse than the NAA. The MO3 and MO4 alternatives 24 consistently demonstrated the greatest improvements in biological performance relative to the NAA. In addition, MO3 and MO4 were the only two alternatives that may be capable of achieving the NPCC average SAR goal of 4% (MO3 above, MO4 near, both ranges overlap 4%). It is also important to note that the PA results are more similar to those for the NAA and MO1 alternatives and indicate a much higher likelihood of dangerously low SARs and a much smaller likelihood of SARs that meet regional goals. In addition, the results for the PA may be overly optimistic because: 1) flex spill allows decreased spill during both daytime and nighttime hours and the analyses were conducted using daily average flow and spill values; 2) the alternative includes high capacity turbines survival estimates that are based on only a few studies and may not attain the projected increase in juvenile passage survivals; and, 3) the PA allows drafting reservoirs below flood control elevations during the winter months that, due to the probability of error associated with forecasting run-off volume early in the runoff period when drafts are occurring, may result in reservoirs being at lower elevations resulting in reduced river flows during the fish migration. The CSS alternative MO34 performed better than any of the alternatives analyzed in the DEIS and is built from actions considered in these alternatives and so would be reasonable to consider but, was not developed or considered by the federal agencies in the DEIS. The MO34 alternative had the lowest probability of producing SARs less than 1% and the greatest probability of SARs greater than 2%. Therefore, MO34 had the best probability of successful restoration of healthy salmon populations and recovery with the lowest risk to extinction of all the alternatives.	The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed by the co-lead and cooperating agencies. Improving juvenile and adult anadromous salmonids were two of the eight objectives of the CRSO EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, Multiple Objective 3 (MO3) and Multiple Objective (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning (1,000 aMW is about the average amount of power consumed by Seattle City Light). As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U..S by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6110	8	ttrue@earthjustice.org	Earthjustice	C. The DEIS attempts to create a dispute about modeling results where there is none. The DEIS description that the differences between CSS and NOAAs LCM results are due to different assumptions about hydrosystem latent mortality is not accurate. The CSS and NOAA models use two different analytical approaches. The NOAA LCM (or COMPASS) 25 model approach used in the DEIS does not address delayed mortality directly. In the general analysis presented in the DEIS, the agencies sometimes make assumptions (that are not themselves derived from data or analysis) for three levels of reduced hydrosystem latent (i.e., delayed) mortality in their sensitivity analysis using the LCM model. The CSS approach does not make any assumptions	The co-lead agencies used current high quality information in the Draft EIS to analyze the effects of operations, maintenance, and configuration of the CRS projects. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. The National Environmental Policy Act (NEPA) does not require the co-lead agencies to resolve uncertainties or disagreements in those models. Rather, consistent with NEPA, the co-lead agencies have made an objective good faith effort to identify high quality, current information and disclose their understanding and use of the informational tools. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				for the level of delayed hydrosystem mortality, because it employs an empirical statistical model analysis that incorporates actual hydrosystem delayed mortality, at whatever level it occurs, by using SARs as the primary metric. As explained in the December 16, 2019 Fish Passage Center memo Response to Questions on Latent Mortality for Lower Snake River Dams Engagement Report, the CSS models are empirical statistical models, which do not make assumptions about hydrosystem delayed mortality. Delayed or latent mortality is mortality that occurs to fish during their first year in the estuary and ocean, after juvenile salmon have survived downstream to Bonneville Dam. The metrics generated by CSS model analyses are juvenile fish survival, juvenile fish travel time, Transport-In-river ratio (TIR), smolt-to-adult return rate (SAR) and ocean survival. The CSS (empirical statistical) model analyses incorporate hydrosystem delayed mortality by utilizing SARs as a primary metric. An assumption about a specific measure of hydrosystem delayed mortality is not necessary in CSS model analyses. In contrast, the DEIS analysis using NOAAs LCM model (Table 7-25 footnote) does not factor latent mortality into either SARs or abundance outputs, but rather assumes different levels of reduction in survival (10%, 25% or 50%) from hydrosystem latent mortality and performs a sensitivity analysis for the different levels. NOAAs COMPASS model is a mechanistic modeling approach. The values of 10%, 25%, and 50% reduction in latent mortality appear to be simply best guesses for use with the LCM modeling analysis. This range of latent mortality 26 reductions does not appear to be directly bounded by any referenced analysis or data (in either the DEIS chapters 3 and 4 or any of the DEIS appendices). In the NMFS (2019) BIOP(page 496) they claim they considered three latent mortality reduction scenarios that were deemed to roughly represent the ranges of potential outcomes (increased productivity) indicated by the CSS (2017) for the up to 120 percent flexible spill operation compared to recent or biological opinion spill operations. However, there is no detailed explanation of how NMFS derived these levels from the CSS report and these latent mortality levels appear inconsistent with analyses or results in CSS (2017). The mechanistic COMPASS model, however, is data hungry and requires many assumptions (FPC December 16, 2019 memo). Many of these assumptions must be made even when data are not available. A mechanistic model structure requires enumeration of all underlying biological processes and as such cannot incorporate hydrosystem delayed mortality (FPC December 16, 2019 memo). The CSS (empirical statistical) model analyses incorporate hydrosystem delayed mortality by utilizing SARs as a primary metric. The CSS (empirical statistical) models do not require enumeration of (or assumptions about) all underlying processes, like the COMPASS (mechanistic) model requires. The inability of the LCM/COMPASS model to incorporate data about latent mortality, except through unverifiable, best-guess assumptions, does not create a dispute about modeling. Instead it presents a significant but unaddressed limitation on the appropriate and credible uses of the LCM/COMPASS results. There is a preponderance of scientific evidence indicating that FCRPS configuration and operation result in delayed mortality to salmon and steelhead. A weight of evidence accumulated since the PATH process has continued to consistently demonstrate major adverse impacts from the Snake and Columbia River dams (the FCRPS) on salmon and steelhead 27 (Schaller and Petrosky 2007; Petrosky and Schaller 2010; Haeseker et al 2012; Marmorek et al. 2011; Schaller et al. 2014). This evidence, from multiple data sets and analytical approaches, has repeatedly demonstrated that survival of Snake River spring/summer Chinook in the smolt to- adult stage, in the ocean, and across the life cycle is lower than that of similar downriver populations that experience fewer dams. There also is considerable evidence that Snake River stream-type Chinook experience substantial delayed mortality in the marine environment as a result of their outmigration experience through the FCRPS (Williams et al. 2005; Schaller and Petrosky 2007; Marmorek et al. 2011; Schaller et al. 2014; Buchanan et al. 2011). This outmigration experience results in an accumulation of injuries, multiple stress events, and alteration of estuary arrival timing: mechanisms that may explain levels of delayed mortality (Budy et al. 2002; Muir et al. 2006; Sheuerrell et al 2009; Rechisky et al. 2012). Decreased water velocity and increased number of powerhouse passages have been related to large increases in the time required for juveniles to migrate to sea and reductions in life cycle survival, smolt to adult returns, and marine survival rates for Snake River Chinook Salmon and steelhead (Schaller et al. 2007; Petrosky and Schaller 2010; Buchanan et al. 2011Haeseker et al. 2012; Schaller et al. 2014). This large body of scientific evidence and analyses identifies a significant level of hydrosystem delayed mortality (latent mortality) for Snake River Chinook and steelhead populations. In light of this scientific evidence, the reasonable conclusion is that delayed mortality should be reduced substantially for options that restore a free-flowing lower Snake River (options MO3 and MO34), and substantially reduce powerhouse passages (MO3, MO4 and MO34). The DEIS LCM results, based on their arbitrary assumptions about delayed mortality, do not set up a disagreement about assumptions with the CSS analysis. Instead, these 28 assumptions of no or negligible reductions in delayed mortality from hydrosystem passage, lack an empirical basis and cannot rationally be relied on to create a disagreement. In addition, the DEIS COMPASS model analysis of MO3 incorporates another important assumption with insufficient data support regarding predation in a restored free-flowing Lower Snake River. The COMPASS model assumes that predation rates would increase because predator satiation on hatchery fish would be reduced as hatchery mitigation fish is terminated under MO3, along with an increase in predator density as the volume of reservoirs decreases to a natural channel (Anderson et al. 2005). The data, analysis and logic behind this predation assumption are not explained in the DEIS and the assumption itself is neither logical nor consistent with available data. The main predatory fishes of juvenile salmonids are associated with the reservoirs as they are adapted to slow-moving waters and lakes. The change from slower to higher velocity habitat under drawdown will greatly decrease suitable habitat, predator densities, and salmonids in their diet, a conclusion supported by both experimental evidence, and comparisons between free-flowing and reservoir predator densities and diets (Brown and Moyle 1981, Buchanan et al. 1980, 1981, Mesa and Olson 1993, Poe et al. 1993, Shively et al. 1996, McMichael 2018). Moreover, the assumption that hatchery mitigation would end with dam removal is simply that, an assumption. It is not a necessary outcome. In fact, it is more likely that mitigation hatcheries would continue for a significant amount of time until the populations actually stabilize and abundance levels reach those required by various mitigation agreements and laws. The disparity of results between CSS and COMPASS/LCM for the PA, appears also to be related to the assumptions that NMFS makes for reductions in latent (delayed mortality). Again, LCM/COMPASS results are driven by sensitivities for their assumed, best-guess latent mortality 29 reduction levels. It is worth nothing that, even so, the LCM/COMPASS Snake River spring/summer Chinook results for the PA does not come close to achieving the minimum 2% SAR goal, and in fact are below 1% for all the assumptions except that for a 50% reduction in latent mortality (1.15% SAR). This translates into the LCM/COMPASS model predicting that a majority of SARs under the PA will be well below 1%, indicating very large risk of further population decline from present depressed levels. These PA SAR results are not consistent with avoiding jeopardy or recovery, let alone achieving broad scale recovery for Snake River spring/summer Chinook populations. The CSS model predicts a higher median SAR (2.7%) for the PA; however a considerable percentage of the CSS predicted SARs for the PA (about 40%) were also well below 1%, indicating a much greater risk of further population decline (McCann et al. 2019, Chapter2). The DEIS Chapter 3 presentation of model results further obscures the poor performance of the PA because it does not capture the probability of achieving various levels of SAR for the different alternatives. The CSS results submitted to the DEIS process for options MO1, MO2, MO3, MO4 and MO34 included the probabilities of SARs less than 1% and greater than 2% for SR spring/summer Chinook and steelhead. These important probability summaries (generated in the CSS analysis) were not captured in the Chapter 3 results, rendering the reported results of a single point estimate for SARs meaningless in assessing the risks posed by the various alternatives (this is particularly alarming considering the potential uncertainties associated with a highly parameterized COMPASS model and the uncertainty that would, consequently, be propagated through the LCM SAR predictions). A search of DEIS Appendix E and Appendix V for SAR probability distributions of modeling results from LCM/COMPASS yielded nothing. More importantly, the assessment does not include or consider the probability distribution of 30 SARs for the different alternatives in the Executive Summary or in the main body of the Chapter 3 of the DEIS. Omitting the relevant indicators of uncertainty for model projections renders the DEIS presentation materially incomplete and presents a flawed assessment of the risk for the alternatives. CSS analysis has found that Chinook SARs less than 1% consistently led to decreased abundance the following generation (CSS 2017). Low abundance and critically low SARs (low productivity) equals an extremely high-risk situation for these ESA listed populations (McElhany et al. 2000; ICTRT 2007). CSS analysis has found that SARs greater than 2% generally allowed at least some level of generational increase in abundance of Chinook populations. The DEIS in chapter 3 states that the essential differences in the models involves how they express the effect of freshwater passage experience on ocean mortality. Again, the DEIS attributes the differences between CSS and NOAAs LCM results to different assumptions about hydrosystem latent mortality and, for reasons stated above, this is not accurate. The DEIS (DEIS Chapter 3 pages 361-362; DEIS Appendix V sections 3 on Latent Mortality) at states that [B]oth modeling groups continue to develop their models to address the ISABs ongoing questions surrounding the magnitude and the causal mechanisms associated with latent mortality through the hydrosystem. The CSS continues to analyze and report each year on patterns in overall SARs. NMFS has recently focused on the ISABs questions on the condition of fish using the powerhouse (more specifically the bypass systems). Their most recent publication (Faulkner et al. 2019) demonstrated size selective tendencies at many of the bypass systems in the CRS which would potentially reduce the benefit of increased spillway passage shown by the CSS model. The claim that these lower SARs are driven by fish size, not powerhouse passage, because more smaller fish pass through powerhouses and smaller fish suffer higher mortality in the ocean (Faulkner et al. 2019) is not accurate and does not address available and credible criticism of the paper on which it is based. What the Faulkner analysis does not show is whether SARs for larger fish that pass through the powerhouses are nonetheless still lower than larger 31 fish that pass via spill. Without this critical data and comparison,	of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effectively increased spill can increase salmon and steelhead returns to the Columbia Basin. Moreover, the EIS includes analysis of the climate change impacts to anadromous fish in Chapters 4 and 7.

				the Faulkner analysis cannot support its conclusion about the role of fish size in dam passage survival. As explained further in the introductory comments, the recent paper by Faulkner et al. (2019) does not weaken the weight of evidence for hydrosystem delayed mortality because of the serious scientific flaws in that paper identified by the Fish Passage Center in their review of it (CSS 2019 Appendix G; 2019 FPC Memorandum 49-19 reviewing Faulkner et al. 2019). In short, the DEIS presents a one-sided and incomplete assessment of the two models used in it. In the Executive Summary of the DEIS (DEIS Exec. Sum., pages12-13) there is detailed criticism, and a call for future evaluation to test the validity, of the CSS model (criticism that is erroneous - see explanation above). There is, however, no criticism, or call for future evaluation, of the NOAA COMPAS/LCM modeling system despite its recognized short comings. This one-sided approach demonstrates an unexplained disparity of standards applied in the DEIS environmental assessment by the Action Agencies. The DEIS appears to pick and choose different model analyses to support or reject different alternatives rather than apply the modeled results consistently across the alternatives. In the case of the PA the COMPASS/LCM SAR results woefully underperform and indicate the PA poses a high likelihood of continued decline for the Snake River spring/summer Chinook. However, the DEIS states According to the CCS model, Snake River Chinook and steelhead are expected to see relative improvements in SARs of 35 and 28 percent respectively. Also for the PA, the DEIS does not focus on the disparity of delayed mortality treatment between the models as an essential concern. By contrast the DEIS states that Model estimates for MO3 showed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the alternatives, but goes on to say that [q]uantitative model results from both the CSS 32 and LCM were available and indicated a range of potential long-term benefits largely due to how the models address latent mortality, the delayed death of salmon following passage through the CRS. (emphasis added) The DEIS thus discounts results from the CSS analysis for MO3 based on the agencies stated concern over how latent mortality is addressed and favors the lower results for MO3 from the LCM model analyses to conclude that the benefits of MO3 to salmon survival will be modest. Picking and choosing different model results to support or discount an alternative is inconsistent with standard risk assessment. In addition, future climate conditions are widely expected to be warmer and more variable, and there is strong evidence for similar change in ocean conditions (Lijing et al. 2019). Neither CSS nor LCM fully incorporate the effects of expected climate change as both use past observations and the historical 80-year water record. Even so, the low end of the CSS model projections (probability of SARs less than 1%) are likely to be the most realistic metric for comparing the effects of the alternatives on salmon and steelhead under future climate conditions. The LCM results do not address this important issue and the DEIS does not acknowledge, let alone apply a precautionary approach (or explain why it chose not to) to using the CSS model results, especially since it fails to present modeled probabilities at all (in DEIS Executive Summary or Chapter 3 model results).	
6110	9	ttrue@earthjustice.org	Earthjustice	V. THE AGENCIES FAIL TO ANALYZE WHETHER ANY ALTERNATIVE WILL BENEFIT SALMON IN A WARMING WORLD. The agencies analyze the impact of the four multiple objective alternatives in Chapter 3. Climate change forms no part of this base analysis. See DEIS 4-1 (noting that the effects analysis in Chapter 3 is based on observed climate in the region over the 80-year period of 1929 to 2008). The agencies then tack on a separate chapter (Chapter 4) that discusses climate change generally. But Chapter 4 fails to offer a meaningful analysis of the effects of the various 33 alternatives in a warming world. Chapter 7, the chapter that discusses the preferred alternative (PA), takes the same approach. First, the agencies describe some of the effects of the PA then include a separate section on climate change without incorporating the additional adverse effects from climate change into their assessment of the effects of the PA. For example, the agencies acknowledge that a warming climate could cause moderate to severe declines in salmon and steelhead populations. DEIS 4-33. And they acknowledge that for each of the multiple objective alternatives, climate change will likely reduce the benefits and increase adverse effects to salmonids from the alternatives. DEIS 4-37 to 38. But nowhere do they discuss the magnitude or specifics of any of these effects nor whether they still expect the alternatives to meet the objective of improving conditions for juvenile and adult salmonids or to what extent. For the preferred alternative, the agencies conclude that it will improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival and improve ESA-listed anadromous salmonid adult fish migration. DEIS 7-17. The agencies characterize the improvements for juveniles as minor to moderate and for adults as minor to major. DEIS 7-17. These assessments are based on the effects of the PA without incorporating climate change. Nowhere do the agencies discuss whether it will still provide any benefit to salmon, or the extent of that benefit, once the impacts of climate are accounted for. Instead they offer a cursory nod to the effects of climate change in a single paragraph that neglects to even mention many of its likely effects. The entire analysis of how climate will change the effects of the preferred alternative to anadromous fish is a single paragraph. It provides: Because temperature is such a critical factor to anadromous fish habitat, increases in stream temperature due to increased air temperature and changes in hydrology, including declining snowpack, could further impact fish in all regions. Increased water temperatures could also increase suitable habitat for invasive species (e.g., 34 shad and small mouth bass) that could have adverse impacts to native anadromous fish. Positive effects for anadromous species in this Preferred Alternative could be offset by adverse effects from changes in flow and increased stream temperature due to climate change. DEIS 7-201. This leaves the public with no idea as to whether the preferred alternative or any other alternative is likely to improve conditions for fish, let alone the extent to which that may occur. Climate change is not a hypothetical add-onit is indisputably a part of the landscape now and in the future. The agencies conclusion that certain alternatives would improve conditions for anadromous fish in the absence of climate change is meaninglessthat is not the world we live in. The agencies must analyze how the alternatives will perform in light of reasonable and available information about climate impacts over different periods of time. For example, the agencies analysis could include a minimal, moderate, and high warming scenario over a 30, 50 and 100 year period. This discussion should include an explanation of the effects on anadromous fish and other resources that is sufficiently detailed to allow a meaningful evaluation of the results of the alternatives in a climate change world. The agencies also must analyze the likelihood that each alternative will lead to recovery in a broad sense in the real world, i.e., in a warming world. Currently the agencies have only considered whether the alternatives will improve conditions for salmon against the baseline of the no action alternative without consideration of climate change and without acknowledging that the no action alternative itself is illegal, and has failed to achieve significant population rebuilding or recovery for any species. Indeed, even with twenty years of effort pursuing the approach of the no action alternative, salmon and steelhead populations remain at dangerously low levels. 35 If the agencies had incorporated the effects of climate into their analysis of the alternatives, it would have shown that the no action alternative, MO1, MO2 and the preferred alternative will be even more likely to lead to the rapid extinction of many runs. A minor improvement that merely slows the rate of a baseline of decline towards extinction cannot meet the various statutory requirements the agencies must meet. The Fish Passage Center analysis of SARs under each alternative does not incorporate climate, because it is based on the CSS model that uses historical data. However, the model produces a range of likely SAR returns. Experts agree that it is reasonable to assume that SARs will be at the low end of the range predicted by the CSS model with the additional adverse effects of a warming world but because the DEIS does not present these probabilities at all or employ them in its analysis of effects their analysis lacks vital and relevant information.	The co-lead agencies have carefully and completely considered high-quality, current information concerning climate change, including the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. The analysis in Chapters 4 and 7 include quantitative climate change hydrologic data that is compared qualitatively with the effects from the alternative analysis. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, there are not existing, reliable models, at the appropriate resolution (river-scale vs. regional or global scale) at this time. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitatively assess potential effects to resources (described in Chapter 4). Regarding the comment that agencies "must analyze the likelihood that each alternative will lead to recovery", the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species.
6110	10	ttrue@earthjustice.org	Earthjustice	A. The DEIS omitted substantial and relevant information that would have provided a rational basis for assessing how the alternatives will perform in a warming world and the extent to which the proposed mitigation measures in the PA will or will not – actually alleviate both climate and hydrosystem impacts on salmon and steelhead. In the DEIS-4.2.3.5, the impacts of climate change on anadromous fish are briefly described. However, any formal evaluations, in both the mainstem and the tributaries, on the ability of the alternatives to meet any of the objectives for listed salmon and steelhead under a warmer future that is almost assured, appears to be absent. This absence is particularly disconcerting considering Crozier et al. (2019) found that several listed distinct population segments in the CRB were considered to have a very high (Snake River spring/summer Chinook and sockeye) or high (Snake River steelhead and fall Chinook, Upper Columbia River spring Chinook, Mid-Columbia River spring Chinook and steelhead) vulnerability to climate change. Under the assumption that the No Action Alternative largely continues to implement the measures of the RPA from the 2014 BiOp, especially for habitat actions, some of the survival 36 improvements from habitat restoration required to mitigate for the impacts of the FCRPS would come from restoration in the tributaries to improve spawning and rearing habitat for salmonids. The ability of these offsite mitigation actions to achieve this goal, under current and future conditions, should have been explicitly addressed in the DEIS but that analysis appears to be missing. The entire analysis of how climate will change the effects of the preferred alternative to anadromous fish is a single paragraph in the main DEIS. It provides: Because temperature is such a critical factor to anadromous fish habitat, increases in stream temperature due to increased air temperature and changes in hydrology, including declining snowpack, could further impact fish in all regions. Increased water temperatures could also increase suitable habitat for invasive species (e.g., shad and smallmouth bass) that could have adverse impacts to native anadromous fish. Positive effects for anadromous species in this Preferred Alternative could be offset by adverse effects from changes in flow and increased stream temperature due to climate change. DEIS 7-201. While not cited anywhere in the DEIS, even in the table of contents, except on pg. 8-1 (only to state a biological assessment has been provided to NMFS and USFWS); the Biological Assessment in Appendix V provides a bit more information on the conclusion that tributary habitat actions will still provide benefits in a warmer future. The reasoning for most of this is referenced in Appendix D of Appendix V, which references NMFS (2019) and RMJOC-II (2018), the latter of which was mainly used for mainstem flows and temperatures, rather than tributary evaluations. An	The agencies have evaluated climate change using high quality, current information. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The analysis in Chapter 4 includes quantitative climate change hydrologic data that is compared qualitatively with the effects from the alternative analysis. The RMJOC-II products available for the climate analysis included two 30-year epochs, the 2030s (2020-2049) and the 2070s (2060-2089). RMJOC-II Part 2 was not finalized at the time of this analysis. The co-lead agencies expect this study to be published in summer of 2020. The conclusions described in Section 4.2 of this study were evaluated with the preliminary outputs and draft conclusions of RMJOC-II Part 2 and were determined to be consistent, and thus not need updating. The climate science community is still developing quantitative models that can address possible effects on water temperature from climate change, and unfortunately, there are not reliable models at the appropriate resolution (river-scale vs. regional or global scale) at this time. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitatively assess potential effects to resources (described in Chapter 4). The co-lead agencies disagree that the absence of modeling of climate change effects on tributary stream temperatures across the Columbia River Basin is an unexplained and important omission in the Draft EIS. The climate change analysis in the Draft EIS provides an objectively reasonable assessment of likely climate change effects throughout the environment affected by operation of the Columbia River System. The co-lead agencies also disagree with the suggestion that they are obligated to mitigate the effects of climate change, but agree that climate change is an important consideration in the selection and design of habitat improvement projects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				unexplained and important omission in the DEIS is the effects of climate change on tributary stream temperatures and the effects this has on the effectiveness of hydrosystem offsite habitat mitigation to improve overall salmon survival under a warmer regime. Among the conditions that may affect the results of these mitigation measures is the loss of suitable natal 37 habitat in low-altitude watersheds (generally below 4000 ft mean sea level), while higher altitude natal habitats remain cool enough to support healthy anadromous fish. Here we demonstrate that much information and analysis exists that could be have been used in the DEIS but was not to evaluate how climate change will impact the spawning and rearing habitat of these species as well as the population responses across all actions. Several empirical temperature models are available to evaluate the effects of increase in air temperature on instream temperature and flows under future scenarios that can be used to inform the DEIS (Whited et al. 2012, Klos et al. 2014, Isaak et al. 2017). The NorWeST database, for example, was created to house temperature data from more than 22,000 sites across the west (Isaak et al. 2017). Spatial stream network autocorrelative relationships between multiple temperature logger data have been used to create continuous models of stream temperatures. These models have been used to evaluate changes to stream temperature under different global climate model future predictions for over 340,000 km of stream. Several mechanistic temperature models also exist (Boyd and Kasper 2003, Baker and Bonar 2019) with HeatSource perhaps one of the most comprehensive. It has been used to model longitudinal stream temperature profiles in several streams (Butcher et al. 2010, Bond et al. 2015, Justice et al. 2017). Because of the mechanistic nature of this model, the ability to extrapolate temperature effects across different alternative restoration and climate scenarios is more robust than empirical temperature models. The model is first calibrated, often to thermal infrared data, to provide a longitudinal temperature profile throughout the stream. Once validated, variables in the model can take on different values relevant to the scenarios to be modeled. For example, change in shading due to riparian vegetation, water withdrawals, channel morphology, decreased flows and increase air temperature can be adjusted to represent 38 alternative restoration actions and climate change scenarios (Justice et al. 2017, Wondzell et al. 2019). These temperature models can be used in the evaluation of expected changes due to restoration and under warming conditions on fish habitat, and ultimately on fish populations, as should be done in the DEIS to determine if off-site mitigation will help offset hydrosystem mortality under warming conditions. Isaak et. al. (2018) confirms that although water temperatures throughout the Snake/Columbia basin have increased in recent decades, particularly in late summer and early fall, the high tributaries of the Snake Basin remain cool, providing healthy, cool-water natal habitat for salmonids. Further, under continued warming trends of 1, 2, and 3 degrees C, the study shows that uppermost Snake Basin natal habitat, much of it in central Idaho, will remain cool - healthy spawning and nursery habitat for salmonids (e.g. Figure 1). In Appendix V, Beechie et al. (2013) is referenced as a means to prioritize restoration to prepare for more resilient habitat in a warming future, using similar maps for changes in temperature and flows. This is an important step if actually used, but the main point of Beechie et al. (2013) is for restoration to mitigate the impacts of climate change, not the hydrosystem plus climate change as the DEIS apparently assumes. [Remainder of page left intentionally blank.] 39 Figure 1: Mean August river temperatures for A) 19932011 baseline scenario thermal suitability for salmonids and B) +3.0 C scenario thermal suitability. Mean August river temperature scenarios classified by thermal suitability for brown trout and rainbow trout. From Isaak et al. (2018). Justice et al. (2017) provides an example of how HeatSource can be used with data on Chinook and their habitat to evaluate potential restoration benefits in the upper Grande Ronde A: B: +3.0 C 40 River and Catherine Creek, for spring/summer Chinook populations of the Grand Ronde/Imnaha MPG, and the Snake River ESU. The inputs to the HeatSource model included topography from LiDAR, local climate data, streamflow, and water temperature data from thermographs. The model was used to evaluate restored riparian vegetation (which included modeling plant growth after planting), channel morphology, and moderate climate change predictions on the longitudinal stream temperature relative to current conditions. They found a warmer future climate increased weekly maximum temperatures above lethal limits across most of the upper Grande Ronde by raising stream temperatures by 2.7 C (Figure 2). Restoring riparian vegetation to historic natural levels could decrease stream temperatures by 5.5 C, but under climate change this was reduced to an average decrease of 1.9 C, and for over half the stream length this change was equal or greater than current stream temperatures (Figure 1). Decreasing the stream width and restoring vegetation resulted in an average decrease of 3.5 C under the climate change scenario but again, over a third of the stream was similar or warmer than current conditions. As the authors acknowledged, the restoration scenario was unrealistically optimistic in assuming that the entire riparian zone was immediately replanted at pre-European densities and the plantings survived across the entire stream length. Similarly, decreases in stream width occurred immediately at very high levels due to restoration. Restrictions by private landowners, grazing by domestic and wild ungulates, and imperfect survival of plantings are likely to greatly reduce the success of these restoration efforts. Although assuming restoration will happen immediately is unrealistic and unlikely, the delayed impacts plus the required tree growth is on a similar time frame as the simulated climate scenarios (i.e. 2080 air temperatures). The planned restoration in the DEIS, even if successful, would do far less than restore conditions to pre 41 European levels and so is much less than that assessed in restoration scenarios, with 140 acres of riparian restoration expanding to 420 acres, stream complexity restoration is 8 miles and 24 by 2026 and 2036, respectively (Table D.2 and D.3, Appendix V, DEIS). In summary, the planned restoration efforts, while vital to maintain a habitable environment, may not even mitigate for climate change alone, especially at the levels planned for in the DEIS, leaving no additional benefits that might help mitigate for the impacts of the hydrosystem. Figure 2. Simulated maximum weekly maximum water temperature (MWMT) in the mainstem Grande Ronde River from the headwaters to the Catherine Creek confluence for four model scenarios including current conditions, 2080s climate conditions, 2080s climate conditions plus riparian vegetation restoration, and 2080s climate conditions plus riparian vegetation and channel-width restoration. From Justice et al. (2017). This exercise by Justice et al. (2017) in examining habitat restoration has been put into a population context in two life-cycle modeling efforts by Pess and Jordan (2019) and Weber et al. (2018). DEIS Appendix D of Appendix V references NMFS (2019), which references Pess and Jordan (2019), as to how to habitat actions can be incorporated into life-cycle models. Pess and Jordan (2019) coupled Zabel et al. (2006; which is the original basis for the COMPASS model) 42 to evaluate the multiple proposed actions outside the spawning and rearing habitat, with the results from Justice et al. (2017) and White et al. (2018) to incorporate tributary habitat restoration, on spring/summer Chinook populations in Catherine Creek and the upper Grande Ronde. Climate change scenarios were reportedly being developed but were not yet available. It is not clear why this work could not be completed or used in any way. The second life-cycle model effort by Weber et al. (2018), evaluates these habitat actions plus climate change impacts, but uses LGD-spawning ground SARs 1992-2011 rather than trying to model multiple hydrosystem configurations. Here we briefly describe, compare, and contrast those two efforts to demonstrate the impact climate change has on restoration efforts. Pess and Jordan (2019) modeled the expected habitat and mainstem actions, supplementation, and harvest schedules plus different assumptions of latent mortality differences between baseline and the preferred actions benefits to Chinook populations. For Catherine Creek, projected to 24 years under the proposed 2020 habitat actions and hydrosystem configuration (i.e. similar to the proposed action), the median quasi-extinction risk (QER; defined as <50 spawners in 4 consecutive years) was >5% (6-12%; assumed acceptable probability of extinction threshold is <5%) unless hydrosystem latent mortality 2 was reduced 50% or more from the baseline level (median QER of 2.8%) (Table 1). Most other combinations of assumptions in the modeled alternative had extinction probabilities <5%. Grande Ronde, however, had very high median extinction probabilities (often >90%) in all modeled scenarios 2 From NFMS (2019; 2.11 pg 496) : The NWFSC also considered three latent mortality reduction scenarios that were deemed to roughly represent the ranges of potential outcomes (increased productivity) indicated by the CSS (2017) for the up to 120 percent flexible spill operation compared to recent or biological opinion spill operations: 10 percent (1.10 multiplier), 25 percent (1.25 multiplier), and 50 percent (1.50 multiplier). Also see DEIS Appendix V 3-13 for more information on the definition of latent mortality. The lack of any rational basis for these assumptions regarding levels of latent mortality is addressed in the discussion of the LCM and CSS models elsewhere in these comments. 43 that encompass the DEIS PA (Table 2). Longer-term benefits (e.g. beyond those considered in the DEIS), suggested that if all actions were implemented, realized, and maintained (before the population went extinct), recovery was likely. But, significantly, Pess and Jordan (2019) did not model impacts due to climate change in these scenarios. Weber et al. (2018) modeled the basic scenarios presented in the Justice et al. (2017), but simply used actual SARs over the past 20 years, rather than evaluating alternative hydrosystem configurations for these two populations. This model was simplified to mainly demonstrate how different habitat restoration and climate change scenarios influenced model predictions. They also ran scenarios that assumed supplementation did not happen in perpetuity but ceased after 40 years. Because of the different timeframes and a few assumptions along with added stochasticity the two model produced slightly different numbers of spawners under current (baseline) conditions with median estimates of 48 and 265 in Weber et al. (2018; Table 3), and of 57 and 140 in Pess and Jordan (2019; Tables 1&2), for Grande Ronde and Catherine Creek, respectively. [Remainder of page left intentionally blank.] 44 Table 1. Projected 24-year natural abundance and quasi-extinction risks for alternative habitat restoration scenarios (5, 25, 50, 75, and 95 percentiles over 500 simulations) for the Catherine Creek population. 2018 Baseline scenario includes increased Lower Columbia predation rates, ongoing hatchery supplementation, and current mainstem harvest schedule. Habitat action scenarios are modeled under current (2018) proposed hydrosystem spill operations constrained by 120% gas cap. Habitat scenarios: 2020: 201820 actions at minimum annual rate; 2024: current Grande Ronde Model Watershed proposed 201924 actions; LT (long-term) Habitat Actions: 20-year implementation of high/moderate-priority reaches	

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				plus recovery plan actions; LT + DS (downstream survival) Habitat Actions: LT Habitat Actions plus improved valley outmigration survivals. From Pess and Jordan (2019). 45 Table 2. Projected 24-year natural abundance and quasi-extinction risks for alternative habitat restoration scenarios (5, 25, 50, 75, and 95 percentiles over 500 simulations) for the Upper Grande Ronde River population. 2018 Baseline scenario includes increased Lower Columbia predation rates, ongoing hatchery supplementation, and current mainstem harvest schedule. Habitat action scenarios are modeled under current (2018) proposed hydrosystem spill operations constrained by 120% gas cap. Habitat scenarios: 2020: 201820 actions at minimum annual rate; 2024: current Grande Ronde Model Watershed proposed 201924 actions; LT (long-term) Habitat Actions: 20-year implementation of high/moderate-priority reaches plus recovery plan actions; LT + DS (downstream survival) Habitat Actions: LT Habitat Actions plus improved valley outmigration survivals. From Pess and Jordan (2019). 46 Table 3. Median population size and quasi extinction risk (pQER) of natural origin spawning Chinook in the Upper Grande Ronde (UGR) and Catherine Creek (CC) for 500 model iterations of restoration scenarios over 50 yrs. Curr is the baseline model calibrated using 2010 temperature, climate, vegetation, and hydrologic conditions, Clim is air temperature and streamflow set to 2080s climate projections, ClimVeg adds vegetation set to potential cover and height at 75 years, and ClimVegWid adds channel width set to historic conditions. While Weber et al. (2018) demonstrated that continuation of the current hatchery supplementation may be crucial for the Grande Ronde population, a perhaps unsurprising outcome, the Catherine Creek population went extinct without aggressive habitat restoration. The differences between the current and climate-change-only scenario, suggests that increased temperatures resulted in 36-50% lower projections of returning spawners. Assuming climate scenarios would have a similar impact to Pess and Jordan (2019) predictions, these results highlight the need to actually incorporate climate change projections into the analysis in the DEIS in order to adequately and rationally evaluate the effects of the different alternatives. We use the Grande Ronde/Catherine Creek fish, considered data-rich populations in the Snake River ESU, as examples to demonstrate that a life-cycle modeling approach that includes evaluating feasible habitat restoration actions meant to mitigate for some of the hydrosystem mortality (assumed in several of the alternatives considered in DEIS) have been developed but are not presented in the DEIS. We also demonstrate methods exist to predict the impacts climate change has on stream temperature – a massively important variable describing habitat suitability Current Supplementation Cease Supplementation Pop Scenario Median natural spawners Median natural spawners pQER UGR Curr 48 16 0.972 Clim 24 5 1 ClimVeg 72 33 0.872 ClimVegWid 89 42 0.784 CC Curr 265 186 0.032 Clim 169 121 0.118 ClimVeg 316 223 0.004 ClimVegWid 346 261 0.01 47 for cold water species such as salmon and steelhead. But both the changes in stream temperature (from climate impacts) and subsequent population responses have not been included in the DEIS, even though spawning and rearing habitat restoration was recommended as a major hydrosystem mitigation tool over 20 years ago by NMFS (2000) and the courts have identified the need to account for climate impacts on these actions if they are to be considered rationally as mitigation for hydrosystem impacts. We provide evidence that these restoration activities are critical but that they will mainly mitigate for a changing climate leaving little scope for these actions to contribute to mitigation of the hydrosystem, a main strategy assumed in the DEIS preferred alternative. The results of Weber et al. (2018) are similar to Battin et al. (2007) that used a similar life-cycle model approach to evaluate moderate and full habitat restoration to recover Snohomish ocean-type (fall) Chinook. They found restoration could not even mitigate for a changing climate unless full restoration was implemented under a more optimistic climate projection. Although not modeled, they expect these conclusions would be even more dire for spring Chinook that rear in freshwater for a year. The approach considered here is far from conservative, and may not include additional factors identified in the DEIS Appendix D (3-31) of Appendix V that may affect the effectiveness of habitat restoration in a climate changed world, such as: projected warmer stream temperatures could increase pre-spawning mortality and cause a decrease in growth, development rates, and disease resistance; changes in flow regimes (projected larger winter floods and lower flows in the summer and fall) could reduce overwintering habitat for juveniles, reduce egg and juvenile survival, reduce spawning habitat access/availability, and alter spawning run timing, timing of smolt migration may change due to a modified timing of the spring freshet; changing ocean conditions and marine food webs could affect ocean survival and growth; 48 projected sea level rise could cause significant reductions in rearing habitat in some Pacific Northwest coastal areas. There is available and credible scientific information the agencies could have used to address some or all of these topics (Crozier 2016, Beechie et al. 2013,Isaak et al. 2018), but they did not do so, and did not explain their choice to disregard these issues. McCullough (1999), for example provides an in-depth synthesis of the effects of temperature on the prevalence of disease growth, survival and behavior across all life-stages of Chinook. Further review across the life-history for interior Columbia River Chinook and sockeye populations can be found in Crozier et al. (2008) with relevant references summarized in Table 1. References addressing the influence of climate and temperature on some of the specific topics include: prespawning mortality and adult upstream migration timing (Rand et al. 2006, Keefer et al. 2009, Crozier et al. 2011), egg survival and development (McCullough 1999), disease susceptibility (McCullough 1999), smolt migration timing and estuary nursery habitat (Munsch et al. 2019), juvenile habitat availability and survival (Crozier and Zabel 2006), ocean conditions and survival (Petrosky and Schaller 2010). These additional issues add doubt to the ability to meet DEIS objectives with the PA and are relevant factors that the DEIS does not consider when evaluating the alternatives. Additionally, given the increased importance of higher altitude natal habitats in upper tributaries (Battin et al. 2007, Isaak et al. 2018), the PA does not address or explain why it substantially underemphasizes the value of improved SARs for Snake River stocks. The DEIS has failed to address this factor rationally in the evaluation of the various alternatives, notably deficient in the PA. SARs below 2% reveal a population that is declining and cannot be sustained. The NPCC (2014) Fish and Wildlife Program objectives include achieving SARs averaging 4% and ranging from 2%-6% on a sustained basis for the rebuilding of listed Snake 49 and upper Columbia salmon and steelhead abundance. SARs measured at Lower Granite Dam (LGR) are most relevant to escapement objectives and ESA population abundance criteria. Wild Snake River spring/summer Chinook SARs (measured at LGR) averaged only 0.8% from 1994 2017; while wild steelhead SARs have averaged 1.4% (CSS 2019). SARs less than 1% have consistently resulted in population decline from one generation to the next for Snake River spring/summer Chinook and steelhead in recent years (CSS 2017, Petrosky et al. in press). SARs averaging 4% or greater would increase the number of returning adults to this best-remaining cold-water natal habitat, potentially protecting salmon basin-wide as climate change continues. The agencies have also failed to analyze the effects of dam breach (MO3) and other alternatives on species-level climate resilience. The agencies acknowledge that breaching the Lower Snake River dams will allow salmon populations from the Snake River Basin system to increase and achieve sustainable SAR levels far more often than other alternatives including the PA. But they fail to consider that dam breach also allows more fish to access the coldest-water habitat remaining in a warming world. Some areas where water is already too warm may not be able to support substantial populations in the future. Decreases in these runs could be offset by increases in runs that rely on the coldest-water habitat. Increasing Snake River runs now will provide salmon with a buffer against the adverse effects of the warming to come. The PA is unlikely to do that.	
6110	11	ttrue@earthjustice.org	Earthjustice	B. The agencies do not explain why they consider climate impacts over only 25 years but consider other impacts over 50 years, especially in light of the evidence available to consider climate impacts at least 50 years out. The agencies define the temporal scope of the EIS as 25 years, except socioeconomic impacts (such as power costs and navigation costs) which inexplicably are analyzed over a 50 year period. DEIS ES-8. For climate, the agencies use the 25-year scope. DEIS 4-1. 50 We know that our climate will continue to warm for decades into the future, even if global greenhouse gas emissions ceased tomorrow. In order to present a rational analysis of the effects of the alternatives, the agencies must consider climate impacts on a longer time horizon at least the 50-year time line used for economic impacts, if not longer to understand whether measures taken today will help recover salmonids over time. All alternatives incorporate a set of mitigation measures from the no action alternative. DEIS 5-5 to 5-13. These include habitat measures that will not begin to benefit salmon for many years. As discussed in more detail above, the agencies cannot rationally conclude that these measures will provide any benefit without incorporating the long-term impacts of climate into their assessment of effects. Habitat restoration in a tributary that will be too warm to support salmon by the time the restoration is complete provides no benefit at all. The underlying studies the agencies use to predict climate conditions 25 years out are studies that include detailed information on climate impacts in the Pacific Northwest over a longer time horizon. DEIS 4-1. For example, they include a graph showing the anticipated range of warming in the Pacific Northwest through the end of the century, DEIS 4-3, which shows a dramatic increase in average daily air temperatures in the Columbia River Basin. They also include estimates showing decreasing snowpack through the 2080s. DEIS 4-5. But the agencies fail to consider the consequences of climate change beyond the 2030s in their analysis of effects and they never connect these effects over a limited period of time to their assessment of the results for the alternatives they consider. The agencies have the information for a more complete assessment at their fingertips. There is no rational reason to ignore it. The inherent uncertainty in predicting climate effects 50 years out is no excuse to ignore those effects. The agencies can and should analyze effects under mild, moderate, and severe warming scenarios. The agencies chose to analyze economic impacts 50 years out, while 51 admitting that many impacts are very difficult to predict over that time horizon for example, the agencies acknowledge that rate impacts are difficult to predict beyond 20 years, but include them all the same. Uncertainly is no excuse to ignore the long-term effects of climate change, particularly when it is certain that the adverse effects of climate change will worsen over that time horizon.	The co-lead agencies explained in various resource sections in Chapters 3 and 4 their reasoning for the time horizons of the impact assessments. In particular, a 50-year horizon was necessary to capture the socioeconomic and other impacts of the major infrastructure measures, including breaching the four lower Snake River dams in Multiple Objective 3 (MO3). Regarding climate change, climate analyses typically rely on statistical composites of discrete periods to describe future conditions. The RMJOC-II products available for the climate analysis included two 30-year epochs, the 2030s (2020-2049) and the 2070s (2060-2089). The CRSO EIS climate analysis used the 2030s 30-year time horizon (2020-2049). The later epoch (2070s) was not used as it was outside the horizon typically considered in NEPA analyses. The co-lead agencies disagree with the claim that they cannot rationally conclude that [mitigation] measures will provide any benefit without incorporating the long-term impacts of climate into their assessment of effects. Mitigation measures are targeted to known limiting factors that will persist, and in many cases worsen, in a changing climate. Moreover, attempting to define the specific effects of climate change on a particular location at a particular point in time, let alone on the aquatic species reliant on that stream for habitat, and in turn the effectiveness of potential habitat improvement actions, would be too speculative to support reasoned decision-making.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6110	12	ttrue@earthjustice.org	Earthjustice	C. The DEIS does not evaluate how the alternatives it considers will be affected by climate change. The preferred alternative includes virtually no new measures to mitigate for the enormous impacts it will have on salmonids. It includes no mitigation at all to compensate for the additional adverse effects of climate change. The mitigation measures for the preferred alternative include a list of previous commitments that are carried forward into the preferred alternative. DEIS 7-38 to 7-43. See also DEIS 5-5 to 5-13. These are all the same actions the agencies have been taking for years, without recovering a single run. In fact, they are a continuation of actions the courts have concluded are not even sufficient to avoid jeopardy under the ESA, partly because they do not take climate impacts into account. The agencies also propose several additional mitigation measures in conjunction with the preferred alternative. DEIS 7-44 to 7-45. Many of these have nothing to do with salmon. There simply are no additional mitigation measures to offset the additional adverse effects of climate. The agencies briefly mention that some of the measures they have been working on for years, such as habitat restoration and connectivity, will help address the effects of climate change. DEIS 5-7. But the agencies are already relying on these mitigation measures to compensate for the devastating effects of the hydrosystem on listed salmon. To provide a buffer against the adverse effects of climate change, the agencies will need to include mitigation above and beyond the mitigation necessary to offset the harm from the operation of the dams. The 52 agencies acknowledge that a warming climate could cause moderate to severe declines in salmon and steelhead populations. DEIS 4-33. The agencies must analyze and include substantial additional mitigation measures to offset these moderate to severe declines. The also agencies do not include any evaluation of the effects of the alternatives on salmon and steelhead habitat above the dams in their analysis of the effects of the CRSO. But even if the dams dont change areas above them directly, they have a major impact on how many fish make it to those tributaries. The agencies need to expand the action area to examine habitat above the dams, the effects of climate there and how these effects will affect salmon and steelhead in the future. In particular, the agencies must analyze the effects of dam breach (MO3) and other alternatives on species-level climate resilience. The agencies acknowledge that breaching the Lower Snake River dams will allow salmon populations from that river system to increase. But they fail to consider that dam breach allows more fish to access the coldest-water habitat in a warming world. Some areas where water is already too warm may not be able to support substantial populations in the future. Decreases in these runs could be offset by increases in runs that rely on the coldest-water habitat. Increasing Lower Snake River runs now will provide salmon with a buffer against the adverse effects of the warming to come.	The co-lead agencies have carefully considered high-quality, current information concerning climate change. The co-lead agencies disagree with the suggestions that they should mitigate the effects of climate change and are responsible for recovering salmon runs. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The agencies also disagree that the affected environment should be expanded to include habitat above the dams since the proper scope of the EIS is to evaluate the effects to resources affected by CRS operations, maintenance and configuration. To the extent that system operations affect salmonid abundance, those effects have been fully described in the No Action, Multiple Objective alternatives, and the Preferred Alternative.
6110	13	ttrue@earthjustice.org	Earthjustice	D. The DEIS fails to address the effects of the alternatives on water temperature, especially in the lower Snake River, rationally and objectively. As explained more completely in comments on the DEIS submitted by Columbia River Keeper, the DEIS fails to describe and disclose the effects of the alternatives, especially MO3, on water temperature in the lower Snake River and hence presents a misleading picture of the effects of MO3 on salmon and steelhead. Rather than repeat these comments here, we refer the agencies to them for a more complete description of the failures of the DEIS with respect to water temperature. Further, American Rivers has or will be submitting comments on the DEIS 53 that address the analysis of sediment impacts from MO3 which we also refer to here for a more complete description of this issue.	The EIS analysis for temperature was conducted using 1 and 2-dimensional water temperature models (CE-QUAL W2 and HEC-RAS) to predict impacts to water temperature from the EIS alternatives. These models went through extensive development and review, with guidance from many well-respected scientists in the region. The CE-QUAL-W2 model (Version 4.2) was used to simulate reservoir water temperature and Total Dissolved Gas (TDG) both by depth and distance longitudinally. The HEC-RAS model (Version 5.0.3) was used to simulate upstream and downstream river (non-reservoir) water temperatures in the Snake, Clearwater, and middle Columbia rivers. In the Snake River Basin, the system model (which refers to the portions of the study area that were analyzed with the CE-QUAL W2 and HEC-RAS models linked together) included the North Fork of the Clearwater River from Dworshak Reservoir, the mainstem Clearwater River downstream of Orofino, Idaho, and the Snake River from Anatone, Washington, to the mouth of the Snake River. The system model required reservoir and river operations data and meteorological data such as wind speed and direction, air temperature, and barometric pressure inputs to predict water quality conditions. The reservoir and river operations data used in the system model included total discharge, spillway and powerhouse operations, other discharge routes, and reservoir/tailwater elevation data. After running the system model, the simulated water temperature and TDG data were compared to state, Federal and Tribal temperature and TDG standards to quantify the effects associated with each alternative, including Multiple Objective 3 (MO3). As these models underwent extensive development and review from many scientists in the region, it is incorrect to suggest that the effects on water temperature were not evaluated rationally and objectively. As described in the Draft EIS, breaching the four lower Snake River dams under MO3 would produce a major change in the volume and the amount of heat stored (e.g., heat storage capacity) in the lower Snake River. Water temperatures would respond accordingly, shifting from a reservoir to river system, with rapid warming in the spring and cooling in the fall. The specific modeling results are presented in Section 3.4.3.6 and Appendix D. Both quantitative and qualitative assessment methods were used to assess relative potential changes to river mechanics (sediment transport and geomorphology) for each Multiple Objective alternative, including MO3. Seven quantitative metrics were developed to represent various physical characteristics and processes that could affect storage reservoirs, run-of-river reservoirs, and free-flowing reaches. These seven scalar metrics are derived as deterministic calculations based on the hydrologic and hydraulic numerical modeling (see Section 3.2.2.1) which established stochastic datasets that represent the system state of hydrology, hydroregulation, and riverine hydraulics. The quantitative metrics were interpreted within a subreach context to estimate qualitative trends for anticipated impacts at various locations within the study area. Additionally, for the Environmental Consequences assessment of the Breach Snake Embankments measure under MO3, a numerical mobile bed riverine hydraulic model was developed as described in Section 3.4 of Appendix C. Additional detail regarding the geomorphology and sediment transport metrics can be found in Appendix C. For each of the regions in the study area, sediment quality effects were evaluated qualitatively, using existing field data and information from past studies (white paper; i.e., CH9). There was no overall model describing sediment quality; however, sediment movement information from Section 3.3, River Mechanics, and the associated white paper; i.e., CH9 were used to inform the sediment quality analysis. For more information on these models and geomorphology and analysis, refer to Appendix D, Water and Sediment Quality Appendix, and Appendix C, River Mechanics Technical Appendix.
6110	14	ttrue@earthjustice.org	Earthjustice	They (and other groups, including Earthjustice) also reserve the right to submit additional comments on these and other issues after April 13, 2020, in light of the inadequate public comment period the agencies have provided for the CRSO DEIS.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6110	15	ttrue@earthjustice.org	Earthjustice	VI. THE DEIS FAILS TO ADDRESS RATIONALLY (OR AT ALL) THE EFFECTS OF OCEAN CONDITIONS ON THE PERFORMANCE OF THE ALTERNATIVES IT CONSIDERS The DEIS is woefully deficient in its consideration of the effects of climate change in the marine environment. In overturning the 2014 BiOp for making unexplained, and unjustifiable, optimistic assumptions about the impacts of climate change on salmon, the Court held that NOAA Fisheries had before it a significant amount of new scientific information on the effects of climate change but chose merely to recite some of the information . [and] failed properly to evaluate the degree to which climate change will cause added harm and and the efficacy of measures the federal agencies had hoped would mitigate the effects of the FCRPS. Natl. Wildlife Fedn. v. Natl. Marine Fisheries Serv., 184 F. Supp. 3d 861, 923 (D. Or. 2016). Rather than meaningfully incorporate climate change into its analyses, the DEIS continues and compounds the federal agencies past failures to account let alone mitigate for the profound effects of rapidly changing ocean conditions on salmon. As the action agencies and others are quick to highlight in other contexts, ocean conditions have a significant effect on salmon populations. But the DEIS contains almost no discussion of, and fails completely to analyze, the effects of rapidly warming oceans on salmon by themselves or in combination with other impacts. Indeed, the only discussion of this significant stressor is a single-page, general recitation of three changes that are likely to affect salmon from the impacts of climate change on the ocean ecosystem: reduced thermal habitat, ocean acidification, and changes in the estuary. 54 DEIS at 4-35 to 4-37 (noting that increased ocean temperatures will reduce salmon marine habitat, but dismissing effects as challenging to predict) (noting generally that ocean acidification will alter food webs and can interfere with salmons olfactory sense) (noting that changes in estuary habitat and salinity levels from sea-level rise and changes to the Columbia River plume could possibly influence survival). Generally recognizing these broad types of effects without analyzing how they affect salmon populations under each of the alternatives falls well short of satisfying NEPAs hard look requirement. Climate impacts are additive to the ongoing harm from FCRPS operations. The agencies must evaluate both the extent to which changing oceans conditions will further degrade the affected environment and associated salmon survival and whether and how its alternatives will ensure salmon survival in this worsening scenario. The DEIS does neither. This failure is not for lack of evidence. As with the freshwater impacts of climate change, there is a wealth of information forecasting the physical and biological impacts – including to salmon populations from the rapid warming of the California Current Ecosystem and the North Pacific Ocean. Ocean heat waves, like the warmwater blob that devastated the West Coast marine ecosystem from 2013-2015, are increasing in frequency, intensity, and duration. Oliver ECJ, Donat MG, Burrows MT, et al. Longer and more frequent marine heatwaves over the past century. Nat Commun. 2018;9(1):1324. Published 2018 Apr 10. doi:10.1038/s41467-018-03732-9; Di Lorenzo, E., and N. Mantua. 2016. Multi-year persistence of the 2014/15 North Pacific marine heatwave. Nature Clim. Change 6(11):1042-1047. Less acute long term temperature increases are shifting and shrinking the range of salmon populations and their prey, with more frequent disruptive transitions between El Nio and La Nia conditions (less time in neutral conditions 55 And ocean acidification is altering the assemblage and distribution of the organisms that form the base of the food web salmon rely upon. For example, while the DEIS briefly mentions that salmon ocean habitat is expected to contract, a 2011 study detailed a range of potential contractions of the ocean range for all species of salmon between now and 2080. Omar I. Abdul Aziz, Nathan J. Mantua, Katherine W. Myers, Potential climate change impacts on thermal habitats of Pacific salmon (Oncorhynchus spp.) in the North Pacific Ocean and adjacent seas, Canadian Journal of Fisheries and Aquatic Sciences, 2011, Vol. 68, No. 9 : pp. 1660-1680, https://doi.org/10.1139/f2011-079 (predicting contraction of Chinook ocean summer range up to 88% by 2080, contractions for other species of up to 50% beginning with contractions of 5-24% by the 2020s). See also Natl. Wildlife Fedn., 184 F. Supp. 3d at, 920-93 (discussing agencies failure to use this study in 2014 BiOp). A more recent study found that sea surface temperatures in the west coast California Current Ecosystem will rise 2C above the 1900-1975 baseline by 2025. Alexander, M. A et al. 2018. Projected sea surface temperatures over the 21st century: Changes in the mean, variability and extremes for large marine ecosystem regions of Northern Oceans. Elementa-Science of the Anthropocene 6 (available at https://www.elementascience.org/article/10.1525/elementa.191/). Even more recently, a climate change assessment of several populations of West Coast salmon, including several stocks for the Columbia River basin, summarized studies concerning marine climate change impacts and concluded that although we have highlighted risks in freshwater stages, these findings suggest that warmer oceans could be catastrophic for salmon populations throughout the California Current Ecosystem. Crozier LG, McClure MM, Beechie T, Bograd SJ, Boughton DA, Carr M, et al. (2019) Climate vulnerability assessment for Pacific salmon and steelhead in the California Current Large Marine Ecosystem. PLoS ONE 14(7): 56 e0217711.	The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NMFS and the Tribes. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such, two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. A number of metrics that monitor ocean temperature and productivity are reported annually and are used to predict salmon returns. These metrics can be seen at: https://www.nwfsc.noaa.gov/research/divisions/fe/estuarine/oeip/g-forecast.cfm.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				https://doi.org/10.1371/journal.pone.0217711 (available at https://journals.plos.org/plosone/article?id=10.1371/journal.pone.0217711). The agencies cannot rationally excuse their failure to consider this and other evidence described below because some of the projections in some of these analyses extend beyond the time frame of the DEIS. Even where this does occur, there is information in these studies that would allow the agencies to address ocean effects over shorter periods of time, including the 50 year time frame the DEIS uses for some issues and even the 25 year time frame it uses for others. See NWF v. NMFS, 184 F.Supp.2d at 918 (rejecting agencys attempt to consider post-2018 benefits of habitat actions in the basin, while ignoring post-2018 harm from climate change); id. at 919 (rejecting agencys disregard of the independent scientists critique because it looked too far in the future when agency had to consider future effects in making its jeopardy determination and some of the information concerned climate impacts in the 2020s). The DEIS does not even acknowledge these impacts from ocean warming and fails completely to consider these effects on salmon under any of the alternatives. The DEIS omits a significant body of scientific evidence detailing the effects of both the geophysical and biological effects of climate change in the ocean, including but not limited to: Impacts of Climate Change on Salmon of the Pacific Northwest A review of the scientific literature published in 2014 Lisa Crozier (Aug. 2015) (available at https://www.nwfsc.noaa.gov/assets/11/8473_07312017_171438_Crozier.2015-BiOpLit-Rev-Salmon-Climate-2014.pdf); Impacts of Climate Change on Salmon of the Pacific Northwest A review of the scientific literature published in 2015 Lisa Crozier (Oct. 2016) (available at https://www.nwfsc.noaa.gov/assets/4/9042_02102017_105951_Crozier.2016-BIOPLit-Rev-Salmon-Climate-Effects-2015.pdf); Impacts of Climate Change on Salmon of the Pacific Northwest A review of the scientific literature published in 2016 Lisa Crozier (July 2017) (available at https://www.nwfsc.noaa.gov/assets/11/8905_07312017_154234_Crozier.2017-BIOPLit-Rev-2016.pdf); 57 Impacts of Climate Change on Salmon of the Pacific Northwest A review of the scientific literature published in 2017 Lisa Crozier and Jared Siegel (July 2018) (available at https://www.nwfsc.noaa.gov/assets/11/9603_02272019_153600_Crozier.and.Siegel.2 018-Climate-Lit-Rev-2017.pdf); Beaugrand G, Conversi A, Chiba S, Edwards M, Fonda-Umani S, Greene C, et al. The agencies failure to use this and other up-to-date information and tools available to disclose and analyze the effects of the alternatives in the context of, and in combination with, warming oceans undermines the publics confidence in the EIS and renders it legally defective. Tribal Village of Akutan v. Hodel, 869 F.2d 1185, 1192 n.1 (9th Cir. 1989) (EIS which is incomplete due to the omission of ascertainable facts, or the inclusion of erroneous information, violates the disclosure requirement); Seattle Audubon Soc. v. Espy, 998 F.2d 699 (9th Cir. 1993) (agency cannot rely on stale science or ignore reputable scientific criticism); Coleman, 521 F.2d at 676 (rejecting agency position that uncertainty is grounds for not disclosing potential impacts). While perfect knowledge is not required, NEPA does require the agencies to address 60 currently available and credible information and actually use that information in its analysis of environmental impacts. The DEIS fails to either acknowledge or use available information on how reasonably foreseeable future ocean conditions with combine with other foreseeable effects to affect how the alternatives analyzed in the DEIS will perform.	
6110	16	ttrue@earthjustice.org	Earthjustice	VII. THE DEIS FAILS TO ADDRESS THE IMPACTS OF THE ALTERNATIVES ON SOUTHERN RESIDENT KILLER WHALES IN A COMPLETE OR RATIONAL WAY The Action Agencies (Agencies) scarcely mention the Southern Resident Killer Whales (SRKWs or Southern Residents) in the DEIS that purports to analyze the impacts of, and alternatives to, the Agencies Preferred Alternative for operation and maintenance of the Columbia River System (CRSO). With scant discussion, the Agencies dismiss impacts to this species from the CRSO as negligible or minor, and claim that the Preferred Alternative is not likely to adversely affect the southern resident killer whale population. DEIS 3-685; DEIS 7 153, Table 7-28. To the extent the Agencies offer support for their conclusions, they append the 2019 Columbia River System Biological Assessment (BA), which itself devotes roughly two and-a-half pages to assessing impacts on the SRKW. DEIS App. V; BA 3-598 to 3-600. The DEIS assessment of the CRSOs impacts is incomplete, inadequate, arbitrary and in some instances simply incorrect. Indeed, as the DEIS introduces the SRKWs in its description of the affected environment in Chapter 3, it provides an inaccurate and dated population count 78 individuals as of 2016 when the current census is decidedly more bleak: 73 whales as of December 31, 2019.3 DEIS 3-685. Whether the Agencies couldnt be bothered to provide the updated figure or sought to downplay the recent steep decline in the SRKW population it 3 Center for Whale Research, Population, updated as of Dec. 31, 2019 https://www.whaleresearch.com/orca-population (accessed April 3, 2020). 61 reflects, it is problematic that the DEIS assessment has at its foundation this incorrect and misleading statement.4 The DEIS fails to identify and consider the considerable body of available scientific evidence relevant to the CRSOs impacts on the SRKW. It also fails fully to evaluate interactions among the effects or to discuss meaningfully the cumulative impacts. As a consequence, its conclusion that the Preferred Alternative is not likely to adversely affect SRKW survival and recovery is not supported by the evidence and arbitrary. A. Background. The Southern Resident Killer Whales (Orcinus orca) is a population of the fish-eating ecotype of killer whales that is genetically distinct from and does not interbreed with other orca	For this EIS, the No Action Alternative describes the operation, maintenance, and configuration of the CRS, from September 30, 2016, the date the Notice of Intent to Prepare the CRSO EIS was published in the Federal Register. Therefore, the 2016 data was used for the reference conditions in the No Action Alternative. The Southern Resident killer whale (SRKW) population estimates of 73 individuals were updated in the Final EIS, from the 2019 census by Center for Whale Research (www.whaleresearch.com). The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				populations.5 SRKWs are keenly social, living in highly stable groupings, or pods, led by matriarchal females, and exhibiting advanced vocal communication and other social behaviors.6 Among the purposes of these communications, according to researchers, is transmission of the ecological knowledge that contributes to group survival, and it is the experienced post 4 In fact, the DEIS figure does not accurately match its cited sources census data for any recent year, and the date in the text (2016) does not match the date given for this source in the DEIS citations, which is Nov. 12, 2018. DEIS 11-9. According to the Center for Whale Research, there were 83 whales in 2016, and then a steep drop to 77 whales in 2017, a continued decline to 75 whales in 2018, and another slide to 73 whales as of the more recent 2019 figures. Center for Whale Research, Population, updated as of Dec. 31, 2019 https://www.whaleresearch.com/orca-population (accessed April 3, 2020). 5 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries Service 5 (Sept. 2019)[hereinafter NMFS CH Biological Report (2019)]; A. Rus Hoelzel, et al., Evolution of a Population Structure in a Highly Social Top Predator, the Killer Whale, 24 Molecular Biology and Evolution 1407 (2007); Andrew N. Foote, et al., Genome-Culture Evolution Promotes Rapid Divergence of Killer Whale Ecotypes, 7 Nat. Commun. 11693 (2016). 6 NMFS CH Biological Report (2019) at 5. 62 reproductive females that guide their group around the salmon foraging grounds and that they especially do this in times of low salmon.7 The three pods that comprise the SRKW, dubbed J, K, and L, divide their year between inland and coastal waters of the Northeast Pacific Ocean. SRKW travel broadly throughout these waters in pursuit of prey (particularly their preferred prey, Chinook salmon) and in the course of breeding, calving, socializing, and other activities. In the summer months, all three pods have typically been present in the inland waters of the Salish Sea (Georgia Strait, Strait of Juan de Fuca, and Puget Sound). In the winter months, the three pods move to coastal waters, albeit to varying degrees, with J pod tending to remain longer in inland waters and to move to the waters off the northwest coast of Washington, while K and L pods spend significant time off the coast of southwestern Washington, near the mouth of the Columbia River, and also range north into British Columbia and as far south as the coast off northern California. As noted above, the SRKW population numbered just 73 whales as of the most recent census in 2019.8 This figure reflects a steep decline since even a few years ago, when the SRKWs numbered 83 whales in 2016. A loss of 10 individual whales to such a small population is substantial and alarming. Indeed, the SRKW population is at its lowest number in more than 40 years despite the Southern Resident Killer Whale DPS having been listed as endangered under the Endangered Species Act (ESA) since 2005 (and under Canadas Species at Risk Act (SARA) since 2003).9 The current perilous status of the SRKWs prompted Washingtons 7 Center for Whale Research, Orca Survey, https://www.whaleresearch.com/orcasurvey; Lauren J.N. Brent, et al., Ecological Knowledge, Leadership, and the Evolution of Menopause in Killer Whales, 16 Current Biology 746 (2015). 8 Center for Whale Research, Population, updated as of Dec. 31, 2019 https://www.whaleresearch.com/orca-population (accessed April 3, 2020). 9 National Marine Fisheries Service, Endangered Status for Southern Resident Killer Whales. 70 FR 69903; DFO (Fisheries and Oceans Canada), Action Plan for the Northern and Southern Resident Killer 63 Governor Inslee to issue an Executive Order and constitute an Orca Task Force, citing the urgency of the need to act to halt the decline of this iconic species.10 Given SRKWs precarious state, there has been a concerted research effort to understand the environmental conditions necessary to SRKW survival and recovery. Among the anthropogenic threats identified by scientists are: reduced prey abundance; acoustic disturbance (SRKW rely on echolocation to target their prey and otherwise depend on acoustic communication) and other vessel impacts; toxic contaminant loads; and also oil spill risk, and climate change.11 Researchers have recognized that there are interactions among these threats, such that their cumulative effects must be considered. That said, according to scientists, a lack of their preferred prey, Chinook salmon, is widely recognized as the primary limiting factor to their immediate survival and future recovery.12 In recognition of recent data supporting SRKWs use of an expanded range as they follow the seasonal movements of their preferred prey and engage in various other behaviors, the National Marine Fisheries Service (NMFS) has currently proposed enlarging the SRKWs Critical Habitat.13 Despite the wealth of recent scientific data regarding SRKWs, the DEIS includes a bare handful of citations to relevant authority. Instead, the Agencies conclusion that the Preferred Alternative is not likely to adversely affect the SRKWs is built upon three unsupported contentions. First, the Agencies start from the premise that it is not clear that reduced prey Whale (Orcinus orca) in Canada. Species at Risk Act Action Plan Series. (Fisheries and Oceans Canada, Ottawa)(2017). 10 Governors Orca Task Force https://www.governor.wa.gov/issues/issues/energy-environment/southernresident-orca-recovery/task-force. 11 Robert C. Lacy, et al., Evaluating Anthropogenic Threats to Endangered Killer Whales to Inform Effective Recovery Plans, 7 Sci. Reports 14119 (2017). 12 Letter from Marine Mammal Scientists to Lynn Barre, National Marine Fisheries Service (Dec. 18, 2019)[hereinafter Marine Mammal Scientists Letter (2019)]. 13 National Marine Fisheries Service, Proposed Rulemaking to Revise Critical Habitat for Southern Resident Killer Whale Distinct Population Segment, 84 Fed. Reg. 49214 (2019). 64 availability is the primary threat to SRKW survival and recovery. Second, the Agencies argue that the Columbia/Snake River runs are relatively unimportant to the SRKWs individual condition or population dynamics, because they comprise only a small percentage of the SRKWs overall diet. Third, the Agencies maintain that hatchery Chinook production in the Columbia/Snake Basin more than offsets losses to SRKWs prey base due to CRSO-caused mortality. Each of these rests on an incomplete or flawed evaluation of the available evidence. Instead, the best currently available science overwhelmingly shows that reduced Chinook prey is a key limiting factor for SRKW; that the Columbia/Snake runs form a critical part of their diet; and that the current and continuing reduction in these runs significantly harms the already imperiled SRKW.	spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	17	ttrue@earthjustice.org	Earthjustice	B. The DEIS fails to adequately acknowledge and evaluate the evidence that Chinook prey is important to SRKW survival and recovery. The DEIS conclusion presumes that Chinook prey is not an important factor in SRKW survival and recovery, yet skips over any discussion of this analytical foundation. For example, the DEIS fails to acknowledge major recent scientific advances in population viability analysis and their finding that chinook prey availability is key to SRKW population growth rates. In fact, the DEIS fails to acknowledge and indeed, appears to try to downplay evidence that Chinook prey availability is important to SRKW survival and recovery. The DEIS itself does not signal whether prey availability is of great or little import to SRKW individual and population health, skipping entirely any discussion of this issue. The BA tees up its discussion of the threats plaguing the SRKW by noting that NMFS Final Recovery Plan identified numerous external factors that may be limiting recovery of this species, but, oddly, re-orders the first three threats presented by NMFS, so that quantity and quality of prey 65 appears last, following after toxic contaminants that accumulate in top predators and disturbance from marine vessel traffic/noise.14 BA 3-598. The BA fails to acknowledge the availability of major recent scientific advances in population viability analysis that identify Chinook prey availability as key to SRKW population growth rates, the results of which are elaborated below. Instead, the BA cites only the 2019 CRS BiOp, which similarly portrays the lack of adequate Chinook prey as just one concern among many, the relative importance of which scientists have yet to have make progress in assessing. After listing the threats identified by NMFS and noting the likelihood that these threats act together to impact the whales, the 2019 CRS BiOp states [a]lthough it is not clear which threat or threats are most significant to the survival and recovery of the Southern Residents, all of the threats identified are potential limiting factors in their population dynamics.15 The Agencies depiction misrepresents the currently available science, which has amassed considerable evidence that a lack of SRKWs preferred prey, Chinook salmon, is a significant threat, if not the primary limiting factor to their immediate survival and future recovery.16 The 2019 CRS BiOp cites NMFS 2008 Final Recovery Plan for its undifferentiated enumeration of the threats to SRKW individual and population health. Yet analyses since, by both NMFS and independent scientists, have produced [a] growing body of 14 Compare the BA ordering with NMFS, Recovery Plan for SRKW (2008); see also NMFS CH Biological Report (2019) at iv, which recounts the threats to SRKW in the order originally set forth by NMFS in 2008. 15 National Marine Fisheries Service, Endangered Species Act 7(a)(2) Biological Opinion and MagnusonStevens Fishery Conservation and Management Act Essential Fish Habitat Consultation for the Continued Operation and Maintenance of the Columbia River System 908 (March 29, 2019)[hereinafter 2019 CRS BiOp]. 16 Marine Mammal Scientists Letter (2019)(unpaginated). 66 evidence [that] documents how the Southern Residents are affected by limitations of the primary prey, Chinook salmon, as NMFS itself recently observed.17 Although an independent science panel in 2012 had found reasonably strong evidence that vital rates of Southern Residents are to some degree ultimately affected by broad-scale changes in their primary prey, Chinook salmon, they suggested the need for further research, in particular into SRKWs diet in the winter months and SRKWs nutritional condition throughout the year.18 This and other data have since been gathered, among other things enabling scientists to conduct sophisticated population viability analyses (PVA) capable of assessing the relative importance of prey and other threats to SRKW population dynamics, most notably, Lacy (2017).19 This PVA concluded that prey availability is the most significant of the threats to SRKW survival and recovery and provided several key insights into the crucial function of prey to SRKW population dynamics, which are elaborated below. The Lacy (2017) PVA also found a negative population growth rate for SRKWs under a business-as-usual scenario, i.e., with no increase to Chinook prey availability and no improvements in the other two threats.20 As one of 17 NMFS CH Biological Report (2019) at 13. 18 R. Hilborn, et al., The Effects of Salmon Fisheries on Southern Resident Killer Whales: Final Report of the Independent Science Panel (2012). While recognizing the reasonably strong evidence of the relationship between SRKW population dynamics and Chinook prey abundance, the panel observed that the relationship is likely not linear at all levels of Chinook abundance, particularly beyond (above) the historical average abundance levels, and called for further research. Id. at xi. 19 Lacy (2017). 20 Lacy (2017) at 2. Under the baseline scenario employed by Lacy (2017), i.e., assuming then-current SRKW population numbers and then-current threat levels due to Chinook availability, acoustic disturbance	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with

				(noise), and contaminants (PCBs), mean SRKW population growth was projected to be slightly negative (r= -0.002), projected over 100 years. The authors noted at the time that their baseline demographic rates might give an overly optimistic projection for the SRKW if rates deteriorate. As one of the co-authors noted in presenting this work to the Governors Orca Task Force, this has in fact turned out to be the case, as the population has declined steeply from the 80-whale baseline assumed by Lacy (2017)s models. Rob Williams, Presentation to Governors Orca Task Force, Relative Importance of the Different Threats to Southern Resident Orcas, (July 24, 2018) https://www.governor.wa.gov/issues/issues/energy-environment/southern-resident-orca-recovery/taskforce. 67 the co-authors of this study, Rob Williams, explained to the Governors Orca Task Force, the datasets informing their analysis are particularly robust as to the impact of prey.21 Neither the DEIS nor its appended BA acknowledge the results of the Lacy (2017) PVA, nor do they disclose the fact that in addition to the Lacy (2017) PVA, the NMFS own population viability analysis, cited in the 2019 CRS BiOp, confirms that the data now suggest a downward trend in [SRKW] population growth projected over the next 50 years.22 Notably, the 2019 CRS BiOp itself hides the ball when it states merely that this crucial conclusion is the outcome of the NWFSC having updated the work on population viability analyses conducted for the 2004 status review for Southern Resident killer whales and a science-panel review of the effects of salmon fisheries [citing, inter alia, Hilborn (2012)].23 The 2019 CRS BiOp fails to mention that this update in fact comes to the opposite conclusion from the 2004 status review respecting the projected SRKW population growth rate. The Hilborn (2012) panel had embraced a positive population growth rate for the SRKW population based on then-available data.24 By failing to highlight this crucial shift in scientists conclusion on this point, the DEIS fails fully to inform public understanding and debate and is significantly incomplete. Moreover, there is no explicit discussion of the implications of this change for the Agencies finding that the CRSO may affect, but is not likely to adversely affect the SRKW. DEIS at 7-153, Table 7-28. The BA states generally that [i]n 2014 and again in 2019, NOAA confirmed the continuing validity of the analyses and conclusion from the 2008 consultation, 21 Rob Williams, Presentation to Governors Orca Task Force, Relative Importance of the Different Threats to Southern Resident Orcas, (July 24, 2018) https://www.governor.wa.gov/issues/issues/energyenvironment/southern-resident-orca-recovery/task-force. 22 2019 CRS BiOp at 910. 23 2019 CRS BiOp at 910. 24 Hilborn (2012) at iii-v. 68 but does not mention this significant change in the underlying data, and the DEIS does not explain how it nonetheless can still support the claim that it is assumed that existing regulatory and best management practices [under the Preferred Alternative] would reduce the likelihood that [the SRKW] population[] would continue declining or become extinct. BA 3 599. DEIS 7-150. 1. The DEIS Fails to Adequately Evaluate Evidence that Chinook Prey is the Most Significant Factor in SRKW Survival and Recovery. The DEIS fails to adequately evaluate evidence that the availability of SRKWs preferred prey, Chinook salmon, is the most important factor to their survival and recovery. As noted above, Lacy (2017) conducted a major population viability analysis (PVA) that assessed the relative importance of three main threats Chinook prey availability, acoustic disturbance (noise), contaminants (PCBs) and, to a lesser extent, other anthropogenic threats such as ship strikes, oil spills, and climate change on SRKW population dynamics. The PVA produced several findings that underscore the crucial role that Chinook salmon prey availability plays in SRKW population health: a. Chinook Prey are the Most Important Among the Three Primary Threats (Prey, Noise, Contaminants). Lacy (2017) found that prey availability is the most important of the three threats in terms of impact on SRKW population growth rate and potential for recovery, or conversely, on the possibility of extinction: Across the ranges of threat levels that we examined, reduction of the prey base was the single factor projected to have the largest effect on depressing the population size and possibly leading to extinction.25 25 Lacy (2017) at 6. 69 b. Only by Addressing Prey Abundance Can Recovery Be Achieved Addressing the Other Two Threats, Even in Combination, is Insufficient. Importantly, Lacy (2017) considered how population growth would respond to reductions in current threat levels for each of the three threats, singly or in combination. They found that only by addressing prey abundance could the NMFS recovery goal of 2.3% growth for the SRKW population be achieved. Even if one were to completely eliminate acoustic disturbance (while holding the remaining threat levels constant), population growth would only reach 1.7%. Even if one were to completely remove PCBs from the habitat (while holding the remaining threat levels constant), population growth would only get to 0.3%. And if one were to address completely both acoustic disturbance and PCBs, one could attain a 1.9% population growth rate. In short, the authors concluded that [t]herefore, reaching the recovery target without increasing Chinook salmon numbers is likely impossible.26 c. So Crucial are Prey, that SRKW Recovery is Achievable by Significantly Increased Chinook Abundance Alone. Lacy (2017) also found that attaining the recovery goal of 2.3% growth for the SRKW population could be achieved by a significant increase in Chinook abundance alone. While the authors found that there are interactions among the three threats, their PVA model showed that the other two threats take on greater concern where the SRKW population is very prey-limited. Accordingly, they concluded, if doubling Chinook salmon numbers were possible, and returning them to levels seen in the 1920s, consideration of the other anthropogenic impacts on the whales foraging efficiency might not be necessary.27 26 Lacy (2017) at 4-5. 27 Lacy (2017) at 7. 70 The results of another PVA of both Southern and Northern Resident Killer Whales, conducted by Clarke Murray (2019) strongly support the significant role of prey availability in determining the population trajectory of these populations, and are consistent with previous work [citing, inter alia, Lacy (2017)], but find that a cumulative threat model has more explanatory power than a single threat model.28 Within Clarke Murrays cumulative threat model, it bears noting, prey availability appears to be a central node, with six linkage pathways to fecundity and mortality, including two interactions with other threats.29 Neither the DEIS nor the appended BA disclose the availability of the Clarke Murray (2019) PVA. d. When Additional Threats are Considered, Including the Predicted Decline in Chinook Due to Climate Change, the SRKW Population is Projected to Decline Dramatically, with a 25% Chance of Complete Extirpation. Lacy (2017) also considered how additional threats from proposed and approved shipping developments (such as catastrophic and chronic oil spills, ship strikes, and increased vessel noise) combine with the predicted decline of Chinook due to climate change and found that the [SRKW] population could decline by as much as 1.7% annually, have a 70% probability of declining to fewer than 30 animals, and have a 25% chance of complete extirpation within 100 years.30 The DEIS and its appended BAs failure to acknowledge or discuss the implications of Lacy (2017), a major relevant study directly responding to research gaps relevant to the Agencies assessment, is a glaring omission. Lacy (2017)s findings have become widely publicized and accepted. They are cited, together with other recent evidence, for the proposition 28 Cathryn Clarke Murray, et al., Cumulative Effects Assessment for Northern and Southern Resident Killer Whale Populations in the Northeast Pacific, DFO Can. Sci. Advis. Sec. Res. Doc. 2019/056 at 64 (2019). 29 Clarke Murray (2019) at 28. 30 Lacy (2017) at 6. 71 that prey availability is a key factor, if not the key factor to SRKW population recovery. Whether in journal articles, government reports, or other public documents, scientists, including NMFS scientists, have acknowledged the vital function that prey of adequate quality, quantity, and timing play in SRKW individual and population health. The available body of evidence has permitted scientists to state, e.g., that the principal impediment to orca recovery is a severe shortage of the whales preferred food, Chinook salmon;31 that [o]ne of the main threats to population persistence is availability and accessibility of prey;32 and that the availability of prey is essential to conservation of the SRKWs.33 As summarized in a recent letter to NMFS from scientists with expertise in marine mammal populations regarding SRKW requirements: A lack of their preferred prey, Chinook salmon, is widely recognized as the primary limiting factor to their immediate survival and future recovery.34 Neither the DEIS nor the appended BA provide an inkling regarding any of this evidence or the considerable light it sheds on the relative role played by the various threats to SRKW population viability, nor that this information underscores that prey availability is at least one of the most important limiting factors to SRKW population health. In addition, several impacts of reduced prey are not fully captured in Lacy (2017)s model, but are important to evaluating the necessity of adequate prey for SRKW survival and recovery. Recent research has contributed multiple lines of evidence lending support to earlier 31 David Bain, et al., Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review of the Available Evidence 8 (Feb., 2020). 32 Jennifer B. Tennessen, et al., Hidden Markov Models Reveal Temporal Patterns and Sex Differences in Killer Whale Behavior, 9:14951 Scientific Reports 2 (2019)(citing, inter alia, Lacy (2017)). 33 NMFS CH Biological Report (2019) at 28. 34 Marine Mammal Scientists Letter (2019)(unpaginated). 72 findings that prey abundance and accessibility are central to SRKW survival and recovery,35 and providing insights into the interactions among reduced prey availability and other threats. Here again, the DEIS is silent. First, recent studies using aerial photogrammetry have provided evidence of declining body condition among SRKWs.36 Fearnbach (2018) set out to address the data gap whether the abundance of [SRKWs] preferred Chinook salmon prey is low enough to cause nutritional stress, citing Hilborn (2012)s recommendation that researchers use photogrammetry to assess the nutritive status of the SRKW population.37 Fearnbach found that 25% of whales monitored in 2008 and 2013 showed significant declines in body condition and, of these, two whales died shortly after being photographed, suggesting a link between body condition and mortality.38 Groskreutz (2019) found evidence of shorter body lengths in adult killer whales between the ages of 20 and 40, as compared to those >40 years old, and stated that their data suggest that these younger adults experienced relatively constrained growth during their maturing years (0-15 yr of age for females and 0-20 yr for males), which align with notable declines in Chinook salmon returns in the 1990s.39 Groskreutz observed that their findings highlight[] the significant long term effects of nutritional stress in salmon-eating killer whales, in addition to the acutely lethal impacts found by earlier researchers.40 Additionally, Fearnbach noted the particular 35 See, e.g., John K.B. Ford, et al., Linking Killer Whale Survival and Prey Abundance: Food Limitation in the Oceans Apex Predator?, 6 Biol. Lett. 139 (2010); Eric J. Ward, et al., Quantifying the Effects of Prey Abundance on Killer Whale Reproduction, 46 J. of Applied Ecol. 632 (2009). 36 Holly	congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).

				Fearnbach, et al., Using Aerial Photogrammetry to Detect Changes in Body Condition of Endangered Southern Resident Killer Whales, 35 Endang. Species Res. 175, 179 (2018); Molly J. Groskreutz, et al., Decadal Changes in Adult Size of Salmon-Eating Killer Whales in the Eastern North Pacific, 40 Endang. Species Res. 183 (2019). 37 Fearnbach (2018) at 175-76. 38 Fearnbach, (2018) at 178. 39 Groskreutz (2019) at 187. 40 Groskreutz (2019) at 187. 73 adverse impact that a prey-limited context visits on female whales at different lifestages, given, among other things, their higher nutritional demands due to the prey-sharing obligations that attend their social position and relationships (e.g., as they continue to provision their offspring and kin into adulthood, apparently at a cost to their own body condition).41 The implications of this point for SRKWs reliance on Columbia/Snake River runs at vital lifestage windows is taken up further below, in Part B.1 Second, recent work regarding the impact of acoustic disturbance on SRKWs has allowed a quantitative estimate of foraging time lost due to vessel noise.42 This evidence has corroborated and built upon earlier studies conclusion that this reduction in whales ability to access, i.e., use echolocation to find and capture, their prey is the most significant adverse energetic effect from vessel traffic (as opposed, for example, to the energetic costs of fleeing or otherwise undertaking avoidance behaviors in response to vessels).43 Joy (2019) found that noise reductions achievable under various vessel speed scenarios in Haro Strait would result in decreased lost foraging time by from 21.5% to 44.1%.44 Again, in a prey-limited context, the quality of SRKWs acoustic environment becomes more of a concern, as noted by Lacy (2017) above. Speaking to the interactions among the various threats facing SRKWs, Joy observed that [i]f animals are already in poor body condition as a consequence of poor Chinook salmon availability, additional lost foraging opportunities could have both direct nutritional (energy) cost[s] as well as indirect [costs] through increased risk of parasite infection and disease, and/or reproductive performance.45 41 Fearnbach (2018) at 179. 42 Ruth Joy, et al., Potential Benefits of Vessel Slowdowns on Endangered Southern Resident Killer Whales, 6 Frontiers in Marine Science (June, 2019). 43 Joy (2019) at 2. 44 Joy (2019) at 13. 45 Joy (2019) at 17. 74 In a related vein, recent research has showed that current and future ocean acidification is projected to alter the acoustic environment that is important, among other things, to SRKWs ability to detect, communicate about, capture, and share prey. As highlighted by the Governors Orca Task Force Final Report: [O]cean acidification extends the spatial spread of underwater noise (for frequencies up to 10kHz), making it more difficult for orcas to communicate. Ocean acidification will continue to amplify underwater noise by reducing the natural absorption of sound at lower frequencies, allowing sounds to propagate further and making it harder for orcas to locate their prey.46 Third, recent research has underscored that a lack of prey interacts with toxic contaminants which have been taken up and stored by SRKWs in their fat tissue. As Mongillo (2016) found, SRKW experiencing nutritional stress due to reduced prey mobilize their fat reserves – along with the contaminants harbored there.47 In discussing the threat posed to SRKW from reduced prey availability, NMFS noted this interaction: Southern Residents need to maintain their energy balance all year long to support daily activities (foraging, traveling, resting, socializing) as well as gestation, lactation, and growth. Maintaining their energy balance and body condition is also important because when stored fat is metabolized, lipophilic contaminants may become more mobilized in the blood stream, with potentially harmful health effects. (Mongillo et al. 2016)48 Fourth, recent studies have provided a window into the multi-dimensional harms that flow from reduced prey abundance effects that adversely impact not only individual whales but the health of the population as a whole. As noted recently by NMFS in describing SRKWs biological requirements in support of its proposal to expand Critical Habitat for the SRKWs: 46 Southern Resident Orca Task Force, Final Report and Recommendations 46 (Nov., 2019) https://www.governor.wa.gov/issues/issues/energy-environment/southern-resident-orca-recovery/taskforce. 47 Teresa Mongillo, et al., Exposure to a Mixture of Toxic Chemicals: Implications for the Health of Endangered Southern Resident Killer Whales, NOAA Tech. Memo. (2016). 48 NMFS CH Biological Report at 27. 75 In addition to the physiological effects of reduced prey abundance that have been observed in Southern Residents, there is also evidence of a negative impact on social cohesion when salmon abundance is low (Foster et al. 2012). Social cohesion plays an important role in Southern Resident survival, growth, and reproduction. When prey abundance is low, whales must spread out to find food and dedicate more of their time to foraging rather than on social interactions such as reproduction and information transmission (Foster et al. 2012). Indeed, researchers have observed a correlation between reduced reproduction in Southern Residents and low salmon abundance (Ford et al. 2010).49 Data from these and other recent studies provide multiple lines of evidence in support of the crucial role played by abundant Chinook prey in SRKW survival and health. The DEIS fails to consider this currently available science, instead downplays the importance of prey availability to the SRKW.	
6110	18	ttrue@earthjustice.org	Earthjustice	C. The DEIS presents an incomplete and inaccurate assessment of the importance of Columbia/Snake River Chinook Runs to SRKW survival and recovery. The DEIS presents an incomplete assessment of the role that Columbia/Snake River Chinook runs play in SRKW individual and population health, leading it to an inaccurate and misleading conclusion about the importance of these runs to SRKW survival and recovery. The DEIS contends that the Columbia/Snake River Chinook runs are relatively unimportant to the SRKWs individual condition or population dynamics, because they comprise only a small percentage of their overall diet. The DEIS states that, under the Preferred Alternative, its various models predict a range of possible changes in Chinook salmon populations that would return to the Columbia and Snake Rivers, such that the prey base available to marine mammals foraging offshore could increase or decrease. DEIS 7-150 to 151. The DEIS notes that the southern resident whales may have a slight increase in available food around the mouth of the Columbia River, but claims that [h]owever, this increase in food availability would have a 49 NMFS CH Biological Report (2019) at 14; Emma A. Foster, et al., Social Network Correlates of Food Availability in an Endangered Population of Killer Whales Orcinus orca, 83 Animal Behaviour 731 (2012). 76 negligible effect on killer whales, given that the Snake River and Columbia Chinook populations constitute a small portion of their overall diet. DEIS 7-151. Thus, the DEIS concludes that [t]he Preferred Alternative is not likely to adversely affect the southern resident whale population. DEIS 7-173 at Table 7-28. Neither the DEIS nor the appended BA provide a complete evaluation of the importance of the Columbia/Snake River Chinook runs in supplying prey of adequate quality, quantity, and timing to meet SRKWs needs throughout the year and during various lifestages (e.g., pregnancy, lactation).	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).

6110	19	ttrue@earthjustice.org	Earthjustice	1. The DEIS Considers Only the Columbia/Snake River Runs Percent Contribution to SRKWs Annual Diet, Failing to Evaluate Key Aspects of the Prey Adequacy Issue, Including How the Various Runs Sync with SRKWs Seasonal Needs and Vital Lifestage Windows. The DEIS finding that the Columbia/Snake River Chinook runs are relatively unimportant to the SRKWs individual condition or population dynamics stems from the agencies narrow focus on these runs percent contribution to SRKWs annual diet. Finding that the Columbia/Snake River Chinook runs comprise only a small percentage of their overall diet the Agencies maintain that any changes caused by the CRSO will have a negligible effect on the SRKW. DEIS 7-151. However, the DEIS incompletely frames the relevant inquiry, thereby failing to evaluate key aspects of the issue: it is not only the total annual quantity of available prey that matters to SRKWs health, but the quality, quantity, and timing of the prey that must be considered, including how various available food sources sync with SRKWs seasonal needs and vital lifestage windows. A more rigorous and complete assessment would show that the Columbia/Snake River Chinook runs are in fact critical to SRKWs individual and population health. 77 As NMFS has recently observed, SRKW require abundant food all year long to meet their daily metabolic needs and to maintain body condition.50 Southern Residents need fuel to support them in their daily activities of foraging, traveling, socializing, and resting, and to meet the particular requirements of certain lifestages (e.g., growth, pregnancy, lactation).51 The most recent scientific information available has afforded a more complete understanding of SRKWs diet throughout the year. These data confirm that SRKWs preferentially consume Chinook salmon, both in their summer and winter diets.52 Recently available analytical methods, including analyses of fish scale and Southern Resident fecal samples, have allowed NMFS scientists to determine that SRKWs rely on both fall and spring Columbia/Snake River Runs at various times throughout the year.53 Notably, recent data show that Chinook are the primary species consumed by SRKWs when they are outside of inland waters, and that most of these originate in the Columbia/Snake River basin.54 The availability of ample prey in the winter is of particular seasonal concern, given that [n]utritional demands on SRKW are presumed to be greatest in winter when their salmonid prey are more widely dispersed, smaller in size, [] other non-salmonid species appear to be a larger fraction of their diet, [and] [t]hermoregulatory demands may also influence nutritional demands.55 The importance of ample year-round prey, particularly for reproductive-age females, is additionally supported by the most recent studies of SRKWs body condition using aerial photogrammetry, which found that 25% of the whales monitored in 2008 and 2013 showed 50 NMFS CH Biological Report (2019) at 27. 51 NMFS CH Biological Report (2019) at 27. 52 NMFS CH Biological Report (2019) at 10-11. 53 NMFS CH Biological Report (2019) at 11. 54 NMFS CH Biological Report (2019) at 11. 55 Samuel K. Wasser, et al., Population Growth is Limited by Nutritional Impacts on Pregnancy Success in Endangered Southern Resident Killer Whales (Orcinus orca), PLoS ONE 12(6): e0179824 3 (2017). 78 significant declines in body condition and that the high proportion of reproductive-age females among those with a decline in body condition likely reflects the increased energetic costs to adult females of lactation.56 In fact, the most recent science shows that SRKWs are likely to be especially reliant on the Columbia/Snake River watersheds early spring, nutrient-rich Chinook salmon runs.57 As NMFS summarized in late 2019, data compiled from satellite-linked tagged whales, dedicated surveys, and passive acoustic monitoring has provided a better understanding of SRKWs movements between December and mid-May, documenting the fact that SRKWs spend significant time in the winter and early spring off the mouth of the Columbia River.58 Indeed, SRKWs were found to be present here as much as 35% more often than would be expected by chance.59 That SRKWs congregate here to avail themselves of the relatively fatty Columbia/Snake River Chinook is corroborated by ONeill (2014), which found that Columbia River spring run Chinook had significantly higher lipid content than any other Chinook populations, at 14.8%.60 Despite the 2019 CRS BiOps recognition that recently available data documenting that [t]he occurrence of K and L pods off the Columbia River in March suggests the importance of the Columbia River spring-run stocks of Chinook salmon in their diet at that time of year, neither the DEIS nor its appended BA address in a complete or objective way the 56 Fearnbach (2018) at 179. 57 Bain (2020) at 9. 58 NMFS CH Biological Report (2019) at 11, 22 Fig. 7. 59 Bain (2020) at 9 and App. A; M.B. Hanson, et al., Modeling the occurrence of endangered killer whales near a U.S. Navy Training Range in Washington State using satellitetag locations to improve acoustic detection data. ONeill, et al., Energy Content of Pacific Salmon as Prey of Northern and Southern Resident Killer Whales, 25 Endang Species Res 265, 271-72, & Table 3 (2014). The next highest population considered was the Skeena River Chinook (13.1%), followed by the Fraser River Chinook (12.4%); Puget Sound Chinook had the lowest lipid content among populations analyzed, at 6.3%. Id. 79 seasonal significance of the Columbia/Snake River runs nor explain why the DEIS limits its evaluation of the impacts on SRKWs prey requirements to a consideration on an annual basis.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	20	ttrue@earthjustice.org	Earthjustice	2. Columbia/Snake River Spring Runs are Critical to SRKWs During Pregnancy, and Thus to SRKW Population Growth. The available scientific information also suggests that Columbia/Snake River Spring runs provide a nutrient-rich source of prey during a vital lifestage window, i.e., pregnancy. The scientific evidence led Wasser (2017) to conclude that the nutritional health of pregnant females depends in important part on the availability of the Columbia/Snake River Spring runs, and that nutritional stress due to low Chinook availability during this window is significantly associated with unsuccessful pregnancies in SRKWs.61 These unsuccessful pregnancies, in turn, are impairing the potential for population recovery through low recruitment as well as risk to the health and survival of the limited number of reproductive age females.62 Wasser (2017) used SRKW fecal samples to identify temporal patterns in hormone metabolites that measure stress and nutrition (glucocoritcoid (GC) and triiodothyronine (T3)), and reproductive status. Notably, [t]he SRKWs had a 69% pregnancy failure rate during [the Wasser (2017)] study.63 An unprecedented half of those [pregnancy failures] occurred at later stages of reproduction, when the energetic cost of failure and physiological risk to the mother was relatively high.64 Temporal patterns in the GC and T3 hormone profiles were found to indicate[] that successfully pregnant females arrived in the Salish Sea in significantly better nutritional condition, and remained so compared to [unsuccessfully pregnant] females that experienced loss some time after mid-pregnancy.65 Wasser found that the temporal patterns in 61 Wasser (2017) at 14. 62 Wasser (2017) at 14. 63 Wasser (2017) at 14. 64 Wasser (2017) at 14. 65 Wasser (2017) at 16. 80 hormone metabolites, together with radio-tagging data, supported a finding that the SRKWs depend on the fat-rich Columbia/Snake River Spring runs to replenish the killer whales after the long winter and sustain them until the temporally and quantitatively variable mid- to late-August peak in the Fraser River Chinook (FRC) occurs.66 NMFS most recent assessment of SRKWs biological needs throughout their coastal range concurred, citing these and other data for the point that [e]levated T3 values in the early spring when the whales first arrive in the [Salish Sea] indicate[] that the whales are foraging on prey with high nutritional value before they get there, suggesting the importance of the coastal early spring Columbia River Chinook run.67 Wasser (2017) concluded that their results strongly suggest that recovering Fraser River (FRC) and Columbia River Chinook (CRC) runs should be among the highest priorities for managers aiming to recover this endangered population of killer whales. SRKW are suffering significant reproductive loss due to lack of Chinook prey and associated effects (e.g., release of lipophilic toxins into circulation).68 The import of Wasser (2017)s findings at the SRKW population level become apparent when one considers that the Lacy (2017) PVA found that improvements to SRKW fecundity, rather than mortality provide a better opportunity for a large benefit to population growth69 and that [o]ver the ranges tested, the effects of Chinook prey abundance on fecundity and survival had a greater effect on population growth rate than did the other two factors [i.e., acoustic 66 Wasser (2017) at 3. Additionally, Wasser noted that [o]nly 4 detected pregnancies between 20112013 resulted in live births when Fraser River Chinook and early spring Columbia River Chinook runs were both exceedingly low. That trend reversed in 2014, with relatively high CRC returns and early onset of FRC returns in 2014 and 2015 that was followed by 8 new births between December of 2014 and October 2015. Id. at 16. 67 NMFS CH Biological Report (2019) at 14. 68 Wasser (2017) at 17-18. 69 Lacy (2017) at 5. 81 disturbance (noise) or toxic contaminants].70 Wasser (2017) echoed the observation that reduced fecundity appears to be a particularly important contributor to SRKWs failure to recover,71 noting that population growth is constrained by low offspring production for the number of reproductive females in the population as well as risk to the health and survival of the limited number of reproductive age females.72 Assuming a median peak fecundity rate of 0.21, the 31 potentially reproductive females in the SRKW population should have had 48 births between 2008-2015. Yet, only 28 births were recorded during that period.73 And note that SRKWs fecundity rate is significantly lower than [Northern Resident Killer Whales] (0.26) or [Southeast Alaskan Resident Killer Whales] (0.27), holding age structure and survivorship constant.74 In fact, whereas Wasser (2017) reported that SRKW typically give birth every 5.3 years, NMFS recently provided an updated and potentially more concerning figure: SRKWs birth interval is 6.1 years.75 Neither the DEIS nor the appended BA discuss in an objective or complete manner how the Columbia/Snake River Chinooks runs function to meet SRKWs seasonal needs and vital lifestage windows. At most, the BA provides only the vague explanation that in the Columbia River Basin, different stocks vary in overall importance for the diet of the SRKW. For example, [Snake River] spring-summer Chinook salmon are mainly available to SRKW when the fish gather off the mouth of the Columbia, whereas [Snake River] fall-run Chinook remain closer to the coast and would be available for a longer period before migrating upriver in the fall. BA 3 598 to 599. DEIS 3-685. This statement fails to inform the reader about the significance of 70 Lacy (2017) at 3. 71 Wasser (2017) at 2. 72 Wasser (2017) at 14. 73 Wasser (2017) at 2. 74 Wasser (2017)at 2. 75 NMFS CH Biological Report (2019) at 9. 82 these runs to SRKWs individual nutritional requirements, to the success or failure of SRKWs pregnancies, and to the	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW.

				implications for fecundity and, ultimately, SRKWs population health and recovery even though credible scientific information to address these issues is available.	Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	21	ttrue@earthjustice.org	Earthjustice	3. The DEIS Provides an Inaccurate Picture of the Chinook Stocks that are Important to SRKW Survival and Recovery by Failing to Acknowledge Relevant Limitations and Biases in the Data. In addition to the inadequacies discussed above, the DEIS provides an inaccurate picture of the Chinook stocks that are important to SRKW survival and recovery by failing to acknowledge relevant limitations and biases in the data on which its portrayal rests. The DEIS and the appended BA contain nearly identical language depicting the Chinook stocks returning to the Columbia and Snake Rivers as among the most crucial stocks to SRKW, according to a 2018 analysis by NMFS and WDFW, alongside those from the Fraser River and other rivers draining into the Puget Sound and the Salish Sea, and the Klamath and Sacramento Rivers. DEIS 3-685. BA 3-598. The BA then states that this analysis showed that Puget Sound Chinook salmon stocks are one of the most important salmon stocks for Southern Resident killer whales, since they surround the heart of the whales habitat, and the whales have access to them for a greater part of the year than fish from the Columbia, Snake, and Fraser rivers. BA 3-598. DEIS 3-685. Neither the DEIS nor appended BA disclose the numerous limitations and biases in the NMFS/WDFW Priority Stock Report, which NMFS and WDFW authors took pains to identify in their text as assumptions and boldface caveats.76 Even taking the NMFS/WDFW ranking at face value, the DEIS summary appears designed to diminish the relative importance of the Columbia/Snake River Chinook stocks in the 76 NOAA Fisheries West Coast Region & Washington Department of Fish and Wildlife, Southern Resident Killer Whale Priority Chinook Stocks Report 2, 3, 4 (June 22, 2018)[hereinafter NOAA & WDFW, Priority Stocks Report (2018)]. 83 agencies analysis. Whereas the DEIS lists the Columbia/Snake River stocks alongside runs returning to a handful of other rivers as the most crucial stocks to SRKW, the DEIS declines to convey that the Columbia/Snake River fall and spring runs constitute 7 of the top 15 priority stocks (out of a total of 31 ranked stocks) in the NMFS/WDFW analysis.77 Moreover, the DEIS portrays the handful of most crucial stocks as an undifferentiated group, yet the Klamath runs are ranked only 17th (Klamath fall) and 18th (Klamath spring), while some of the Columbia and Snake River stocks rank much higher according to NMFS/WDFW.78 More significantly, NMFS/WDFW offered their priority list as a preliminary effort that was intended to be adapted with further data and analysis, and conceded explicitly several limitations and biases in the data on which their prioritization was made.79 Among the limitations and biases flagged by NMFS/WDFW and echoed by other scientists are that the list reflects (a) a spatial/seasonal bias in fish sample collection in favor of inland locations, flagged by notations that the majority of samples have been collected in the summer months in inland waters of WA and British Columbia, and [c]aveat: [t]here is currently no spatial correction factor for sample collection (stocks originating from near the sample locations are more likely to be collected);80 (b) a sampling bias in fish sample collection in favor of currently abundant stocks over stocks that have already been depleted relative to historical abundance, indicated by the overall study design focusing on SRKWs current/recent diet and flagged by the notation [c]aveat: [t]here is no correction factor for abundance (more abundant stocks are more likely 77 NOAA & WDFW, Priority Stocks Report (2018) at 7-8. 78 NOAA & WDFW, Priority Stocks Report (2018) at 7-8. 79 Bain (2020) at 10, n. 48; NOAA & WDFW, Priority Stocks Report (2018) at 2, 3, and 4 (noting the agency authors understanding that every aspect of their analysis, i.e., the factors, scoring and priority list can be adapted as new scientific information becomes available). 80 NOAA & WDFW, Priority Stocks Report (2018) at 2 (boldface in original). 84 to be identified in the [SRKW] diet);81 (c) a seasonal gap in data on the ocean distribution of prey, flagged by the notation that detailed analyses of data from spring runs had not yet been completed, and [c]aveat: [i]n particular, ocean distributions of spring run stocks tend to be less well understood than fall stocks.82 Additionally, scientists have noted that the priority list does not take into account potential for recovery of stocks, a point taken up below.83 As a consequence of these limitations, scientists have observed that the priorities are based more on conditions at the time data were collected than on actual stock priority to SRKW survival and recovery.84 The DEIS, however, discloses nothing of the qualifications and biases to the NMFS/WDFW stock priority list they cite for their summary de-emphasizing the importance of the Columbia/Snake River Chinook stocks. Nor does the DEIS discuss the import of more recently available data speaking to some of the data gaps and weaknesses identified by NMFS/WDFW and other scientists as limitations on the resulting stock priority list. For example, the 2019 CRS BiOp recognized the more recent data underscoring the importance of Chinook to SRKWs throughout the year, and highlighting the importance of the Columbia/Snake River runs: it reported that Chinook comprise a high percentage of SRKW diet throughout the year, not only in the summer but also in the winter, in both inland and coastal waters; that salmon and steelhead comprise up to 98% of the whales summer diet, of which almost 80% were Chinook; that Chinook and chum are primarily [sic] contributors to the whales diet in inland waters from October through December; and that fecal samples and prey remains sampled during the winter and spring in coastal waters indicated that the majority of prey samples were Chinook (80 percent of prey remains and 67 percent of fecal 81 NOAA & WDFW, Priority Stocks Report (2018) generally and at 2 (boldface in original). 82 NOAA & WDFW, Priority Stocks Report (2018) at 3-4 (boldface in original). 83 Bain (2020) at 10, n. 48. 84 Bain (2020) at 10, n. 48. 85 samples were Chinook salmon); and that Chinook salmon genetic stock identification from samples collected in winter and spring in coastal waters included 12 U.S. west coast stocks, and over half the Chinook salmon consumed originated in the Columbia River.85 Similarly, in NMFS recent Biological Report in support of expanded Critical Habitat for SRKW, its discussion of SRKWs range, foraging and prey, and its depiction in Fig. 5 of the overlap of location and prey species samples for SRKW predation events appears to indicate that Columbia/Snake fall Chinook provide food for SRKWs not only near the mouth of the Columbia River and off the coast of Westport, WA (where Columbia/Snake spring Chinook are also a source of prey) but also further north, off the coast from LaPush to the western entrance of the Strait of Juan de Fuca (where J pod also occurs).86 Although it is admittedly not possible to parse further the figures and data in NMFS Biological Report, it should not be left to the reader of the DEIS to undertake independent research in order to fill in the details and reconcile NMFs data with the conclusions reached by the Agencies in the DEIS. The DEIS fails to explain how its conclusions are supported by the available scientific evidence. Finally, the DEIS does not disclose that the SRKWs in the summer of 2019 were largely absent from the Salish Sea, appearing on just two days in June and July.87 While the cause of this departure from SRKWs typical patterns is unclear, the Governors Orca Task Force remarked upon this unprecedented seasonal shift in use of their historic core and critical habitat and suggested that continued or worsening pressure from known threats such as lack of prey and vessel noise and disturbance likely led or contributed to their displacement. For 85 2019 CRS BiOp at 909. 86 NMFS CH Biological Report (2019) at 10-13, Fig. 5, 21-23, Fig. 7. 87 Southern Resident Orca Task Force, Final Report and Recommendations 17 (Nov., 2019) https://www.governor.wa.gov/issues/issues/energy-environment/southern-resident-orca-recovery/taskforce. 86 example, several Chinook stocks, such as from the Fraser River, saw extremely low numbers of returning Chinook.88 The DEIS failed to discuss the extent to which the SRKWs extended absence from the Salish Sea might raise questions about their assessment of the priority stocks for SRKW, given that it rests in part on, as the BA puts it, the fact that Puget Sound stocks surround the heart of the whales habitat, and the whales have access to them for a greater part of the year. BA 3-598. In fact, because of the weighting system used by NMFS/WDFW in identifying priority Chinook stocks, the typical overlap in time and space of SRKW presence and particular runs timing (e.g., Salish Sea in summer/fall) is counted three times as heavily as the other two factors considered.89	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	22	ttrue@earthjustice.org	Earthjustice	4. The DEIS Obscures the Important Contribution of Columbia/Snake River Chinook to SRKW Survival and Health by Focusing Narrowly on Current Chinook Abundance. The DEIS obscures the important contribution of Columbia/Snake River Chinook to SRKW survival and recovery by focusing narrowly on current Chinook abundance as the basis for its assessment of the CRSOs effects, its claim that the Snake River and Columbia Chinook populations constitute a small portion of [the SRKWs] overall diet, and its conclusion that the Preferred Alternative is not likely to adversely affect the southern resident killer whale population. DEIS at 7-151, 7-153 Table 7-28. The DEIS fails to provide any sense of the outsized role historically played by the magnificent Columbia/Snake River Chinook runs in providing for the SRKW. Deprived of this information, a reader might fail to grasp that the Southern Residents evolved in the context of the extraordinary and reliable abundance of its preferred prey, Chinook, supplied by the 88 Southern Resident Orca Task Force Final Report (2019) at 17. 89 NOAA & WDFW, Priority Stocks Report (2018) at 3-5 (whereas Factor 1 and 2 were accorded 1 point each, Factor 3, Degree of Spatial and Temporal Overlap [of SRKW and Chinook], was accorded 3 points, out of a total possible 5 points. 87 Columbia/Snake River Chinook in quantities of significance through much of the year, and, with timing that is particularly crucial during some seasons (i.e., late winter/early spring, as discussed above in Part B.2).90 As NMFS itself stated in its 2008 Recovery Plan for the SRKW, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin.91 A widely adopted estimate by the Northwest Power Planning Council (now Northwest Power Conservation Council) puts average adult Columbia/Snake River salmon and steelhead runs at 10 million to 16 million fish,92 an order of magnitude higher than runs in some recent years. Recent graphic estimates by Mike Ford, of NOAAs Northwest Fisheries Science Center, highlight the stunning losses in Columbia Basin Chinook salmon abundance.93 According to Ford, whereas historical Columbia Basin Chinook run size exceeded 4,500,000 fish, present runs number less than 1,000,000 fish.94 The Columbia Basin figures dwarf those of those of the other regions considered (Puget Sound; Washington Coast; Oregon Coast; Klamath; Southern Oregon/California Coast; and Central Valley), both in terms of their historical contribution and their dramatic decline. The Central Valley runs place second on both scores,	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013

				with a historical run size at about 1,200,000 fish and a present run size of just under 250,000 fish.95 By comparison, Puget Sound Chinook run size has fallen from around 700,000 fish to around 90 Bain (2020) at 8-9, 11. 91 NMFS (2008) SRKW Recovery Plan at II-8. 92 Northwest Power Planning Council, 1987 Columbia River Basin Fish and Wildlife Program 36 (1987); an earlier BPA estimate put this figure at 35 million fish. Chinook, of course, comprise only a portion of the total salmon and steelhead runs. 93 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC (May, 2018). 94 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC (May, 2018). 95 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC, Slide 14 (May, 2018)(historical reference point is undefined on slide; all numbers based on a visual inspection of graphs). 88 400,000 fish during this same period.96 Fords estimates also show the jarring change to the relative seasonal abundance of the various Columbia Basin runs, with the Interior Columbia River Basin Spring runs having declined from extraordinary runs of some 2,500,000 fish to less than 200,000 fish.97 While Columbia Basin fall runs have also suffered losses, these have been comparatively smaller.98 The seasonal hole in prey availability caused by the dramatic decline in the Columba Basin spring runs is of significant concern to SRKW, who evolved in sync with this late winter/early spring influx of nutrients and who continue to ply the waters near the mouth of the Columbia, as noted above, now as in the past. Yet, as discussed above, the DEIS leans heavily on the NMFS/WDFW Priority Stock Report, with its biases in favor of currently abundant stocks, stocks sampled in the summer in the inland waters of the Puget Sound, and stocks comprised of fall, rather than spring, runs. Fords figures shed light on how these limitations of the NMFS/WDFW analysis likely function to understate the importance of the Columbia/Snake River Chinook runs to SRKW survival and recovery, which are likely to be impacted by one or more of these biases in the data. Scientists have recently emphasized this criticism of the NMFS/WDFW priority list, specifically noting the consequent belittling of these biological agencies prioritization of the Columbia/Snake River stocks.99 Neither the DEIS nor its appended BA, however, present the relevant historical data nor otherwise explain its implications for their claim that the Columbia/Snake River Chinook are 96 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC, Slide 14 (May, 2018)(historical reference point is undefined on slide; all numbers based on a visual inspection of graphs). 97 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC, Slide 20 (May, 2018)(historical reference point is undefined on slide; all numbers based on a visual inspection of graphs). 98 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC, Slide 20 (May, 2018)(historical reference point is undefined on slide; all numbers based on a visual inspection of graphs). 99 Bain (2020) at 10, n.48, and App. B. 89 unimportant to the SRKW because they (currently) comprise but a small portion of their overall diet. DEIS 7-151.	were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	23	ttrue@earthjustice.org	Earthjustice	5. The DEIS Fails to Consider the Columbia/Snake River Chinook Runs Potential for Recovery, Omitting a Key Consideration Relevant to the Importance of the Columbia/Snake River Runs to SRKW Survival and Recovery. The DEIS fails to consider the Columbia/Snake River Chinook runs potential for recovery, omitting a key consideration relevant to the importance of the Columbia/Snake River runs to SRKW survival and recovery. Scientists have underscored the need to increase, rather than merely maintain, SRKWs Chinook prey base if current negative population growth rates are to be addressed and NMFS stated recovery target of 2.3% SRKW population growth is to be achieved.100 According to Mike Ford, of NOAA Fisheries, Northwest Fisheries Science Center, increasing Chinook abundance for SRKW will likely need to include a variety of measures, including not only those that remedy the large declines in Chinook numbers dating to early in the 20th century, but those that ensure diversity and address losses of particular runs, e.g., the great loss in spring run populations.101 Scientists have identified significantly increasing the Columbia/Snake River runs, and particularly the Snake River spring runs, as offering perhaps the best potential for reversing these historic losses and addressing some of the particular requirements for SRKW recovery highlighted by Ford. Bain (2020) observed that the largest potential for increased Chinook abundance by orders of magnitude anywhere in the Southern 100 See, e.g., Lacy (2017). 101 Mike Ford, Salmon Recovery and Southern Resident Killer Whale Status, Presentation to MMC, Slide 32 (May, 2018); Richard G Gustafson, et al., Pacific Salmon Extinctions: Quantifying Lost and Remaining Diversity, 21 Conservation Biology 1009 (2007). 90 Residents range is Chinook from the Columbia-Snake River Basin.102 Bain explained: Wilderness acreage provides the highest quality in-stream spawning habitat for spring Chinook. Breaching the four lower Snake River dams would open the gateway to a vast, 5,500-mile expanse of largely intact spawning and rearing stream that run through millions of acres of wilderness.103 Moreover, according to Bain (2020), [t]hese are the highest elevation streams, and therefore, the most global warming resistant salmon streams in the entire lower 48 states.104 Bain (2020)s conclusions raise additional inadequacies in the DEIS. Whereas scientists have pointed to breaching the four lower Snake River dams as opening the gateway to the greatest increase in Chinook abundance anywhere in the SRKWs range, the DEIS alternatives analysis does not give adequate consideration to this point. The DEIS concludes that the Multiple Objective Alternative 3 (MO3), i.e. lower Snake River dam breaching alternative, would affect prey availability by resulting in a moderate to major increase in smolt-to adult returns and overall abundances of adult salmon and steelhead over the long term, and over the long term, this would lead to an increase in the prey base available to . . . killer whale[s]. DEIS 3-758. However, the Action Agencies conclude without citation or analysis that the effect for the prey limited SRKWs would be only minor. DEIS 3-758. This conclusion for MO3 presumably hinges once again on the flawed contention that t]he food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet, the infirmities of which are discussed above in Part B. DEIS 3-758, 3-759, Table 3-106. This point is quite apart from the flaws in the analysis of how MO3 would actually affect Chinook 102 Bain (2020) at 12 and App. C (citing and appending a slide from a presentation by Fish Passage Center to the Governors Orca Recovery Task Force (Oct. 2018), illustrating the order-of-magnitude increase in spring Chinook returns to the Columbia River mouth afforded by a breach + 125% spill management scenario as compared to various other scenarios). 103 Bain (2020) at 11. 104 Bain (2020) at 11. 91 abundance, including whether MO3 would actually introduce uncertainties into hatchery operations, discussed elsewhere in these comments. Additionally, Bain (2020)s conclusions underscore the DEIS failure to adequately discuss the implications of climate change on these runs future abundance and thus, their ability to provide an adequate prey base to SRKWs in the face of a warming climate.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	24	ttrue@earthjustice.org	Earthjustice	6. The DEIS Considers the Impacts of Losses to the Columbia/Snake River Chinook Run in a Vacuum, Failing to Evaluate the Impact of this Loss Together with Losses to Chinook Runs Coastwide on SRKW Survival and Recovery. The DEIS fails to evaluate the impact of the losses of Columbia/Snake River Chinook runs together with losses to Chinook runs coastwide, such that their cumulative impacts to SRKW survival and recovery can be adequately assessed. The DEIS states that, under the Preferred Alternative, the southern resident whales may have a slight increase in available food around the mouth of the Columbia River, but claims that [h]owever, this increase in food availability would have a negligible effect on killer whales, given that the Snake River and Columbia Chinook populations constitute a small portion of their overall diet. DEIS 7-151. Even if one takes at face value the claim that Chinook from the Columbia/Snake constitute only a small portion of SRKWs overall diet, the contention that the loss of this portion will not have much impact on SRKW survival and recovery is a claim that, were it made with respect to every run that provided a similar portion of the SRKWs overall diet, would permit the SRKW population to die the death of a thousand cuts. Under NEPA, the cumulative impacts resulting from individually minor but collectively significant actions must be considered.105 Rather than river by river, these collective losses to the SRKW must be considered in concert. Moreover, recall that, as NOAA Fisheries scientists have observed (see discussion in Part B.4) efforts to 105 40 C.F.R. 1508.7. 92 increase Chinook abundance for SRKW survival and recovery will likely need to include a variety of measures that address losses in Chinook run numbers and diversity throughout Chinooks historical and current range. The DEIS must also consider other past, present, and likely future effects that cumulatively affect the SRKW. These must include, for example, increases in vessel noise and disturbance due to planned and proposed terminal expansions in Washington and British Columbia, and changes to the SRKW ocean and Puget Sound habitat as the climate warms. The Agencies must consider these and other impacts in concert with the current reductions in food supply across the entire SRKW range, and the potential continuing downward trend in these runs	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. 				due to increased stressors such as climate change and increased development. Rather than consider the cumulative impacts of the many threats to SRKW, the DEIS only notes that restrictions on commercial fishing might benefit orca. DEIS 6-8. The benefit from fishery closures is fairly small. Including this very limited benefit while ignoring all of the other threats that have dramatically depleted these populations over time is irrational.	According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	25	ttrue@earthjustice.org	Earthjustice	D. The DEIS rests on a dated and inaccurate accounting of SRKWs Chinook prey requirements and thus concludes incorrectly that hatchery production compensates for the losses occasioned by the CRSO. The DEIS rests on a dated and inaccurate accounting of SRKWs Chinook prey requirements, and thus concludes incorrectly that hatchery Chinook production in the Columbia Basin compensates for losses occasioned by the CRSO. The DEIS claims that [f]ish hatchery production would continue at similar rates to the No Action Alternative into the future and the change in Chinook salmon abundance by the Preferred Alternative would be negligible. DEIS 7-151. The DEIS states that, under the Preferred Alternative, its models indicate either a negligible adverse decrease or a moderate increase in Chinook salmon populations that would return to the Columbia and Snake Rivers, such that the prey base available to marine 93 mammals foraging offshore may be negligibly lower to moderately higher. DEIS 7-151. The DEIS continues to note than any changes, including slight increases, in food availability would have a negligible effect on killer whales. DEIS 7-151. The appended BA provides a somewhat conflicting assessment, but concludes that hatchery Chinook production more than offsets losses to the SRKWs Chinook prey base. BA 3-599. The BA states that in 2008 NOAA conservatively calculated total mortality for Chinook caused by the CRSO, and concluded that Chinook salmon produced by hatchery programs supported by the Action Agencies more than mitigates for total Chinook mortality, and that in 2014 and again in 2019, NOAA confirmed the continuing validity of its earlier analyses and conclusions, once again based in part (and conservatively) on the fact that Chinook salmon hatchery production by the Action Agencies more than offsets near-term losses to the SRKW prey base resulting from all sources of mortality caused by the CRSO. BA 3-599.	In the Draft EIS, the effects of each alternative are analyzed relative to the No Action Alternative. Chinook size was not used as a metric to evaluate effects of CRSO EIS alternatives because the co-lead agencies are not aware of any information suggesting that operations of the CRS affect adult salmon and steelhead length-at-age. Therefore, Chinook would likely be smaller than pre-1970s under any CRSO EIS alternative formulated. With respect to hatchery practices on Chinook salmon size, Ohlberger et al. (2019) noted that wild populations of Chinook salmon in western Alaska that were not exposed to hatchery introgression or potential competition with hatchery stocks, such as Chinook salmon in western Alaska, experienced similar declines in length-at-age for older fish. Thus, it is not likely that smaller length-at-age is an adverse effect of co-lead agency-funded hatchery production. In their analysis of the effects of CRS operations on salmon and steelhead, the co-lead agencies chose smolt-to-adult survival (SAR), abundance of returning adults, in-river juvenile fish survival, and other metrics which are well known to be affected by CRS operations. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the CRS include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which would benefit SRKW foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The SAR is the rate at which a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets would require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.
6110	26	ttrue@earthjustice.org	Earthjustice	1. The DEIS Calculus of the Level of Hatchery Production Needed to Meet SRKWs Prey Requirements Does Not Account Fully for the Declining Per-Fish Energetic Quality of SRKWs Preferred Chinook Prey. The Agencies calculus of the level of hatchery production needed to meet SRKWs prey requirements does not account fully or rationally for the declining per-fish energetic quality of SRKWs preferred Chinook prey. Specifically, recent quantitative evidence regarding shifting Chinook population demographics appears not to have been considered in the DEIS or its appended BA. First, as the recent NMFS Biological Report in support of expanding Critical Habitat explains, SRKW are widely recognized to preferentially target older (> 3 year-old, and especially 4- and 5-year-old, Chinook), larger Chinook age classes.106 Chinooks large size, high fat and energy content, and year-round occurrence in SRKWs 106 NMFS CH Biological Support (2019) at 10-11. 94 range contribute to this preference.107 Scientists assessments of the age profiles of Chinook consumed by SRKWs show that Chinook age-4 and older comprise upwards of 87% of Southern Residents diet: Ford (2010) reported this 87% figure generally; the NMFS CH Biological Report (2019) reported a figure of 89% for SRKWs winter diet.108 Second, using new technologies to directly track SRKWs subsurface behaviors, scientists have recently revealed the degree to which SRKW are highly specialized hunters, with methods honed to avail themselves of the higher per-fish energy payoff provided by Chinook particularly by older, larger Chinook. This more recent evidence adds to earlier studies finding that SRKWs use echolocation to identify and preferentially target Chinook.109 Wright (2017) employed multi-sensor archival Dtag technology to obtain high-resolution dive tracks for foraging and other dive behaviors, finding that resident killer whales dive depth selectivity overlaps with and reflects the vertical distribution of their preferred prey, Chinook salmon, suggest[ing] that resident killer whales are intentionally diving to depths where preferred prey is more likely to occur.110 Wright (2017) found, further, that resident killer whales foraging dives extended to the deeper depths (>200 m) that correspond to the deep 107 NMFS CH Biological Support (2019) at 10-11. 108 Ford (2010) reported SRKW Chinook diets to be comprised of 43.4% age-4 fish, 37.7% age-5 fish, 4.4% age-6 fish, and 1.3% age-7 fish. John K.B. Ford, et al., Chinook Salmon Predation by Killer Whales: Seasonal and Regional Selectivity, Stock Identity of Prey, and Consumption Rates, Department of Fisheries and Oceans Canada, Research Document 2009/101(2010). NMFS CH Biological Report (2019) reported SRKWs winter Chinook diets to be comprised of 60% age-4 fish and 26.7% age 5 fish. NMFS CH Biological Report (2019) at 11. Ohlberger (2018) corroborates these numbers, albeit for all Northeast Pacific Ocean resident killer whale populations combined (2300 individual whales), inasmuch as they find that about 90% of the Chinook consumed by resident whales are 4-6 years old. Ohlberger (2018) at 543. 109 See, e.g., Whitlow W.L. Au, et al., Echolocation Signals of Free-Ranging Killer Whales (Orcinus orca) and Modeling of Foraging for Chinook Salmon (Oncorhynchus tshawytscha), 115 J. Acoustical Society of America 901 (2004). 110 Brianna M. Wright, et al., Fine-Scale Foraging Movements by Fish-Eating Whales (Orcinus orca) Related to the Vertical Distributions and Escape Responses of Salmonid Prey (Oncorhynchus spp.), 5(3) Movement Ecology (2017). Note that chum also swim at depths used by Chinook, although perhaps not at the greater depths used by the oldest and largest Chinook. Id. at 14. 95 dives performed by Chinook salmon that are significantly larger than those performed by smaller Chinook, consistent with the depths used by 4- to 5-year-old Chinook, which are the age classes preferred by resident killer whales: Although the foraging dive depths of killer whales overlapped with the vertical distribution of Chinook salmon, whales also extended their foraging dives to much greater depths of up to 379 m. Ultrasonic tracking has also shown that Chinook salmon swim to depths of 300400 m, and that fish performing deep dives (>200 m) are significantly larger (x = 87.2 cm) than those remaining at shallower depths (x = 77.3 cm). These deep-diving individuals correspond in length to 45 y Chinook, which are the size classes most frequently consumed by resident killer whales. This suggests that whales may dive beyond the average swimming depth of most Chinook to increase their chance of locating the larger and more energetically profitable 45 y old fish.111 Notably, Wright (2017) recognized that there are implications for energetics of these observed diving behaviors by resident killer whales when abundance of larger Chinook is low: This means that when Chinook salmon abundance is low, killer whales may continue to dive to the deeper depths used by their preferred prey, but would experience low encounter rates and poor energetic returns.112 Tennessen (2019) similarly analyzed newly available foraging behavior data regarding SRKWs subsurface movements afforded by Dtag technology.113 The authors observed that Chinook salmon, the largest salmon species, provide a significant energetic return, but given that they occur deeper than other salmon species, up to several hundred meters, SRKW must invest significant energy in the forms of breath holding and locomotion costs associated with fluking and drag, in order to pursue these larger caloric payoffs.114 Tennessen (2019) built on the findings of Wright (2017) to reveal that killer whale subsurface activity budgets are 111 Wright (2017) at 14. 112 Wright (2017) at 14. 113 Tennessen (2019) at 1. 114 Tennessen (2019) at 1-2. 96 complex, involving at least five distinct behavioral states, that relate to differing aspects of foraging and other behaviors, among these states the deep dives associated with prey capture but also a state associated with prey searching.115 Third, two recent studies, by Ohlberger (2019)116 and Ohlberger (2018),117 have documented a decline in Chinook body size-	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. Removing the dams alone will not recover the Chinook salmon to 1 million. The CFC did independent research that indicated that if dams were breached and the spill to 125% over the lower Columbia dams would "recover" the salmon populations. However, for the CRS that was not an alternative because it would not serve the obligations of the Lead agencies, including the Pacific Northwest Power grid. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4) individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in every seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. For reference, 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The condition of the chinook salmon is partially dependent on oceanic conditions, which have been poor for some years. This is beyond the scope of the EIS. In addition, the poor quality of chinook is found throughout the SRKW feeding range, not just within the Columbia and Snake River populations. Therefore, there is no guarantee that condition would improve with removal of the dams. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be minor, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.

				at-age and altered population structures. Ohlberger (2019) observed that: Chinook salmon have exhibited marked shifts in demographic structure throughout most of the North American range over the past 4 to 5 decades. In most populations, fish now mature at younger ages, and while the size of younger fish has been stable or increasing, older fish that return to spawn after several years in the ocean are increasingly smaller. In other words, size at age is declining for older fish but not for younger fish. As a result, the contributions of the largest and oldest fish to populations have declined since the 1970s, a trend that is remarkably consistent among populations along the west coast of North America.118 Specifically, Ohlberger (2018) documented that, in populations coastwide, there has been a decrease in size-at-age (measured by length (mm)) of ocean ages -3, -4, and -5 Chinook of about 5%, 7% and 9% respectively.119 Although this decline in size-at-age for these older classes of Chinook has occurred almost continuously over time, the size-at-age of ocean age-4 and age-5 has declined considerably, especially since about 2000.120 In addition, Ohlberger (2018) found that the proportion of Chinook populations comprised by 115 Tennessen (2019) at 8. 116 Jan Ohlberger, et al., Resurgence of an Apex Marine Predator and the Decline in Prey Body Size, PNAS 1910930116 (2019). 117 See, e.g., Jan Ohlberger, et al., Demographic Changes in Chinook Salmon Across the Northeast Pacific Ocean, 19 Fish & Fisheries 533 (2018). 118 Ohlberger (2019) at 1. As Ohlberger notes, their model considered the typical life history of North American Chinook salmon and did not account for differences among Chinook populations/stocks. 119 Ohlberger (2018) at 539. 120 Ohlberger (2018) at 539-540. 97 older fish has declined in most regions, albeit to a lesser degree in runs from Washington and Oregon than in runs from Alaska.121 Ohlberger (2019) considered these demographic trends in Chinook and noted the negative impacts to SRKWs in particular, given the significant reduction in the resulting per-fish caloric value 30% to 40% for an average Chinook: While increasing predation pressure is likely contributing to declining average sizes in Chinook salmon, some populations of fish-eating killer whales may in turn be negatively affected by reduced abundances and body sizes of their prey. A decline of 10% in mean length, as indicated by our data, implies a reduction in caloric value of an average-sized Chinook salmon of about 30 to 40%. Food limitation may be one of the factors responsible for the recent decline in the abundance of the southern resident killer whales (SRKW), the only population of fish-eating killer whales in the northeast Pacific Ocean that is not thriving.122 Ohlbergers findings, when taken together with previous studies (including Wright (2017) and Tennessen (2019)) insights into SRKWs foraging behaviors, including their significant energetic investment in pursuing and capturing Chinook salmon, one fish at a time, highlight the dire implications for SRKW when even successful captures result in only smaller caloric rewards. Importantly, these studies, which the DEIS does not address, call into question the calculations undergirding the Agencies claim that hatchery production at similar rates more than offsets wild Chinook mortality due to the CRSO. DEIS 7-151. BA 3-599. If the per-fish energy content of orcas preferred prey has declined significantly, then presumably SRKWs will require a greater number of fish to satisfy their daily and annual metabolic needs. Put differently, estimates of the number of fish needed to supply the SRKWs prey requirements are now likely too low. The agencies assurance that hatchery production is an ample substitute rests 121 Ohlberger (2018) at 537-38. 122 Ohlberger (2019) at 5. 98 on these dated figures about how many fish would need to be replaced and are incomplete and this omission is not addressed or explained. Consider, for example, Ohlberger (2018)s finding that there has been about a 9% decrease in the size attained by ocean age-5 Chinook coastwide between the late 1970s and the mid-2010s. If this decrease is applied to Ford (2009)s figures for the average length of an age-5 Chinook (939 mm), using ONeill (2014)s equation for calculating energy content in kcal/fish for Chinook of a given length, one can calculate that a 9% decline in size for an age-5 Chinook would mean a reduction from 939 mm to 854.5 mm and a consequent decrease from 20,992.0 kcal/fish to 15,638.0 kcal/fish.123 Thus, this decline in the quality of SRKWs preferred prey, i.e., the energy content that a Southern Resident whale can expect to obtain from an age-5 fish, makes each successful capture only 75% as valuable to that individual whale from an energetics perspective.124 Put differently, if the downward trend documented by Ohlberger (2018) holds, where three Chinook once sufficed, four Chinook will now be required. The BA cites the 2019 CRS BiOp for its contention that hatchery production will provide an adequate substitute for the prey base loss to SRKW. However, the 2019 CRS BiOp concedes 123 Comment authors calculations using Equation 15, ONeill (2014) at 275; these figures accord roughly with Ohlberger (2019) at 5 A decline of ~10% in mean length, as indicated by our data, implies a reduction in caloric value of an average-sized Chinook salmon of about 30 to 40%. (citing ONeill (2014). These figures are intended to provide a rough estimate; among other things, it should be noted that the decline in size-at-age documented by Ohlberger (2019) occurred continuously over a period beginning in the mid-1970s through 2015 (the last year for which they had data), although they noted a recent, steeper decline in age-4 and age-5 fish especially since about 2000. Ohlberger (2018) at 539-40. ONeill (2014)s study was based on Chinook sampled from 2000-2004. It is possible that some portion of the decline documented by Ohlberger (2018) and (2019) was already being reflected by the time of ONeills (2014) sampling. 124 And, all else being equal, a Southern Resident whale will need to undertake four energetically costly deep dives to pursue and capture a Chinook to net the same caloric payoff once afforded by three. See, generally, Tennessen at 51. Things are only somewhat better for the SRKW for age-4 Chinook. If Ohlbergers observed 7% decrease in the size attained by ocean age-4 Chinook is applied to Ford (2010)s Chinook length figures, using ONeill (2014)s equation for kcal/fish, an orca whale would have to consume five Chinook in order to obtain the same energy formerly provided by four. 99 that [s]ome of the assumptions used in its analysis [concluding that hatchery production will more than offset any CRSO-caused loss to the SRKWs prey base] have changed in the last decade, including killer whale biomass and prey energetics.125 But it doesnt cite Ohlbergers (2019) or (2018) work (or Tennessen (2019) or Wright (2017)), and doesnt address in a rational way the evidence that Chinook are trending younger and smaller.	The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6110	27	ttrue@earthjustice.org	Earthjustice	The DEIS Discussion of the Level of Hatchery Production Needed to Meet SRKWs Prey Requirements Also Fails to Consider the Marked Increase in Chinook Prey Required to Support an SRKW Population that is Not Teetering on the Brink of Extinction and, Ultimately, Necessary to Support SRKW Population Growth Necessary for Recovery. The Agencies discussion of the level of hatchery production needed to meet SRKWs prey requirements also fails to consider the marked increase in Chinook prey required to support an SRKW population that is not teetering on the brink of extinction and continuing to decline and, ultimately, the level of prey required to support SRKW population rebuilding and recovery. Scientists have emphasized the point that significantly more Chinook salmon would be needed to support a recovered SRKW population than are necessary to feed a depleted SRKW population. Writing in 2010, Ford (2010) projected that, as of 2018, assuming a recovering population of 113 southern residents and 332 northern residents, their annual requirement for Chinook salmon would need to be increased by 32% over that necessary to feed the reduced SRKW and NRKW populations as of 2008. Fords calculations assumed an optimal 2.6% annual population growth rate, which they reported as the rate observed in the population during the period of 125 2019 CRS BiOp at 912. 126 Rather, it follows its concession that some of the assumptions, including prey energetics, have changed with but a recent qualitative analysis (NMFS and WDFW 2018) affirmed our conclusion that hatchery Chinook salmon more than compensate for fish lost to the dams in terms of total numbers of Chinook salmon available to the killer whales. 2019 CRS BiOp 912. It is difficult to see how this 8-page document, which does not speak to changing prey energetics or how this change might affect a calculus of how many hatchery fish it would take to compensate for impacts to SRKW, could have provided the affirmation claimed. 100 positive growth between 1973 and 1995, and assumed appropriate changes in the age- and sexclass composition of the SRKW population from the then-current baseline.127 Williams (2011) similarly recognized that any accounting for SRKW prey requirements for a recovered population would need to include significantly more Chinook than necessary to support the then current, depleted SRKW population. Specifically, Williams found that the U.S. recovery goal of 2.3% annual population growth over 28 years implies roughly a 75% increase in prey energetic requirements (i.e., adequate to support a recovered population of 155 southern residents in 2029).128 Finally, recall that Lacy (2017)s PVA model also considered the U.S. recovery goal of 2.3% annual population growth and found that SRKW recovery cannot be achieved without reaching the highest levels of salmon abundance observed since 1979, which was 30% higher Chinook abundance than the long-term average between 1979 and 2008.129 While there is variation in these assumptions and in the bottom-line estimate of the level of increase in Chinook prey necessary to support a larger recovering or recovered SRKW population, it is clear nonetheless that the increase is considerable. Neither the DEIS nor its appended BA discuss the point that a significantly larger Chinook prey base is needed to support a larger, recovered SRKW population than to support the current depleted SRKW population. The DEIS appears to contemplate little change on any front, stating that [f]ish hatchery production [under the Preferred Alternative] would continue at similar rates to the No Action Alternative into the future and the change in Chinook salmon 127 Ford (2010) at 12. Note that for purposes of their projections, Ford (2010) assumed that Chinook generally comprise 70% of the resident killer whales diet. 128 Rob Williams, et al., Competing Conservation Objectives for Predators and Prey: Estimating Killer Whale Prey Requirements for Chinook Salmon PLoS ONE 6(11) e26738 5 (2011). 129 Lacy (2017) at 6. This assessment considered SRKW by addressing the most significant threat identified by the authors, i.e., prey availability. They also offered alternative multi-threat prescriptions, e.g., reducing acoustic disturbance while increasing Chinook prey by 1.15x. 101 abundance by the Preferred Alternative would be negligible; observing that, for all ESA-listed species, it is assumed that [they] will remain listed, and existing regulatory and best management practices would reduce the likelihood that populations would continue declining or become extinct; and stating that [c]hanges to food availability may change the [SRKWs] foraging behavior patterns slightly but will not change their overall condition or population dynamics. DEIS 7-151. DEIS 7-150. The Agencies simply fail to provide any evidence that they contemplate a larger, recovered SRKW population and have accounted for the significantly increased prey base that would be necessary to support this	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the CRS include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKW foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.5). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.

				SRKW increase. As noted above, the BA contends that hatchery production will more than offset any Chinook mortality caused by the CRSO. These documents are not entirely in agreement as to whether hatchery production levels will remain the same or be increased. Even if hatchery production is at somewhat improved levels (BA 3-599), production would need to be significantly increased to supply the 30% - 70% greater Chinook quantities that scientists have found would be required to support a SRKW population assuming NMFS 2.3% population growth rates necessary for SRKW recovery. Note that here too, calculations of the quantity of Chinook that would be necessary to meet SRKWs needs must take into account the changes to the per-fish energetic quality of Chinook, given the declining Chinook population demographic trends discussed above, in Part C.1. Again, The discussions in the DEIS and BA fail to explain whether or how these considerations have been accounted for in the Agencies assertions that hatchery production will compensate for losses to SRKWs Chinook prey base.	
6110	28	ttrue@earthjustice.org	Earthjustice	The DEIS Conclusion that Hatchery Chinook Production Will Compensate for Losses to SRKWs Chinook Prey Base is Not Adequately Supported by the Evidence. The DEIS conclusion that hatchery Chinook production will compensate for losses to SRKWs Chinook prey base is not adequately supported by the evidence. As noted above, the DEIS appears to contemplate hatchery production at similar rates to current levels. DEIS 7 151. In the appended BA, the Agencies point generally to past improvements to the operation of the CRSO and the resulting improved survival of Chinook salmon through the hydrosystem. BA 3-599. Additionally, the BA cites improvements as a result of completed estuary and tributary habitat actions, and states that these past improvements will continue. BA 3-599. The BA contends that these past improvements, together with the prospective non-operational conservation measures proposed in Chapter 2, all contribute towards maintaining and improving Chinook abundance, and result in a net gain in Chinook abundance available as a prey source for SRKW. BA 3-599 and 3-600. To the extent the Agencies offer support for their claim, Appendix E to the BA contends that [a]nnual survival estimates indicate an upward trend in survival of juvenile steelhead and Chinook salmon migrating through the Snake and Columbia Rivers over the last two decades. In general, more adult fish and more wild adult fish are returning to the river; however there has been a downward trend in the last 5 years of returning adult salmon and steelhead. BA App. E E-10. The multiple flaws of this analysis are addressed in some detail in the sections of these comments that address the effects of the alternatives on salmon and steelhead populations. Further, the DEIS analysis fails to recognize that the appropriate baseline for assessing impacts to SRKW survival and recovery is the historical rate of Chinook salmon abundance in the Columbia/Snake River system, the evidence for which is discussed above, in Part B.3 Thus, even considering generous figures for current Chinook survival and returns, including wild and 103 hatchery Chinook, there is a significantly reduced quantity of Chinook salmon available to supply SRKWs daily and annual prey requirements when considered in light of this appropriate, historical baseline. And, here again, one would need to account for the declining trend in size-at age for older Chinook documented by Ohlberger (2018) and (2019), such that the per-fish energy value is lower, as discussed in Part C.1. Additionally, the Agencies point in the appended BA to (a) a general increase in adult Chinook salmon returning to the Snake and Columbia Rivers, including wild and hatchery-origin fish, (with the exception of the last 5 years), as well as (b) an upward trend in juvenile Chinook survival over the past two decades as the basis for their optimism that CRSO-caused losses to the available Chinook prey base will continue to be more than offset. However, the available scientific evidence calls into question both of these bases for the Agencies assessment as explained elsewhere in these comments. As to (a), the Agencies portrayal of the data as suggesting a general or consistent upward trend also fails to convey the degree to which adult returns, and particularly adult returns of Snake River spring/summer Chinook, have plummeted in recent years. The Agencies characterization may thus mislead as to the import of this significant recent downward trend of 5-years duration. According to Idaho Department of Fish & Game data on returns for the Snake River spring/summer Chinook runs, returns of wild Chinook adults numbered 15,939 in 2016, but fell markedly in the following years, to: 4,108 (2017), 6,863 (2018), and 4,723 (2019); and returns of hatchery Chinook adults numbered 58,187 in 2016, but fell markedly in the following years , to: 30,179 (2017), 31,820 (2018), and 18,893 (2019).130 Notably, these recent years of extremely low wild and hatchery returns for the Snake River spring/summer Chinook runs 130 Idaho Department of Fish & Game spreadsheet data. 104 coincide with the recent precipitous decline in the SRKW census: recall that whereas the SRKW population numbered 83 whales in 2016, their population declined to 77 whales in 2017, 75 whales in 2018, and just 73 whales in 2019.131 Yet the DEIS neither notes nor evaluates this correlation, despite Wasser (2017) and other scientists findings regarding the relationship among nutritional stress, reduced SRKW females body condition upon arrival in the Salish Sea in the spring due to low Columbia/Snake River spring runs, and unsuccessful pregnancies, discussed above in Part B.1. To the extent that the DEIS purports to offer the graph at DEIS 3-300 to suggest that runs in recent years are higher than theyve been in decades, with a record 2.5 million fish (wild and hatchery combined) returning to Bonneville in 2014, the DEIS is misleading for several reasons. First, the correct baseline is the historical level of fish from this river system, as discussed above. Second, even if the start date for comparison is 1930s Chinook returns, this graph neglects to account for historic harvest levels, which approximated 50% before the fish arrived at Bonneville (where DART data depicted in the graph is from). This means there were as much as twice as many fish in the ocean then for SRKWs to catch. Finally, these Chinook were all wild, not hatchery, fish and they were a lot bigger because the decline in size discussed above in Part C.1 had not set in. Thus, it is reasonable to assume that the Southern Residents had a much better opportunity to meet their nutritional needs under these circumstances and the much greater SRKW population size estimates from this earlier period tend to support this assumption. As to (b), the Agencies claim of improved survival of juvenile Chinook through the hydrosystem (and resulting increased abundance) has been challenged by scientists as not being 131 Center for Whale Research, Population, updated as of Dec. 31, 2019 https://www.whaleresearch.com/orca-population (accessed April 3, 2020). 105 supported by the best available data and analysis. With respect to SARs a key indicator of survival Bain (2020), summarizes: There is uncontroverted evidence that the current SARs for Snake River spring/summer Chinook at are or below 1%, barely half of the minimum 2% SAR level the Northwest Power and Conservation Council has identified as necessary for maintaining existing populations, and only one quarter or less of the 4% to 6% SAR level that must be achieved and sustained for this population to rebuild and recover. [citing the CSS 2016 Annual Report, Chapter 7] This evidence is at odds with NOAAs claim of increased abundance. Moreover, this unacceptably low SAR has been consistent for many years, indicating that the extensive and expensive efforts so far to rebuild the Snake River spring/summer Chinook populations have not been successful.132 This issue is also addressed in more detail elsewhere in these comments. Additionally, whereas the BA in Chapter 3 touts benefits for Chinook survival from past improvements to CRS operations, its own data in Appendix E, Columbia River System Operational and Structural Improvements Under the Endangered Species Act 2020 Progress Report, call into question this reliance. The Agencies presented the results of in-river reach juvenile Chinook and Steelhead survival monitoring initiated under the 2008 and 2019 BiOps to assess the effects of management actions. Without further textual discussion, the Agencies state that the results presented in Figure E-9 indicate the benefits from improved system operations, passage improvements, and predation deterrent actions implemented to date are generally accruing at least as well as expected in the 2008 BiOp analysis. BA App. E E-24. However, an inspection of the four bar and-whiskers graphs in Figure E-9 shows benefits generally accruing in the most recent three years reported (2013, 2014, and 2015) to two populations (wild and hatchery Upper Columbia River yearling Chinook, and wild and hatchery Upper Columbia River Steelhead) through the McNary to Bonneville reach, and to one population (wild Snake River Steelhead) through the 132 Bain (2020) at 5; Fish Passage Center, Comparative Survival Study of PIT-Tagged Spring/Summer/Fall Chinook, Summer Steelhead, and Sockeye, 2019 Annual Report (2019) http://www.fpc.org/documents/CSS/2019CSSAnnualReport.pdf. 106 Lower Granite to Bonneville reach, but not accruing in any of these three recent years to wild spring/summer Snake River yearling Chinook through the Lower Granite to Bonneville reach. BA App. E E-24. The Agencies textual generalization thus obscures the lower-than-predicted rates of in-river survival for wild Snake River juvenile Chinook through this reach, undermining the BAs claim of and confidence in the benefits of past improvements to operations of the CRS for increased Chinook abundance to meet SRKW Chinook prey needs. The Agencies do not elucidate why the prescribed operational measures appear not to be resulting in the projected increases to juvenile wild Snake River Chinook survival through this reach, and nowhere evaluate the implications of these disappointing survival rates for the spring/summer Snake River Chinook for the SRKWs particular dependence on this run, as discussed above in Part B.1. As discussed in greater detail elsewhere in these comments, SARs are the appropriate measure of abundance, not juvenile reach survival data. This is particularly true for SRKW, who consume the largest adult Chinook. More juvenile fish that make it past the dam do nothing for SRKW if they fail to mature and return as suitable-sized adult prey. Finally, the Agencies belief that they can maintain or increase hatchery populations at will is belied by their record. As noted in the comments submitted by the Nez Perce Tribe, adult spring and summer Chinook salmon returns have never met their mitigation targets and have often fallen far short. The agencies fail to explain why they will be able to increase hatchery returns now when they have consistently failed in the past. Nor do they explain how they will maintain populations or even achieve increases despite the additional stressors of climate change and increased development, among others, which will increase in future years. In sum, the Agencies contention that hatchery production will be able to more than offset any mortality losses to Chinook caused by the CRSO is not supported by the scientific 107 evidence, including the Agencies own data. Thus their conclusion that there will be a	The co-lead agencies evaluated alternatives to operating, configuring and maintaining the CRS projects, including an alternative that evaluated the effects of breaching the four lower Snake River dams. Consistent with existing caselaw on ongoing actions, the co-lead agencies used the year in which the Notice of Intent to Prepare the EIS was issued (2016) as the No Action Alternative as the basis for comparison against the action alternatives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA-listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.6. Please also see responses to Comments 6110-16 and 6110-25; and, updated language of effects on Southern Resident killer whale in Sections 3.6 and 7.7.8.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				resulting [] net gain in Chinook abundance available as a prey source for SRKW (BA 3-600) and that with continued hatchery production at similar rates such that the Preferred Alternative is not likely to adversely affect the SRKW (DEIS 7-153 Table 7-28) is unsubstantiated.	
6110	29	ttrue@earthjustice.org	Earthjustice	The DEIS Assumption that Hatchery Programs Will Cease Under MO3 is Unsubstantiated. The Agencies assume in the DEIS that under MO3, available prey for SRKW would actually decrease because the LSR hatcheries would cease to exist upon implementation of this alternative. This assumption is entirely unfounded, for several reasons. As the Agencies acknowledge, even after breach of the four LSR dams under MO3, it would take some time for the river to return to a natural state and still more time for wild salmonid runs to rebuild. This transition period is still an effect of the action of maintaining the LSR dams for decades, and continued hatchery production at least through the transition period until wild runs fully recover would be required under existing law. The Agencies might also have the option or the obligation to maintain LSR hatcheries even beyond a lengthy transition period. While the Agencies might need additional funding and/or authority to continue to operate the LSR hatcheries, that is no reason to assume they would cease to exist. Indeed, NEPA requires consideration of actions beyond an agencys existing authority. In short, there is no reason to assume that the LSR hatcheries would vanish under MO3, or that the SRKW would suffer further declines in available prey.	The Draft EIS does not state that all lower Snake River hatcheries would cease to exist. The Draft EIS acknowledges that upon the breaching of the four lower Snake River dams under MO3, Bonneville would no longer have an obligation to fund the operations and maintenance of the Lower Snake River Compensation facilities because Bonneville's funding authority is directly tied to the operation of the four lower Snake River projects. As stated in the CRSO EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made through the CRSO EIS process. Future Fish and Wildlife funding decisions would be made in consultation with the region, through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Finally, there are other hatcheries in the Snake River basin, which are not tied to operations of the four lower Snake River dams, that would continue to operate.
6110	30	ttrue@earthjustice.org	Earthjustice	The DEIS is Out of Step with Other Federal Documents in Failing to Acknowledge that Any Decrease in SRKW Food Supply is a Major Adverse Effect. The Agencies claim that the CRSO will not significantly impact the prey available to SRKW. For all of the reasons above, that conclusion is untenable and at odds with an 108 overwhelming body of scientific evidence. Because the CRSO does decrease the Chinook prey available to SRKW, it has a significant adverse effect on this imperiled population. Federal agencies have recognized in other planning documents that a reduction in Chinook prey adversely affects the SRKW. For example, in the 2014 Biological Opinion on the National Flood Insurance Program carried out in the Puget Sound area, NMFS recognized that a reduction of up to 132,724 Chinook would jeopardize the continued existence of the SRKW.133 NMFS considered the impact of this prey reduction on the amount of prey available to be consumed by SRKW, the additional energy it would require SRKW to expend locating and capturing prey, and the impact of the loss of Chinook diversity and local abundance. NMFS acknowledged that this reduction in prey would result in effects on SRKW including reduced fecundity and reproductive success, and acknowledged that insufficient prey works in concert with other threats to adversely affect SRKW, for example, by leading to mobilization of lipids with high levels of toxic contaminants. Finally, NMFS recognized that this loss in prey affects not only the current, depleted population of SRKW but would also impact the ability of a larger, recovered SRKW population to meet their prey needs. On the basis of these and other factors, NMFS concluded that the loss of 132,724 Chinook would jeopardize SRKW. These and other factors apply with even greater force to the loss of prey due to the CRSO, as discussed in detail above. Moreover, since 2014, the additional scientific studies discussed above reinforce the harmful impact of a reduction in Chinook prey. Indeed, at the time the 2014 Biological Opinion on the National Flood Insurance Program was written, experts believed that the SRKW population was increasing, whereas now it is declining from an already perilously low level. While the loss of 132,724 Chinook would be from the SRKW Puget Sound 133NMFS, National Flood Insurance Program 138-50, https://www.fema.gov/media-librarydata/20130726-1900-25045-9907/nfip_biological_opinion_puget_sound.pdf. 109 habitat, as discussed above in Part B, the best available science demonstrates that the Columbia/Snake Chinook runs form a critical part of the SRKW seasonal diet.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. Please also see responses to Comments 6110-16 and 6110-25; and, updated language of effects on SRKW in Sections 3.6 and 7.7.8.
6110	31	ttrue@earthjustice.org	Earthjustice	VIII. THE DEIS FAILS TO ADDRESS THE EFFECTS OF THE ALTERNATIVES ON ELECTRICITY PRODUCTION IN A COMPLETE OR RATIONAL WAY AND ITS ANALYSIS OF THRSE ISSUES IS ARBITRARY As explained more completely in comments on the DEIS submitted by the Clean Energy Advocates/NW Energy Coalition, the DEIS fails to describe and disclose the effects of the alternatives, especially MO3, on energy generation and system reliability, among other energy related issues, and hence presents an incomplete and misleading picture of the effects of MO3 on both energy generation and ratepayers. Rather than repeat these comments here, we refer the agencies to them for a more complete description of the failures of the DEIS with respect to energy issues.	Section 3.7.3.5 of the Draft EIS describes the impacts to power and transmission from Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams, including the impacts to hydropower generation and power system reliability. This section also includes the rates impacts analysis. The EIS power analysis relies on industry standard models, data from the Northwest Power and Conservation Councils Seventh Power Plan and Midterm Assessment as well as various Bonneville power models. Section 3.7.1 Methodology, and Appendices H, I and J describe the methods and data used in the power analysis. This Appendix T includes responses to the comments from Clean Energy Advocates/NW Energy Coalition, which this commenter may wish to review.
6110	32	ttrue@earthjustice.org	Earthjustice	IX. THE DEIS DISCUSSION OF THE SOCIOECONOMIC IMPACTS OF THE ALTERNATIVES IT CONSIDERS IS ARBITRARY, CAPRICIOUS AND CONTRATY TO LAW The socioeconomic assessment of the alternatives in the DEIS fail to address or employ widely accepted professional standards applicable to ensure a thorough, objective and transparent evaluation of the alternatives. These standards are expressed jointly in court interpretations of the National Environmental Policy Act (NEPA), the Corps guidance documents for socioeconomic analyses, the Principles, Requirements, and Guidelines for Federal Investments in Water Resources (PR&G) developed in response to the requirements of the Water Resources Development Act of 2007 (WRDA), the Department of Interiors Agency Specific Procedures for implementing the Principles, Requirements, and Guidelines, Executive Order 12866 Regulatory Planning and Review, and the Office of Management and Budgets Circular A-4. The deficiencies in the socioeconomic analysis in the DEIS result in deep, systemic gaps in the document and arbitrary and misleading conclusions regarding the socioeconomic effects of 110 the alternatives. These issues are addressed in more detail in the Comments On the Socioeconomic Elements of the Columbia River System Operations Draft Environmental Impact Statement prepared by Natural Resource Economics and dated April, 2020 (Doc. # EJ199) which we have submitted or are submitting as part of these comments and this document and those referenced in it should be included in the administrative record for the CRSO EIS and as part of these comments.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Consistent with the National Environmental Policy Act (NEPA) analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. The Preferred Alternative was chosen to meet the Purpose and Need Statement and EIS objectives, including anadromous and resident fish, hydropower, water management and water supply, while minimizing adverse effect to biological and socioeconomic resources. The process of developing the Preferred Alternative is described in Chapter 7. The methodologies employed to evaluate the socioeconomic resources throughout the EIS used co-lead agency and other water resources guidance. In addition, the socioeconomic models and approaches were reviewed by a panel of experts as part of the Independent External Peer Review. The primary goal of Independent External Peer Review is to establish that models, analyses, results, and conclusions are theoretically sound, computationally accurate, based on reasonable assumptions, well-documented, and in compliance with the requirements of the OMB Peer Review Bulletin (OMB 2004). As noted previously, the socioeconomic resources have been evaluated qualitatively in some cases. In these cases, the evaluations relied on the hydrology and hydraulics; river mechanics; aquatic habitat, aquatic invertebrates and fish; and vegetation, wetlands, wildlife, and floodplains evaluations to wildlife to infer the impacts to the socioeconomic resources. However, it should be noted that even though the effects of the alternatives on fish are not expressed as monetized economic values, does not mean they were not considered in the context of the analysis.
6110	33	ttrue@earthjustice.org	Earthjustice	X. THE DEIS FAILS TO RATIONALL ADDRESS TRANSPORTATION AND NAVIGATION ISSUES RATIONALLY, ESPECIALLY ITS DISCUSSION OF THE EFFECTS OF MO3 ON THESE RESOURCES The transportation analysis in the DEIS is inadequate and incomplete, particularly the scenarios used to assess transportation impacts and alternative transportation for freight shipments under MO3. A. The DEIS arbitrarily relies on stakeholder interviews without any supporting data or analysis. The DEIS reliance on stakeholder interviews with inland shippers, deep draft shippers and barge companies providing their undocumented opinions about what will occur to rail rates and other shipping costs under MO3 or a similar river restoration alternative is arbitrary and affects the objectivity and frame of assumptions put forth in the analysis. DEIS App. L at 2-5, 134-137. A specific example of this defect can be found at L 3.1 during the overview of the model used, Transportation Optimization Model (TOM), where there is confusion over what goods ship through lower Snake River locks vs. those that only ship through Columbia locks. Here and in other places in the DEIS upriver fuel shipments are indicated as part of the freight volume shipped through Snake River locks, when, in fact they are transported only as far as Port of Pasco on the McNary reservoir. Industry analyses often erroneously include fuel shipments in 111 Snake River shipping statistics, and it is reflected here in the characterization of goods moving on the lower Snake River vs. to Columbia ports, DEIS at 3.4.2.1; App. L-3-12). It is not until deep into the appendix where it is clarified that fuel does not travel through Snake River locks, Id. at 3.4.2.1, 626-634, and the agencies never address how this contradiction affected their analysis or the vague reports of shipper interviews. B. The transportation analysis is a snapshot and does not adequately look at transportation trends. The transportation analysis in the DEIS relies on numbersshipping volumes, state of the transportation system -- that are a snapshot of a moment in time (most data comes from 2016-2017) and has only limited projections of longer term major shifts occurring in transportation, including investments in rail, which have reduced barge shipping on the lower Snake River by more than 50 percent in the past 20 years. The DEIS does not explain why it did not use available information regarding past or future shipping trends for the lower Snake River waterway, including independent assessments (as opposed to vague interviews) for these issues. New rail infrastructure continues to be built and planned in the region, including new unit train facilities. While these recent investments are mentioned, there is no analysis of this continuing shift or what it means for the value of the barge corridor for transportation over the long-term, a value that will likely it will continue to decline. C. Dam repairs and barge infrastructure costs are inexplicably not addressed: While speculative impacts to potential rail rate increases under MO3 are described in some detail, as well as some of the costs of some rail investments, these costs are not compared to the current and future capital and maintenance costs of the lower Snake navigation system, including lock repairs, dredging and other costs needed over the next 20 to 40 years to maintain the aging waterway. Available analyses indicate that these costs may be very high and they 112 cannot properly be omitted. If the analysis is going to take into account additional costs for highway maintenance under MO3 (which under the worst scenario would be $10 million annually), at a minimum, it needs to weigh these costs against the full suite of direct and indirect costs of maintaining the waterway. D. The rate data in the DEIS for each shipping mode is inadequate and unreliable. The DEIS notes that getting accurate rate data is difficult, especially in regard to shuttle rail, as these rates are negotiated between the shipper and the rail carrier and not made public. The proposed rate increase scenarios (no rate increase, 25 percent 50 percent) are based on limited data, as well as the personal opinions of shippers who were interviewed, positing what they think rate increased could be (some suggesting 50 percent higher) rather than on any attempt to collect and describe actual rate data. E. The DEIS analysis inexplicably assumes grain shipping on the Snake will remain constant. The DEIS notes the historic trends of precipitous declines of grain shipping on the lower Snake River due to the opening of two additional shuttle rail facilities (McCoy and High Line Shuttle Terminals). Grain projections over the long-term should have been discussed or analyzed, rather than assuming grain shipments would continue into the future unchanged at 2.4 million tons per year. The region served by the lower Snake waterway has been experiencing steady declines of wheat shipments on the waterway for many years as more rail comes on line and there is no reason to expect this trend to change. The DEIS also failed to	A. and D. Rate information is generally not public; it is negotiated privately. Because it is competitive information (confidential business information), shippers are reluctant to share this information. The CRSO EIS analysis involved a rigorous effort to develop a survey of shippers that was approved by the Office of Management and Budget (OMB). Strict protocols for survey administration from OMB were adhered to when administering the survey. Nonetheless, responses to the survey were somewhat limited. Every attempt was made to acquire accurate and verified rate data from shippers. Although there may be inefficiencies with the rate data presented in the Draft EIS, it is the best possible estimate that is available to replicate a rate that is decided upon privately. The commenter is correct that there were some instances where the termination point of fuel shipments was not clear in the Draft EIS. These have been clarified in Section 3.10 and in Appendix L where relevant in the Final EIS. B. The demand for waterway transportation is influenced by many factors, both related to the river operations and competing transportation modes. In many cases, that demand is affected by private sector choices (investments by Class I railroads, construction of shuttle rail elevators by grain companies) that are largely difficult to predict into the future. The approach taken here is to utilize historical volumes as a barometer of what generally has been demanded and to provide impacts relative to that since it is known with certainty. Information has been added to the Navigation Appendix L that puts the EIS findings into context using recent historical highs and lows as a guide. C. Infrastructure costs, including dam maintenance costs, are described in Appendix Q, Costs Analysis. E. Additional information has been added in the Final EIS in Appendix L to better describe ongoing trends in the region from an expanded universe of commodities. F. One major issue when considering rail is that shippers are only using rail for a small subset of goods. To accommodate a larger range of commodities, rail in the region would need to make substantial capital investments in the construction of new terminals. Given that it is the Class I railroads that decide where they will invest in their infrastructure and when, there was no reasonable process for predicting how and where they choose to invest to maximize profits on a national rail network that moves far more products than wheat from the Northwest. The EIS acknowledges in Section 3.10.3.5 that employment affected estimates do not include increased demand for trucking employment that would accompany these shifts, and that, because trucking is more labor intensive than barge operations, increased trucking demand would likely increase employment demand for shipping handlers. However, the EIS also acknowledges that stakeholders have noted that, in the short-term, an already tight market for truck drivers would be made even tighter. G. Section 3.10.3.5 acknowledges that it is likely that the facilities with rail access would continue to be used to some extent for storage and transport via rail or truck; however, these facilities are assumed to be closed for purposes of this analysis. It further states that to the extent that some terminals on the lower Snake River could continue to be used, the effects to shippers would be lower than model results suggest. H. As stated, the analysis of rail and port storage capacity in a breach scenario is based on stakeholder surveys. The co-lead agencies verified interpretations of capacity from shippers, ports, and other stakeholders where possible. To investigate beyond these findings would require resources and time beyond the constraints of this EIS. I. It is impossible to know how or if the state will attempt to mitigate the effects of an increase in rail rates. Many rail lines in the region are privately owned. Attempting to predict how the state would interact with these rail roads and their rates during a breach scenario would create unjustified assumptions. J. The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID, to Ayer Junction, WA. Research completed for the EIS, suggests that elevator to river port movements via short-line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. Information has been added to Appendix L that describes the impacts of modifying this assumption on quantified costs to shippers. K. A caveat has been added in the discussion of shipment of oversized objects in Chapter 3 to acknowledge that there has been litigation and controversy surrounding these types of shipments in the past.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				address in any way changing international markets/demand for grain shipped on the lower Snake River. The trend for demand for these products, which largely supply international markets, also is declining but this information is not presented or addressed. 113 F. The DEIS does not rationally examine benefits to rail and highway investments that would come with implementation of a rationally constructed dam removal alternative. While the costs to some shippers from a shift away from barge transportation under MO3 is described in some detail, there is no analysis of the socio-economic benefits to the Inland Northwest from shifting to rail over barge for products that move through the lower Snake waterway. Very few commodity types are shipped by barge on the lower Snake River, today primarily wheat, fertilizer, some timber products, all of which can be shipped by rail as well. Yet many key products that are produced in the region, or could be produced, cannot easily go by barge. Providing rail investments to communities in the Inland Northwest would likely promote new manufacturers and businesses moving to the area but these potential benefits are not explored even generally. G. The DEIS doesnt adequately acknowledge that Snake River ports would continue to exist and operate even with lower Snake River dam removal Today ports along the lower Snake River rely heavily on transportation modes other than river navigation to support their businesses, including Port of Lewiston (which ships little to nothing on the river currently and relies mostly on a trucking facility) and Port of Wilma which has rail capacity. While the DEIS recognizes that ports with rail access would continue be used for grain storage and shipment, the facilities are assumed to be closed for purposes of this analysis. DEIS at 3.4.2.1, 362-375; App. L at 3-13. This is an arbitrary and unexplained assumption that also is almost certainly false too. H. The DEIS provides an inadequate analysis of the rail and storage capacity that would be built after the lower Snake River dams are removed The DEIS notes that additional rail and other investments would be built if the dams were removed, but does not describe, analyze or adequately take these changes into account. Instead, it falls back on the stakeholder surveys, with Ports claiming that they wont have land available 114 to build more rail infrastructure, but with no actual investigation of or data to support these claims. These claims are at odds with how businesses actually behave when the economy changes. As explained elsewhere in these comments, businesses are adaptable and will change to meet changing circumstances. Often this new equilibrium involves gains or losses in some aspects of the existing economy but it rarely involves complete cessation of one kind of activity with no replacement. The DEIS arbitrarily makes no effort to examine future port operations in the context of a real world economy. I. The DEIS provides no information or analysis to potential mitigation for any rail rate increases that may occur with dam removal. The three rail rate increase scenarios described in the DEIS for MO3 are all based on assumptions about how rates for rail and other transportations alternatives will rise in cost, with the assumption that a rail monopoly and price-gouging by rail companies may raise rates upwards of 50 percent. The DEIS makes no effort to identify or describe any mitigation measures (regulatory, investments, or otherwise) that could be available and implemented to address possible future changes (which, as noted above, are not actually supported by any rational analysis in any event). DEIS at 3.4.2.1 376-385; App. L-3-13). J. The analysis assumes that all grain shipped out of Pasco would need to transported to that Port by truck. The DEIS suggests that without the lower Snake River dams in place, all grain now leaving from Pasco would be transported to the port by truck. The analysis does not look at rail infrastructure and other solutions that would enable grain to be economically and efficiently delivered by rail to the Port of Pasco. These mitigation measures exist but the DEIS fails to identify or consider them. DEIS at 3.4.2.1, 412-425; App. L-3-14, DEIS at 3.4.2.1, 461-464; App. L-15. 115 K. The DEIS includes Shipments of Oversized Objects as a value of the lower Snake dams. The shipment of so-called mega-loads from Port of Lewiston and then over the winding Wild & Scenic Highway 12 corridor is mentioned as a benefit of continuing the current lower Snake River navigation system. These kinds of shipments have been opposed by the Nez Perce Tribe, local residents along the Highway 12 corridor, and have been extremely controversial. Many of these shipment have been planned but never occurred. In the absence of any information or analysis, consideration of these shipments should not be included as a benefit of the existing navigation system in the DEIS analysis.	
6110	34	ttrue@earthjustice.org	Earthjustice	XI. THE DEIS ANALYSIS OF THE IMPACTS OF MO3 ON IRRIGATED AGRICULTURE IS INCOMPLETE, INCONSISTENT WITH PRIOR ANALYSES AND ARBITRARY The 2002 Lower Snake FEIS analyzed breaching the 4 lower Snake River dams and asked the question, can irrigation systems that irrigate farmland along Ice Harbor be modified so that farming can continue? The conclusion in 2002 was yes. That EIS analyzed an alternative, Option 3, that could technically work and that met the following criteria: operational prior to breaching of the Ice Harbor reservoir; function through a full range of river stages without interruption; and able to handle a potentially large quantity of suspended sediment. This was detailed in Appendix D, Natural River Drawdown Engineering and Technical Appendix D, Existing Systems and Major System Improvements Engineering. The report concluded that it was possible to modify the irrigation systems to continue farming the existing crops, orchards, vineyards, and tree plantations. However, the report also concluded in Appendix I, Economics, that modifying these systems would cost too much ($291,481,000) relative to the land value ($137,940,000). 116 The underlying assumption throughout this analysis is private entities (the landowners) would be required to pay for those modifications and they would choose not to modify their systems. This was not a necessary or even a reasonable assumption in 2002. Given the high public cost of maintaining the dams, it is reasonable to consider including at least some of the costs of irrigation modifications within the public costs of dam removal and river restoration but the DEIS fails to even consider, let alone evaluate this approach. We support maintaining these lands as productive agricultural lands, and we support including the costs of irrigation modifications in the cost of breaching the dams. The agencies never explained in 2002 why that would not be reasonable. And they have still not done so in the DEIS. Similarly the costs of modifying wells, including the sequencing of work in order to maintain a water supply during drawdown, was estimated to be $56,447,000 in 1998. These costs are not discussed or updated in the DEIS or considered as part of the public costs of implementing MO3. The DEIS discussion of irrigation dismisses even the possibility of modifying irrigation systems and simply assumes that all irrigated land it identifies will go out of production at a cost of more than $350 per acre per year and that these costs will continue annually for the next 50 year. This approach leads to an arbitrary and misleading presentation of the effects of MO3 on agriculture. From the 2020 DEIS: The current analysis also assumed that all irrigated acres (approximately 47,926 acres) receiving water from the current pumps would no longer be irrigated (with condition) and would convert to dryland pasture (without condition). This assumption was based on conversations with several extension agents in Washington and Oregon. 117 No actual source or detail information is given for this statement. Only a slightly more extensive statement on this topic appears in the 2002 FEIS in Section 5.11 under Farmland Value, where it stated, This analysis based the determination of economic effects to irrigators under Alternative 4 Dam Breaching on a change in farmland values that would occur with elimination of the current water supply. Typical land values for farm properties near Ice Harbor were used. This information was compiled through discussions with farm managers, cooperative extension agents, farmland appraisers, agricultural economics professors, and the use of published enterprise budget sheets for a number of crops. The above quote was a discussion of land values. The DEIS apparently treats this statement as a conclusion that all irrigated land would go out of production. As the 2002 FEIS makes clear, the pumps and wells can be modified. The question is: who pays for it? The agencies never explained in 2002 and do not explain now in the DEIS – their conclusion that none of these costs can or should be included in the costs of MO3. More importantly, neither the 2002 FEIS nor this DEIS make any effort to explore reasonable mitigation alternatives for irrigated agriculture lands that will be affected by river restoration (in the DEIS under MO3). As noted above, there is no analysis of irrigation alternatives under MO3 in the DEIS at all. To the extent the agency is relying on the analysis in the 2002 FEIS, that analysis sets criteria for replacing irrigation systems the most extreme possible and never considers any other criteria. Thus the 2002 FEIS only considered irrigation replacement approaches that meet the following requirements: operational prior to breaching of the Ice Harbor reservoir; function through a full range of river stages without interruption; and able to handle a potentially large quantity of suspended sediment. The 2002 FEIS never explains why these are the only criteria it would be reasonable to consider when it is apparent that there are other reasonable approaches to mitigating the impacts of river 118 restoration of current irrigation uses. Since the DEIS does not address this at all, it goes without saying that it fails to do any better. For example, rather than consider an approach that would need to be in place and operational from day one and able to handle both the initial, short-term high sediment loads of a restored river and a more normalized flow regime, the DEIS today (and the FEIS in 2002) could have examined an alternative that would pay irrigators that grow annual crops to fallow their land for two or three years following dam removal until the river and groundwater stabilize and much of the initial sediment load from upstream has moved past irrigation intakes. At that point, existing intakes could be modified and supplemented with booster pumps (a common practice) as necessary. There would be no need for a massive settlement pond or a single new intake. This approach and its costs have never been discussed or considered. Similarly, for non-annual crops that would require continuous irrigation, the DEIS (and the 2002 FEIS) never considered any alternative that would provide a temporary, one to three year, water supply for these acres (or identified how many such acres there are) or the feasibility or costs of such an approach. In short, for the irrigation impacts of MO3, the DEIS identifies the most extreme version of potential impacts, treats that as the only possible outcome, and then describes those impacts in one-sided and arbitrary economic terms. This approach is not rational and fails to meet the fundamental purposes of NEPA.	The co-lead agencies reviewed the 2002 study and came to similar conclusions as the study. First, the conclusions reached about the infeasibility to deepen wells or extend individual pumps were based on engineering and hydrogeologic facts that had not changed since 2002. Second, though building a new pump structure and modifying existing irrigation infrastructure was considered to be technically feasible, it was not economically feasible; this conclusion was based on high-quality information. Last, the determination that these lands would not convert to dryland farming was based on conversations with experts that had knowledge of rainfall, soil types, and farming practices in the region; there was no reason to doubt their judgment as to whether these lands would be dryland farmed. Therefore, assuming that these lands would no longer be irrigated was considered reasonable for the purposes of Multiple Objective 3 in the EIS.
6110	35	ttrue@earthjustice.org	Earthjustice	XII. THE CUMULATIVE IMPACTS ANALYSIS IN THE DEIS IS INADEQUATE Pursuant to NEPA, an environmental analysis for a single project must consider the cumulative impacts of that project together with past, present and reasonably foreseeable future actions. 40 C.F.R. 1508.7, 1508.25, 1508.27(b)(7); see also id. 1508.25(c)(3). Regulations define cumulative impact as the impact on the environment which results from the 119 incremental impact of the	The CRSO EIS includes an analysis of direct, indirect and cumulative effects consistent with 40 C.F.R. 1508.25(c). The direct and indirect effects analysis is included in Chapters 3 and 7 and the cumulative effects analysis is included in Chapters 6 and 7. The cumulative effects analysis in Chapter 6 sets the stage for the analysis in Chapter 7 by discussing how past and present actions are considered in the analysis, and then identifies over 20 reasonably foreseeable future actions that may

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				action when added to other past, present, or reasonably foreseeable future actions[.] 40 C.F.R. 1508.7. By this approach, NEPA seeks to prevent piecemeal degradation of the environment by individually minor but collectively significant actions taking place over a period of time. Id. A cumulative impact analysis must be more than perfunctory[.] Kern v. Bureau of Land Mgmt, 284 F.3d 1062, 1075 (9th Cir. 2002). It must provide sufficient detail to be useful to the decisionmaker in deciding whether, or how, to alter the program to lessen cumulative impacts. Muckleshoot Indian Tribe v. United States Forest Service, 177 F.3d 800, 810 (9th Cir. 1999) (quoting City of Carmel-By-The-Sea v. United States Dept of Transportation, 123 F.3d 1142, 1160 (9th Cir. 1997)). Importantly, [t]o consider cumulative effects, some quantified or detailed information is required. Neighbors of Cuddy Mountain, 137 F.3d 1372, 1379 (9th Cir. 1998). The agencies cumulative impacts analysis fails to offer a meaningful analysis of how the alternatives, and in particular MO3, differ with respect to the many cumulative threats that will adversely affect salmon over time. There is significant information available that shows that the cumulative impacts of many anthropogenic threats to salmonids will be damaging and sometimes synergistic. These threats are likely to grow far more quickly in areas of the Columbia River basin that have more anthropogenic alterations than in the wilderness and protected public lands surrounding the Lower Snake River in Idaho. These public lands include the Frank Church/River of No Return wilderness area, a vast wilderness of 2,366,757 acres the largest contiguous wilderness area in the lower 48 states along with multiple other wilderness areas and forest service lands. (See map of public lands in Idaho submitted as part of these comments.) MO3 will allow far more salmon to reach habitat that will be subject to far fewer 120 cumulative effects than other areas in the basin. The agencies utterly fail to consider this key point in their cumulative impacts analysis. Moreover, the agencies fail to analyze cumulative impacts to salmonids with any specificity, even where significant information is available. And the agencies fail to consider and discuss additional measures to benefit salmon in light of these cumulative impacts. For example, Landis et al. (2018) found that salmonid populations, including Chinook in the Yakima River are less likely to meet recovery goals when the effects of water temperature and dissolved oxygen (both driven by climate change) are combined with the effects of chlorpyrifos, a toxic organophosphate pesticide that functions as an acetylcholinesterase inhibitor for salmon, leading to direct mortality and a range of sublethal effects that lead to population-level harm. While chlorpyrifos use may be declining, other pesticides also function as acetylcholinesterase inhibitors and harm salmonids, as NMFS has recognized in multiple published biological opinions on the effects of various organophosphates and other pesticides on salmonids in the Pacific Northwest. See also Baldwin et al. (2009). There is specific available information on the magnitude of these cumulative and synergistic effects, including Landis (2018), that the agencies must use to assess the magnitude of these impacts. The agencies must also consider which salmonid populations will be most impacted. Because organophosphate pesticides are used more heavily in agricultural and urban areas than in the wilderness areas surrounding the LSR, the LSR runs will suffer less cumulative and synergistic harm from these toxins. Under MO3, more salmonids will be able to reach the habitat that is least affected by these threatsa major benefit that the agencies never acknowledge or discuss. Similarly, there is substantial research showing that stormwater is toxic to both adult and juvenile salmonids. See, e.g., Stormwater Quality in Puget Sound, Impacts and Solutions in 121 Reviewed Literature (2017). Research also shows that the adverse effects of stormwater are particularly associated with the presence of high-vehicle-intensity impervious roads. See Feist, Roads to Ruin (2017). As with toxic pesticides, stormwater runoff, and the high-vehicle intensity impervious roads that are a major factor in generating it, is not distributed evenly across the landscape. The wilderness and protected public lands surrounding the tributaries of the Lower Snake River in Idaho are not riddled with highways. Many other areas throughout the Columbia/Snake River basin currently do have many impervious roads, and as human development continues throughout the region, those areas will likely experience increased cumulative impacts from urbanization, including stormwater runoff. Under MO3, more salmonids will be able to reach the habitat in the LSR basin that will experience fewer cumulative impacts from stormwater runoff. Again, the agencies never acknowledge or discuss this benefit. Stormwater runoff associated with urbanization, and pesticide use associated with agriculture and urbanization, are just two of the cumulative threats to salmonids that will likely increase over time. A long list of additional anthropogenic threats cumulatively impact salmonids now, and these threats will grow over time. These include the absence of mature riparian forested buffers along salmon-bearing streams, water withdrawals for agriculture and development that deplete flows, and toxics such as PCBs and PBDEs that cause direct mortality and sublethal harm to salmonids, to name a few. The agencies acknowledge that many of these threats will cumulatively impact salmonids, but they fail to offer meaningful detail about the magnitude of these impacts and they utterly fail to recognize that these cumulative impacts will all be far less severe in the protected public lands surrounding the Lower Snake River. 122 Elsewhere in these comments we discuss the agencies failure to consider that MO3 will allow for species-level climate resilience by allowing more salmonids to reach the coldest-water habitat off the LSR. In its cumulative impacts analysis, the agencies must also consider that cumulative impacts compound this benefit of MO3 by allowing more salmonids to reach habitat surrounded by public lands that will be far less adversely affected by a suite of anthropogenic threats. Additionally, the presence of a suite of cumulative impacts, virtually all of which will likely increase adverse effects to salmonids, underscores the need for the agencies to evaluate and include a substantial buffer in the actions they claim will mitigate for the harm caused by the CRSO. The agencies proposed mitigation allegedly will offset harm from the CRSO (though it will not even do that, as discussed elsewhere in these comments), but the agencies do not even attempt to assert that they have included enough mitigation to offset the harm from the CRSO as well as the additional harm from climate and other cumulative impacts. Without an additional, substantial buffer of beneficial mitigation, these populations will continue to slide toward extinction. Finally, the agencies include a vague assertion that state, local, and tribal efforts to benefit salmon could partially alleviate[] the harm from the suite of anthropogenic threats that cumulatively impact salmon. DEIS 7-209. By the agencies own admission, at best these other efforts will only partially reduce the harm. Additional mitigation is necessary.	cumulatively affect resources affected by CRS operations, maintenance and configuration. This analysis includes the cumulative effects to fish, including salmon and steelhead from varied actions, including population growth, water withdrawals, additional renewable energy development and fishery management plans, among others. The agencies have clarified the language in Chapters 6 and 7 to acknowledge the cumulative effects analysis does include consideration of the climate change analysis in Chapters 4 and 7 as well as the mitigation information provided in Chapters 5 and 7.
6110	36	ttrue@earthjustice.org	Earthjustice	THE DEIS FAILS TO ADEQUATELY AND OBJECTIVELY EVALUATE ALTERNATIVES THAT ARE BEYOND THE AGENCIES CURRENT AUTHORITY TO IMPLEMENT. The agencies have failed to adequately and objectively evaluate alternatives that they believe are beyond their current authority to implement.134 One of the most important aspects of NEPA is its demand that agencies consider alternatives beyond their current authority to implement. Implicit in this authority is the ability to recommend implementation of those alternatives as their preferred alternative if appropriate. See, e.g., 40 C.F.R. 1502.14(c) (directing agencies to include in an EIS reasonable alternatives not within the jurisdiction of the lead agency). Without this kind of authority, NEPA becomes a straightjacket, limiting agency consideration of reasonable alternatives to a range circumscribed by existing authority that may be decades old, at odds with both available information and actions that would be reasonable now but were not in the past, and at odds with sound public policy and environmental protection today. See, e.g., Natural Res. Def. Council v. Morton, 458 F.2d 827, 837 (D.C. Cir. 1972) (noting that NEPA was intended to provide a basis for consideration and a choice by the decisionmakers in the legislative as well as the executive branch); Forty Most Asked Questions Concerning CEQs National Environmental Policy Act Regulations, Answer 2(b), 46 Fed. Reg. 18,026, 18,027 (1981) (noting that an EIS may serve as the basis for modifying the Congressional approval or funding). While the agencies do analyze and consider one alternative (MO3) that they believe is beyond their current authority to implement, one of the primary reasons they reject recommending this alternative and seeking additional authority or funding to implement it is 134 These comments assume but do not accept or agree with -- the agencies view of the scope of their existing legal authority and consequently reserve the right to raise these legal issues subsequently if necessary. 124 their view that it is beyond the scope of their existing authority. This circular reasoning we can consider alternatives beyond our current authority to implement but we cannot recommend them if they exceed our existing authority -- turns one of the most important aspects of NEPAs action forcing power to lead to improved environmental decision-making and protection into a hollow exercise. See Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 350 (1989) (observing that NEPAs action-forcing procedures that require a hard look at environmental consequences ensure that the sweeping policy goals of the statute are realized). In fact, the agencies approach risks reducing NEPA to a meaningless, paper-pushing exercise where agencies must simply jump through the procedural hoop of considering an alternative beyond their authority to implement in order to reach a predetermined result. See 40 C.F.R. 1500.1(c) (stating that it is not better documents but better decisions that count); see also NWF v. NMFS, 235 F. Supp. 3d 1143, 1153-56 (W.D. Wa 2002) (explaining flaws in agency failure to fully consider an alternative beyond the scope of their authority without any reasoned explanation). The agencies circular approach to rejecting MO3 is in addition to the agencies failure to fully and objectively evaluate that alternative as explained further in these comments. Indeed, in light of the agencies unreasonably narrow statement of purpose and need, their view of their existing authorities, and the way they apply these as yardstick to assess the various alternatives, the DEIS actually presents only one reasonable alternative under their criteria, the preferred alternative, because it is the only alternative they conclude will meet their interpretation of their existing statutory authority and their interpretation of the purpose and need for the CRSO EIS. See Natl Parks & Conservation Assn v. Bureau of Land Mgmt, 606 F.3d 1058, 1070 (9th Cir. 2010) (finding that an agencys objectives cannot be so narrow that only one alternative would accomplish the goals, resulting in an EIS that is a foreordained 125 formality (citation and quotation marks omitted)). Each of the other alternatives fails to meet one or more of these purposes or some aspect of their existing authority and on that basis, the agencies conclude the alternative is not reasonable. In other words, instead of developing a range of reasonable alternatives to meet a properly drawn statement of purpose and need for the CRSO EIS, including reasonable alternatives that would require new or additional authority, the	The co-lead agencies note that although a Preferred Alternative was identified in the Draft EIS, the co-lead agencies have not determined which alternative will be selected, or whether any alternative ultimately selected will include modifications resulting from comments or input received on the Draft EIS. With respect to the Draft EISs treatment of Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams, the co-lead agencies disagree that one of the primary reasons that it was not identified in the Draft EIS as the Preferred Alternative is because they do not have existing authority to implement breaching the four lower Snake River dams. The co-lead agencies conducted extensive analysis of the direct, indirect and cumulative effects of the Multiple Objective Alternatives (including breaching the four lower Snake River dams under MO3 and the Preferred Alternative). Based on this effects analysis (see Chapters 3, 4, 5, 6 and 7), the co-lead agencies evaluated the tradeoffs to affected resources and CRS purposes. The agencies developed an alternative, which was identified as the Preferred Alternative in the Draft EIS that seeks to balance multiple purposes identified in the Purpose and Need Statement, the EIS objectives and the effects analysis. The Preferred Alternative strives to minimize adverse effects to resources affected by CRS operations, maintenance and configuration. However, the Preferred Alternative is not the only alternative that remains under consideration, all of the MOs are. This includes MO3. Indeed, consistent with the aims of NEPA, the agencies provided notice to the public in the Draft EIS of the Corps' existing authorities and the stepwise process that would be required if the co-lead agencies selected MO3 as the Preferred Alternative. If this occurred, the Preferred Alternative would serve as a recommendation to Congress, which Congress would need to authorize. Congress would also need to authorize additional studies, including NEPA analysis, and funding appropriations for implementation. The co-lead agencies also disagree that the Draft EIS indicates that only the Preferred Alternative is a reasonable alternative under their criteria. As explained in Chapters 2 and 7, the agencies did develop objective criteria to help gauge the degree to which each of the evaluated alternatives met the Purpose and Need Statement and EIS objectives. However, none of the evaluated alternatives meet all of the objectives, including the Preferred Alternative (which, for instance, as discussed in Chapter 7 does not meet the EIS objective for greenhouse gas emissions). The co-lead agencies developed a reasonable range of alternatives, analyzed these alternatives and then determined which alternatives met the Purpose and Need Statement and EIS objectives. The Draft EIS does not indicate that some alternatives are unreasonable and thus, not subject to further consideration just because they did not meet particular purposes or objectives. Finally, the co-lead agencies disagree that the Preferred Alternative, or any of the other alternatives, other than the No Action Alternative, do not make meaningful modifications to operational, structural and mitigation measures that are beneficial to ESA-listed species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				agencies have developed and analyzed a range of alternatives that they conclude are unreasonable because they fail to meet their statement of purpose and need or their understanding of their existing authority or both. Consequently, late in the process they developed the only alternative they conclude will satisfy their criteria, the preferred alternative, even though they did not actually conduct an analysis of it and its effects as they did for the other alternatives they concluded were unreasonable. This crabbed approach to understanding and applying a statement of purpose, and the role of their existing authority, in analyzing alternatives arbitrarily but effectively transforms the DEIS into a lengthy justification for the only alternatives the agencies conclude is reasonable, an alternative that looks remarkably like a continuation of status quo river operations. But see Natl Wildlife Fedn, 184 F.Supp.3d at 876 (noting that a comprehensive EIS can break through any logjam and allow, even encourage, new and innovative solutions to be developed, discussed, and considered). It also confirms that they have failed to explain why their approach to both a statement of purpose and need for this EIS and their approach to alternatives they believe they do not have the current authority to implement is either rational or complies with the requirements of NEPA or any other statutes intended to protect salmon, steelhead and orcas. See City of Carmel-by-the-Sea v. U.S. Dept of Transp. 123 F.3d 1142, 1155 (9th Cir. 1997) (finding that an agency cannot define its objectives in unreasonably narrow terms).	
6110	37	ttrue@earthjustice.org	Earthjustice	THE DEIS COMMENT OPPORTUNITY WAS INADEQUATE TO MEET THE PURPOSES AND REQUIREMENTS OF NEPA The federal agencies issued the DEIS on February 28, 2020, and provided the public with the bare minimum comment period of 45 days. The DEIS is nearly 8,000 pages long, poorly organized and presented in a way that makes comparison and consideration of the alternatives difficult if not impossible for the public even with the investment of an exceptional amount of time. In addition, the agencies previously had made clear in the NWF v. NMFS case their reasons for concluding and telling the Court that a considerably longer comment opportunity would be needed. Nonetheless, in response to a December, 2018 presidential memorandum, the agencies shortened the process for preparing an EIS that they had sought and the court had allowed by more than a year, including reducing the public comment period to the minimum of 45 days. The presidential memorandum failed to provide any rational basis for shortening the time allowed to prepare an EIS and complete the remand process.135 Numerous individuals, organizations and elected leaders requested and extension of the comment period beginning soon after the agencies announced their new schedule and continuing through and after release of the DEIS. The agencies never explained their basis for rejecting these requests or provided any rational account for their actions in light of their prior statements to the Court. This approach is arbitrary on its own. In addition, however, as the agencies released the DEIS, the public health emergency brought on by the coronavirus erupted and grew to unprecedented proportions. This pandemic led to the cancellation of public hearings on the DEIS and replacement of these with 135 If litigation over the CRSO EIS should ensue, the plaintiffs in the NWF v. NMFS case reserve the right to seek discovery to determine the basis for the agencies decision to shorten the remand process, including, but not limited to, the basis for the presidential memorandum to the extent the agencies seek to rely on it as a basis for shortening the process. 127 teleconferences that were poorly attended and difficult to participate in. The pandemic also created circumstances in which almost all public activity ceased including through the end of the public comment period. These circumstances led to yet another round of requests for suspension or extension of the comment period and again from individuals, organizations and elected leaders. Again, the agencies refused to extend the comment period even under these unprecedented circumstances without any explanation except to state their view that they were satisfied with how the public comment process was proceeding. The Ninth Circuit has explained that under NEPA, agencies must provide the public with sufficient environmental information, considered in the totality of circumstances, to permit members of the public to weigh in with their views and thus inform the agency decision-making process. See Bering Sea Citizens v. Corps of Engineers, 524 F.3d 938, 953 (9th Cir. 2008). While the Court issued this holding in the context of an environmental assessment, its logic also applies to the preparation of an EIS given the fundamental informational purposes of NEPA. The agencies arbitrary refusal to allow any more than a minimum 45-day comment period on the DEIS under the extraordinary circumstances that faced the public even without the coronavirus emergency, but certainly in light of that, make the agencies refusal arbitrary, capricious and contrary to law and a more than adequate basis for requiring the agencies to either re-open the comment period on the DEIS when the public health emergency has passed or risk having the DEIS remanded to them for failing to meet the procedural requirements of NEPA under the present circumstances.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6111	1	anna.kr.roberts@gmail.com	N/A	The preferred alternative claims to improve Chinook salmon and steelhead populations by 35 and 28%, respectively, as the best outcome. These values are relative, and misleading, in that they improve only the current populations by that much. The current populations are at an incredible low point of about 1% of their historic abundances, and a 35% improvement will not have the same impact as is implied by that number. Not only are these numbers skewed and represent an entire lack of effort at revival, but they are based upon a 25 year timeline, equal to only five generations of Chinook salmon, which is an inadequate amount of time to truly determine the effects on the fish and the possibility of their extinction. Beyond that, if populations remain at this low level, even with a small increase of 35%, the populations remain at extremely high extinction risks, as salmon would only reach a maximum of about 1.5% of their historic numbers. These improvement estimates, that clearly do not meet with CRSO objectives, do not even consider the other factors that impact salmon populations, such as hatcheries and climate change.	Relative comparisons of trends is appropriate when comparing outputs from different models or comparing trends in different metrics. Values of absolute change are also reported for all metrics, however the co-lead agencies echo the advise of the CRSO modeling teams that trend analysis is an appropriate framework to analyze complex model results with their inherent uncertainty. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. A 25 year analytical time frame is appropriate based on CRS model teams declining confidence in model output beyond that point. Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). A full assessment of considerations of climate change and water temperatures are in section 3.4 Water Quality, Chapter 4 Climate, and Chapter 7 of the Preferred Alternative of the analysis.
6111	2	anna.kr.roberts@gmail.com	N/A	When addressing the minimization of greenhouse gases in these alternatives, the fact that dams themselves contribute to methane emission was never addressed. Instead of ignoring this, it must be considered in alternatives that retain these four dams, and in the reduction of methane emission from MOA 3 in order to report accurate findings. Anytime there is a build up of nutrients, like getting trapped along with sediment behind a dam, there is going to be eutrophication and algal blooms which lead to an increase in methane emissions. MOA 3 was said to increase greenhouse gases, but in this EIS it was never considered how removing the dams could actually decrease the methane they produce themselves.	This comment correctly identifies that hydropower reservoirs can act as a source of greenhouse gas (GHG) emissions. Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River System, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the lower Snake River dams.
6111	3	anna.kr.roberts@gmail.com	N/A	Additionally, the preferred alternative states a predator control mitigation measure to increase salmon survival that entails disrupting the nesting habitat of the Caspian tern via the John Day reservoir. What happens to these species when they experience habitat loss?	The Predator Disruption Operation discourages nesting within the John Day reservoir and would result in terns searching for other suitable nesting locations other than the John Day reservoir. In coordination with USFWS, this project would comply with the Migratory Bird Treaty Act by obtaining permitting for new avian predation actions, if necessary. Ongoing avian predation actions would rely on existing permitting. As part of this projects monitoring and adaptive management plan (Appendix R, part 1), monitoring of the Predator Disruption Operations measure would occur to determine the measure effectiveness on reducing the avian predators nesting habitat.
6112	1	bre.l.anderson@gmail.com	N/A	The DEIS must include a comprehensive economic analysis of Idahos salmon sportfishery and its POTENTIAL in the event of restored abundant wild salmon and steelhead returns. Salmon and steelhead fishing supports guides, outfitters, and businesses in river towns throughout the state. This money supports the economy of Idaho in a HUGE way and can not be ignored. A more robust salmon and steelhead run will only increase this value. Facts provided by Idaho Rivers United: In 2019 anglers spent $750 million dollars in the state. In the Clearwater region in 2003, during a decent return year, salmon and steelhead anglers spent $8.6 million a month.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For MO3, Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.
6112	2	bre.l.anderson@gmail.com	N/A	Alternative MO3 needs to include an accurate cost-benefit analysis of the four Lower Snake River dams and the power they generate Purchasing replacement power on the open market would cost $11 million/year. This is $38 million/year cheaper than estimated LSRD maintenance and operation expenses and does not include benefits from reduced fish and wildlife and turbine rehab costs. Turbine replacements and maintenance in the next decade at the four dams will cost tens of millions of dollars a year.	A benefit cost analysis is not a requirement of NEPA or the basis of alternative selection under NEPA (40 C.F.R. 1502.23). Instead the direct and indirect effects to the natural and human environment were evaluated, including some effects that were evaluated quantitatively and monetized, while others were evaluated qualitatively. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					(Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6112	3	bre.l.anderson@gmail.com	N/A	Breaching the dams is the only option that meets life-cycle survival criteria, achieves meaningful recovery, and minimizes the jeopardy of extinction. According to the scientific models in the DEIS, only MO3 will lead to smolt-to-adult ratios (SARs) that meet regional goals. Averaging 4 adults returning for every 100 smolts migrating out (4% SAR), with a range of 2-6% SAR has been deemed necessary for recovery to sustained, harvestable abundance. MO3 is the only alternative that adequately minimizes the risk of extinction for Snake River stocks as a baseline; something legally required of this DEIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
6112	4	bre.l.anderson@gmail.com	N/A	The DEIS needs a more thorough economic analysis on the benefits of a restored Lower Snake River corridor. With out the dams 140 river miles, one-seventh of the entire Snake River, would be restored in the event of dam breaching. This would increase opportunities for fishing, hunting, wildlife viewing, rafting, and general tourism would positively impact the local economy.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For MO3, Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Regions C which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.
6125	1	fredcoriell@gmail.com	N/A	The EIS does not articulate any discussion other than a chart (Figure 3-61) about how both the CSS and COMPASS models converge on the actions outlined in MO3 as having the greatest potential for Snake River anadromous survival in the CRSO. Please include a more robust discussion, other than one couched in the agency's own biased policies, of how the removal of the four dams achieves the greatest likelihood of species survival.	This is presented in Chapter 3, section 5 and Chapter 7, section 3. The two models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NOAA COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NOAA Life Cycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. However, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6125	2	fredcoriell@gmail.com	N/A	Further, the EIS does little to discuss or make any attempt to quantify the economic costs and environmental impacts that the alteration of, and break in, the nutrient cycle of salmon has had on inland watersheds, especially in Idaho.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) and also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The CRSO EIS addresses abundance of anadromous fish among alternatives, which is the driving mechanism of marine nutrient cycling. The actual mechanisms, effects, magnitudes, and processes are nutrient cycle from salmon to terrestrial locations is very complex and uncertain. The analyses used in this Draft EIS were for the purposes of comparing the effects of operation, maintenance and configuration of the CRS projects to one another and to the No Action Alternative. For the purposes of comparing alternatives, a more detailed analyses of marine nutrient transfer throughout the spawning habitats was not completed or relevant to the proposed Federal actions. Section 3.5.2.3 recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. The EIS provides an evaluation of recreation (Section 3.11) and commercial fisheries passive use values (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Benefits that may occur to fish and fisheries are described in Sections 3.5 and 3.15, respectively.
6125	3	fredcoriell@gmail.com	N/A	The purpose and need statement is narrow. It does not recognize the purpose to protect and preserve cultural resources or provide for the conservation of fish and wildlife resources on equal footing as other purposes stated in the analysis (DEIS ES-16). As a result the alternatives in the EIS are biased towards the culturism and outdated policy initiatives of the co-lead agencies. The alternatives read very much like a corporate marketing presentation that touts the enduring benefits from services provided by and actions undertaken by the corporation without any meaningful discussion of the negative consequences these have on other interests outside the corporation and its network of reliant cohorts.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. These objectives were developed in coordination with cooperating agencies, tribes, and from comments received from the public during scoping. As stated in the Executive Summary and Chapter 1, the Purpose and Need Statement includes provisions for protecting Native American treaties and reserved rights and trust obligations for natural and cultural resources throughout the environment affected by CRS operations. The Purpose and Need Statement also includes, under the Legal and Institutional Purpose, the need to comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, including those specifically addressing the CRS such as requirements under the Northwest Power Act to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated. 16 U.S.C.A. 839b(11)(A).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Chapter 3, 4, 6, and 7 discuss the benefits and adverse affects to resources. Chapter 7 discuss the Preferred Alternative development and how it meets those criteria in the Purpose and Need Statement. Additionally, Chapter 7 includes a discussion and Table 7-1, which provides a summary of how well or if the alternatives meet the Purpose and Need Statement, objectives, and a summary of resources effects. The Preferred Alternative includes a combination of measures that meet the Purpose and Need Statement and objectives of the Columbia River System Operations (CRSO) EIS, while providing a balance to the authorized purposes of the 14 Federal dam and reservoir projects that make up the CRS.
6125	4	fredcoriell@gmail.com	N/A	The discussion of ghg emissions for MO3 is flawed in that it does not address the shift towards electrified transportation and the reduction this has on ghg emissions. Bonneville Power Administration (BPA) has a surplus to sell. Even with thermal generation retirements this surplus can be used at off peak times when cars are charging, and with a little creative thinking integrating this with the growing renewables market, should be a priority for investment in infrastructure.	The EIS does describe potential shifts towards cleaner transportation options (see EIS Section 3.8.3.2 pages 3-992 and 3-996 in the Draft EIS) and the power load forecasts developed by the Northwest Power and Conservation Council, which are the basis of the power analysis in Section 3.7, include considerations for increasing transportation electricity demands.
6125	5	fredcoriell@gmail.com	N/A	Please provide a true and accurate annual cost analysis of the lower four Snake River Dams. First, the DEIS admits its replacement analysis was constrained by the timeframe imposed on the co-lead agencies to produce the document: Developing a zero-carbon portfolio that would replace all attributes of the lower Snake River projects for the base case analysis was not possible given the time constraints with this analysis (DEIS 3-905). This is unacceptable because it is an admission that the co-lead agencies will not be taking a hard look at information truly significant to the action in question (40 C.F.R. 1500.1(b)). It also fails to guarantee relevant information is available to the public. N. Plains Res. Council, Inc v Surface Transp. Bd., 668 F.3d 1067, 1072 (9th Cir. 2011. Unfortunately other reasonable scenarios for replacement have not been discussed. The 2550MW necessary could also be satisfied by placing 6-8KW of solar capacity on roughly 350,000 homes, commercial buildings, and industrial facilities coupled with onsite battery storage (consider 350,000 distributed batteries that store an average of 16 kwh) that is primarily used to provide power during peak loads thus flattening the peak curve. There are many ways to approach this problem, which only a handful of BPA-centric ones have been discussed in the EIS analysis. The analysis seems to only look at utility scale options; a clear nod to the expected bias of an industry that views itself as generator first, distributor second. Further, the IMPLAN model has proven to be problematic when used to create an economic cost/benefit analysis (see Crompton, J. (2019), "Uses and abuses of IMPLAN in economic impact studies of tourism events and facilities in the United States: a perspective article", Tourism Review, Vol. 75 No. 1, pp. 187-190). It tends to 1 quantify one or the other quite well, but not both. Also please include the rationale for choosing the particular multipliers used in IMPLAN (3-932, 3-934). There is no attempt to quantify costs that these dams put on the state of Idaho recreation economy. It is tens of millions of dollars per year and will continue to be so as long as these dams further precipitate the decline of anadromous fish. This cost needs to be accounted for in the economic model.	High-quality information was used for the cost analysis of the Draft EIS (See Sections 3.7 and 3.19, Appendix H, and Appendix Q). For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four lower Snake River dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four lower Snake River dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRP capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. The comment expresses concern that (a) time constraints prevented the co-lead agencies from giving the replacement resource analysis a hard look; (b) only a subset of potential replacement resource options were considered; and (c) the IMPLAN analysis has been proven to be problematic in similar contexts and does not consider impacts to Idaho's recreational economy. Contrary to the comments suggestion, the EIS does identify a potential replacement portfolio for the full capability of the four lower Snake River dams consistent with NEPAs requirement that the agencies rely on high-quality information in EISs (40 C.F.R. 1500.1(b)). The portfolios for MO3 were developed sequentially. At the outset of CRSO EIS power modeling in 2017, the process outlined in the Methodology Section 3.7.3.1, step 3 (pages 3-819-822 in the Draft EIS) produced the base case portfolio. However, as the analysis progressed, information about the coal-plant retirements became public and Bonneville assessed the loss-of-load probability in light of coal-plant retirements, it became clear that the base case portfolio relied heavily on other resources in region, meaning that the base case portfolio did not replace all of the capabilities of the four lower Snake River dams. Bonneville chose to design a Full Replacement Portfolio separately, without altering the base case methodology applied to all alternatives. See Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, at pages 3-829-830 in the Draft EIS. The co-lead agencies took a hard look at all the effects of MO3, which includes breaching of the four lower Snake River dams, regarding hydropower generation, the required replacement resources to maintain system reliability and the associated costs. See Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166; See Section 3.7.3.5, Effects on Power System Reliability, at pages 3-903-905 in the Draft EIS; see also Appendix H, Table 2-1; Section 3.7.3.5, Potential Replacement Resources And Associated Costs, Table 3-160. About replacement options, the EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their Seventh Power Plan (Seventh Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS; see also Appendix H, Power and Transmission, at Section 2.2. Given this, residential distributed solar was not specifically considered as a potential replacement resource. However, if Bonneville or its customers pursue resource acquisitions, these would occur through careful selection among all available options, potentially including roof-top solar. Although the use of storage technologies was considered a long-term resource of the 7th Power Plan and not a primary resource, it has become more commercially available since the release of the 7th Power Plan and was examined in the EIS. Storage will likely be considered a primary resource in the Councils 8th Power Plan. Regarding the IMPLAN analysis, that analysis is described in additional detail in Section 5.2.2 of Appendix H, including how the analysis identified the appropriate IMPLAN multipliers. IMPLAN is a widely-used, industry standard input-output (regional economic) model and relies on a variety of data sources such as the Census Bureau and Bureau of Economic Analysis. The regional economic effects analysis modeled household changes in electricity expenditures, and IMPLAN takes the household income change as an input, and calculates the corresponding Induced Effect of changes in household spending on goods and services. For the commercial and industrial sectors, the analysis modeled changes in electricity expenditures as changes in industry output. The specific multipliers were calculated based on the relative spending on electricity for each industry in the states examined. The relative spending was then weighted to calculate the appropriate multipliers associated with changes in industry outputs. Section 3.11.2.2 describes gaps in the recreational visitation data. Data were not available for all sites, including along the Snake River below Hells Canyon Dam and above Lower Granite Lake in Idaho. The 2016 report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho was considered for the EIS, but not relied upon directly due to the limited types of visitation data in the report, so it does not appear in the references. In addition, this region was not anticipated to be affected by changes in water surface elevations. However, the EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6125	6	fredcoriell@gmail.com	N/A	The upward rate pressure predicted by removal of the four dams is inaccurately calculated (see number 4 above and DEIS 3-918). As any classic lord of yesterday the co-lead agencies cannot see outside their own fish counting window at Bonneville because they are too risk adverse to do otherwise. Investments in distributed solar and wind on residential, commercial, and industrial properties, power cooperatives with these same groups, investment in building infrastructure retrofits/upgrades, and 1 https://doi.org/10.1108/TR-05-2019-0159 investing in and planning for a distribution system that can integrate technologies (such as electric vehicle fleets) on a larger scale are examples of the potential that BPA has to change course and lead the future northwest energy landscape. It is no surprise that the only study considered inline with the costs identified in the EIS analysis was produced by a special interest group that aligns with the culturism of the co-lead agencies (DEIS 3-913). Not a single alternative looks at a new model for the CRSO that bucks the status quo and shows innovative thinking and leadership. In fact the EIS analysis appears to dismiss this as an unlikely scenario. If the average household reduced consumption, then the costs under MO3 would be reduced by between $16 and $38 per year (DEIS 3-932). A fresh line of thinking might do everyone some good at this point, especially thinking that provokes these potential scenarios forward.	The comment claims that rate pressures in Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams, are incorrectly calculated due to resource portfolio assumptions that are narrow and incorrect, and describes a variety of potential alternative energy technologies. Bonneville used resource costs and other data from the Northwest Power and Conservation Council (Council) as well as the Councils GENESYS model for calculating the Loss-of-Load Probability and the contributions of various replacement resource portfolios on regional reliability. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS; see also Appendix H, Power and Transmission, at Section 2.2. The need for additional resource replacements was driven by maintaining regional reliability at the No Action Alternative levels. See Section 3.7.3.5, Effects on Power System Reliability, at page 3-903 in the Draft EIS; see also Appendix H, Table 2-1, in the Draft EIS. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS; see also Appendix H, Power and Transmission, Section 2.2. If Bonneville or its customers pursue resource acquisitions, these would occur through careful selection among all available options, potentially including distributed solar and wind. Although the use of storage technologies is considered a long-term resource of the 7th Power Plan and not a primary resource, it has become more commercially available since the release of the 7th Power Plan and was examined in the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS. Storage will likely be considered a primary resource in the Councils 8th Power Plan. These Council sources and the Mid-term Update were the source of all resource costs. The EIS examines the similarities and differences of a variety of different studies produced by other interest groups. See Section 3.7.3.1, Step 3, at page 3-820 in the Draft EIS; Section 3.7.3.5, Related Study, at page 3-913 in the Draft EIS; Appendix H, Power and Transmission, Section 2.4. As described in the EIS, these studies are not comparable to the analysis in the EIS because of methodological, data, and scope differences. The Preferred Alternative includes operational, structural and mitigation measures that include innovative thinking from the co-lead and cooperating agencies (see Chapter 7 for additional details).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					It is true that reductions in household energy consumption would likely lower the cost of electricity under MO3 or any of the alternatives. Although the cited range of potential household cost effects for MO3 is consistent with the findings of the EIS, this is the potential consumption response to increasing rate pressures under MO3, i.e. customers choosing to use less electricity as the price goes up, not a potential savings independent of the rate pressures. Households still spend more overall in MO3.
6125	7	fredcoriell@gmail.com	N/A	Lastly, please provide or cite evidence that backs up the claim that major short-term adverse effect[s] on water quality due to the mobilization of sediment during dam breaching (DEIS 3-7).	Several studies provide data to evaluate the sediment quality in the Lower Granite Reservoir. A study conducted in 1997 was comprehensive in both physical extent and analyses included (CH2M Hill 1997). Despite the age of the data, the comprehensive nature of this study makes it a worthwhile inclusion. This study was conducted as part of a general evaluation of conditions and data collection for the lower Snake River. A study conducted in 2003 included samples at discrete locations where sediment accumulation was known, as well as specific analyses of bio accumulative compounds such as dioxins (Corps 2004). This study was conducted in support of proposed dredging events along the Snake River, so the sample locations are not evenly distributed throughout the river segment, but rather represent discrete locations of interest. Only samples with fines greater than 20 percent were used for chemical analyses. The most recent sampling events were conducted in 2013 and 2014. The Lower Snake/Clearwater Sediment Sampling (Corps 2014b) study included sediment evaluation in support of navigational maintenance activities on the lower Snake and Clearwater Rivers, upstream of the Lower Granite Dam. Eleven dredge material management units and four separate areas of dockface/port facilities were assessed, representing 479,926 cubic yards of sediment. For the discussion here, the results from this sampling event are discussed in terms of the management units defined above (the Lewiston Management Unit and the Clarkston Management Unit).
6127	1	gocougs9798@yahoo.com	N/A	There are lengthy lists of action items that are currently being tried and need to be implemented that could and likely would provide a significant difference for salmon populations and many of these actions could be implemented sooner and at a lower cost than dam breaching. These items include cleaning up Puget Sound and the waterways that flow into it; funding and installing fish-friendly culverts; eliminating all non-native fish farms in the Pacific Northwest; looking into shellfish harvest practices and the impacts of that industry on salmon and orcas (see Toxic Pearl by M. Perle). Eliminating the predators of salmon at multiple points in their lifecycle around the dams, including birds, sea lions and non-native fish species need to be stepped up. These species are increasing in population as they teach others where to come for the salmon buffet and the process for eliminating these threats are too slow. Consider salmon fishing practices in the rivers and oceans. What impacts do gill nets have on the salmon? While treaty rights should be honored, all sides need to consider the current salmon population and be responsible in their harvest practices. Increase hatchery funding. The data shows that salmon numbers rose and subsequently fell with the funding.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Many of these effects are outside the scope of this EIS that analyzes operations and maintenance of the Columbia River System dams. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Regarding the Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
6137	1	annie4208m@gmail.com	N/A	The alternatives MO1, MO2 and MO4 are proposed to potentially improve adult salmon, juvenile salmon, and resident fish species. With the CRS being an important aspect for the lives of endangered species such as Chinook and steelhead, action should be taken to ensure the species increase in numbers rather than decrease. In each of the alternatives listed above, programs involving conservation hatcheries for ESA-listed fish and other hatcheries to mitigate for the construction and operation of the dams are used. However, peer reviewed science proves that hatcheries are more detrimental to wild fish populations than they are beneficial. Hatcheries dont work to recover the endangered and wild salmon and other fish species. Instead, the hatchery fish released negatively impact wild fish species by breeding with them, diluting the wild gene pool, competing for resources and so forth. Wild fish species are robust and resilient, but introducing hatchery fish to the wild species dilutes the genetic diversity and decreases their size advantage, making the offspring and the population as a whole more vulnerable.	Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Many ESUs/DPSs of ESA-listed fish include fish produced in hatcheries. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
6137	2	annie4208m@gmail.com	N/A	Not only are hatcheries harmful, but increasing spill over dams in order to aid juvenile migration downriver has yet to recover salmon runs. Few juvenile fish are able to make it through turbines in the dam during their migration, and spill operations are thought to be an effective way to allow juveniles over the dam. However, this system is also harmful to the juvenile fish. Impacts with spillway structures can result in physical injury, brain damage and death. The hydraulic forces associated with spill and the sudden depth changes are also potential hazards that are associated with this hydropower-related passage option.	The Draft EIS used high-quality data and best available science in its analysis. The commenter is correct that some juvenile fish are injured and killed as a result of passage through spillways and turbines. The Draft EIS analysis and modeling results included incorporation of empirical data on effects of dam passage, such as through spillways. Even with these effects the CSS model predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative.
6137	3	annie4208m@gmail.com	N/A	Sediment transfer is slightly discussed in the alternative MO3 and I believe it is worth being elaborated on. River sediment is full of rich nutrients that can be utilized for agricultural areas. In a river system, sediment is transported downstream and forms river banks and deltas. In the case of placement of dams, the blocked rivers result in a loss of riparian habitats along inundated reaches. In the case of the LSRD, there is also a loss of sediment transport to the Columbia delta. Without the flow of sediment, the delta cannot grow. The Columbia delta is important because it is a system that absorbs runoff from both floods and storms. It also acts to provide nurseries and spawning grounds for a large number of aquatic organisms. Sediment is no longer free-flowing down the CRS, rather its collecting in the upper reservoir of the dams. Pristine habitat for an abundance of aquatic and terrestrial species is impacted by this impeded flow.	The historical effects of dam construction are described under affected environment in Chapter 3. It is generally known that the dams within the Snake and Columbia River basins disrupt the movement of sediment, blocking most material from moving downstream to the Columbia delta except for small amounts of fine suspended material that are carried to the ocean. This condition is described under the Affected Environment Sediment Supply Section 3.3.2.2. It is also recognized that the operation of the dams has altered sedimentation processes in the lower Columbia River and estuary as further described under the Affected Environment Aquatic Habitat Section 3.5.2 and Vegetation, Wetlands, Wildlife, and Floodplains Section 3.6.2. It is important to note that the direct analysis of historical effects of dam construction such as sediment delivery to the Columbia delta are outside the scope of this study as the No Action Alternative is based on the conditions at the beginning of the study in 2016.
6137	4	annie4208m@gmail.com	N/A	Another topic brought up in the MO3 alternative was the potential for an increase in the release of greenhouse gases. It was explained that with the loss of hydropower from the four lower dams, power would need to be replaced with natural gas. I understand that some cleaner options are less reliable, but solar and wind power combined with other clean alternatives is something that should be considered. Geothermal energy uses heat energy from the earth, and is capable of supplying renewable power around the clock that emits little to no greenhouse gases. It also requires a small environmental footprint to develop. Bioenergy is another power source that should be considered. This process utilizes biomass as an organic renewable energy source, including materials such as agriculture and forest residues, energy crops, and algae. The energy biomass produces can be converted into electricity, heat or biofuels.	The EIS analyzed a zero-carbon resource portfolio to replace the hydropower generation of the four lower Snake River dams, identifying a cost-effective portfolio of solar power, demand response and battery storage. See draft EIS, Section 3.7.3.5 at pages 3-904-910. Regarding the range of renewable technologies considered, the EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. The source of resource information used in the EIS is from the Northwest Power and Conservation Council's (Council) 7th Power Plan and Mid-Term update. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. Geothermal and bioenergy technologies were not considered primary technologies and thus, were not included as a replacement resource. See draft EIS, Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H for additional details. The conventional least-cost and the zero-carbon resource portfolios were intended to provide a range for the cost and emissions impacts of the Multiple Objective Alternatives assuming current technologies could be scaled to replace the four lower Snake River dams capabilities. The EIS acknowledges that with further technological advances and substantial increases in power storage capacity, other options may be available in the future. See draft EIS, Section 3.7.3.2, Potential Replacement Resources, page 3-848, for example.
6137	5	annie4208m@gmail.com	N/A	The report discusses species listed on the ESA such as salmon and steelhead, yet the requirements have yet to be met. The ESA requirements involve restoring listed species to all or a significant number of that range.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6137	6	annie4208m@gmail.com	N/A	Another topic that I believe the DEIS failed to discuss is the issue of climate change, and how climate change will influence mitigation processes of each alternative. For there to be a cumulative analysis of all potential factors relating to the dam processes, climate change should be included, as it greatly changes the estimated number of salmon return. In regards to the no action alternative and the other various alternatives made to improve juvenile and adult salmon, estimates of salmon return are drastically lowered once climate change is acknowledged. If climate change forecasts were to be included in the alternative, the no action alternative would lead to extinction. The only alternative that will drastically result in salmon return will be the dam breaching alternative. With climate change, the numbers proposed for salmon return upon dam breaching will also be lower than expected, but the numbers will be much higher than those suggested in the other proposed alternatives, and the species will be well away from extinction.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6137	7	annie4208m@gmail.com	N/A	I think the DEIS overlooked some notable factors that make it more of a preferred alternative. I think with alternative renewable energy sources being available, the overall benefits drastically outweigh the costs of breaching the dams. Natural gas is not the only power source that could replace hydropower, should the dams be removed. A combination of solar, wind, geothermal, and bioenergy power sources would allow the MO3 alternative to meet the objective to minimize GHG emissions, along with meeting the objective to provide a reliable and economic power supply.	The EIS analyzed a zero-carbon resource portfolio to replace the hydropower generation of the four lower Snake River dams, identifying a cost-effective portfolio of solar power, demand response and battery storage. See draft EIS, Section 3.7.3.5 at pages 3-904-910. Regarding the range of renewable technologies considered, the EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. The source of resource information used in the EIS is from the Northwest Power and Conservation Council's (Council) 7th Power Plan and Mid-Term update. The EIS analysis focuses on primary technologies identified by the Council in its 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. Geothermal and bioenergy technologies were not considered primary technologies, and thus, were not included as a replacement resource. See draft EIS, Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H for additional detail. The conventional least-cost and the zero-carbon resource portfolios were intended to provide a range for the cost and emissions impacts of the Multiple Objective (MO) Alternatives assuming current technologies could be scaled to replace the four lower Snake River dams capabilities. However, it should be noted that the EIS finds that even with a renewable power portfolio, carbon emissions increase under MO3 as other existing fossil fuel generation increases (see draft EIS, Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The EIS acknowledges that with further technological advances and substantial increases in power storage capacity, other options may be available in the future. See for example Section 3.7.3.2, Potential Replacement Resources, page 3-848 in the draft EIS.
6140	1	maxbeach@hotmail.com	N/A	While everyone of us is concerned about the salmon in the rivers and want to make sure they remain here for our children and grandchildren, we must look beyond the rivers and dams and begin focusing more on the ocean. I have included a slide from BPA " the whole dam story" that shows most of the decline in salmon came after the dams were installed. The Nez Perce tribe also showed a similar decline in salmon from 1855 until the 1930's during the governor's workshop in Lewiston, ID last year, yet the dams get all of the blame. It should also be pointed out that rivers up and down the coast and even up to Alaska are seeing similar declines in Salmon and they don't have dams in the river. This points to a much larger issue than just the dams in our rivers.	The majority of a salmon's lifespan is spent in the ocean. Therefore, the habitat, food, and predator conditions in the ocean will have a large influence on the proportion of salmon surviving to reproduce. When ocean conditions are good, the Columbia Basin enjoys large returns of salmon such as in 2014 for example. Nearly every ESU had record returns. However, when conditions are poor as has been the case for the past several years, the number of adult salmon are much smaller. In the context of the EIS, while the ocean would not be affected by any of the Alternatives, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Among the objectives are improving passage conditions and survival of both juvenile and adult anadromous fish through the CRS. The more healthy juvenile salmon that enter the ocean, whether the conditions there are good or poor, the greater the returns to the Columbia Basin can be. The greater the success adults migrating up the Columbia and tributaries and spawning, more juvenile can be produced for the next generation.
6162	1	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Errors in Need of Correction in the DEIS The DEIS states that the BPT, FMPST, and the SPT of the Duck Valley Reservation are cooperating agencies in the CRSO process. That is not accurate. USRT was asked by BPT, FMPST, and SPT to represent their interests in the process and chose not to be cooperating agencies. The only member tribe of USRT that is a cooperating agency is the SBT.	Thank you for bringing this error to our attention. It has been corrected in the Final EIS, Section 1.4.3.
6162	2	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Purpose and Need USRTs position has been consistent since 2017, that the Purpose and Need (P & N) should be tied directly to the ruling of Judge Michael Simon. The P & N sets the stage for the range of alternatives to be considered. The action agencies (AAs), in crafting a P & N that gives short shrift to Judge Simons order, assured the development of an inadequate CRSO DEIS. The quotes below from Judge Simon were instructive to the AAs. Had they been acknowledged and used as a guide during the DEIS process we would not be at the point we are currently with a DEIS that fails to ensure the protection, enhancement, and increased abundance of salmon and steelhead moving into the future.	The Purpose and Need Statement includes the co-lead agencies' requirement to respond to the U.S. District Court's order, as stated in the Executive Summary and Chapter 1. Specifically, the Purpose and Need Statement says "The on-going action that requires evaluation under NEPA is the long-term coordinated management of the System projects for the multiple purposes identified above. An underlying need to which the co-lead agencies are responding is reviewing and updating the management of the System, including evaluating measures to avoid, offset, or minimize impacts to resources affected by the management of the System in the context of new information and changed conditions in the Columbia River basin. In addition, the co-lead agencies are responding to the Opinion and Order issued by the U.S. District Court for the District of Oregon such that this EIS will evaluate how to insure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat, including evaluating mitigation measures to address impacts to listed species." The EIS analysis demonstrates the co-lead agencies understood the U.S. District Court for the District of Oregon's Opinion and Order.
6162	3	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	USRT and its member tribes have a different perspective of the values that make the Columbia River Basin unique for those who call this place home. The Northwest Power Act requires the AAs to develop programs to protect, mitigate, and enhance fish and wildlife: 4(h)(11)(A)(i) exercise such responsibilities consistent with the purposes of this Act and other applicable laws, to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated The concept of Equitable Treatment is often used as a measure of inputs compared with received outputs, it does not necessarily mean that all scales are equally balance; but it does require a demonstration of fairness and equal consideration for different user groups. In the current evaluation one of the primary drivers for the in-depth evaluation of the entire system is that there are significant impacts to anadromous fish, to the point that the current system configuration contributes to species level decline and in some instances, impedes that species ability to recover. From a concept of equitable treatment, the fish and user groups who rely on them would be viewed as an input, while the resulting decision made in this DEIS would determine the projected output for that group of users and the actual resource itself. USRT and its member tribes primary concern is that the Preferred Alternative (PA) does not adequately balance the scale of equity by promoting a condition where listed salmonids in USRTs member tribes homelands will thrive and recover.	The co-lead agencies are aware of their legal responsibilities under the Northwest Power Act, including the equitable treatment mandate. The Act requires the agencies to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects … in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated. 16 U.S.C. 839b(h)(11)(A)(i). On a systemwide basis, the co-lead agencies ongoing management of the CRS will continue to provide fish and wildlife equitable treatment with the other authorized purposes of the system. See NW. Envtl. Def. Ctr. v. Bonneville Power Admin., 117 F.3d 1520, 1533-34 (9th Cir. 1997) (While each power marketing action that affects the system implicates the equitable treatment provisions, Bonneville may properly exercise its obligation by insuring equitable treatment for fish on a systemwide basis.); Confederated Tribes of the Umatilla Indian Reservation v. Bonneville Power Admin., 342 F.3d 924, 931 (9th Cir. 2003) (The equitable mandate of [the Northwest Power Act] does not require every Bonneville decision to treat fish and wildlife equitably. For example, Bonneville may make some decisions that place power above fish, so long as on the while, it treats fish on par with power.). The agencies provide equitable treatment on a systemwide basis primarily by implementing hydrosystem management and operations identified in relevant NMFS and USFWS biological opinions, in the Columbia Basin Fish Accord agreements, and in measures included in the Northwest Power and Conservation Councils fish and wildlife program. In addition, we note that the express language of the statutory provision prescribes equitable treatment for fish and wildlife only not for states, Tribes, or other entities.
6162	4	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Another stated purpose is to promote the protection of Indian treaty rights and interests for natural and cultural resources. It has been clear that federal agencies and most tribes do not view the obligations in the same manner. For example, the USRT member tribes would consider the perpetuation and presence of anadromous fish on their homelands, that they have a reserved treaty or inherent right to harvest, are a trust asset that the federal agencies must protect in a conservative manner; this is not a view shared by the AAs. For the right to have meaning, to promote the protection of the traditional harvest of anadromous fish throughout the Columbia River Basin, there must be fish to harvest to sustain tribal communities. Minor or negligible improvements in anadromous fish returns will not alleviate the nearterm risks of anadromous stocks currently at risk of extirpation, and they will not provide meaningful fisheries at the population level in the Snake River.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study.Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
6162	5	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The underlying need the AAs are responding to is to evaluate the management of the system in the context of new information or changed circumstances in the Columbia River Basin. From the outset of petitions to list various anadromous stocks in the Snake River under the Endangered Species Act conditions have not experienced significant benefits, in some cases the returns in 2019 were close to conditions that led to their listing in the early 1990s. USRTs member tribes view the need of this evaluation as responding to several decades of litigation over the direction the management of the Snake and Columbia River basins are taking to recover listed stocks of salmonids; of course, there are other significant issues but the primary driver since the early 1990s has been how we will develop appropriate measures to recover fish in a meaningful manner and ameliorate the impacts listing has had on the Snake River Basin. The recovery of anadromous fish in the Columbia River Basin is the primary driver for most of the conflict, and it relates to the current abundance issues that we are collectively facing as managers. Having a hard line on promoting the recovery of anadromous fish in the face of the current crisis is no less significant for the Tribes than generating energy, navigating goods downriver, or delivering contracted water from reservoirs.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a substantial contribution towards recovery.
6162	6	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Draft Alternatives Framework and Objectives On September 15, 2017, USRT submitted comments on the Draft Preliminary Alternative Framework and Objective developed by the AAs. In addition, USRT proposed the development of at least one additional alternative: Natural River and Lakes Focus. Further, we requested an analysis of Endangered Species Act (ESA)-listed Chinook salmon and steelhead production capability within blocked habitat in the Columbia River Basin either in the Adult Fish Survival and Juvenile Anadromous Fish Survival Focus alternatives or the development of a standalone alternative. It is important to note that although USRT is a cooperating agency, our comments dated September 15, 2017 received no attention and no meaningful response from the AAs. This unfortunately was not an isolated incident. Throughout the CRSO DEIS process USRT has believed our comments and concerns were not being fully considered and addressed.	The co-lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies (including USRT), and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. The co-lead agencies analyzed alternatives capable of meeting the EIS Purpose and Need Statement and objectives. As discussed with the USRT, a Natural River and Lakes focus alternative was not analyzed because it is not a reasonable alternative because of its unreasonable impacts to public health and safety (e.g. power and transmission reliability events and flood risk management issues) and would not meet the Purpose and Need Statement or many objectives.
6162	7	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Draft Preliminary Alternative: Natural River and Lakes Focus Summary: The Natural River Focus Preliminary Alternative is intended to mimic as feasibly as possible the natural river hydrograph in all but high-water years to provide for increased spring and early summer freshets, keeping reservoirs more stable with less drafting, particularly in dry water years, while maintaining local flood risk management. This alternative seeks a balanced approach for system flood risk management through use of both existing reservoirs and an updated levee system. The outcome desired is for dramatically increased juvenile and adult salmon and steelhead survival by decreasing inriver juvenile transit time, providing for more natural river, estuary, and river plume conditions, and ultimately increasing smolt to adult survival (SARs). Keeping reservoirs more stable, with less frequent and deep drafting, will also improve conditions for resident fish and wildlife and will help to preserve precious tribal cultural resources. Context: During the Columbia River Treaty sovereign review process for developing a regional recommendation to the US Department of State, USRT member tribes, as active members of the 15- Columbia Basin Tribal Coalition, endorsed a natural river-focused alternative described as the Ecosystembased Function scenario. That scenario was designed to provide additional flows for spring and summer, reduce variability of reservoir elevations year-round, provide additional spring flows in	Thank you for providing your views on the consideration of a natural river focused alternative in the SRT process. The current operations of the Columbia River System, including current Treaty-related operations, are included in the EIS analysis. Section 2.5.10 of the Draft EIS explains why re-evaluating system flood risk management, including a "natural rivers focus", was screened out from further consideration in this EIS. Section 2.5.10 also explains that while the U.S. Entity Regional Recommendation stated support for the pursuit of Congressional authorization and appropriations for a region-wide public process to assess potential changes to the current level of flood risk protection, no such authorization or appropriation was provided. As such, a study for this purpose was determined to be outside of the scope of this EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				driest water years (dry year strategy), maintain a similar level of system flood risk in high water years, and maintain local flood control. Modeling and fish survival analyses of this alternative showed dramatic improvements to ocean entry conditions for juvenile salmon and steelhead, improvements in fish metrics such as decreased juvenile inriver travel time, increases in SARs, and improvements in reservoir conditions for resident fish. Results were unclear for adult fish fallback, as well as for any negative impacts from increased total dissolved gas production. However, time and funding constraints in the sovereign review process did not allow for fine tuning of this alternative to more fully capture and document additional benefits for fish and wildlife. More time would also have allowed for improved integration or blending of this alternative with hydropower and flood risk management alternatives to lessen the modeled impacts to these river uses, while providing for increased benefits to fish and wildlife.	
6162	8	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Draft Preliminary Alternative: Adult Fish Survival and Juvenile Anadromous Fish Survival Focus USRT requests that blocked areas be analyzed for the purpose of "improving" fish survival. Specifically, under the Adult Fish Survival Focus and Juvenile Anadromous Fish Survival Focus draft alternatives, a blocked areas strategy should be analyzed to assess the benefits of additional available habitat for propagating fish production in natural, environmental conditions, which would increase the overall number of fish within the Columbia River Basin. This alternative would include both adult and juvenile passage into historically used habitat above all projects within the Columbia River Basin. Much of the blocked areas contain some of the best water quality within the Columbia River Basin and can provide important cold-water refugia and rearing habitat, which are currently limiting factors. By utilizing these habitats, it will allow the AAs to spread the risk of uncontrollable environmental factors such as extreme weather events and climate change. Continuing to exclusively allocate resources into the downstream reaches cannot produce the same results as providing more suitable habitat that currently exists in blocked areas. USRT understands that the AAs cannot decide whether the expanded populations are considered for protection under ESA, but USRT believes these critical issues can be addressed with collaboration between NOAA Fisheries, states, and tribes. In using this strategy, however, USRT will not consider the action to supersede Idaho Power Companys responsibility to pass fish above and below the Hells Canyon Complex, but will consider this action as complementary to both Idaho Power Company and the AAs trust responsibilities to the tribes to restore fish within the Columbia River Basin. USRT believes that utilizing a natural flow strategy, coupled with increasing available habitat by using a blocked areas habitat strategy, will address Judge Michael Simons need to minimize ESA threats to listed stocks. Reestablishment of juvenile and adult anadromous species within blocked areas of the Columbia Basin should be analyzed in the CRSO EIS.	Measures to reintroduce salmon above Chief Joseph Dam and Grand Coulee Dam were evaluated early in the process of developing alternatives but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. The analysis described would have value moving toward recovery of anadromous fish populations. However, co-lead agencies prepared this Draft EIS in response to the need to review and update operations, maintenance, and configuration of the 14 CRS dam. In this process the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility.
6162	9	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Draft Preliminary Alternative: Hydropower Generation Focus In reviewing this alternative, USRT has significant concerns with the proposal to analyze hydropower operations in the System under a pre-Northwest Power Act (NPA) scenario. The National Environmental Policy Act (NEPA) requires that alternatives must be reasonable and meet the P & N of the EIS. Rather than reasonable, we believe that this alternative is speculative and not technically feasible, as required by NEPA, given the contemporary existence and implementation of the NPA. We disagree that the alternative, as currently written, will be valuable in comparing the EIS alternatives to better understand the impacts of various resources and will be used in the analysis to help illuminate trade-offs. Instead, this alternative appears to be narrowly-focused to showcase how much hydropower generation has been lost due to protections afforded fish under the NPA, ESA, and other subsequent laws and agreements. Reasonable alternatives should meet the P & N of the EIS. This alternative does not meet the P & N in several respects. First, the alternative assumes analyzing the maximization or near maximization of hydropower generation in the System. Yet, the P & N calls for an adequate and reliable power supply within the System. As operated today, under NPA requirements, the power supply in the System is both adequate and reliable. Second, stripping away NPA protections will not meet the P & N of fish and wildlife conservation. Finally, as ordered by Judge Michael Simon, and included in the P & N, the EIS should evaluate how to ensure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat. We opine that this pre-NPA alternative does the exact opposite and will both adversely affect critical habitat and facilitate the further decline and potential extirpation of certain fish species and populations. The AAs must significantly revise the Hydropower Generation Focus alternative so that it is both reasonable, not hypothetical and speculative, and also meets the P & N.	The Single Objective alternatives were eliminated from further consideration by the co-lead agencies because they were not considered complete alternatives. However, the analysis of the Single Objective alternatives did inform the development of the final range of alternatives, the Multiple Objective alternatives, and helped to demonstrate the trade-offs associated when one resource is elevated above another. The EIS focuses on the analysis of the multiple objective alternatives (MOs) throughout Chapter 3, 4, 5, 6 and the Preferred Alternative in Chapter 7.
6162	10	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Draft Preliminary Alternative: Water Supply Focus While important for future municipal, industrial, agricultural, and some tribal needs, water supply appears to be an issue that could best be evaluated by a process outside the scope of the CRSO EIS. The construction of reservoirs and dams for hydropower and irrigation, as well as their operation, have also severely impacted wildlife throughout the Columbia River Basin. Additional water drawn from the Columbia River Basin for other than improving anadromous and resident fish survival, as well as for protecting wildlife and their habitat, seems contrary to the intended P&N for ESA and NEPA analysis of the impacts of river operations on these critical fish resources. While we are aware of the current numerous and diverse benefits and uses of the Columbia River, we believe that mechanisms to provide a more equitable sharing or distribution of those benefits towards improving the health of fish, wildlife, water quality, and cultural resources that have been severely degraded or lost irreparably over time, need to be evaluated in this CRSO EIS.	The CRS is a complex system with multiple, sometimes competing, congressionally authorized purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. This EIS was developed to evaluate the operation and maintenance of the CRS over the next 20 years. Water supply is one of the authorized purposes, and like any other, the EIS was developed to plan for and evaluate the effects of continuing to operate to meet this purpose. The co-lead agencies consider effects to fish and wildlife in every action taken to meet congressionally authorized purposes, as required by law and described in Chapters 3, 4, 6 and 7 of this EIS.
6162	11	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Draft Objectives Development All seven objectives are inherently conflicting with one another and cannot possibly be mutually met in the development of alternatives. Priorities need to be identified, tested, and agreed to before tradeoffs among these objectives can be made. If the focus of this CRSO EIS is improving river operational conditions for ESA-listed anadromous and resident fish, which USRT member tribes believe is the case, proposed tradeoffs may still be difficult, although these would be much easier and clearer to formulate and describe. Language is very important. This point was made abundantly clear during the CRSO EIS Executive meetings in Spokane and Portland in August 2017. Improve fish survival vs. Maximize operating flexibility, mean very different things to sovereigns, cooperating agencies, stakeholders, and interested parties across the region. USRT requests that this language be clarified and defined, particularly if the focus of the CRSO EIS is legitimately designed to develop a comprehensive approach to recovering ESAlisted fish. The Evaluation Criteria for the alternatives are not yet fully developed and cannot possibly be useful in analyzing their effectiveness. We propose that the AAs work together with the cooperating agencies to more fully develop criteria.	The Purpose and Need and the eight objectives developed for this EIS reflect the complex, sometimes competing multiple purposes of the CRS, as do the alternatives developed to meet them. Combined, the Purpose and Need and the objectives establish the framework for evaluating the ability of the alternatives to satisfy the co-leads' numerous legal obligations. This EIS was developed to evaluate the operation and maintenance of the CRS. The analysis of the multiple objective alternatives have allowed the co-lead agencies to understand the effects of emphasizing some purposes over others in order to find the most acceptable balance for future operations. Chapter 7, Table 1 describes how well each alternative can meet the multiple objectives and Purpose and Need Statement, and if an alternative can equally or fully meet these. Chapter 7 describes the process of developing the measures for the Preferred Alternative. Based on the effects analysis in Chapter 7, the Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also most likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6162	12	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Climate Change USRT and its member tribes would like to see climate change addressed in greater detail throughout the DEIS and how potential changes in climate could drive significant impacts to member tribes resources located within the affected environment. USRT and its member tribes recommend including specific adaptation strategies to ameliorate the projected effects of climate change within the affected environment in an effort to increase ecosystem resiliency. The presented analysis should establish quantifiable recovery metrics based on the available data to promote climate regulating ecosystem services, as well as maintenance and enhancement of large landscapes that are dominated by native assemblages of species. USRT and its member tribes have completed or are in the final phases of completing four climate-related projects beginning in early 2016. USRTs first climate project was a climate change vulnerability assessment (CCVA) of the Upper Snake River Basin (Figure 1). The CCVA used two climate scenarios and two timeframes (2050 and 2080) to evaluate anticipated effects on animal/plant species and habitattypes. The two climate scenarios were representative concentration pathway (RCP) 4.5 (best case scenario) and RCP 8.5 (business as usual). Recent climate models suggest that we are now exceeding the RCP 8.5 business as usual scenario. Expected temperature increases under scenarios 4.5 and 8.5 in 2050 and 2080 are in the table below and Figure 2. Equally troubling is the seasonal variations in temperature increases (Figure 3). Of particular concern are winter temperature increases of 8 9.5 F, which will transform much of the Upper Snake River Basin from either snow-dominated or transitional to rain-dominated. Temperature Increase in the Upper Snake River Basin RCP 2050 2080 4.5 + 4.5 5.3 F + 5.7 6.5 F 8.5 + 6.0 6.5 F + 9.5 10.9 F Because of this anticipated temperature increase, USRTs climate assessment finds that species such as bull trout, Chinook salmon, redband trout, and steelhead are extremely vulnerable to the effects of climate change by the 2050s (Figure 4 and Chinook salmon and Steelhead Summary Sheets). Even under RCP 4.5, which assumes that global greenhouse gas emissions will peak by the 2040s and then begin to decline, those previously described four fish species are expected to be extremely vulnerable to climate change. Specific measures, even adaptive management triggers that are clearly described, should be included in the Final EIS and Record of Decision to demonstrate the AAs awareness of this issue and commitment to operate the system in a manner that prioritizes fish survival during low water conditions or extreme weather events. USRTs full suite of climate work can be found at: https://uppersnakerivertribes.org/projects/. Figure 1: The Upper Snake River Watershed project area for this assessment, an area of more than 97,000 square miles. Figure 2: Projections of average annual temperature change (left) and changes to an average annual Hamon moisture metric (right) across the full project domain. Figure 3: Seasonal temperature and precipitation projections for the 2050s (2040-2069) in the South subdomain of the Upper Snake River Watershed. Figure 4: Overall vulnerability rankings for the 16 quantitatively assessed species of Shared Concern for the 2050s. Chinook Salmon (Oncorhynchus tshawytscha) Existing Conditions & Observations by USRT Member Tribes223 Chinook salmon have been central to the culture and diet of the four USRT member tribes for thousands of years. They played an especially important part in the tribes seasonal migration and subsistence diet. Unfortunately, these connections have been greatly diminished over the last century as eight dams on the Upper Snake River have prohibited Chinook salmon from reaching the USRT member tribes traditional harvest areas. The Burns Paiute Tribe and Shoshone-Paiute Tribes have recently reinitiated ceremonial Chinook salmon	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). It is not known what global policy changes will be put into place in the future to mitigate the effects of global greenhouse gas emissions. For this reason, the climate change community develops multiple scenarios of future emissions. Due to the uncertainty in future greenhouse emissions, the EIS evaluated two emissions scenarios, RCP4.5 and RCP8.5. Each emission scenario is evaluated separately so that the interpretations can be explicitly attributed to the emissions scenarios. The effects of the two emissions scenarios do not diverge greatly until later in the 21st century, a period largely outside the analysis of Chapter 4 (2020-2049).There are many effects to salmon and steelhead populations outside the operation and maintenance of the dams (see Chapters 6 and 7 for more information). Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. While none of the Multiple Objective alternatives would affect ocean conditions or directly impact tributary habitat conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of these environments in the return of adult salmon and steelhead. Many of the types of habitat improvement actions implemented by the co-lead agencies in cooperation with regional stakeholders can provide improved conditions for many fish species. Habitat mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				fisheries on the upper Malheur River and East Fork Owyhee River by live-transporting Chinook salmon around the dams. Currently, the Fort McDermitt Paiute-Shoshone do not have access to Chinook salmon, while the ShoshoneBannock Tribes can exercise their treaty right to harvest Chinook salmon. Climate change poses additional complex stressors to this already significantly impacted fishery. Chinook Salmon Vulnerability Rankings 2050s 2080s Rankings above represent climate change vulnerability in the 2050s and 2080s for two different climate change scenarios. The higher climate change scenario (RCP 8.5) is labeled More Warming and the lower climate change scenario (RCP 4.5) is labeled Less Warming. The rankings reflect the assessment of local climate change projections and species-specific sensitivities and adaptive capacity from the CCVI analysis. Factors Affecting Vulnerability Physiological Thermal Niche greatly increases vulnerability. Chinook salmon inhabit deep, cold pools prior to spawning.224 Water temperatures exceeding 48-50F may reduce survival of Chinook salmon embryos and alevins.225 Additionally, migration delays and blockages can form when stream temperatures exceed 69.8F and can contribute to reproductive failure.226 As stream temperatures continue to rise, the frequency with which these thresholds are exceeded and total river miles affected may increase. Physiological Hydrological Niche greatly increases vulnerability. Large, deep, pools offer important holding habitat for Chinook salmon prior to spawning. While sufficient flows are required to ensure incubating embryos receive sufficient oxygenation, extreme low or high flows can destroy embryos and fry residing within the streambed.227,228 Shifting precipitation patterns under climate change could threaten these sensitive hydrological conditions. Figure 46: Chinook Salmon. Photo credit: Andy Kohler. Anthropogenic Barriers increases vulnerability. Many streams and rivers within the assessment area have dams that would prevent Chinook salmon access to more suitable, cooler habitat if the present habitat becomes too warm. There are eight dams on the mainstem Snake River from below Shoshone Falls to Hells Canyon include the Upper Salmon Falls Dam, Lower Salmon Falls Dam, Bliss Dam, C.J. Strike Dam, Swan Falls Dam, Brownlee Dam, Oxbow Dam, and Hells Canyon Dam.229 Sensitivity to Pathogens or Natural Enemies increases vulnerability. Warming stream temperatures may increase mortality caused by fish pathogens and diseases. Vibrio and Ceratomyxa shasta are two infections known to negatively affect salmonids, and their effects could be exacerbated with warming stream temperatures.230 Increasing water temperatures can stress salmonids, reducing their ability to mount an effective immune response to disease. Many important salmonid diseases become virulent when water temperatures reach or exceed 60-61F.231 Climate Change Mitigation somewhat increases vulnerability. Future dam building is possible in the region. Dams act as barriers to movement for Chinook salmon accessing stream reaches in the Upper Snake River and more dams could further limit their ability to move as habitat conditions change.232 Disturbance Regime somewhat increases vulnerability. The survival of salmonid (i.e., salmon, trout, and char) eggs and embryos is strongly influenced by sediment deposition, shifts in water quality, and streambed scour and fill.233 As air temperatures rise, watersheds are projected to become increasingly rain-dominant. This shift will increase the risk of winter flooding and sediment transport, which can negatively affect the survival of salmonid eggs. Sensitivity to Competition from Native or Non-Native Species somewhat increases vulnerability. Chinook salmon compete with resident brook trout, which feed on other fish species and are known to prey on young salmonids.234 Climate change may alter this competitive interaction. Measured Genetic Variation somewhat increases vulnerability. Populations of Chinook salmon in the Snake River have low genetic variability compared to Chinook salmon populations in the Columbia River Basin.235 Less genetic variability may somewhat restrict the ability of Chinook salmon to adapt to changing climate conditions. Diet has a neutral effect on vulnerability. In freshwater, juvenile Chinook salmon feed on terrestrial and aquatic insects. In salt water, Chinook salmon eat crustaceans and other bottom invertebrates. Adult Chinook salmon mostly prey on fish.236 Species that can readily switch among different food types are less likely to be negatively affected by climate change than dietary specialists. Dispersal/Movement has a neutral effect on vulnerability. Chinook salmon are excellent dispersers, as they are anadromous and migrate several hundred miles to the stream in which they were spawned.237 This dispersal ability may help facilitate successful response to changing climate conditions. Phenological Response has a neutral effect on vulnerability. No observed shift in Chinook salmon run timing has been recorded in the Snake River.238 Steelhead (Oncorhynchus mykiss) Existing Conditions & Observations by USRT Member Tribes293 Three of the four USRT member tribes no longer have access to Steelhead on their reservations. Over the last century, eight dams on the Upper Snake River have limited the ability of steelhead to reach the USRT member tribes traditional harvest areas. USRT tribes are actively working to help reintroduce steelhead into their historical habitat on reservations. Steelhead Vulnerability Rankings 2050s 2080s Rankings above represent climate change vulnerability in the 2050s and 2080s for two different climate change scenarios. The higher climate change scenario (RCP 8.5) is labeled More Warming and the lower climate change scenario (RCP 4.5) is labeled Less Warming. The rankings reflect the assessment of local climate change projections and species-specific sensitivities and adaptive capacity from the CCVI analysis. Factors Affecting Vulnerability Physiological Thermal Niche greatly increases vulnerability. Optimal water temperature for steelhead egg hatching is 50F. Optimal growth for juvenile steelhead occurs between 57.2F and 59F. Water temperatures of 69.8F lead to the formation of thermal migration barriers for steelhead in the Snake River. Daily maximum water temperatures above 66.2-68F present lethal conditions for steelhead.294 Warming water temperatures under climate change may increase the frequency with which these sensitive thermal limits are exceeded. Physiological Hydrological Niche greatly increases vulnerability. Steelhead inhabit cool, clear lakes and cold, fast-flowing streams. During winter, steelhead require deep pools in slowmoving streams.295 Warming water temperatures under climate change may impact some of these sensitive hydrological requirements. Disturbance Regime increases vulnerability. The survival of salmonid (i.e., salmon, trout, and char) eggs and embryos is strongly influenced by sediment deposition, water quality, and streambed scour and fill.296 As air temperatures rise, watersheds are projected to become increasingly rain-dominant. This shift will increase the risk of winter flooding and sediment transport, which can negatively affect the survival of salmonid eggs. Sensitivity to Pathogens or Natural Enemies increases vulnerability. Warming stream temperatures may increase salmonid mortality from fish pathogens. Vibrio and Ceratomyxa shasta are two infections known to negatively affect salmonids and these effects could be Figure 52: Steelhead. Photo credit: USFWS Mountain-Prairie. exacerbated with warming stream temperatures.297 Increasing water temperatures can stress salmonids, reducing their ability to mount an effective immune response to disease. Many important salmonid diseases become virulent when water temperatures reach 60-61F.298 Anthropogenic Barriers increases vulnerability. Many streams and rivers within the project area have dams that would prevent steelhead from accessing more suitable, cooler habitat if their current habitat becomes too warm. There are eight dams on the mainstem Snake River from below Shoshone Falls to Hells Canyon include the Upper Salmon Falls Dam, Lower Salmon Falls Dam, Bliss Dam, C.J. Strike Dam, Swan Falls Dam, Brownlee Dam, Oxbow Dam, and Hells Canyon Dam.299 These barriers to migration may hamper steelhead ability to respond effectively to changing climate conditions. Climate Change Mitigation somewhat increases vulnerability. Future dam building is possible in the region. Dams act as barriers to steelhead movement and may limit their ability to move in response to changing climate conditions.300 Sensitivity to Competition from Native or Non-Native Species somewhat increases vulnerability. Resident brook trout, which are known to eat young salmonids, compete with steelhead.301 Climate change may affect this competitive dynamic. Measured Genetic Variation has a neutral effect on vulnerability. Steelhead populations in the Upper Snake River exhibit relatively high genetic variation.302 Species with average to high levels of genetic variation are expected to be better able to adapt to changing climatic conditions.303 Diet has a neutral effect on vulnerability. Steelhead have a broad diet in both lakes and streams. In lakes, their diet mainly consists of bottom-dwelling invertebrates (e.g., aquatic insects, amphipods, worms, fish eggs) and plankton. In streams, steelhead consume drift organisms. In the ocean portion of their lifecycle, the steelhead diet includes fish and crustaceans.304 Species that can readily switch among different food types are less likely to be negatively affected by climate change than dietary specialists. Dispersal/Movement has a neutral effect on vulnerability. Steelhead have excellent dispersal abilities. Anadromous forms can migrate hundreds of miles between spawning streams and non-spawning marine waters.305 Steelheads dispersal ability increases the likelihood that it has the ability to adapt to shifting climatic conditions.	
6162	13	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Preferred Alternative Regretfully, the AAs CRSO DEIS and the PA do not meet the EIS intent as expressed in the Purpose and Need or Objectives. The DEIS does NOT provide for the conservation of fish and wildlife resources, including threatened, endangered, and sensitive species. The DEIS does NOT protect and preserve cultural resources. The DEIS does NOT comply with environmental laws and regulations and all other applicable federal statutory and regulatory requirements, including those specifically addressing the System such as requirements under the Northwest Power Act to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with other purposes for which such system and facilities are managed and operated. The DEIS does NOT protect Native American treaty and reserved rights and trust obligations for natural and cultural resources throughout the environment affected by System operations. Furthermore, the DEIS and associated PA do NOT meet the stated CRSO Objectives. The PA does NOT Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival. and does NOT Improve ESA-listed anadromous salmonid adult fish migration. Using the CRSO Definition of Effects, the best available science (CSS and COMPASS) suggests that, at best, the DEIS PA would have a Negligible or Minor effect on juvenile and anadromous adult survival relative to the No Action Alternative (NAA). For example, the DEIS states that the PA represents a 35% increase in survival relative to the NAA. Presently, many listed Snake River Basin stocks have an average SAR survival of 0.7% (or less). A 35% increase	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the draft EIS, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws, including those pertaining to natural and cultural resources. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies used high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Council recovery targets for the region) increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				from 0.7% would be a 0.95% SAR. Given current freshwater productivity levels, SARs less than 1% put listed stocks in a steep decline, below replacement, and at a high risk of near-term extirpation. In fact, the best-available science suggests that Snake River populations need to be at or above a 2% SAR just to be at replacement; population recovery will only occur in the SAR range of 2-6% (4% average) consistent with Northwest Power and Conservation goals. Therefore, the DEIS PA appears to knowingly put ESA listed Snake River stocks in jeopardy. This outcome is unacceptable to USRT and its member tribes.	See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Chapter 8 demonstrates the co-lead agencies' compliance with Federal laws, including the Northwest Power Act and ESA. Finally, tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
6162	14	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The PA Does Not Ensure ESA Recovery The measures in the PA are insufficient in magnitude and scope to recover and delist all populations under the ESA. To rationalize the selection of an alternative that does not meet the minimum standards of viability for all populations, over alternatives that are projected to far exceed these standards, the AAs emphasize their lack of obligation to contribute affirmatively toward recovery achievement (DEIS 7-4). USRT disagrees with this characterization of the AAs responsibility. By the DEIS analysis, the AAs have a tremendous ability to directly affect the recovery trajectory of anadromous species, and arguably a responsibility to operate one of the largest directly-controllable and system-wide influences in a manner that produces upward trends in anadromous populations. If the AAs prioritize anadromous populations through selection of an alternative that integrates that responsibility, changes in the CRSO have the potential to amplify the collective investments of federal and state agencies, tribal governments, and NGOs in producing meaningful recovery.	Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation.
6162	15	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The PA Directly Impedes the Achievement of Goals Outlined by the Northwest Power and Conservation Council Columbia Basin Fish & Wildlife Program The Northwest Power and Conservation Council (NPCC), comprised of two governor-appointed representatives from each state, is tasked under the Northwest Power Act of 1980 with oversight of the Columbia Basin Fish and Wildlife Program (NPCC Program). Through several NPCC Program iterations, developed in collaboration with regional fish and wildlife managers, the NPCC has maintained a long-term commitment to achieving smolt-to-adult returns (SARs) of 2-6%. While realizing important milestones in habitat restoration, at an expenditure of over $250 million per year and nearly forty years in existence, the NPCC Program has not met that goal. This suggests that, if the region is truly committed to these goals, mitigation for the CRS, even at its current magnitude, must be accompanied by new and innovative system-wide approaches to hydropower operations. The DEIS outlines several measures that would comprise meaningful steps towards adopting and institutionalizing measures that would redirect the region towards realizing NPCC Program goals; however, the AAs have opted to discount such measures in the PA. Instead the AAs propose measures that may result in SARs of less than one percent for stocks such as Snake River spring/summer Chinook salmon and move the region further from its collaboratively developed mitigation goals.	It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced throughout this comment refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution to recovery, but the Councils broad sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used current high quality information and best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average SAR return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Council's recovery targets for the region) as a result of implementation of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6162	16	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The PA Directly Impedes the Achievement of Goals Outlined by State, Federal, and Tribal Parties in the Columbia River Basin In an unprecedented scope and scale of collaboration, the National Marine Fisheries Service (NMFS) convened the Marine Anadromous Advisory Committee Columbia Basin Partnership Task Force (MAFAC CBP) in 2017 to develop long-term salmon and steelhead abundance targets, strategies to meet those targets, and consensus on a path forward. The formation of the MAFAC CBP is a direct response to the growing urgency of and public interest in reaching meaningful salmon and steelhead abundances. Toward this purpose, NMFS recognized the necessity of soliciting broad participation of state and tribal governments, industry representatives, and NGOs. In an effort to maintain a robust and empirically grounded approach to goal and strategy development, the MAFAC CBP informs its process with NMFS developed models; state, tribal and federal expert review and input; and social, cultural, economic and ecological considerations. To date, the MAFAC CBP has adopted ambitious quantitative targets for most of the Columbia Basin and that are several magnitudes greater than current run sizes. Several entities have already adopted or intend to adopt these goals into policy including states and the NPCC. The MAFAC CBP goals track with the same 25-year timeline of the DEIS but, in contrast to the DEIS, emerging strategies incorporate aggressive changes to hydropower operations as central to the feasibility of increasing salmon and steelhead abundances. Several measures outlined in the DEIS, such as dam breaching, would greatly advance the region towards the MAFAC CBP abundance targets. Implementation of the PA will directly impede that progress.	The NMFS Columbia Basin Partnership is focused on developing regional goals for recovery of ESA-listed species and a set of actions to achieve those goals. The actions developed are not the responsibility of any one regional entity, but rather are actions to be taken by a number of entities and sometimes by multiple entities in collaboration. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In the Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing ESA consultation on the Preferred Alternative.
6162	17	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Measures in the PA are Insufficient to Meet the Needs of USRT Member Tribes The SBT, a cooperating agency and a member tribe of USRT, have identified the magnitude of their fishery needs to the AAs throughout the development of the DEIS. In the context of minimum federal definitions of subsistence harvest, the SBT estimate an annual minimum of 95,812 salmon to ensure sufficient availability for each current member to consume little more than one fish per month. Considering the AAs emphasis on their lack of obligation towards meeting the ESA recovery threshold, and that the PA may result in a decrease in Snake River SARs, implementation of the PA will deprive the SBT of salmon and steelhead harvest. During the development of the DEIS, USRT remained hopeful that the AAs would propose a PA that would produce different outcomes. Other alternatives, such as MO3, would by contrast direct the AAs to implement critical first steps towards meeting the needs of the USRT member tribes. Three of the four USRT member tribes did not have the resources to commit to the intensive role as a cooperating agency. Yet their needs are equally as dire. The BPT, FMPST, SPT completely lack access to salmon and steelhead fisheries. Annually, they are only able to acquire a few hundred fish at best, due to a lack of availability of fish for release into blocked areas of the Basin. This continued inequity careens USRT member tribes towards complete extinction of the cultural practices unique to the pursuit of salmon and steelhead. The DEIS belabors this point explicitly, yet the PA hastens this cultural extinction by ensuring that low abundances continue to exclude USRT member tribes from the critical opportunity to fish. The AAs have a trust obligation to USRTs member tribes to ensure that cultural extinction does not occur and to meet the needs of each sovereign nation as defined by that sovereign nation. The AAs cannot carry out this obligation while implementing the PA because it fundamentally contradicts the needs the tribes have articulated to the AAs directly.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 and the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by Resource.
6162	18	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The PA Will Preclude USRT From Achieving Its Goals in Non-Federal Hydropower Mitigation The USRT and member tribes have developed and filed with the Federal Energy Regulatory Commission (FERC) a comprehensive plan for the restoration of salmon and steelhead to the Upper Snake River above the Hells Canyon Complex. The USRT Hells Canyon Complex Fisheries Resource Management Plan details incremental steps towards the restoration of salmon and steelhead to meet both cultural and ecological goals. USRT intends that this Plan be incorporated into the pending FERC license for the Hells Canyon Complex. Its member tribes have endeavored to cross-walk that effort with NPCC Program activities and multiple federal, state, and private pathways to produce the largest possible benefit to Snake River stocks. Implementation of the PA severely hinders USRTs efforts by committing to a suite of measures that may result in lower returns to the Snake River, entrenching the region on a path of persistence, versus recovery, and in currently accessible areas only.	The Hells Canyon complex are private dams and not in the scope of this EIS.
6162	19	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Fulfilment of the Court Order Requires a Serious Analysis of Dam Breaching As a cooperating agency, throughout the development of the DEIS, USRT has emphasized the necessity of a meaningful analysis of dam breaching, per the 2016 District Court Opinion and Order, and serious consideration of the inclusion of dam breaching in the PA. USRT does not consider the District Court Opinion and Order to contain nominal, heuristic, or hypothetical directives to the AAs. However, in disregard of multiple years of intensive modelling and collaboration with cooperating agencies, the AAs have arrived at the perfunctory conclusion that dam breaching conflicts with Congressional intent. This conclusion signifies that, despite years of collaboration and rigorous analysis, the AAs did not intend to construct a meaningful solution to the crisis of salmon and steelhead decline. It also signifies that the AAs intended to satisfy the District Court Opinion and Order in semantics only. Assuming the AAs are generally aware of the limits of their Congressionally-delegated authority from the onset of a NEPA process, this approach to the NEPA process verges on, if not eclipses, the pre-decisional. The AAs had an obligation to engage cooperating agencies directly on this issue from the commencement of DEIS development, and explicitly acknowledge their interpretation of their jurisdictions in implementing actions such as dam breaching. Instead, cooperating agencies engaged in good faith that dam breaching, per the District Court Opinion and Order, was a contender in the final PA and as one of the few actions analyzed that would increase abundances.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The Preferred Alternative involves spilling to the 125% TDG limit at Snake and Columbia River dams. The effect of this operation will be to reduce the proportion of juvenile fish passing through powerhouses, which is project to increase smolt to adult return rates. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6162	20	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	Major Flaws in Analyzing the Effects to Anadromous and Resident Fish Populations Muddle Potential Tradeoffs in Each MO Support for the premature exclusion of dam breaching exists throughout the effects analysis. In its previous cooperating agency comments, USRT identified several analytical flaws. The effects analysis selectively handles empirical information, particularly in analyzing the effects of dam breaching on anadromous and resident populations. These flaws fall into several categories. 1) The effects analysis emphasizes short-term adverse impacts (e.g., DEIS 7-9) while downplaying possible long-term effects. This approach assigns a false equivalency between short and long-term effects to anadromous and resident populations. That equivalency is not empirically supported; nonetheless, it is handled in the DEIS as such. 2) The analyses exclude any empirical examples of dam breaching effects, for example, studies from the Elwha River in Washington, the Eklutna River in Alaska, or the Penobscot River in Maine. In recognition that dam breaching is a relatively new approach to river management, it remains unclear why the DEIS analyses would exclude empirical research and	In terms of anadromous populations, in particular the Snake River salmon and steelhead, the Draft EIS clearly presents MO3 (includes the measure to breach the lower Snake River dams) to show the largest improvement relative to the No Action Alternative. However, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding the effects of dam breaching on anadromous fish populations not including other empirical examples of dam breaching: There have been many dam removals that have had significant fish and other benefits. However, these have limited relevance to the lower Snake River Dams. The Elwha dams, for example, had no passage, or provided economic benefits. Regarding extrapolation of effects: it would be helpful to have an example from the commenter here, but in terms of the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				instead rely on the hypothetical to inform its analyses. 3) Putative effects to resources are extrapolated to a degree that is generally considered to be inappropriate in the sciences. When discussing potential ecological effects, or the chain of effects to multiple resources by one type of action, the DEIS assumes causation where causation cannot be empirically demonstrated. 4) The DEIS rejects potentially relevant work due to subjective reasoning and philosophical disagreement with conclusions. For example, the results of the 2019 ECONorthwest study Lower Snake River Dams: Economic Tradeoffs of Removal were largely excluded from the effects analysis because the AAs subjectively determined that ECONorthwest correlated dam breaching with recovery in its findings and despite the empirical support for that relationship, its wide acceptance by fisheries experts, and most notably the modelled projections of the DEIS. Effects analysis cannot exclude relevant reports and literature due to a disagreement with findings. These four analytical flaws undermine the conclusions drawn from the DEIS analysis of tradeoffs between each alternative, and ultimately, the selection of the PA.	anadromous fish the Draft EIS does extrapolate the effects of increased spill and dam breach (in the Preferred Alternative, MO4 and MO3) into areas that have no empirical demonstration of these effects. The two primary models used for the fish analysis output a range of possible outcomes. The Preferred Alternative will be implemented using adaptive management that includes a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin. As described in the Passive Use Section (3.15.2.2), passive use values, also referred to as 'non-use values', are the values people hold for the continued existence of a resource beyond any current or future use. The existing literature on passive use was gathered and reviewed for the CRSO EIS, however as described in the subsection titled 'Relevance to the CRSO EIS' the analysis considered the applicability of the existing literature to the CRSO EIS given best practices for benefit transfer. The ECONorthwest Report, which bases its monetary estimate of non-use value on how survey respondents answered the following question: "Removing four dams on the Lower Snake River would restore wild salmon and improve water quality, but might lead to a slight increase in electricity costs. Would you be willing to pay an additional____on your electric bill in order to ensure that wild salmon would be protected?" It's implied in that question that removing the four LSR dams would "ensure" the protection of wild salmon. The fish analysis in Chapter 3 of the Draft EIS does indicate that dam breach would contribute the most toward protecting salmon and steelhead relative to the No Action Alternative, however the absolute value of the increase in survival due to dam breach is uncertain. For example, the NMFS Life Cycle Model predicts that Smolt-to-Adult survival (SAR) for Snake River spring/summer Chinook increases from 0.88% to 1% under the dam breach alternative, while the CSS model predicts SARs for these fish will increase from 1.8% to 5%. While the ECONorthwest literature identifies a positive WTP for improving salmon populations, it is also clear that the specific value of a given population-level effect is uncertain as is the level of protection dam breach will provide to salmon.
6162	21	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The Cumulative Effects Analysis Does Not Consider Licensing of Non-Federal Projects in the Snake Basin The Council on Environmental Quality (CEQ), which regulates NEPA implementation, defines cumulative effects as the impact on the environment which results from incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-federal) or person undertakes such other actions (40 CFR 1508.7). However, the DEIS cumulative effects analysis excludes FERC re-licensing of the Hell Canyon Complex upstream of the CRS. FERC re-licensing of the Hells Canyon Complex is in active proceedings. Both states have recently issued Clean Water Act Section 401 certifications, and the FERC has solicited comments on a proposed settlement for select aspects of the license. Due to active proceedings, license issuance is a reasonably foreseeable future action and notably one that will affect fish populations synergistically with the PA. For example, given the modelled changes in returns of anadromous populations under the PA, a license issued without changes to current mitigation measures will continue to limit the recovery of Snake River stocks by continuing to block a large swath of the Columbia River Basin and through effects to downstream water quality. That potential is not analyzed in the DEIS effects analysis. Since the cumulative effects analysis for the PA does not consider this imminent action as directed by CEQ regulations, the cumulative effects analysis underestimates the effects of implementing the PA, particularly on Snake River stocks.	Chapters 6 and 7 evaluate effects from known issues related to the Hells Canyon complex including, RFFA21, Idaho Power Hells Canyon Complex Mercury Contamination Issues/Remediation and RFFA22, Idaho Power Hells Canyon Complex Temperature Issues. Other potential issues associated with these dams are speculative and thus, not included in the cumulative effects analysis.
6162	22	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	The PA Focuses More on Reducing Uncertainty Than Taking Action The AAs state explicitly that the PA is designed to reduce the uncertainty in the regions collective understanding of latent mortality, and therefore improve the accuracy of federal models. For stocks such as Snake River spring/summer Chinook salmon, even marginal improvements in SARs under the PA are predicated on up to a 50% reduction in latent mortality. If the AAs pursue uncertainty research at the expense of actions that could redirect population trajectories now, such as dam breaching, the region hedges bets on an unacceptable tradeoff. Delaying actions with reasonably anticipated outcomes, such as dam breaching, for the purpose of evaluating uncertainty in actions, with few assurances that latent mortality will be reduced, propels the region into yet another period of delayed recovery of salmon and steelhead. If the uncertainty around latent mortality is not resolved, or if the AAs are unable to reduce latent mortality, the effects analysis predicts that the PA will actually reduce Snake River spring/summer Chinook salmon SARs. At best, if the AAs resolve the uncertainty around latent mortality to the extent sufficient to take action, the analysis predicts only marginal improvements in SARs.	The model results presented in Section 3.5 and Section 7.7.4 address latent mortality and reservoir mortality. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results. Reservoir mortality is captured in the juvenile survival metrics presented in Chapter 3. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the Draft EIS. Addressing the uncertainty of the impacts of latent mortality is one of many benefits of the Preferred Alternative. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. In order to narrow the uncertainty between the two models utilized for the analysis, the Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6162	23	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	USRT Request for a Regional Coordination Accord for Fish Recovery Efforts Tribal leaders from USRTs member tribes authored the USRT Motherhood Document in 1998, which was followed by the USRT Charter in 2007. That year USRT established 501(c)(3) status, opened an office in Boise, Idaho, and hired an executive director. Soon after USRT began receiving annual Bonneville Power Administration (BPA) coordination funding. Currently, USRT has four full-time employees and one parttime employee. At its inception, tribal leaders envisioned that a primary function of USRT and its staff would be to focus on increasing the abundance and range of salmon and steelhead in the Upper Snake River Basin. This included and continues to include the currently accessible areas, as well as the blocked areas of the Basin that were historically accessible. We have established ourselves as important regional player and partner in salmon and steelhead forums and processes that include federal, state, local, and tribal governments, NGOs, and stakeholders. Our most recent BPA coordination contract includes the following seven work elements: Participate in Regional Fish & Wildlife Program Forums and Activities Participate in Processes and Forums directly affecting Program Implementation Facilitate Consensus-based Coordination in the Upper Snake Province Provide Technical Review of the Fish & Wildlife Program Support the Fish & Wildlife Program Data Management Framework Disseminate Information to Tribal Communities and to the Public Manage BPA Contracts and Subcontracts USRT greatly appreciates annual coordination funding received from BPA. However, year to year funding creates much uncertainty and inhibits USRT from more fully representing our four member tribes in regional fish and wildlife forums. The current level of funding that we receive also does not allow for hiring additional staff, which is sorely needed to fulfill the mission envisioned by USRTs tribal leaders. The Upper Snake River Basin is both incredibly important and woefully underrepresented and recognized in the Columbia River Basin and in fish and wildlife arenas. As such, we are requesting that BPA enter into negotiations with USRT in regard to a stable, long-term regional coordination Accord that will fund efforts to promote and improve salmon and steelhead abundance in not only the Upper Snake, but the Columbia River Basin as a whole. USRT is eager to discuss an Accord with BPA and looks forward to having an initial conversation in the near-term.	Bonneville appreciates its ongoing relationship with USRT. Accord discussions are outside the scope of the EIS.
6162	24	scott.hauser@usrtf.org	Upper Snake River Tribes Foundation and its Four Member Tribes	For more than two years the cooperating agency were led to believe that the AAs would choose either the No Action Alternative or MO 1, 2, 3, or 4. However, in Portland, Oregon on September 4, 2019 they announced that in fact, none of the preceding would be the PA. The cooperating agencies were told repeatedly month after month that we would get a preview of the PA. That timeline kept getting pushed back further and further. We never truly saw a full PA until the release of the DEIS. Once we did see it, we realized that we had been betrayed this whole time.	The cooperating agencies served a critical role in the development of the objectives and measures for the EIS evaluation, and working on technical teams to identify the impacts of the four Multiple Objective alternatives. The co-lead agencies utilized the measures and analysis that was developed with the cooperating agencies to select a combination of measures from the MOs to develop the Preferred Alternative (PA). The selection of measures to include in the PA is based on how well the measures met the Purpose and Need Statement and EIS objectives, with consideration of environmental, economic, and social effects. As the co-leads expedited the analysis of the PA, multiple meetings were held with cooperating agencies to discuss the proposed measures in the PA and solicit comments, until a draft of Chapter 7 Preferred Alternative was available for cooperating agency review. The draft of Chapter 7 was shared with the cooperating agencies in advance of the release of the Draft EIS.
6171	1	broznowski.sofie@gmail.com	N/A	Another issue that could be easily be solved is that of irrigation, omitting the solution of simply extending the pipes for the irrigation is biased and a large oversight. Thus, it is necessary that the final EIS include these solutions in its assessment.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences, specifically under Region C under the MO3 alternative (see page 3-1267, line 3244 in the Draft EIS) and in Appendix N. The report from which this EIS draws, as discussed, concluded that modifying the existing pump system was cost prohibitive.
6171	2	broznowski.sofie@gmail.com	N/A	Endangered species mandates are required by law and must be met, the only option that meets these mandates fully is breaching the dams.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. As described in Chapter 7 of the EIS, the Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy.
6194	4	N/A	N/A	MO4 provides that juvenile fish passage spill would be set to 125% total dissolved gas (TDG) levels during the spring and summer, which could run for seven days a week, 24 hours a day from March 1 to August 31. Such a high degree of spill does not meet the EIS objective of providing a reliable and economic power supply and thus does not work for electric cooperatives receiving BPA power. MO4 results in hydropower generation decreasing by an average of 1,300 MW under average water conditions, or the largest impacts to hydropower generation of any of the multiple objectives considered in the DEIS. Therefore, MO4 results in the highest probability of power shortages of any of the alternatives considered, and foresees blackouts or emergency conditions in roughly one in three years. That outcome is unacceptable for electric cooperatives and the communities they serve. The costs to avoid such drastic power reliability problems would be astronomical. The least-cost resource option for replacement resources would be $156 million per year and include 3,240 MW of simple cycle natural gas turbines, in conflict with regional clean energy targets. Replacement resources utilizing variable renewable generation would require $350 million per year. Bonnevilles wholesale power rates could increase by up to 25.3 41 percent. This would be compounded by the major adverse economic effects the DEIS found would occur under MO4. All these pressures would be added on top of the economic pressures that communities are now facing due to the coronavirus pandemic.	MO4 was not identified as the Preferred Alternative. The comment statements about MO4 and the impact of spill on hydropower operations are consistent with the findings of the EIS, specifically that MO4 has the largest impact to hydropower generation and would increase power costs due to resources needed to replace lost hydropower generation. See Section 3.7.3.6, Electricity Rate Pressure, at pages 3-945-950 in the Draft EIS, Table 3-182. Due to these effects, the EIS finds that MO4 does not meet the objective of providing a reliable and economic power supply, consistent with the concerns voiced by the comment. See Section 7.3.5, Multiple Objective Alternative 4, at pages 7-13-15 in the Draft EIS.
6194	5	N/A	N/A	We support the co-lead agencies modification of its analysis following the implementation of the flexible spill operations that were agreed to in the 2018 flexible spill agreement. Under the Preferred Alternative (based on the flexible spill agreement), spill operations would be adapted if conditions dictate that a temporary or permanent change to the plan is needed. Hydropower customers should be represented as a part of any stakeholder process to make such operational changes. We have concerns about the decrease in hydropower generation of an average 160 300 MW in the Preferred Alternative. However, this decrease would not result in the reliability concerns presented by the other alternatives. Importantly, no additional resources would be needed to maintain regional reliability. While hydropower revenues will decrease, avoiding the need to build additional resources and the	The measures from MO3 and MO4 creating the large rate pressure impacts, were not included in the Preferred Alternative identified in the EIS. The statements in the comment about hydropower generation and wholesale power rate effects under MO3, MO4, and the Preferred Alternative are consistent with the findings of the EIS. See Sections 3.7.3.5, 3.7.3.6 Electricity Rate Pressures, and 7.7.9 Power Generation and Transmission. The power estimates presented in the EIS are a comparison to the No Action Alternative, rather than the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				associated annual costs as described under MO3 and MO4 would keep wholesale rate pressure on Bonneville to 2.7 percent. While this rate increase may seem modest compared to other outcomes under consideration, the co-lead agencies should be aware that any and all rate increases are burdensome for electric cooperatives and their consumer-members.	Consistent with the comment, the co-lead agencies developed a Preferred Alternative that strives to balance the multiple objectives. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. Bonneville plans to continue regular course of business meetings with power customers on all relevant fish and wildlife issues including juvenile fish passage spill operations. Power customers are encouraged to participate in the public portions of the Regional Forum, such as the Technical Management Team, where in-season management of fish passage spill operations would continue to occur.
6194	6	N/A	N/A	Finally, while we believe that the Preferred Alternative represents a balanced solution, we have significant concerns around its operationalization of unprecedented and untested levels of spill. Unfortunately, scientific uncertainty remains around the efficacy of spill at the 125% TDG level contemplated in the Preferred Alternative. We are concerned that the extensively different findings from the two bodies of science included in the DEIS (NOAAs Life Cycle Model and the Fish Passage Centers Comparative Survival Study model) will continue to be a flashpoint as the region searches for durable consensus around Columbia River System operations. Given this uncertainty in fisheries science, NRECA urges the co-lead agencies to closely monitor the higher levels of spill as part of the Preferred Alternative and rigorously apply adaptive management measures should those spill levels be shown to be harmful to ESA-listed fish. This should include consideration of dialing back spill should large-scale negative impacts on fish be found.	Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and COMPASS models predict that power house encounters would be cut in half relative to the No-Action Alternative for Snake River spring/summer Chinook salmon. The uncertainty lies in the hypothesis that reduced powerhouse encounters will result in increased adult returns. To address this uncertainty, the Preferred Alternative includes an adaptive management plan, which will allow the co-lead agencies to respond to any future harmful impacts to ESA-listed species. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6202	1	Suzanne.Grassell@chelanpud.org	Chelan County PUD	Effects on Emissions and Regional Reliability Hydropower is uniquely positioned to support the grid as it transitions toward deep decarbonization. It provides the essential reliability services needed to integrate wind and solar such as frequency response, voltage and ramp capability, black start, fuel assurance, flexibility and black start. At the same time, it is emission free. With western states setting ambitious carbon reduction goals, the region would be shortsighted to remove emission-free capacity resources. Notwithstanding the immediate reductions in demand the nation is seeing in light of the COVID-19 pandemic, utility planners expect to face a capacity deficit of thousands of megawatts by the mid-2020s. In October 2019, the Northwest Power Pool released a report1 that compiles the findings of several studies. It found that deep decarbonization will bring reliability challenges as coal plants retire, making the system more vulnerable to blackouts. The studies identified a capacity risk even with the Lower Snake River dams in place. In the DEIS, the federal action agencies found that breaching the four Lower Snake River dams would double the regions risk of a blackout by eliminating 2,000 megawatts of sustained peaking capabilities during the winter and a quarter of the federal power systems current reserves holding capability.2 It would also significantly increase carbon emissions. Chelan PUD agrees that this action must be rejected, and our Board of Commissioners passed a resolution to this effect last year.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative (PA) identified in the Draft EIS. The effects of the PA on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The statements regarding the importance of hydropower as a carbon-free power source, and the ability of hydropower to integrate variable renewables and adjust generation to meet load are consistent with the findings of the EIS. The comment that regional reliability would decrease substantially without replacing anticipated coal retirements is consistent with information presented in the EIS. See Section 3.7.3.2, No Action Alternative, pages 3-845-84, Table 3-123; Appendix H, Power and Transmission, Section 2.3. at H-2-8 15 in the Draft EIS.
6202	2	Suzanne.Grassell@chelanpud.org	Chelan County PUD	Predation Management Protecting salmon and steelhead from predation throughout their lifecycle is critical to ensuring that regional investments in hydropower improvements, hatcheries and habitat achieve the desired result of protecting and enhancing fish populations. Returning adult fish are particularly valuable for meeting recovery goals and the future of fisheries. Predation by native and non-native fish, pinnipeds and avian species is clearly having a negative impact on overall Columbia River Basin salmon and steelhead recovery goals. However, the DEIS only describes fish and avian predation measures as localized actions that appear to have little to no correspondence to basin wide predation control. In addition to outlining current ongoing actions, Chelan PUD recommends that the final EIS go further in describing comprehensive actions that address predation throughout the Columbia River system. Specifically, the federal action agencies should describe new actions that approach predation holistically. We respectfully suggest that the federal action agencies evaluate and implement the suggested mitigation measures outlined in the letter from the Northwest River Partners with regard to avian predation and Northern Pike control. The final EIS also should encourage state and federal agencies throughout the Columbia River Basin to exercise, to the extent possible, their management authorities to address the serious threat of predation on native fish species. We also support, and have advocated for, an increase in take permits for pinnipeds, in accordance with federal action agency data on predation levels within the entire basin. 1 Exploring a Resource Adequacy Program for the Pacific Northwest. October 2019 2 Columbia River System Operations Draft Environmental Impact Statement. Executive Summary, page 25. 3 In 2019, our Board of Commissioners approved a resolution opposing the removal of the Lower Snake River dams because they are significant, carbon-free capacity resources in the Northwest. 4 Columbia River System Operations Draft Environmental Impact Statement. Executive Summary, page 34.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
6202	3	Suzanne.Grassell@chelanpud.org	Chelan County PUD	Spill and Total Dissolved Gas The Preferred Alternative describes spill operations of up to 125 percent total dissolved gas (TDG) at most projects with the intention of benefiting juvenile outmigration. 5 At the same time, it describes how planned hours of reduced spill each day provide a degree of protection against unexpected or unintended consequences that may occur due to spilling up to the 125 percent TDG cap during juvenile fish passage spring operations such as adult migration delay, gas bubble trauma, or damage to infrastructure. 6 Chelan PUD has an interest in monitoring risk factors in the basin that may impede the recovery of salmon and steelhead species listed under the ESA and covered by our HCPs. In apparent recognition of the uncertainties surrounding increased spill and its long-term effects on juvenile migrants and adults returning to spawn, the DEIS states that such operations would be adaptively managed through the Regional Forum processes to address unexpected challenges, such as potential delays to adult migration, effects to navigation, and other challenges or opportunities that may require either a temporary or permanent change. 7 We therefore agree that adaptive management in this respect will be necessary. As recommended by Northwest River Partners, we urge the federal action agencies to include clear language describing how spill reduction will occur should higher TDG levels be shown to have a significant negative impact on vulnerable fish populations.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. Any unforeseen adverse consequences during implementation of 125% TDG spill levels will initially be addressed through the existing Technical Management Team, and any disputes will be elevated through the Regional Forum as necessary. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6216	1	elenanataliaede@gmail.com	N/A	For the sake of us as humans, in the middle of this Global Pandemic, unable to go out and speak to you face to face. Stop. I wish to speak directly to someone within your buisness, and have a conversation on what responses youve taken, why this has been happening (whats to gain, whats to lose, cost), and to have a conversation on what we can do as the people watching you take away our livelihoods from a distance to stop it.	Unfortunately, in-person meetings that were scheduled during the public comment period were moved to virtual meetings in light of the COVID-19 pandemic.
6231	1	david.konz@tidewater.com	Pacific Northwest Waterways Association	In conclusion, Tidewater remains committed to supporting salmon recovery in the Columbia River Basin and urges the co-lead agencies to continue to generate an implementable DEIS that includes a salmon recovery plan in the Columbia River Basin that addresses the multifaceted factors that affect salmon populations, including avian and pinniped predation, ocean conditions, and climate change without adversely impacting the viability Washington, Oregon and Idaho's economies and the maritime industry that supports many family wage jobs.	Thank you for your comment. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding salmon recovery: the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6235	1	Shiva Rajbhandari	N/A	Greetings, I'm asking you now to extend the period for public comment for the DEIS on the CRSO. On the last telecomment opportunity, the line was packed. It ended up going an hour later than expected and still not everyone got to speak.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period. Regarding the last virtual public meeting, it is true the public meeting time was extended to address any additional comments. We kept the lines open and executive leadership listening and extra 30 minutes without any additional comments, then closed out the meeting. Everyone on the meeting was able to provide comments.
6240	1	N/A	N/A	Usacehq is violating the Endangered Species Act and the National Environmental Policy Act by not breaching the four lower Snake River dams.	Chapter 8 discusses how the co-lead agencies, including the Corps complied with the ESA and NEPA. NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement of NEPA, after evaluating scoping comments from the public, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single objective alternatives, and then four MOs. The MOs were also determined to be more efficient and reasonable, as MOs were composed of combinations of measures from the single objective alternatives. The Draft EIS considered the environmental consequences of the range of alternatives and disclosed to the public those consequences. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat.
6242	1	orcaconservancy@gmail.com	N/A	Orca Conservancy strongly feels that the 45-day comment period is severely inadequate as the DEIS is 8,000 pages long, and by the agencies own admission, is the result of more than three years of regional collaboration between the lead federal agencies and more than 30 entities from across the region, consisting of tribes, federal agencies, and state and local governments, who contributed their technical expertise and input as cooperating	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				agencies in this National Environmental Policy Act (NEPA) process. Additionally, restrictions on activities due to the COVID-19 Pandemic have been in place in the Pacific Northwest (PNW) throughout most of the comment period and has severely limited opportunities to meet with colleagues efficiently and access older and other written materials in libraries that are not readily available online. Even members of Congress and many other organizations have requested your agencies extend the public comment period back to its original 120-day timeline.1 Therefore, Orca Conservancy highly recommends that said agencies either extend the public comment period to at least 120 days, or provide a supplemental public comment period after the COVID-19 crisis has subsided.	determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6242	2	orcaconservancy@gmail.com	N/A	Due to our focus on advocating for recovery to allow delisting of SRKWs under the Endangered Species Act (ESA), the majority of our findings with the DEIS were failures in representing the SRKWs properly and it falls short of making recovery efforts fully discussed within the ESA.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
6242	3	orcaconservancy@gmail.com	N/A	In November 2006, the Salish Sea was designated as Critical Habitat for the SRKW Distinct Population Segment (DPS) and is part of the migration route for Columbia River System (CRS) Chinook salmon. The SRKW population is the most intensively studied population of marine mammals in the world, and the best available science tells us that healthy wild Chinook salmon runs are critical to SRKW recovery. The SRKWs historic use of west coast waters qualifies this community as an important resource to the states of Washington, Oregon and California, and therefore SRKWs should be considered when evaluating the potential impact of continued operation of the Lower Snake River Dams (LSRD). As National Marine Fisheries Service (NMFS) recently acknowledged, new information confirms that [S]outhern [R]esidents spend substantial time in coastal areas of Washington, Oregon and California and utilize salmon returns to these areas.11 These coastal waters are recognized as an essential foraging area for 2 2020. Center for Whale Research 3 16 U.S.C. 1531(b). 4 Id. at 1531(c)(1). 5 Id. at 1532(3). 6 Id. at 1536(a)(1). 7 Id. at 1538(a)(1)(B). 8 Id. at 1532(19). 9 50 C.F.R. 222.102; see also Babbitt v. Sweet Home Chapter of Cmtys. for a Great Or., 515 U.S. 687 (1995) (upholding same regulatory definition of harm in 50 C.F.R. 17.3). 10 2018. Center for Biological Diversity and Wild Fish Conservancys 60-day notice of intent to sue the U.S. Department of Commerce, the Secretary of Commerce, the National Marine Fisheries Service (also known as NOAA Fisheries), and the Northwest Regional Administrator for the National Marine Fisheries Service (collectively NMFS) for violations of the Endangered Species Act (ESA), 16 U.S.C. 1531, et seq. 11 Michael J. Ford, Natl Marine Fisheries Serv., Status Review Update of Southern Resident Killer Whales 26 (2013). In fact, evidence indicates that Southern Residents spend the majority of time in coastal and offshore waters. Cf. M. Bradley Hanson, et al., Assessing the Coastal Occurrence of Endangered Killer Whales Using Autonomous Passive Acoustic Recorders, 134 J. OF THE ACOUSTICAL SOCY OF AMERICA 3486, 3486 (2013) [hereinafter Coastal Occurrence] (explaining that on average the whales occur in inland waters less than half of the days each year). Orca Conservancy PO Box 16628 Seattle, WA 98116 3 this critically endangered population in the winter and spring, and are currently under consideration to be designated as critical habitat for the SRKW12, which will include a much larger and densely populated portion of the CRS Chinook salmon range along the Pacific coast. The DEIS relies on an inaccurate description of the distribution of SRKWs. In fact, the majority of SRKWs spend the greater part of the year within the main range of CRS Chinook. Between 1976 and 2004 there had been only 11 documented sightings in United States (U.S.) coastal waters.13 Between 2006 and 2011, 131 acoustic detections were collected by deploying acoustic recorders in seven locations on the continental shelf of the U.S. west coast from Cape Flattery, WA to Pt. Reyes, CA to detect and record endangered SRKWs. Detection rates of SRKWs were greater in 2009 and 2011 than in 2006 - 2008, were most common in the month of March, and occurred with the greatest frequency off the Columbia River and Westport, which was likely related to the presence of their most commonly consumed prey, Chinook salmon.14 The use of passive acoustic recorders has greatly increased the knowledge of seasonal and annual occurrences of SRKW in the coastal waters of the United States. Satellite tracking of individual SRKWs also revealed the extent to which they used Pacific coastal waters, and their focus on the migratory routes of CRS Chinook for most of this time. Further, use of this portion of the range has increased as Fraser River Chinook runs have declined, indicating CRS runs are likely to be more important in the coming years than they were in the first 40 years of intensive study of SRKWs.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects.
6242	4	orcaconservancy@gmail.com	N/A	The DEIS relies on an incomplete report on the importance of different river systems in providing food for SRKWs. The authors noted many sources of bias they did not have time to address. These biases lead to an underestimation of the importance of CRS Chinook. One bias is weighting the importance of rivers based on recovery of scale samples confirming predation. While thousands of samples have been collected in the Salish Sea, little effort has been undertaken on the Washington Coast north of the Columbia River mouth, and negligible effort has been invested to look for CRS Chinook to the south of it. Since the geography of sampling does not reflect the seasonal distribution of the whales, this results in bias from different relative abundance of salmon from different runs where data were collected. I.e., if you sample in the Salish Sea, you will find fish migrating through the Salish Sea, and if you sample off the Columbia, you find fish bound for the Columbia, and if you sampled off the Klamath you would likely find fish migrating to the Klamath, as well as to the Columbia and Sacramento. The authors noted that correction for this bias had not yet been completed. The report also considered samples from a limited time frame. Presumably, if the work had been conducted at a time before CRS Chinook had been decimated, these fish would have been a much important part of the diet. Likewise, future studies conducted after a run is enhanced would likely show that run has become a more important part of the diet. That is, the recovery potential of a run is an important consideration that was omitted from the report. Klamath River spring Chinook have had returns below 1,000 individuals in recent years, so it would not be surprising if these are currently a negligible portion of the diet. However, when returns were a million individuals, or if the runs were restored to over 100,000 individuals, they would likely become a very significant part of the diet. No river system in the SRKW range has more restoration potential than the Columbia River System. Finally, the report did not consider body size. Wild run Chinook from the upper Columbia basin had among the largest individuals in the species because of the large energy reserves required for a long migration to high altitude 12 12-Month Finding on a Petition to Revise the Critical Habitat Designation for the Southern Resident Killer Whale Distinct Population Segment, 80 FR 9682, published 2/24/2015. 13 2004. Krahn, et al. 14 2013. M. Bradley Hanson,a, Candice K. Emmons, and Eric J. Ward. Assessing the coastal occurrence of endangered killer whales using autonomous passive acoustic recorders. Orca Conservancy PO Box 16628 Seattle, WA 98116 4 and defending a redd. Large fish require few successful prey captures relative to small fish, allowing the high net energy gain required for growth and successful nursing of calves.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects.
6242	5	orcaconservancy@gmail.com	N/A	The DEIS fails to consider the effects of inbreeding on jeopardy to Distinct Population Segment (DPS) survival. Maintaining constant numbers will result in loss of genetic diversity and increased inbreeding, both of which reduces the likelihood of recovery. That is, a plan that does not contribute toward significantly increasing SRKW numbers results in jeopardy. In his ruling on the Maury Island gravel mine case, Judge Martinez noted that even small threats to an already endangered population were likely to result in jeopardy. Thus, the DEIS should have concluded that the preferred alternative is likely to adversely affect SRKWs and result in jeopardy to the DPS survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. 					whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. SRKW analysis has been done and described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
6242	6	orcaconservancy@gmail.com	N/A	Removal of LSRDs would support recovery of wild Chinook and SRKWs but was not seriously considered. It could be combined with spill up to 125% Total Dissolved Gas (TDG). High spill levels help lower river temperatures, and the increased flow helps juvenile salmon move downstream. However, if spill levels become too high, water becomes supersaturated with gas. If salmon at depth equilibrate with high gas levels, then move close to the surface, they can suffer gas bubble lesions, just as human scuba divers develop the bends. However, just as there are safe limits for no decompression dives, there are safe levels for TDG given actual conditions. Empirical evidence suggests 125% TDG falls within the safe limit for juvenile Chinook, so the benefits to migration outweigh the risk of injury. Further, the timing of the runs and electrical demand suggest there will be negligible impact on the ability of BPA to meet its power obligations by increasing spill to the 125% TDG limit during outmigration. The State of Washington has been updating its water quality rules to allow use of this mechanism to improve salmon survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The Preferred Alternative involves spilling to the 125% TDG limit at Snake and Columbia River dams. The effect of this operation will be to reduce the proportion of juvenile fish passing through powerhouses, which is projected to increase smolt to adult return rates.
6242	7	orcaconservancy@gmail.com	N/A	While the DEIS considered replacement power generation, it did not consider conservation as a means to offset the loss of power generation, even though it is the most cost-effective approach. Clean energy replacement is a good deal. If future energy prices are in the medium range of projected levels, replacing power produced by the dams with clean, pollution-free alternatives would cost no more than replacing it with fossil fuel sources. If future prices are high, clean energy would be cheaper than market energy options. Market intervention would be needed to promote energy conservation and renewable energy resources. The Bonneville Power Administration (BPA) system will continue to provide benefits to Northwest customers if dams are removed to restore salmon. The cost of removing the dams and replacing their power with clean energy would increase residential electric bills by just $1 to $3 per month, assuming monthly electricity use of 1,000 kilowatt hours. BPA, which markets electricity produced by federal hydropower dams to Northwest utilities, would still have some of the lowest electricity rates in the nation, even after paying to remove the dams and replace their energy from clean sources.15 In fact, the Northwest Power and Conservation Council has concluded that the Northwest has an electrical generation surplus and can meet expected increases in demand through at least 2030 with energy efficiency and planned new renewable energy.	Contrary to the comment, the EIS included all cost-effective conservation identified by the Northwest Power and Conservation Council (Council) in its 7th Power Plan, which is the current power plan. See Appendix H, Power and Transmission, Section 2.2, H-2-3 in the draft EIS. The EIS analysis considered that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in Multiple Objective (MO) Alternative 3. Moreover, cost effective conservation in the region will be acquired pursuant to current law regardless of the status of the four lower Snake River dams. In addition, as explained in the EIS, substantial amounts of regional coal generation will be retiring over the next decade. See draft EIS, Section 3.7 at page 3-841. Without replacing these resources, regional reliability would decrease substantially. See draft EIS, Section 3.7.3.5, Effects on Power System Reliability, at page 3-903 and Appendix H, Table 2-1. Selecting conservation as a resource to replace the generation of the four lower Snake River dams would risk double-counting. The EIS finds that under MO3, reducing hydropower and replacing the generation with zero-carbon resources would increases costs by up to $130 per year for an average household or over $10/month, contrary to the statement in the comment. In October 2019, The Council issued their Resource Adequacy Assessment. In the Addendum, the Council forecasts a Loss-of-Load-Probability of 12.8 percent in 2024 and 26 percent in 2028 both of which are above the Councils 5 percent standard. https://www.nwcouncil.org/reports/pacific-northwest-power-supply-adequacy-assessment-2024.
6242	8	orcaconservancy@gmail.com	N/A	The DEIS failed to consider expanding rail capacity to replace barging. Eastern Washington has been experiencing an agricultural boom unlike anywhere in the United States. Washington State is set to overtake California in wine production by 2020. Ten million tons of commercial cargo and nearly 67 million bushels of wheat are transported on the Columbia/Snake River annually, an essential part of the regions economic competitiveness. Before the LSRDs were completed in 1975 commodities moved by rail and truck. Subsidized navigation undercut terrestrial shipping rates and essentially put rail out of business for moving goods along the river. Consider improved rail as 15 Going with the Flow - Replacing Energy from Four Snake River Dams. bluefish.org April 2000. http://www.bluefish.org/goingwth.htm 16 Seventh Power Plan. NW Council, Feb 25, 2016 https://www.nwcouncil.org/energy/powerplan/7/plan/ Orca Conservancy PO Box 16628 Seattle, WA 98116 5 an alternative to barging as there is potential in keeping the farm communities healthy and growing without destroying the remaining salmon. Electrified rail would minimize impact on climate and discharges of toxins into the environment.	The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments that would be required. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road maintenance costs may occur. The co-lead agencies lack the authority to invest in or mitigate for private infrastructure, such as rail lines.
6242	9	orcaconservancy@gmail.com	N/A	The DEIS failed to consider alternate means for cooling summer flows, providing irrigation water to farmers, and ensuring that farms could remain viable without irrigation. Irrigated agriculture has diverted water from the Columbia and its tributaries. Counting tributaries, there are almost 13.5 million acre-feet of storage capacity in the Snake River Basin.17 Irrigators probably remove 7-8 million-acre feet of water from the Snake River every year.18 But since the Hells Canyon Complex stopped the salmon from going upstream anyway, it is hard to assess the adverse impact of irrigation. It would appear that the biggest problem with irrigation is a problem of governance: since state and federal governments have been incapable of providing clear and reliable property rights in water, irrigators are unable to sell or lease excess water for experiments in fishery management.19 The salmon recovery option in the draft has failed due to not effectively considering mitigating impacts on people. Therefore, there needs to be a good faith effort to define an alternative that maximizes salmon production and effectively mitigates the impact on people who depend on the dams for power, water, transportation, and other uses.	The co-lead agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Additionally, the EIS examines impacts to irrigation and explores alternate means to supply water. Changes to state water rights administration are not within the scope of this EIS.
6242	10	orcaconservancy@gmail.com	N/A	The DEIS failed to consider continued hatchery operation as a conservation measure rather than as a mitigation measure. Snake River spring/summer Chinook abundance has actually declined and adult return rates are well below levels necessary for species survival, let alone for rebuilding and recovery. There is uncontroverted evidence that the current smolt-adult ratio (SAR) for Snake River spring/summer Chinook are at or below 1%, barely half of the minimum 2% SAR level the Northwest Power and Conservation Council has identified as necessary for maintaining existing populations, and only one quarter or less of the 4% to 6% SAR level that must be achieved and sustained for this population to rebuild and recover.20 Moreover, this unacceptably low SAR has been consistent for many years, indicating that the extensive and expensive efforts so far to rebuild Snake River spring/summer Chinook populations have not been successful. National Oceanic and Atmospheric Administrations (NOAA) own publication confirms that wild Snake River spring/summer Chinook returns to the uppermost Snake River dam have declined by at least 60% since the late 1960s when the lower Snake River dams were built (from an average of 47,615 fish to just 18,774).21 NOAAs claim that spring/summer Chinook abundance has increased relies entirely on the fact that over this same period, Snake River spring/summer Chinook hatchery returns to the uppermost dam have increased by at least 15- fold (from 4,933 fish to 73,487),22 an increase that actually reflects increased hatchery production to mitigate for losses of salmon due to the FCRPS, rather than improved survival from restoration measures. The point here is not to criticize the role of hatcheries, but to highlight the extent to which NOAAs claim of increased Chinook abundance relies on increased hatchery production, not increased survival rates. NOAA has set a target of 96% survival for out migrating salmon at each dam and appears to have achieved this. While this appears impressive, by the time eight (8) dams have been crossed -- four (4) on the Lower Snake River that we recommend be removed, four (4) on the mainstem Columbia River whose removal we do not recommend -- cumulative survival is only 72%. As survival of the entire migration can be as high 65%, this suggests that 75-80% of all mortality still occurs at the dams, and mortality rates are hundreds of times higher per mile near dams than in the rest of the watershed. It is also important to remember that wild Snake River spring/summer Chinook are protected by law and ultimately must recover and rebuild to sustain the species health over the long-term.	The most recent ESA Status reveiew reported that the Snake River spring/summer Chinook population trends in total spawner abundance were positive over the period 1999 to 2014 for 23 of the 26 population natural origin abundance series, but the relative rates of increase for each population were lower than estimates of trends for the prior review period (Table 15). Northwest Fisheries Science Center. 2015. Status review update for Pacific salmon and steelhead listed under the Endangered Species Act: Pacific Northwest. However, return rates have been low over the three years this EIS has been in process.

6242	11	orcaconservancy@gmail.com	N/A	Placing greater weight on the impact of this decision on Native Americans, whose treaty rights need to be protected, relative to other inhabitants in the region is needed. A broader consideration of actions to mitigate impact on people who would be negatively affected by dam removal should be included in the final DEIS to provide a roadmap for legislative action at the federal, state and local level. As we have seen in the response to COVID-19, much stronger actions than those considered in the DEIS are now considered viable means to protect economic interests. E.g., checks to homeowners to cover emergency increases in energy costs are now thinkable. Paying coal companies to shut down to free up rail capacity for agricultural products until improved rail service is available while maintain coal employee income levels is now the kind of emergency action that could be taken to recover SRKWs. These actions could mitigate concerns of proponents of maintaining the LSRD to the degree that dam removal and increasing flow up to 125% TDG would become the preferred alternative.	As described in Chapter 5 Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental impacts. If breaching the dams were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures. Many of the mitigation measures that the commenter references are not currently within the authorities of the co-lead agencies.
6242	12	orcaconservancy@gmail.com	N/A	Additionally, climate change will need to be considered both from the perspective of how alternatives affect climate and how the alternatives affect resilience to climate change. As mentioned above, how power generation is managed will have impacts on climate. How flow and salmon passage are managed will affect resilience to climate change, as high elevation habitat currently inaccessible would provide cool refuges, and spawning over a wider area ensures that at least part of the watershed has suitable conditions for listed species. Elimination of reservoirs would increase the effectiveness of shade in keeping the water cool. Replacement of artificial flood control facilities with restoration of natural flood control processes will need to go hand-in-hand to address the expected increase in variability of rain and snow melt. Changes in vegetation could be promoted that increase carbon sequestration, such as reforestation. Most river basins around the world suffer from anthropogenic influences, and climate change is a universal phenomenon. To successfully manage a river basin, it is necessary to understand the recent geologic history and the human management trajectory of the system. Furthermore, management strategies based only on streamflow may prove sub-optimal. Thus, for example, the flood control and hydropower management strategies used in the Columbia have had unintended impacts on the sediment budget and juvenile salmonids. It is also important (and will become increasingly important in the future) to provide a clear separation between human and climate impacts on the streamflow and sediment transport.	The co-lead agencies agree that climate change may impact hydrology, water temperatures, flood risk management operations. That is why the agencies used the best available information, from on-going regional climate change studies and work, to investigate climate change impacts on CRS operations. The co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The assumption that elimination of reservoirs would result in cooler water may not be true, because the hydrologic modeling demonstrates a shift to earlier runoff and lower flows during summer months. Water resource management, through storage and regulation may be increasingly important. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4).
6245	1	Steven Orzack	Fresh Pond Research Institute	There are important biological and economic consequences that must be considered in any decision about the removal of the four dams. These include the potential for a loss of power generated by the dams (which might engender greater use of fossil fuels that would contribute to climate change), the potential for economic damage to nearby agriculture that relies on the dams to supply irrigation water, and the carry-on economic and social effects of these disruptions. These are all consequences that can and must be addressed. The Preferred Alternative in the DEIS does so but in a way that does not aid the recovery and protection of the salmonids and the Killer Whales. They will continue to be endangered if the Preferred Alternative is adopted. However, there is no necessary tension between the imperative to generate clean power and to protect agriculture and the imperative to aid the recovery and protection of salmonids and the Killer Whales. Both imperatives can be satisfied by a plan that includes dam removal, includes the use of further development of renewable energy generation capacity in the region in order to replace the power generated by the dams, and includes measures that ensure that agricultural interests in the vicinity of the dams have adequate access to irrigation water. (A plan that addresses the replacement of power generated by the dams is contained in the Lower Snake River Dams Power Replacement Study that was released in 2018 by the Northwest Energy Coalition. See https://nwenergy.org/featured/lsrdstudy/). 3 The combined plan would be a win for the biology and ecology of the Pacific Northwest and the United States and a win for the culture and the economy of the Pacific Northwest and the United States. I strongly urge the U.S. Army Corps of Engineers, the Bureau of Reclamation and the Bonneville Power Administration to redraft the DEIS and to propose as the Preferred Alternative a combined plan that truly protects and serves the entirety of biological, cultural, economic, and ecological interests of the Pacific Northwest and of the United States. Such a plan must include dam removal in order to protect salmonids and Killer Whales.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding your comment on killer whales: The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
6246	1	rhayden@portofpasco.org	Port of Pasco	Piscivorous Fish Predators Non-native piscivorous fish play a significant role in the mortality of juvenile salmonids. We recommend that Chapter 5 (Mitigation) and Chapter 7 (Preferred Alternative) of the DEIS expand mitigation options to include the following actions: Implement a Brook trout suppression effort in the tributaries of the Snake River above Lower Granite Dam, including the Salmon and Clearwater Rivers and their tributaries. Only 14% of spring and fall Chinook parr in these natal waters survive to ever reach their first dam. One likely reason is that the highly aggressive Brook trout stays in the salmons natal waters and the surrounding lakes and streams year round. Brook trout were imported to the waters of the PNW in the 1890s and have little or no mitigation to their predation on juvenile salmon. Increase Northern Pike suppression efforts in areas above Chief Joseph Dam Begin planning a suppression plan that could be impremented if Northern Pike are detected below Chief Joseph Dam. Bolster early detection measures for Northern Pike in areas below Grand Coulee Dam.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The impacts from brook trout did raise to the level that the co-lead agencies determined would require additional mitigation in this EIS. The co-lead agencies welcome continued discussion on non-native fish suppression efforts including on brook trout. For example, Bonneville's Fish and Wildlife Program would continue to provide funding for suppression of non-native fish, including brook trout, northern pikeminnow, lake trout and northern pike.
6246	2	rhayden@portofpasco.org	Port of Pasco	Transporation The DEIS grossly underestimates the transportation impacts that would be caused by the dam breaching measures included in MO3. We question why the DEISs traffic impact analysis under M03 only considers downriver grain shipments, and not the other commodities moving on the river. Much of our Port district relies on the fuel, agricultural fertilizer, and wood chips Port of Pasco DEIS Comments April 13, 2020 Page 2 of 4 u:\agency\pnwa\comment-crso deis-2020-0413.docx that are transported on the river. We urge you to account for all current freight on barge to assess transportation impacts.	In 2018, 72 percent of overall freight volume on the Lower Snake system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the lower Snake River was petroleum products that terminated below Ice Harbor Dam. These shipments do not utilize the Snake River locks and would not be directly affected by dam removal under MO3. Other commodities that utilized the Snake River system included pulp and paper products (4 percent) as well as chemicals and iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under MO3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5.
6246	3	rhayden@portofpasco.org	Port of Pasco	The transportation infrastructure costs calculated for MO3 were $86 million total. The infrastructure that would be needed to supplant the river barging capacity under M03 would be far, far more extensive and costly. An independent engineering study concluded that the new infrastructure needed to just move the 2.4 million metric tons of grain from farms to overseas ports by truck/rail instead of barge would cost more than 10 times the amount reflected in the DEIS or closer to $800 million. As a Port, we are constantly investing in road and rail upgrades and can attest to the high cost of replacing this type of heavy infrastructure. The DEIS estimate of only $86 million should be thoroughly reviewed to capture comprehensive and accurate costs and specify exactly who will be providing those funds. The DEIS does not account for costs that are typically used for long-term budgeting of transportation capital facilities, such as lifecycle costs, safety issues, fuel costs, and property value impacts. Using the United States Department of Transportations (USDOT) Benefit-Cost Analysis Guidance for Discretionary Grant Programs, the national cost impacts associated with MO3 may exceed $4 billion over 30 years, or a net present value of $1.9 billion. This figure far exceeds the roughly $100 million reflected in the DEIS. A longer term methodology should be used in the DEIS to account for these higher costs.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. As described in Section 3.10.3.5, Navigation and Transportation analysis for MO3, the EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are double, depending on their specific location and other conditions. The evaluation completed for the EIS is an economic analysis of potential effects by evaluating social welfare or the total change in transportation costs, regional economic effects and community or other social effects. This economic analysis is different from the financial analysis used for long-term budgeting needs. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur.
6246	4	rhayden@portofpasco.org	Port of Pasco	Power Costs and Industrial Jobs One of our primary goals as a Port is to support the development of family wage industrial jobs. We are therefore very concerned about questionable assumptions in the DEIS relating to the affordable, reliable power that is an essential element to the success of industrial businesses. The DEIS assumes the region will acquire adequate replacement resources for the reduction in hydropower generation contemplated by many of the alternatives. However, if replacement resources do not become available, reliability would suffer and outages would become frequent, both having severe effects on industry. Since our state of Washington has mandated the elimination of fossil fuel power generation, power capacity models should be performed without the benefit of coal and natural gas plants. Under this scenario, the upward pressure of power rates would be substantially higher than predicted by the DEIS.	The statement that without replacement resources regional power reliability could decrease is consistent with the findings of the EIS. Since the start of the CRSO EIS process in 2016, additional coal retirements have been announced as well as new energy policy. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See draft EIS, Section 3.7.3.1, Availability of Coal Resources, at pages 3-841-842 and Section 3.7.3.2, Table 3-123. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017, and the EIS presents base case analysis first before discussions of information resulting from additional sensitivities and potential cost pressures. Because of anticipated changes to the regional resource mix, for Multiple Objective (MO) Alternative 3 the full replacement portfolio discussed in Section 3.7.3.5, at pages 3-905-911, was developed to minimize reliance on the regional resource mix to replace lost hydropower generation.
6246	5	rhayden@portofpasco.org	Port of Pasco	The DEIS predicts the highest upward pressure for industrial customers, with an increase of up to 29 percent in some counties. The total increase in spending on electricity for industrial businesses would be between $100 million and $240 million per year. That increased cost pressure would result in the loss of up to $400 million in regional output and up to 2,700 jobs. It could also cause industry to leave the region all-together, which would cause secondary economic consequences to Port of Pasco DEIS Comments April 13, 2020 Page 3 of 4 u:\agency\pnwa\comment-crso deis-2020-0413.docx ripple through local economies. Those secondary effects, which would include harm to local businesses and loss of jobs that serve departing industries, are not fully accounted for in the DEIS.	The highest upward rate pressure, increase in spending and regional economic effects cited by the comment are consistent with the findings of the EIS under MO3. See Section 3.7.3.5, at 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS. The comment that increasing electricity rates will cause job losses and economic risk to communities is also consistent with the findings of the EIS. The EIS used the IMPLAN model to assess potential effects to regional businesses. IMPLAN aggregates all economic output and employment at the county level, so the EIS is unable to evaluate effects on specific businesses. Although the EIS examined economic effects at the county level, it acknowledges that localized effects of rate increases may be more pronounced as described in Section 3.7.3.5 Summary of Effects. Specifically, customers of utilities receiving power from Bonneville would experience greater upward rate pressure. See Section 3.7.3.5, Residential Effects, at 3-929, and Chapter 5 of Appendix H, Power and Transmission.
6246	6	rhayden@portofpasco.org	Port of Pasco	Overall, the DEIS predicts that the reduction in hydropower generation across the Pacific Northwest would result in an average annual economic cost of $150 million when valued at the market price for the foregone power generation. However, the estimated increase in the marginal cost of producing power to meet demand based on additional average annual fixed and variable costs is $270 million to $540 million. If these social welfare effects persist over a 50-year timeframe, the present value cost is up to $15 billion. We recommend that the DEIS revisit power capacity models to remove all fossilfuel based power sources when calculating the effects of foregone power from the Snake River dams. Power rates, system reliability, industrial sector output, and industrial jobs will be more impacted than currently reflected in the DEIS.	The EIS did include a rate sensitivity analysis for two coal-retirement scenarios and the additional effects on replacement resources needed to accommodate for changing fossil-fuel generation and state law. See Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, 3-829-830 in the Draft EIS; Appendix H, Power and Transmission, Section 2.3 at H-2-8-15 in the Draft EIS. The exact cost impacts are uncertain because they are dependent on what resources the non-federal utilities in the Northwest and neighboring regions select as replacement resources. Section 3.7.3.5 in the Draft EIS, Electricity Rate Pressure, and specifically the lower half of Table 3-166, give a range of some of the cost effects estimated due to the retirement of coal plants in the region. The EIS did not address the retirement of all existing fossil-fuel resources including natural gas generation, as regional utilities have so far focused on retiring coal-plants first; thus, the analysis retained natural gas generation.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6246	7	rhayden@portofpasco.org	Port of Pasco	Fish Survival Models The two models used to assess fish survival in the DEIS produce vastly different conclusions. The Comparative Survival Study (CSS) predicts smolt-to-adult returns (SARs) would increase by 170% under MO3, while the Life Cycle Model (LCM) predicts a modest 14% increase. This gap in outcomes is too wide to support far-reaching policy decisions and challenges the credibility of the DEIS. We would like these models to undergo additional technical scrutiny to determine their validity. The CSS model relies heavily on the premise of delayed mortality to predict substantial increases in survival under MO3. Multiple studies refute the importance or existence of delayed mortality. In fact, the Action Agencies have acknowledged this challenge in the DEIS with the following statement, The degree to which latent mortality is affecting salmon and steelhead is one of the critical uncertainties in this EIS analysis. Peer reviewed studies examining latent mortality are already available and should be evaluated to determine whether CSS is valid before it is employed in the DEIS. Another discrepancy with the CSS model is how it predicts vast smolt-to-adult return (SAR) survival by breaching Snake River Dams even though undammed rivers are experiencing similar SAR declines without dams. SAR survival rates for Snake River Chinook salmon consistently have fallen short of objectives provided by the Northwest Power and Conservation Council, and they have hit a record low in recent years. But importantly, the same is true with respect to the smolt-to-adult survival rates for the John Day River basin, which have experienced a dramatic decline observed since 2013 and are also at a record low and which have no dams. Given this declining trend throughout much of the Columbia Basin, the CSS Port of Pasco DEIS Comments April 13, 2020 Page 4 of 4 u:\agency\pnwa\comment-crso deis-2020-0413.docx SARs prediction solely based on the removal of the Snake River dams is questionable. A more reasonable explanation are the many studies suggesting this trend is due to a diverse array of factors including warming ocean water temperatures, predation and pollution. We encourage the Action Agencies to consider these significant challenges to the CSS and latent mortality theory. If evidence mounts that the CSS model is producing spurious results, the Action Agencies must be willing to abandon its advice.	The NMFS COMPASS/Life Cycle models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival, and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of CRS operations with respect to flow and spill. The Fish Technical Teams for the CRSO EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. The reason Life Cycle models were included in the EIS analyses was to partially address factors outside of the CRS which can influence wild adult spawner abundance, including abiotic and density effects in tributaries, upper reaches, the Columbia River estuary and ocean. The results of third-party review, both the Corps' Independent Expert Peer Review as well as a recently released ISAB review of the CSS results will be included in the Final EIS and will provide more technical review of these models. Initial review of the results of the peer review do not indicate fundamental flaws in either the CSS or NMFS approach and both models will continue to frame the potential outcomes associated with all MOs and the Preferred Alternative. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The Preferred Alternative provides the opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. Some of the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies.
6264	1	rkrehbiel@defenders.org	Defenders of Wildlife	Please accept the attached documents as comments on the CRSO DEIS. These documents include: 1. A detailed letter from the Center for Biological Diversity, Defenders of Wildlife, the Audubon Society of Portland, Earth Ministry, the Idaho Conservation League, Orca Conservancy, Orca Network, the Save Our Wild Salmon Coalition, the Sierra Club, the Western Environmental Law Center, Whale Scout, Wild Earth Guardians, and Willamete Riverkeeper 2. Two documents submitted as attachments to compliment to detailed letter from our organizations (Attachment A and Attachment B) If you have any questions to problems accessing these documents, please reach out to Robb Krehbiel at rkrehbiel@defenders.org or at 206-883-7401. Thank you.	Commenter had trouble submitting comments, but was able to resubmit and noted prior unsuccessful submission attempt. These comments are coded as Letter 6588. Please see responses to comments under Letter 6588.
6272	1	Kurt Miller; kurt@nwriverpartners.org	Northwest River Partners	East Sand Island & Columbia River Estuary Northwest RiverPartners (RiverPartners) has heretofore focused its comments related to avian predation on the mid and upper Columbia River. In this appendix, RiverPartners wants to expand on the need for downstream predation managementespecially in the Columbia River estuary. We would like to thank the Columbia River Inter-Tribal Fish Commission (CRITFC) for providing the data points referenced below. Of particular concern, RiverPamters notes that the US Army Corps of Engineers (USACE) has publicly stated that it considers both the East Sand Island1 double-crested cormorants and the East Sand Island Caspian tern management actions complete, without further plans to reduce either population. RiverPartners notes that neither plan has achieved the agreed upon population reduction levels for either species. Without further reductions in nesting habitat on East Sand Island, the Caspian tern population will likely continue to hover in the 4,000 to 5,000 pair range. This is an unbalanced level of avian predators if the region desires sustainable Columbia Basin salmonid populations. It is believed that every thousand pairs of Caspian terns will consume on average about 740,00 smolts each spring. Likewise, the double-crested cormorants, based on the last three years of consumption data, averaged 1.4 million smolts per 1,000 pairs of cormorants. This relationship is for the birds on East Sand Island. Birds nesting on the Astoria-Megler Bridge often feed upstream, where the percentage of smolts in their diet can be up to three times greater. Last year there were approximately 3500 pairs of double-crested cormorants on the Astoria-Megler Bridge. We can conservatively estimate that they ate approximately five million smolts. For the Columbia River estuary, this issue is especially problematic, because the smolts that make it to the estuary have successfully navigated hundreds of miles of river, numerous hydro projects, a multitude of predators, but then are killed just as they reach saltwater. Said another way, the smolts that make it to the estuary represent of a minority of all of the smolts in the Basin, so the percentage killed in the estuary will have an outsized effect on the overall percentage of returning adult salmon. Given this context, we urge USACE to reconsider its previous decision to end monitoring efforts of double-crested cormorants in the Columbia River estuary in 2020.	The co-lead agencies recognize the importance of addressing avian predation throughout the project area and have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. This includes continued implementation of (1) dissuasion measures at the Corps' CRS facilities as described in the annual Fish Passage Plan and coordinated with the FPOM, (2) the Inland Avian Predation Management Plan (IAPMP), (3) CATE management plan for reduction in habitat at East Sand Island, and (4) the Double-crested cormorant (DCCO) management plan at East Sand Island. Other entities in the region also have authorities and obligations to mitigate the impacts from predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. Specifically, under the ESA, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Ultimately, recovery, including predation management actions, is a broader regional goal that is the role of NMFS and the USFWS and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Based on our analysis in the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation, would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6272	2	Kurt Miller; kurt@nwriverpartners.org	Northwest River Partners	Need for Lethal Removal Efforts Unfortunately, the millions of dollars spent on bird wires, land and boat-based hazing, and pyrotechnics did not prevent the losses described in the Evans et. al paper noted in the body of our comments.2 As soon as birds relocate to other areas of the river, these measures are no longer effective. It is clear that the numbers of predatory birds in the Columbia River must be reduced using lethal measures such as egg oiling and lethal take at the dams. Those measures should be included within this EIS process and could result in much improved effectiveness of mitigation efforts associated with the Preferred Alternative. In support of this point, we reference a letter from the Northwest Power Planning & Conservation Council Council) to Mr. Jerome Ford, US Fish & Wildlife Service, Assistant Director of Migratory Birds, dated February 28, 2020. In that letter, the Council notes that, From 2015 to 2017, the Fish and Wildlife Service authorized the lethal removal of double-crested Cormorants in the Columbia River estuary. More than 5,000 cormorants were removed and more than 6,000 nests were destroyed. We know that this action, combined with natural predation by other bird species, helped to significantly reduce cormorant predation on juvenile fish. But since that time, only non-lethal methods of harassment have been available, and they only have had the effect of moving cormorants from one place to another in the estuary. The predation continues and, in fact, is increasing.3 We encourage the Action Agencies to reintroduce these lethal removal measures. Without these measures, the region risks undoing all of the good it has worked so hard for in its mitigation efforts. To quote Blaine Parker, biologist for the Columbia River Inter-Tribal Fish Commission (CRITFC), If we do not more effectively address the serious threat of avian predation, we risk turning the regions $17 billion salmon recovery investment into guano.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. Under the Preferred Alternative, actions to reduce pinniped and avian predation would continue. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. In coordination with USFWS, this project would comply with Migratory Bird Treaty Act by obtaining necessary permitting for new avian predation actions. Ongoing avian predation actions would rely on existing permitting. As part of this projects monitoring and adaptive management plan (Appendix R, part 1), monitoring of the Predator Disruption Operations measure would occur to determine the measure's effectiveness of reducing the avian predators nesting habitat and monitor if the migratory bird species (Caspian terns) would remain at healthy and sustainable levels. As analyzed in Section 7.7.7, the Predator Disruption Operations measure could cause waterfowl to delay nesting, forego nesting, or relocate to other areas. As discussed in Section 3.6.3.2, Caspian terns are highly mobile during the breeding season and move between breeding colonies in a given year and between years, demonstrating a willingness to nest away from the Columbia River while still foraging on juvenile salmonids (Corps 2014, 2018, 2019). If a depredation permit is needed, depredation permits are issued to alleviate some form of damage, not to achieve population control. As a result, depredation permits are issued only if the requested lethal take of birds is consistent with the conservation of the species (e.g., the species remains at a healthy and sustainable level). (From USFWS DCCO FAQ website: https://www.fws.gov/pacific/migratorybirds/pdf/DCCOQ_A_USFWS03212016.pdf).
6283	1	rkrehbiel@defenders.org	Defenders of Wildlife	I am very disappointed that the DEIS failed to fully or accurately consider southern resident orcas. The DEIS continuously states that Snake River salmon runs are not important to the orcas. This is patently false. The country's leading southern resident orca scientists have clearly stated that the four lower Snake River dams must be breached if we hope to prevent the extinction of these orcas. According to a study by NOAA and the Washington Department of Fish and Wildlife, two of the ten highest priority salmon runs for the southern residents are Snake River runs. Historical evidence suggests that prior to the Snake River dams being built, there were more Snake River salmon and these fish likely constituted a larger portion of the orcas' diet. It is also important that we protect and restore salmon runs throughout the orcas' seasonal range. Typically, the southern residents forage for salmon off the west coast of the U.S. in the winter and spring. According to GPS data from NOAA, they spend a considerable amount of time at the mouth of the Columbia River foraging for salmon returning to both the Columbia and Snake Rivers to spawn. Despite the scientific consensus that orcas rely on Snake River salmon and the hundreds of thousands of comments the agencies received about orcas, there were roughly two paragraphs about the orcas in the entire 7,584-page document. I strongly urge the agencies to update this section of the DEIS and reevaluate the impact of all the alternatives on southern resident orcas. Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly 1 million adult chinook salmon returning to the mouth of the Columbia River, providing a significant and important source of food for endangered southern resident orcas. These orcas primarily eat Chinook salmon and forage for these fish from central California into the Salish Sea. The Columbia basin supports salmon runs that the orcas have relied on for centuries. Historically, half of all the salmon returning to the Columbia Basin were bound for the Snake River.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. The 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
6283	2	rkrehbiel@defenders.org	Defenders of Wildlife	With climate change, the number of days where temperatures will reach lethal levels in these reservoirs are expected to increase. Independent research has stated that removing these four dams would ameliorate this hot water problem. By removing these dams, we can increase salmon access to over 5,500 miles of free-flowing. climate-resilient, federally protected spawning habitat in Central Idaho.	It is well understood that the CRS dams have an impact on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS document. A system water quality model was developed to look at water temperature and TDG effects throughout the Columbia and Snake River system for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6283	3	rkrehbiel@defenders.org	Defenders of Wildlife	It is important that any dam breaching action be coupled with a package of infrastructure investments to support local communities and economies transition. This includes expanding rail lines, extending irrigation lines, installing renewable energy, and increasing energy efficiency. Through forums like Governor Inslee's Lower Snake River Stakeholder Process, people identified the types of investments needed to support local communities after the dams are breached. The DEIS ignores these important conversations.	Many of the infrastructure items listed in the comment are described within the relevant environmental consequences section of the EIS. For example, change infrastructure costs related to changing transportation modes are described in Infrastructure Costs subsection under Section 3.10.3.5. However, as described in Chapter 5, Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental impacts. If breaching the dams were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather provide a list of potential mitigation needs which could potentially include some infrastructure items, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measure. Many of the specific mitigation measures that the commenter lists are not within the co-lead agencies' current authorities. The specific process that the commenter mentions was published just before publication of the Draft EIS, and finalized after the Draft EIS, and was prepared to inform the Governor of the many stakeholders and their views on the lower Snake River dams.
6283	4	rkrehbiel@defenders.org	Defenders of Wildlife	The agencies also failed to fully analyze the economic benefits of dam breaching, particularly for tribal, commercial, or recreational fishing businesses. When discussing the costs of replacing the energy from these dams with other renewable energy sources, the agencies grossly over-estimated the costs. A report from the Northwest Energy Coalition shows that through strategic investments, the energy produced by these dams can be replaced at a miniscule cost to ratepayers while also improving the reliability of the electrical grid. The DEIS also did not accurately assess the projected costs associated with maintaining the four lower Snake River dams.	The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.As described in Appendix H, Power and Transmission, and Section 3.7.3.5, the EIS considered the NWEC study cited by the commenter, but that study is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries subsection and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries subsection of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Most sections of chapter 3 include a Tribal Interests Section at the end that attempts to summarize issues by topic. The method used to calculate the O&M costs of maintaining the four lower Snake River dams is detailed in Chapter 5 of Appendix Q.
6297	1	kimapperson@icloud.com	N/A	May I first state that the 45-day comment period on this draft is woefully inadequate, especially in light of the pandemic that is taking our world by storm. Many people, including myself, have been personally overwhelmed by this event. Citizens need more time to critically and constructively review this important document.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6297	2	kimapperson@icloud.com	N/A	The recovery of Snake River anadromous fishes will, in turn, enhance many resident species of animals that rely on ocean derived nutrients to thrive. The DEIS makes no effort to address such secondary benefits of restoring anadromous populations. Not to even mention making effort toward saving the imperiled Southern Resident Orca population.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The CRSO EIS addresses abundance of anadromous fish among alternatives, which is the driving mechanism of marine nutrient cycling. The commenter is correct that there are broad ecological effects from marine nutrient cycling. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in this Draft EIS were for the purposes of comparing the effects of operation, maintenance and configuration of the CRS projects to one another and to the No Action Alternative. For the purposes of comparing alternatives, a more detailed analyses of marine nutrient transfer throughout the spawning habitats was not completed. Section 3.5.2.3 recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS.

6297	3	kimapperson@icloud.com	N/A	The multitude of economic benefits from recovered anadromous fish populations throughout the Snake River Basin were not quantified, and barely even mentioned. Benefits from the removal of the four Lower Snake River dams would be far reaching and include increases in recreational fishing throughout the Snake, Salmon, Clearwater and other rivers, decreases in hatchery mitigation efforts, and eventual decreases in very intensive recovery monitoring efforts.	The EIS provides an evaluation of recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. A decrease in hatchery operations is likely in the long-term under MO3. Regarding hatchery impacts associated with MO3, as described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels.
6297	4	kimapperson@icloud.com	N/A	I would like to have an opportunity to provide more and detailed constructive comments to this document. Please consider lengthening the comment period for this DEIS.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6299	1	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	2.1. The Yakama Nations Treaty with the federal government serves as the cornerstone of the Lead Agencies responsibility to the Yakama Nation with respect to the CRSO EIS. The Yakama Nation is a sovereign, original Native Nation federally recognized under the Treaty of 1855. Article III of the Treaty of 1855 expressly guarantees the Yakama Nations right of taking fish at all usual and accustomed places. Article III also reserves the Yakama Nations right to hunt game and gather traditional foods on open and unclaimed land. The Yakama Nations elders present at the treaty negotiations knew that securing these rights was crucial to guaranteeing the survival of their culture and the livelihood of their people. For the Yakama Nations people, the exercise of the right to take fish in particular was not much less necessarythan the atmosphere they breathed."8 The Treaty of 1855 and the rights reserved therein are not, as the Lead Agencies imply, a legal formality.9 They are an expression of the Yakama Nations traditional way of life that creates an affirmative legal duty that the federal government must honor as the supreme law of the land.10 These Treaty rights must be understood as bearing the meaning that the Yakamas understood [them] to have in 1855.11 With respect to taking fish, the Yakamas understood that they would forever be able to continue the same off-reservationfishing practices as to time, place, method, species and extent as they had or were exercising.12 Rather than securing a mere equal opportunity to catch fish, then, the Treaty of 1855 guarantees to 6 Id. (quoting City of Sausalito v. ONeil, 386 F.3d 1186, 1206 (9th Cir. 2004)). 7 See Lands Council v. McNair, 537 F.3d 981, 994 (9th Cir. 2008) (applying the APAs arbitrary and capricious standard to the National Forest Management Act). The Lead Agencies have acted arbitrarily and capriciously where the record plainly demonstrates that [they] made a clear error in judgment in concluding that the CRSO EIS meets the requirements of NEPA. Id. 8 U.S. v. Winans, 198 U.S. 371, 381 (1905). 9 LEAD AGENCIES, COLUMBIA RIVER SYSTEM OPERATIONS DRAFT ENVIRONMENTAL IMPACT STATEMENT (2020) (DEIS) at 3-1415. 10 U.S. CONST. art. VI, cl. 2. 11 Wash. State Dept. of Licensing v. Cougar Den, Inc. 139 S. Ct. 1000, 1011 (2019). (citing Winans, 198 U.S., at 380-81; Seufert Brothers Co. v. United States, 249 U.S. 194, 196-98 (1919); Tulee v. Washington, 315 U.S. 681, 683-85; Washington v. Washington State Commercial Passenger Fishing Vessel Assn., 443 U.S. 658, 677-78 (1979)). 12 See United States v. Washington, 384 F. Supp. 312, 381 (W.D. Wash. 1974). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 8 the Yakama Nation a portion of the harvest.13 This guarantee is worthless without harvestable fish.14 Therefore, the destruction of salmon runs and habitats caused by manmade despoliation, such as the building and maintenance of barriers in a river, constitutes a violation of the Treaty of 1855.15 More precisely, an action may violate the Treaty of 1855 if it causes a greater than de minimis impact on access to fish, in which case it interferes with the exercise of the Yakama Nations Treaty rights.16 The Lead Agencies must evaluate any impacts to the Yakama Nations Treaty rights through the lens of the Yakama Nations understanding of those rights in 1855. The environmental conditions that provide for the full exercise of rights reserved under the Treaty of 1855 serve as the proper baseline for the Lead Agencies analyses of impacts from federal actions in the CRSO EIS.17 This would require the Lead Agencies to evaluate impacts against the conditions that existed on the Columbia River in 1855, since this is the context in which the Yakama Nation would have viewed its reserved rights. The Yakama Nation recognizes the difficulty of such an analysis. However, this approach is the only way to accurately assess the CRS EISs impacts to the Yakama Nation and its Treaty-reserved rights and is consistent with Supreme Court precedent concerning treaty interpretation. Under these standards, the Lead Agencies must provide an analysis in the final CRSO EIS (FEIS) that assures that the Lead Agencies will not violate the Treaty of 1855 through configuration and operation of the CRS. Specifically, the Lead Agencies must assure that the suite of actions ultimately selected in the ROD, at the very least, do not create greater than de minimis adverse impacts to fish populations or to time, place, method, species and extent of taking fish. Any alternative that would risk a total depletion of harvestable fish or otherwise destroy salmon runs and habitats would clearly violate the Treaty of 1855. The Yakama Nation urges the Lead Agencies to develop and adopt a Preferred Alternative in the FEIS that is clearly consistent with the Treaty of 1855 and promotes its objectives. Key elements of such a Preferred Alternative include measures that provide clear and measurable benefits to fish populations and will also be sufficiently protective of the Yakama Nations right to take those fish at usual and accustomed sites and to hunt and gather traditional foods on open and unclaimed land.	Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative includes a modification of the John Day Reservoir operations for predator disruption. Reservoir levels would be increased before Caspian tern nesting season to dissuade terns from nesting on islands in the John Day Reservoir, where they are currently nesting and foraging on ESA-listed salmon and steelhead. In early June, after most of the spring juvenile salmon and steelhead have migrated through the reservoir, the John Day Reservoir will be reduced to the minimum irrigation pool range, which mimics the previous operation of the reservoir to benefit juvenile fish migration season. The Preferred Alternative has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
6299	2	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	2.2. The Lead Agencies development of the CRSO EIS is subject to the federal governments fiduciary obligation to protect the Yakama Nations resources. 13 Washington State Commercial Passenger Fishing Vessel, 443 U.S. at 681-82. 14 See United States v. Washington, 827 F.3d 836, 852 (9th Cir. 2016) (affd by an equally divided court, Washington v. United States, 138 S. Ct. 1832 (2018)). 15 See Id. at 865. 16 See Northwest Sea Farms v. United States Army Corps of Engnrs, 931 F. Supp. 1515, 1522 (W.D. Wash. 1996). The Corps itself has utilized this standard to evaluate the impact of a proposed coal terminal on Treatyreserved fishing rights. See Memorandum for Record from Michelle Walker, Chief, Regulatory Branch, Corps (May 9, 2016). 17 The Lead Agencies current environmental baseline for the DEIS is 2016. The Yakama Nations resources were already imperiled by this point. Therefore, the DEIS does not assess the true scope of impacts to the Yakama Nations resources. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 9 The federal government, including the Lead Agencies, has a fiduciary trust obligation to the Yakama Nation.18 This obligation is based on the Yakama Nations cession of certain rights to roughly ten million acres of land in reliance on federal promises to protect the Yakama Nations resources for future generations. The trust responsibility imposes fiduciary duties on the federal government with respect to any Federal government action which relates to the Yakama Nation.19 The U.S. Supreme Court has stated that the federal trust obligation to the Native Nations should be judged by the most exacting fiduciary standards.20 Where Tribal interests potentially conflict with other interests, the federal government must resolve the conflicting claims in a precise manner that would indicate the weight given each interest before [it].21 The federal government cannot resolve conflicts through a judgment call.22 The federal governments trust obligation is distinct from but related to its responsibilities stemming from the Treaty of 1855. Where a Native Nation has reserved treaty rights, the federal government has a duty to protect those rights.23 Therefore, in carrying out its fiduciary duty, it is the [federal governments]responsibility to ensure that Indian rights are given full effect.24 The Lead Agencies must honor the federal trust responsibility to the Yakama Nation. In the context of the CRSO EIS, this amounts to meaningfully engaging with the Yakama Nation on impacts to Treaty-protected resources and integrating avoidance of those impacts into the Preferred Alternative selection and the ROD. The Yakama Nation expects that the Lead Agencies will fulfill these duties in accordance with the most exacting fiduciary standards. The Lead Agencies cannot make a vague judgment call as to whether the Yakama Nations interests affected by the CRS operations will be subordinate to other interests; instead, the Lead Agencies must resolve any conflicts between competing interests with clear and thorough analyses. Where these conflicts implicate resources reserved under the Treaty of 1855, the law provides that the Yakama Nations Treaty rights prevail and the Lead Agencies must protect those resources and give full effect to the associated Treaty rights.	Tribal input, concerns, interests, and treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 and the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource.

Babbitt, 70 F.3d 539, 547 (9th Cir. 1995) ([T]he Tribes federally reserved fishing rights are accompanied by a corresponding duty on the part of the government to preserve those rights.) 24 Northwest Sea Farms, 931 F. Supp. at 1520 (citing Seminole Nation, 316 U.S. at 296-97. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 10 The CRS and its operation have contributed greatly to the decline of fish populations in the Columbia River. In 1987, the Northwest Power Planning Council, which became the Northwest Power and Conservation Council (Council), completed an exhaustive study of the historical size and then-current status of salmon and steelhead populations.25 The study concluded that these populations had declined by seven to fourteen million fish, with salmon runs at less than five percent of historical levels.26 According to the Council, dams were responsible for five to eleven million of these losses.27 This decline limits the ability of the Yakama Nation to exercise its fishing rights to the full extent reserved under the Treaty of 1855. The loss of Treaty-reserved fish also amounts to a loss of the Yakama Nations cultural resources. Again, the rights reserved under the Treaty of 1855 are expressions of the Yakamas traditional way of life. Fishing is a cultural practice that is inextricably tied to the Yakama Nations identify. In testifying before the Washington Supreme Court, George Meninock articulated this connection: God created this Indian country and it was like He spread out a big blanket. He put the Indians on itThen God created the fish in this river and put deer in these mountains and made laws through which has come the increase of fish gameWhen we were given our ground to live on, and from that time these were our rightsMy strength is from the fish; my blood is from the fish, from the roots and the berries. The fish and game are the essence of my life28 The Yakama Nations agreement with the Creator to act as a steward over the Columbia River predates the Treaty of 1855. As such, the decimation of salmon populations recounted in the Councils study directly impairs resources essential the Yakama Nations cultural values and traditional way of life. The CRS has also foreclosed access to certain archeological sites and traditional cultural properties through inundation. Finally, the CRS has intensified the economic hardship faced by the Yakama Nation and its members. Salmon provide a valuable commercial resource for Tribal fisherman and their families. The degradation of this resource can be linked to increased poverty and unemployment in the Yakama Nations communities.29 Furthermore, the loss of traditional foods such as salmon contributes to the poor health and reduced life expectancy that many Yakama members face.30 These indicators reveal the more practical effects of harm to Treaty-reserved rights and cultural practices.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
6299	4	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	2.4. The disproportionate adverse impacts of the CRS on the Yakama Nation create significant environmental injustice issues that the Lead Agencies must address in the CRSO EIS and the ROD. 25 A summary of the 1987 study, prepared by Yakama Nation technical consultant Tom Iverson, is included as Appendix A to these comments. 26 COUNCIL, COLUMBIA RIVER BASIN FISH AND WILDLIFE PROGRAM (1987). 27 Id. 28 COLUMBIA RIVER INTER-TRIBAL FISH COMMISSION (CRITFC), THE YAKAIMA NATION, THE NEZ PERCE TRIBE, THE CONFEDERATED TRIBES OF THE UMATILLA INDIAN RESERVATION, AND THE CONFEDERATED TRIBES OF THE WARM SPRINGS RESERVATION OF OREGON (COLLECTIVELY, TREATY TRIBES), TRIBAL PERSPECTIVES REPORT (2019) at 5. 29 Id. at 7-10. 30 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 11 Both previous and subsequent comments note the significant and unique adverse effects of the CRS on the Yakama Nation and its members. The present configuration of the dams and their continued operation perpetuates these adverse effects in the absence of affirmative actions to mitigate those adverse effects. Environmental justice is defined by the Department of Energy as: [T]he fair treatment and meaningful involvement of all people, regardless of race, color, national origin, or income, with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no population bears a disproportionate share of negative environmental consequences resulting from industrial, municipal, and commercial operations or from the execution of federal, state, and local laws; regulations; and policies.31 Executive Order 12898 directs that federal agencies consider environmental justice by identifying and addressing disproportionately high and adverse human health or environmental effects of [federal] programs, policies, and activities on minority and lowincome populations.32 The accompanying Presidential Memorandum further states that, in the context of NEPA, federal agencies shall analyze the environmental effects, including human health, economic and social effects, of federal actions on minority and low-income communities.33 Any mitigation measures developed by federal agencies in an EIS should address significant and adverse environmental effects on these communities.34 The Council on Environmental Quality (CEQ) 1997 guidance on environmental justice affirms these directives as wholly consistent with NEPA.35 CEQ recommends that federal agencies should, among other actions, acknowledge that impacts to low-income, minority, and Tribal communities may differ from impacts to the general population.36 Once a federal agency identifies these distinct impacts, the agencies should clearly state in its EA or EIS whether a disproportionately high and adverse impact to the community is likely to result from its proposed alternatives.37 If so, the federal agency should consider distribution as well as magnitude of impacts in selecting a preferred alternative.38 Any mitigation measures that the federal agency adopts as part of its preferred alternative should reflect the needs and preferences of low-income, minority, and Tribal communities.39 More recently, the Federal Interagency Working Group on Environmental Justice, which includes the Department of the Interior and the Department of Energy, published a report 31 What is Environmental Justice?, DEPARTMENT OF ENERGY, https://www.energy.gov/lm/services/environmentaljustice/what-environmental-justice (last visited March 27, 2020). 32 59 Fed. Reg. 7629 (Feb. 16, 1994) 33 Executive Order on Federal Actions to Address Environmental Justice in Minority Populations and LowIncome Populations (Feb. 11, 1994). 34 Id. 35 CEQ, ENVIRONMENTAL JUSTICE: GUIDANCE UNDER THE NATIONAL ENVIRONMENTAL POLICY ACT (1999) at 7. 36 Id. at 14. CEQ also notes that [w]here environments of Indian tribes may be affected, agencies must consider pertinent treaty, statutory, or executive order rights and consult with Tribal governments in a manner consistent with the government-to-government relationship. 37 Id. at 15. 38 Id. 39 Id. at 16. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 12 with more specific guidance on for federal consideration of environmental justice. For example, in determining the affected environment for an EIS, federal agencies should, after properly identifying minority and low-income communities,40 consider a proposed actions: 1) exposure pathways (routes by which the minority or low-income population may come into contact with chemical, biological, physical, or radiological effects); 2) ecological, aesthetic, historic, cultural, economic, social, or health consequences to the communities; and 3) distribution of adverse and beneficial impacts.41 Likewise, federal agencies should consider distinctive conditions of potentially affected minority and low-income communities such as: 1) human health vulnerabilities (e.g., heightened disease susceptibility, health disparities); 2) socioeconomic vulnerabilities (e.g., reliance on a particular resource that may be affected by the proposed action, disruptions to community mobility and access as a result of infrastructure development); and 3) cultural vulnerabilities (e.g., traditional cultural properties and ceremonies, fish consumption practices).42 As to alternative development and selection, the report provides that federal agencies should consider whether proposed alternatives would avoid or mitigate impacts to minority or low-income communities.43 Federal agencies should clearly identify which alternatives would cause disproportionately high and adverse impacts to minority or low-income communities and consider alternatives that would minimize or mitigate such impacts when selecting a preferred alternative.44 Furthermore, federal agencies should be cognizant that minority and low-income communities in the affected environment may be uniquely affected by past, present, or reasonably foreseeable future impacts than the general population.45 These impacts may be intensified by factors such as non-chemical stressors, which include health conditions and standard of living, or climate change-related hazards.46 As such, a federal agencys evaluation of an impact to the general population may be inadequate if it does not consider unique and disparate effects to minority and low-income communities.47 40 FEDERAL INTERAGENCY WORKING GROUP ON ENVIRONMENTAL JUSTICE, PROMISING PRACTICES FOR EJ METHODOLOGIES IN NEPA REVIEWS (2016) at 12-13. 41 Id. at 15. 42 Id. at 17. 43 Id. at 20. 44 Id. 45 Id. at 30. 46 Id. at 31-32. 47 Id. at 33. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 13 With respect to mitigation, additional measures are necessary to avoid or reduce disproportionately high and adverse impacts to minority and low-income communities.48 Such measures may include: a. Avoiding an impact by not taking a certain action or parts of an action. b. Minimizing an impact by limiting the degree or magnitude of the action and its implementation. c. Rectifying an impact by repairing, rehabilitating, or restoring the affected environment. d. Reducing or eliminating an impacts frequency over time, such as through preservation and maintenance operations during the life of the action. e. Compensating for an impact by replacing or providing substitute resources or environments.49 Where federal agencies will not or cannot adopt mitigation measures to avoid or minimize environmental harm to minority and low-income communities, they should explain why.50 The Lead Agencies must abide by these guidelines with respect to the CRSO EIS. The guidelines will facilitate the Lead Agencies understanding of the Yakama Nations affected resources and vulnerabilities. The guidelines will also assist the Lead Agencies with determining how adverse impacts of the CRS disproportionately fall on the Yakama Nation while other non-Native communities see immense benefits. This information is crucial to a meaningful and objective analysis of the impacts of the CRS. This will in turn lead to development of a purpose and need statement,	The co-lead agencies understand the concern regarding the continued effects of the CRS on intangible cultural heritage, traditional knowledge, and other tribal interests. The co-lead agencies appreciate the unique connection between tribes and the Columbia River Basin ecosystems and recognize the difficulty in fully communicating these connections in the context of the EIS. The co-lead agencies appreciate the commenter providing this summary of guidance for use in evaluating potential environmental justice impacts resulting from the CRS. As described in Section 3.18.1 the environmental justice analysis was conducted in accordance with the documents cited in the comment (e.g., E.O. 12898 (1994), the CEQ Guidance (1997) and the more recent guidance from the NEPA Committee and Federal Interagency Working Group on Environmental Justice (2016). Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. In order to ensure potential impacts on tribal communities were represented as accurately as possible, Appendix P presents first-hand tribal perspectives that were provided by 11 regional tribes, including the Columbia River Treaty Tribes, on the operations and maintenance of the CRS, and the effects it has had on tribal life for consideration in the EIS. Section 3.17 summarizes these perspectives on the importance of the Columbia River Basin resources and landscapes to tribes, and the potential impacts of the CRSO alternatives. In addition, where applicable or pertinent, for specific EIS resources, the EIS described how tribal interests would be impacted by the different action alternatives in Chapters 3 and 7 so that this information would be provided to readers throughout the document. Based on public comments, the co-lead agencies also revised the Environmental Justice analysis (Section 3.18) to provide additional discussion of the potential effects to environmental justice populations.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				affected environment evaluation, and range of potential alternatives that appropriately plans for operation and management of the CRS moving forward.	
6299	5	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	2.5. For a Preferred Alternative to be adequate, it must fully account for the Yakama Nations interest and sufficiently safeguard the Yakama Nations resources. The Yakama Nation advises the Lead Agencies to adopt a Preferred Alternative that broadly conforms with the following requirements: Prioritizes total compliance with the Treaty of 1855 (and any applicable statutes, regulations, and court orders) over the maximization of economic gains; Clearly and specifically describes planned hydropower operations over the entire operations period within the scope of the DEIS, with subsequent adaptive management actions being based on accumulated performance data and information; 48 Id. at 49. 49 Id. These are the same types of mitigation measures prescribed in 40 C.F.R. 1508.20. However, the Federal Interagency Working Group on Environmental Justices applies them specifically to impacts to minority and low-income communities. 50 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 14 Preferentially avoids rather than mitigates impacts to the Yakama Nations resources; Where avoidance of impacts to the Yakama Nations resources is infeasible, includes mitigation measures consistent with the recommendations in Promising Practices for EJ Methodologies in NEPA Reviews;51 and Plans for a transition away from dependence on hydropower and toward a restoration of the natural state of the Columbia River, with the goal of restoring the resources necessary for the Yakama Nations full exercise of its Treaty rights and associated cultural values. To meet these general parameters, the Yakama Nation recommends that the Lead Agencies include certain specific measures in the FEIS Preferred Alternative and associated BiOp: Set appropriate benchmarks for success by acknowledging the Tribal Wy-Kan-UshMi Wa-Kush-Wit Salmon Recovery Plan52 and the Councils Fish and Wildlife Program53 goals and objectives and measure the potential benefits of the Preferred Alternative and the BA towards achieving those goals and objectives; Memorialize the Lead Agencies obligation to help the region meet the established benchmarks; Provide for development of a phased plan for investigating and implementing mainstem Columbia River dam removal at the fastest possible pace, evaluating individual dams on a case-by-case basis, including action plans for implementation of dam evaluations and mitigating impacts to affected communities in the interim; Adopt a Flex Spill CRS operation with a fifteen-year plan and an adaptive management process that requires consensus from the Yakama Nation to deviate from that fixed operation; Restrict excursions on turbine efficiency (1% operation) so as not to detract from fish benefits from Flex Spill operation, particularly at McNary Dam; Restrict winter drafting of upriver reservoirs to ensure spring flow augmentation targets are met through the mid-Columbia reach; Establish and fund a Regional Predator Management Forum, with additional monitoring, that includes all funding and implementation partners to collaboratively and comprehensively evaluate and address predation (including piscivorous, avian, and pinniped predation) on salmon, steelhead, lamprey, and sturgeon from the river mouth to the spawning grounds; 51 See pg. 11-13, supra. 52 The Plan: Wy-Kan-Ush-Mi Wa-Kish-Wit, CRITFC, https://www.critfc.org/fish-and-watersheds/fish-andhabitat-restoration/the-plan-wy-kan-ush-mi-wa-kish-wit/ (last accessed April 12, 2020). 53 2014 Columbia River Basin Fish and Wildlife Program, COUNCIL, https://www.nwcouncil.org/reports/2014columbia-river-basin-fish-and-wildlife-program (last accessed April 12, 2020). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 15 Provide financial support for further lethal removal of predator fishes and dissuasion actions for birds from the river mouth to the spawning grounds based on priorities and recommendations from the proposed Regional Predator Management Forum; Fund and support actions to remove non-native fish species such as shad, walleye, smallmouth bass, and catfish from the mainstem Columbia and tributaries; Fund and support actions to remove non-native aquatic plant species from the mainstem Columbia and tributaries; Fund and support actions to minimize and remove invasive species from the mainstem Columbia and tributaries; Fund and support actions to reduce adverse impacts to fish populations caused by excessive sediment levels; Fund a Corps Columbia River Fish Management (CRFM) program at an adequate level to address new initiatives for the fifteen-year operating period addressed in the Biological Assessment (BA) (e.g., add notched gates for steelhead fallback during non-spill season); Fully fund Fish and Wildlife Program hatcheries to meet their hydro system mitigation goals according to the recent U.S. v. Oregon hatchery assessment;54 Support the sovereign role of the Yakama Nation and other Native Nations in identifying and setting tributary habitat priorities and project selection; Include the Yakama Nation in its sovereign capacity on the Tributary Habitat Oversight Committee; Fund robust reach survival studies for upper Columbia stocks and Snake River steelhead to better ascertain survival gaps and address Adaptive Management Implementation Plan (AMIP) triggers; Fund additional habitat actions where AMIP population triggers have been met to address survival gaps; Fund mainstem habitat actions at tributary river mouths to create transition zones and cold-water refuges for migrating fish; 54 The 2018 BPA Integrated Program Reviewed budgeted $238,000,000 in capital infrastructure at federal hydro system dams in 2020 alone. This amount was set to increase to $340,000,000 in 2029. Hatchery facilities authorized to mitigate for the hydro system, on the other hand, are rapidly aging with zero dollars identified for capital upgrades, repairs, and maintenance. Estimated costs for deferred maintenance of the Lower Snake River Compensation plan facilities is over $100,000,000. The DEIS fails to note the federal governments obligation to fund the John Day Mitigation, Grand Coulee Mitigation, Dworshak Mitigation, and Lower Snake River Compensation Plan programs. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 16 Identify lamprey funding beyond 2022 commensurate with the proposed term of the salmon and steelhead BA; Fund outreach and education opportunities across the Columbia River Basin to encourage incorporation of salmon recovery principles into local everyday land and water management decision making; and Ensure that the Yakama Nation retains access to usual and accustomed fishing sites and open and unclaimed lands for hunting, gathering, and other traditional practices.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Moreover, recovery goals from other entities are outside the scope of this EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are committed to fulfilling their treaty and trust obligations and providing early, open, transparent and meaningful consultation. See Sections 2.3 and 9.3.2. The co-lead agencies look forward to continuing to consult on the EIS, which covers changes to the water management of the existing 14 projects on the Columbia and lower Snake Rivers. The co-lead agencies recognize these obligations while also acknowledging that construction of the Federally authorized CRS projects directly impacted many of the regions Tribal communities. Many of the actions requested by the Yakama Nation are included in the Preferred Alternative while others are outside the scope of this EIS. However, the co-lead agencies look forward to continue to work with the tribe on these issues.
6299	6	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	3.1. The Lead Agencies rushed timeline and failure to incorporate comments during the cooperating agency process undercuts transparent and meaningful consideration of important aspects of the CRS alternatives and impacts and obscures the necessary rational connection between those factors and the choices made in developing the DEIS. The Lead Agencies invited the Yakama Nation to participate as a cooperating agency in the development of the DEIS. The invitation was based on the Yakama Nations comanagement authority over Treaty-reserved fish in the Columbia River and special expertise concerning resources affected by the CRS.55 In addition, the invitation was based on the existing partnership between the Lead Agencies and the Yakama Nation pursuant to the Memorandum of Agreement Among the Umatilla, Warm Springs, and Yakama Tribes, Bonneville Power (Fish Accord).56 55 Memorandum of Understanding Between U.S. Department of the Army, Corps of Engineers, Northwestern Division; U.S. Department of the Interior, Bureau of Reclamation, Pacific Northwest Region; and U.S. Department of Energy, Bonneville Power Administration, as Co-Lead Agencies; and the Confederated Tribes and Bands of the Yakama Nation, as a Cooperating Indian Tribe, in the Columbia River System Operations Environmental Impact Statement Process (2018) (Memorandum of Understanding) 1. Specifically, the Memorandum of Understanding noted that the Yakama Nation has special expertise concerning Cultural Resources assessment, protection and preservation; Intergovernmental relations and regional management frameworks governing fisheries and wildlife management, including requirements for Indian treaty rights and fulfillment of federal trust obligations to Indians and Indian tribes; Hydrosystem management and operations related to life cycles of anadromous salmonids, lamprey, and sturgeon; Ecosystem functions and habitat, and habitat restoration processes, required to support the life cycles of anadromous salmonids, lamprey and sturgeon; Artificial fish production mitigation requirements and methods applicable to mitigation of fish habitat loss and hydrosystem configuration and operations; Research, monitoring and evaluation expertise concerning fish and wildlife environmental baseline conditions, impacts from hydrosystem configuration and operations, and methods for mitigating impacts; [] Socioeconomic parameters of hydrosystem configuration and operations concerning the Yakama Nation and its tribal members, including environmental justice considerations; Flood risk management and modeling in the Columbia River Basin[;] In Lieu and Treaty Fishing Access sites developed pursuant to P.L. 79-14 and P.L. 100-581 in the Bonneville, The Dalles, and John Day project areas; Tribal members uses of the Columbia and Snake Rivers and their environs; [and] Management of invasive and nuisance species present in the Columbia and Snake Rivers. 56 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 17 The Yakama Nation accepted the invitation in order to assist the Lead Agencies with analyses related to the Yakama Nations co-management authority and special expertise, ensure that the CRSO EIS process reflected the Yakama Nations perspective, and maintain the existing partnership with the Lead Agencies. The Yakama Nation expected that, in light of the considerable resources necessary to participate as a cooperating agency, the Lead Agencies would meaningfully consider and incorporate its input. This expectation was memorialized in the Yakama Nations Memorandum of Understanding with the Lead Agencies.57 The Yakama Nation submitted significant comments on the Lead Agencies draft technical products during the cooperating agency process.58 Yakama Nation staff developed these comments despite two significant challenges to the review process. First, the Lead Agencies often released products with incomplete data and analyses. Second, the Lead Agencies truncated timeline (discussed above.) demanded an extremely short turnaround window for each review and comment opportunity. It was not at all apparent that the Lead Agencies actually considered and incorporated the Yakama Nations comments. No specific provisions in the DEIS correspond substantially with the Yakama Nations comments. In one instance, the Lead Agencies outright refused to consider a fish impact analysis by the Yakama Nation and other cooperating agencies for being outside the limits of the CRSO EIS framework.59 This failure to consider, much less incorporate, the Yakama Nations	The co-lead agencies appreciate the valuable contributions of the Yakama Nation and other cooperating agencies. The cooperating agencies served a critical role in the development of the objectives and measures for the EIS evaluation, and working on technical teams to identify the impacts of the four Multiple Objective alternatives. The co-lead agencies utilized the measures and analysis that was developed with the cooperating agencies to select a combination of measures from the Multiple Objective alternatives to develop the Preferred Alternative (PA). The selection of measures to include in the PA is based on how well the measures met the Purpose and Need Statement and EIS objectives, with consideration of environmental, economic, and social effects.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				input does not conform to Yakama Nations expectations with respect to the cooperating agency Memorandum of Understanding,60 the Fish Accord partnership, or the federal trust obligation. It also casts uncertainty as to the basis for the choices made in the production of the DEIS.	
6299	7	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	3.2. The Lead Agencies arbitrarily adopted a condensed timeline that hindered meaningful analysis. The CRSO EIS process was originally set to conclude, at the earliest, in September 2021. This schedule was proposed by the Lead Agencies and adopted by the District Court for the District of Oregon as necessary to successfully complete a system-wide comprehensive [EIS]that includes a full evaluation of reasonable alternatives, addresses potential environmental effects of operating the multiple-use [CRS] projects, and provides for meaningful public participation[.]The Yakama Nation relied on this schedule as a means of 57 Id. at 3.D (stating that the Lead Agencies shall, [c]onsistent with their responsibilities as co-lead agencies, consider and incorporate the data, environmental analyses, technical analyses, and recommended alternatives and mitigation measures of the Yakama Nation to support the decision-making process as appropriate, giving particular weight to those topics on which the Yakama Nation is acknowledged to possess special expertise.). 58 As noted in n. 1, all previous comments provided by the Yakama Nation in its capacity as a cooperating agency are incorporated into these comments by reference. 59 As described on pg. 24-25, infra, the Lead Agencies formally rejected the Yakama Nation and other cooperating agencies offer of to perform a measure-by-measure analysis for impacts to fish. 60 The Yakama Nations participation as a cooperating agency did not appear to make an appreciable difference on the development of the DEIS. Accordingly, the Lead Agencies reference to the Yakama Nation in the cooperating agency section of the DEIS should not be read as indicating any degree of Yakama Nation authorship on the CRSO EIS. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 18 assuring an informed, well-considered, and publicly vetted long-term strategy for the [CRS] that complies with all federal laws, including [the ESA]. The Trump administrations 2018 executive memorandum, Executive Memorandum on Promoting the Reliable Supply and Delivery of Water in the West (Executive Memorandum) imposed a condensed schedule onto the development of the CRSO EIS. The stated policy of the Executive Memorandum directed the Secretary of the Interior to minimize unnecessary regulatory burdens and foster more efficient decision-making so that water projects are better able to meet the demands of their authorized purposes.61 To that end, the Executive Memorandum directed the Lead Agencies to complete the CRSO EIS process by September 2020.62 This revision eliminated one-fifth of the previously adopted minimum timeline for an exceedingly complicated scientific and legal undertaking. Neither the Executive Memorandum nor the Lead Agencies associated press release offer any justification as to why a September 2020 completion date was essential or appropriate to minimize unnecessary regulatory burdens or foster more efficient decision-making. Without justification, the Executive Memorandums deadline is simply an arbitrary date on a calendar. Moreover, neither of the documents explains how the Lead Agencies would adjust their approach in order to ensure effective decision-making and compliance with the Lead Agencies Treaty, trust, and statutory obligations. The Lead Agencies hurried through each step of the process in order to remain on the arbitrary schedule mandated in the Presidential Memorandum. The Lead Agencies frequently released draft sections of the DEIS to the cooperating agencies that were incomplete or rampant with errors. The cooperating agencies had around five days to review and comment on these documents before the Lead Agencies released another set of draft sections. Again, there was no evidence that the Lead Agencies meaningfully considered or incorporated any of the Yakama Nations comments during this process. The Lead Agencies hurried pace extended to the public comment period of only forty-five days, the shortest time allowable under NEPA.63 The Executive Memorandum resulted in a sprint through the NEPA process that is not indicative of thorough and meaningful evaluation (i.e., a hard look) of all available information to reach an informed decision. Likewise, this rushed process is inconsistent with the Lead Agencies trust obligation to engage with the Yakama Nation on impacts to Treaty-protected resources to ensure a Preferred Alternative that does not result in impacts to fish populations or to time, place, method, species and extent of taking fish. Instead, it appears that the Lead Agencies simply made a judgment call to prioritize water projects over the rights reserved under the Treaty of 1855. 3.3. The Lead Agencies refused to adjust the CRSO EIS timeline despite the national emergency caused by the COVID-19 pandemic. 61 Executive Memorandum (Oct. 19, 2018) at 1. 62 Id. at 6. The Yakama Nation submitted a letter to the Council on Environmental Quality (CEQ) on September 23, 2019, requesting that CEQ advise the Lead Agencies on, among other things, appropriate adjustment or suspension of the scheduling to ensure compliance with the Order and applicable Treaty, trust, and statutory requirements. 63 40 C.F.R. 1506.10(c). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 19 The forty-five-day public comment period for the DEIS began on February 28, 2020. The next day, officials in Washington state confirmed the first death in the United States attributable to COVID-19.64 On March 11, 2020, the World Health Organization declared the novel coronavirus outbreak a pandemic and Governor Jay Inslee banned gatherings of more than 250 people.65 Two days later, President Trump declared a national emergency.66 Public libraries on the Yakama Reservation and across the state closed around March 17, 2020. By March 20, 2020, the Yakama Nation had formally closed all non-essential facilities and offices. The beginning of the public comment coincided almost precisely with the explosion of the COVID-19 health crisis in this country. The Yakama Nation spent the majority of March focusing exclusively on its response to this crisis, prioritizing the protection of its members and employees health while also ensuring that essential government services continue to function. Consequently, the Yakama Nations elected officials have had little time for policy consideration of the DEIS, including its potential impacts to Treaty-reserved resources and implications for the Fish Accord partnership. The health crisis also affects the Lead Agencies ability to engage with the Yakama Nation regarding the DEIS. Federally and Tribally-mandated social distancing measures mean that Lead Agencies cannot feasibly engage in government-to-government consultation with the Yakama Nation if requested. This means that, under the current circumstances, the federal government is unable to meet its trust obligation to the Yakama Nation in the solicitation of comments on the DEIS. Most importantly, the overall disruption to societal function has frustrated the ability of Yakama members and the general public to provide input on the DEIS. Public participation is one of the core purposes of NEPA.67 This purpose is compromised where the public is too preoccupied with adapting to a radically different way of life to provide input on an environmental review document. NEPA requires federal agencies to provide public notice of NEPA-related hearings, public meetings, and the availability of environmental documents so as to inform affected parties, [h]old or sponsor public hearings or public meetings regarding the NEPA process, and solicit input from the public.68 The closure of public libraries means that individuals without home computers or internet access, which includes a significant number of the Yakama Nations members, are without notice of the public comment teleconferences and availability of the DEIS. These individuals are unable to review and provide comments on the DEIS because the Lead Agencies will only provide hardcopies of the Executive 64 Coronavirus in Washington state: A timeline of the outbreak through March 2020, KIRO 7, https://www.kiro7.com/news/local/coronavirus-washington-state-timelineoutbreak/IM65JK66N5BYTIAPZ3FUZSKMUE/ (last accessed April 12, 2020). 65 Id. 66 Id. 67 Price Rd. Neighborhood Assn v. United States DOT, 113 F.3d 1505, 1511 (9th Cir. 1997) (citing Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 349 (1989). 68 40 C.F.R. 1506.6. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 20 Summary rather than the entire document.69 This is a far cry from the level of public involvement required under NEPA. Despite being fully informed by numerous governmental entities of the impediments to public comment on the DEIS and the adverse implications for NEPA compliance, the Lead Agencies declined to suspend the public comment schedule. Their failure to do so is inconsistent with the Lead Agencies trust obligation to the Yakama Nation (and its members) and responsibilities with respect to public participation under NEPA.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6299	8	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	4.1. The Purpose and Need statement allows for a balancing of interests that is inconsistent with the Lead Agencies Treaty, trust, and statutory obligations. A purpose and need statement in the DEIS must briefly specify the underlying purpose and need to which the agency is proposing the alternatives including the proposed action.70 The statement may be found to be invalid if it unreasonably narrows the agencys consideration of alternatives so that the outcome is preordained.71 The Lead Agencies have appeared to frame the Purpose and Need in a manner that results in narrow consideration of purposes that at best preserves no more than the status quo fisheries benefits from the CRS operations and configuration. That result is inconsistent with the Lead Agencies obligations to the Yakama Nation, the Order, and the Northwest Power Act as described above. The Lead Agencies indicate that that need for the EIS is to review and update the management of the CRS, including measures to avoid, offset, or minimize impacts to resources affected by managing the CRS [in light of new information and changed conditions].72 The Lead Agencies also correctly note that they are developing the EIS in response to the Order and, therefore, the EIS will evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species, or result in the destruction or adverse modification of designated critical habitat.73 An implicit purpose of this effort must be the configuration and operation of the CRS in a manner that responds to Yakama Nation treaty reserved rights and cultural resources, consistent with the Lead Agencies legal obligations to the Yakama Nation. 69 See Columbia River System Operations EIS, CORPS, https://www.nwd.usace.army.mil/CRSO/#top (last accessed April 12, 2020). 70 40 C.F.R. 1502.13. 71 Alaska Survival v. Surface Transp. Bd., 705 F.3d 1073, 1084 (9th Cir. 2013) (citing Natl Parks & Conservation Assn v. Bureau of Land Mgmt., 606 F.3d 1058, 1070 (9th Cir. 2010)). 72 DEIS at 1-4. 73 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 21 The list of Resource Purposes in this section includes flood risk management (FRM), power supply, irrigation, waterway transportation, fish and wildlife	We disagree that the Purpose and Need section of the Draft EIS must be restructured. The statement goes well beyond power generation capabilities. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				conservation, climate change planning, recreational opportunities, and cultural resources protection.74 There is a disconnect between this broad list of purposes and the stated need for the EIS, which focused on the impacts of the CRS to affected resources; particularly, endangered or threatened fish populations and critical habitat. This disconnect results in a dilution of obligations, wherein fish and wildlife interests are balanced alongside the other purposes.75 The balancing fostered the Lead Agencies development of alternatives (and associated measures) that will result in business as usual with respect to the CRS. This outcome is not consistent with the Courts order, which reiterated a prior federal courts statement the CRS cries out for a major overhaul in order to improve fish survival rates.76 The Lead Agencies have no authority to simply balance the resources reserved under Treaty of 1855 on par with other resource and use purposes. Under federal law Treatyreserved rights cannot lawfully be subordinated to other CRS project purposes a fact which perhaps explains the Lead Agencies failure to provide a legal basis in the DEIS for engaging in such an exercise. Only Congress, not federal agencies, can abrogate Treaty rights under current federal law;77 and the Yakama Nation submits that even Congresss source of authority in this respect is founded on an absurd colonialist principle and not reasonably based in modern principles of law The Doctrine of Discovery a colonial legal doctrine on which Congresss plenary legal authority to abrogate treaty rights was based provided that the discovery of land by a Christian Euro-American government gave rise to that governments legal control over that land.78 This concept is also the source of the federal governments assertion of authority over the Native Nations.79 Specifically, historic U.S. federal case law provided that the United States, as successor to the European nations, possessed absolute ultimate title as acquired by discovery over Native lands.80 The Supreme Court found excuse, if not 74 Id. 75 A review of the suite of measures proposed in the Preferred Alternative (DEIS at 7-23) demonstrates that the number and cost of operation and structural measures for power operations, flexibility, and water supply far exceed fish operations and structural improvement measures. Thus, it appears that the other resource purposes ultimately outweighed fish and wildlife conservation in the Lead Agencies balancing act. 76 Nat'l Wildlife Fedn, 184 F. Supp. at 876. 77 See United States v. State, 641 F.2d 1368, 1371 (9th Cir. 1981) (The Department of the Interior cannot under any circumstances abrogate an Indian treaty directly or indirectly. Only Congress can abrogate a treaty, and only by making absolutely clear its intention to do so.) (citing Menominee Tribe v. United States, 391 U.S. 404, 412-13 (1968)). 78 Indeed, the federal governments assertion of authority over the Columbia River is, at its roots, based on the Doctrine of Discovery. In 1792, the American merchant Robert Gray became the first Euro-American to sail into the Columbia River. Cf., SUSAN SLEEPER-SMITH ET AL., WHY YOU CAN'T TEACH UNITED STATES HISTORY WITHOUT AMERICAN INDIANS 96 (2015). Reportedly, Gray claimed the northern river bank on behalf of the United States by raising an American flag and burying American coins under the sand. In the early 1800s, Merriweather Lewis, William Clark, and other used discovery-style rituals to claim the Columbia River for the United States. Id. at 92-94. In 1838, Senator Lewis Linn spoke before the United States Senate concerning the United States claim to Oregon Country (through which the Columbia River ran). He cited Grays voyage up the Columbia River and Lewis and Clarks expedition as important circumstance[s] in [United States] titlethat was notice to the world of claim, and that Lewis and Clarks solemn act of possession was followed up by a settlement and occupation made byJohn Jacob Astor. Id. at 96-97. 79 See Johnson v. MIntosh, 21 U.S. 543 (1823). 80 Id. at 592. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 22 justification, for the Europeans assertion of authority based on its characterization of the Native Nations as fierce savages, whose occupation was war, and whose subsistence was draw from the forest.81 Federal courts later relied on the Doctrine of Discovery to create the plenary powers doctrine, which purports to give Congress the power to govern Native Nations and unilaterally abrogate Treaty rights.82 The federal government has relied on this doctrine, which has no basis in the Constitution, to unilaterally renege on Treaty guarantees for over two hundred years.83 The Doctrine of Discovery and the jurisprudence that stem from it are irrational, racist, and unjust. Nevertheless, the federal government has never formally renounced the Doctrine of Discovery. Fish and wildlife conservation is mandated under the Treaty of 1855. Under current federal law, only Congress has authority to subordinate this mandate to other interests (and, as described above, even Congresss authority here is dubious). The Lead Agencies plainly lack authority to diminish Treaty rights by balancing their fulfillment against satisfying other interests in the context of the CRSO EIS. Conserving Treaty-protected fish and wildlife resources can, in many instances, conflict with the other stated resource purposes. However, consistent with the federal trust obligation and federal Treaty obligations, the Lead Agencies must resolve these conflicting claims in a precise manner that would indicate the weight given each interest before [them]. Any resolution must ensure that the Yakama Nations Treaty rights are given full effect, including the protection of time, place, method, species and extent of fishing practices and avoidance of damage to fish runs and habitat. Furthermore, although the Purpose and Need section references the Northwest Power Acts directive to give fish and wildlife mitigation equitable treatment with other authorized purposes, it is silent as to other relevant language from that statute.84 Critically, the Lead Agencies must protect, mitigate, and enhance fish and wildlife to the extent affected by the development and operation of any hydroelectric project of the Columbia River and its tributaries in a manner consistent with the Councils Fish and Wildlife Program.85 The Councils Fish and Wildlife Program has a number of objectives, including doubling the salmon runs in the Columbia River. A Purpose and Need that balances the stated purposes despite significant adverse impacts to fish and wildlife fails to make progress to achieve this or any of the Councils other objectives. The determination to balance the stated purposes despite significant adverse impacts to fish and wildlife does not fulfill the purposes of the Northwest Power Act.86 81 Id. at 589-90. 82 See United States v. Kagama, 118 U.S. 375 (1886) 83 See, e.g., Lonewolf v. Hitchcock, 187 U.S. 553, 566 (1903). 84 DEIS at 1-5. 85 16 U.S.C. 339b4(h)(10)(A). These directives are consistent with the Lead Agencies obligations under the Treaty of 1855 and the federal trust responsibility. 86 While the DEIS references the Councils Power Plan and power system analyses over fifty times, there is only one reference the Councils Fish and Wildlife Program and three references to other Council fish and wildlife analyses or reports. There is no evidence that the Lead Agencies considered the Councils Fish and Wildlife Program in developing alternatives or measures. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 23 Finally, the Lead Agencies balancing act of co-equal purposes is contrary to their acknowledgment of the Orders directive. The Order did not charge the Lead Agencies to develop an EIS that balances (or deprioritizes) fish survival against the perceived benefits of FRM and power, but rather sought a system overhaul to ensure fish survival as demanded by the ESA and other applicable federal laws and Treaty obligations.87 The Purpose and Need section of the DEIS must be restructured to give appropriate priority to fish and wildlife conservation consistent with the Yakama Nations Treaty rights. In other words, the CRSO EIS must pursue project purposes in a manner that enhances Tribal fisheries and cultural resources rather than merely preserving power generation capabilities. The Lead Agencies may weigh the other resources purposes against one another once fish and wildlife conservation is ensured but not before. This approach would be more consistent with the stated need for the CRSO EIS and appropriately reflect the Lead Agencies obligations to the Yakama Nation under the Treaty of 1855, the federal trust responsibility, the Northwest Power Act, and the Order.	
6299	9	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	4.2. The range and consideration of alternatives is incomplete. Federal agencies are required to evaluate all reasonable alternatives in an EIS.88 This includes those alternatives not within the jurisdiction of the lead agency.89 Whether an alternative is reasonable is bounded by some notion of feasibility.90 Alternatives must be reasonably related to the purposes of the project.91 More specifically, alternatives must derive from the Purpose and Need section of an EIS, as the stated goal of an EIS dictates the range of alternatives.92 A. The Lead Agencies failed to evaluate all reasonable alternatives. As described above, there is a disconnect between the need and the purposes in the Lead Agencies Purpose and Need section. If the Lead Agencies had framed the purpose more consistently with the need for the CRSO EIS, the Lead Agencies reasonable alternatives would include a range of measures aimed at protecting fish (rather than alternatives that maximize hydropower production and FRM at the expense of fish and wildlife). Various cooperating agencies offered several fish-focused alternatives that would have conformed to such an approach. The Lead Agencies either outright or effectively rejected these recommendations in the framing of the alternatives ultimately included in the DEIS. For example, the Nez Perce Tribe proposed a comprehensive alternative that set a benchmark for possible fish benefits. MO4 may have been intended to capture the Nez Perce recommendation but instead constitutes a drastic modification of the proposal. MO4 strips away the majority of fish benefits by inserting power flexibility and water 87 See n. 85, supra. 88 40 C.F.R. 1502.14(a). 89 Id. at (c). 90 Laguna Greenbelt v. United States Dept of Transp., 42 F.3d 517, 524 (9th Cir. 1994) (citing Vermont Yankee Nuclear Power Corp. v. Natural Resources Defense Council, 435 U.S. 519, 551 (1978)). 91 Laguna Greenbelt, 42 F.3d at 524 (9th Cir. 1994) (citing City of Angoon v. Hodel, 803 F.2d 1016, 1021-22 (9th Cir. 1986)). 92 City of Carmel-by-the-Sea v. United States DOT, 123 F.3d 1142, 1155 (9th Cir. 1997) (citing Citizens Against Burlington, Inc. v. Busey, 938 F.2d 190, 196 (D.C. Cir. 1991). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 24 management measures. MO4 also extends the spill season to periods of minimal fish benefit (including March and August).93 This extreme particular measure at McNary obscures the reasonableness and viability of other MO4 fish benefits measures. Although the McNary measure spill may support fish life, its effect in the analysis of MO4 is to operate as a poison pill to overall acceptability and political achievability of the MO4 option by creating significant negative impacts on all other water users. These changes make the Nez Perce proposal nearly unrecognizable: an alternative that provides minimal benefits to fish (except for the politically untenable McNary measure) while devastating power supply cost and unreliability. As a package of measures that could have been a fish-friendly candidate for a Preferred Alternative, MO4 is made unappealing to nearly all parties and, consequently, easily dismissed. The Lead Agencies missed an opportunity to	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The development of MO3, which includes breaching the four lower Snake River dams, followed strict public health and safety standards, which are within the expertise of the co-lead agencies. Regarding MO4, the co-lead agencies disagree MO4 is constructed to neutralize or undermine the benefits for fish associated with maximizing spill at the CRS dams. The co-lead agencies proposed this alternative as bookend to determine potential benefits to anadromous from maximized spill and flow levels. MO4 resulted in potential substantial improvements to anadromous fish.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				meaningfully evaluate a fish-focused alternative. Had the Lead Agencies evaluated the Nez Perce alternative as submitted, that analysis would likely have demonstrated significant fish benefits with marginal additional costs to the system. Cooperating agencies also recommended a more reasonable, graded approach to evaluating dam removal under MO3. However, the Lead Agencies applied strict assumptions that all four Snake River dams would have to be removed within two years (with removal of each dam not to exceed a single year) and outside of the fish migration window. While it is possible that the full breach assumption was the basis for maximally capturing potential impacts, the Lead Agencies have never explained why such assumptions were necessary for a dam removal alternative or why a more careful approach would not mitigate the potential maximal impacts. This approach artificially exaggerated the costs and arbitrarily restricted the Lead Agencies ultimate analysis of MO3. In addition, the Lead Agencies evaluated alternatives that largely consisted of similar measures (i.e., several power system and water management measures were included in three or four alternatives) and focused on system purposes other than fish benefits. An appropriate hard look requires evaluation of feasible alternatives reasonably related to the broad resource purpose list without an inappropriate balancing of tribal interests with other authorities for the CRS.	
6299	10	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	B. The Lead Agencies utilized a framework for developing and evaluating alternatives that obscured the impacts and benefits of configuration and operations measures. The Lead Agencies unilaterally, without input from the Yakama Nation, created four multiobjective (MO) alternatives from a pool of approximately fifty individual measures. There was considerable overlap between measures included within the four alternatives making it difficult for the Yakama Nation to determine which measures were driving fish impacts and benefits. Likewise, the approach did not allow the Yakama Nation to identify, quantify, or evaluate individual impacts caused by particular measures because the Lead Agencies included a number of measures in several, but not all, multiple objective alternatives. This obscures rather than discloses the impacts of a Preferred Alternative that draws on the identified pool of measure. 93 Moreover, the DEIS exaggerates the costs and impacts of this spill season on power production. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 25 Even so, the Yakama Nation, in consultation with other cooperating agencies, developed a draft measure-by-measure analysis for impacts to fish based on cooperating agency expertise; but the Lead Agencies rejected this effort as outside the limits of the CRSO EIS framework.94 Such an analysis is plainly within the scope of the CRSO EIS and is relevant to the Lead Agencies development of alternatives that will inevitably impact fish populations. The Lead Agencies failure to even consider the information that the cooperating agencies presented underscores Yakama Nation concerns about whether the Lead Agencies impact assessment adequately evaluated all reasonable alternatives. Ultimately, this flawed framework taints the development and evaluation of the alternatives proposed in the DEIS and the reliability of impact assessment overall. The Lead Agencies assembled various measures from each alternative to produce the Preferred Alternative described in Chapter 7, but without disclosure of the reasoning for selection of these measures, how the measures were evaluated given the obscurity of impacts from individual measures, or what impact the measures included in the Preferred Alternative would cumulatively have on a particular resource.	The alternatives in this EIS were developed to meet the objectives identified by the co-lead agencies, cooperating agencies, and from public comments during scoping, as well as the stated Purpose and Need Statement, which describes all congressionally authorized purposes and legal requirements for the CRS. The development of alternatives was guided by objectives identified by the team early in the process. The Single Objective alternatives, developed and analyzed early in the process with input from co-lead and cooperating agency team members provided the foundation for the final array of alternatives. Team members from the cooperating agencies participated in the technical team meetings, in which alternative development, alternative analysis, and effects were discussed and presented for inclusion in the EIS. The co-lead agencies and cooperating agencies understood which measures the co-lead agencies would employ from the fish analysis, were part of the evaluation of the measures and alternatives, and were provided opportunities to comment on this analysis during development of the EIS. Development of alternatives outside of the co-lead agency process by select few team members does not meet the transparency required by NEPA. The co-lead agencies requested this work be conducted within the team, and not a separate effort.
6299	11	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	C. The Lead Agencies cannot cite a lack of Congressional authorization to scrutinize MO3 differently than other alternatives. Consistent with 40 C.F.R. 1502.14(c), the Lead Agencies chose to include an alternative (MO3) that would require additional Congressional authorization. However, the Lead Agencies appear to conduct a more thorough analysis on the remaining alternatives, citing the lack of congressional authorizations for MO3 as a reason to not give that alternative a hard look. In addition, NEPA contemplates that EISs are prepared for legislative proposals as well. The fact that additional authority must be asked for does not in any obvious way warrant truncated evaluation of such measures. Given that the Lead Agencies appropriately included MO3 as a reasonable alternative with the awareness that additional legislative action would potentially be necessary, the Lead Agencies must evaluate it with the same level of scrutiny and consideration as the other alternatives.	MO 3 received the same modelling, analysis, and scrutiny that the other alternatives received, as described in Chapter 3 and the technical appendices. It was noted in the EIS that additional congressional authority would be required to deauthorize and breach the dams in order to be fully transparent and set expectations with readers about the process that would be required to implement the alternative and to correct misinformation disseminated by some members of the public. The lack of authority was not used as an evaluation or screening criteria for MO 3 or any of the other alternatives.
6299	12	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	D. The Lead Agencies failed to adequately explain why the natural rivers alternative was unreasonable. The Lead Agencies describe a rejected alternative that would have created natural rivers to mimic pre-dam construction conditions by breaching all fourteen dams in the CRS. The Lead Agencies note that the creation of natural rivers was previously studied and found to be infeasible.95 The Lead Agencies do not provide any details on these studies or the conclusions therein. The Lead Agencies also fail to explain why they consider the studies reliable. Furthermore, 94 See Letter from Francis E. Coffey, Programs Director, Northwestern Division, Corps (July 11, 2019). A summary of the measure-by-measure analysis, prepared by Yakama Nation technical consultant Tom Iverson, is included as Appendix B to these comments. 95 DEIS at 2-79. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 26 the reference to previous studies is inconsistent with the Lead Agencies subsequent point that they have no existing data for breaching the remaining dams such that completion of necessary analysis would take years to gather data and develop a model.96 The Lead Agencies should include citations for the studies and describe why the studies are reliable. The Lead Agencies should clarify why the conclusions reached in the studies demonstrate that the alternative is not reasonable, and explain why the studies are reliable. Finally, the Lead Agencies should explain the discrepancy between the reference to the studies and the statement concerning a lack of data.	Adoption of an alternative to breach all 14 CRS dams would fail to meet the Purpose and Need, and would not allow the co-lead agencies to meet any of the purposes and authorities directed by the U.S. Congress. As discussed in the Council on Environmental Quality's NEPA regulations and its 40 Questions document, alternatives must be reasonable, which includes "practical or feasible from the technical and economic standpoint and using common sense." It is neither practical or feasible to breach all CRS dams given the unreasonable risks to public health and safety due to impacts to power and transmission reliability, flood risk management, among other reasons. This type of alternative is not a reasonable alternative under NEPA. Instead, as required by by NEPA, the co-lead agencies developed a reasonable range of alternatives intended to allow the co-lead agencies to evaluate trade-offs of operations intended to benefit one purpose over another, and make an informed recommendation about continued operations of the CRS.
6299	13	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	5.1. The Lead Agencies cultural resources analyses does not address the full scope of impacts to the Yakama Nations cultural resources. This section describes flaws in the Lead Agencies cultural resources analyses. A. The Lead Agencies use an overly-narrow definition of cultural resources. The Lead Agencies define cultural resources as [t]he non-renewable evidence of human occupation or activity as seen in any district, site, building, structure, artifact, ruin, object, work of art, architecture, or natural feature that was part of human history at the national, state, or local level.98 This definition may be consistent with the National Historic Preservation Act (NHPA), but is too narrow in this context. NEPA requires consideration of impacts to the human environment.99 This includes the natural and physical environment and the relationship of people with that environment.100 Therefore, the Lead Agencies current definition is too narrow for an adequate NEPA analysis. First, the definition should not be narrowly framed to only include historical resources. Indeed, the NEPA regulations expressly distinguish between historic and cultural with respect to analysis of effects.101 Second, the definition should not reduce cultural resources to mere places and objects. This reduction causes the Lead Agencies to entirely fail to consider an important aspect of the problem with respect to cultural resources analyses: the CRSs impacts on Yakama members relationship with the natural and physical environment. For example, the Lead 96 Id. 97 As a general note, the FEIS must assure that assertions and conclusions are substantiated with facts or analysis. The time available for review of the DEIS has prevented the compilation of examples of unsubstantiated statements. 98 DEIS at xlvii. 99 42 U.S.C. 4332(C). 100 40 C.F.R. 1508.14. 101 40 C.F.R. 1508.8. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 27 Agencies Preferred Alternative primarily discusses impacts in terms of exposure and erosion of archeological resources.102 It does not address impacts to the Yakama Nations cultural and religious connection to the Columbia River Basin environment. The definition must allow for a more comprehensive analysis that should systematically addresses human, social, and cultural aspects of the environment.103 The Yakama Nation believes that a more defensible definition is: The non-renewable evidence of human occupation or activity as seen in any district, site, building, structure, artifact, ruin, object, work of art, architecture, or natural feature that was part of human history at the national, Tribal, state, or local level; culturally significant elements of the biophysical environment including, but not limited to, plants, wildlife, geological features, and waterways; the cultural use of or reliance on the biophysical environment; and social cohesion, social institutions, lifeways, religious practices, and other cultural institutions. The Lead Agencies acknowledge that various Native Nations made similar recommendations throughout the cooperating agency review process. The Lead Agencies characterize these recommendations as products of indigenous peoples learning systems, but do not provide a reason for rejecting them.104 This dismissal of information provided by Native Nations by branding it as some mysterious tradition that the federal government is incapable of understanding is arbitrary and willfully ignorant. The Yakama Nations definition is entirely consistent with NEPAs requirement that federal agencies consider impacts to the natural and physical environment and the relationship of people with that environment. The Lead Agencies improper use of an unreasonably narrow cultural resources definition in the DEIS compromises the related analysis, which must be corrected in the FEIS. If the Lead Agencies do not adopt the Yakama Nations recommendations, they should develop their own definition that is inclusive of natural cultural resources, cultural practices, and cultural institutions, and refine their cultural resource analyses accordingly.	In the Draft EIS, the co-lead agencies used a property-based definition of "cultural resources," as this is consistent with Federal laws and regulations, which focus on specific bounded properties. Tribal interests and holistic perspectives on the integration of Native American culture with the environment were addressed throughout the EIS and by inclusion of statements from the Tribes. The co-lead agencies note that many of the traditional cultural properties analyzed in the Draft EIS incorporate elements of the natural environment. Please see Section 3.16.2.6 for the traditional cultural resource types, many of which explicitly include hunting, fishing, and gathering areas, Section 3.17.2 for Tribal Perspectives Summaries and Section 3.17.3 for Tribal Interests. Additionally, the EIS evaluates the impacts of the social and economic effects as well as effects to the natural and physical environment consistent with 40 C.F.R. 1508.14 and 1508.8.
6299	14	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	B. The Lead Agencies cultural resources analyses fail to consider the larger historical context of the CRSs impacts on the Yakama Nations cultural resources. In outlining resource concerns for the DEIS, the Lead Agencies note that: Native Americans, archaeologists, historians, members of the general public, and state and Federal agencieswould like to minimize damage to cultural resources from the effects of reservoir operations, which include but are not limited to water level fluctuations, wave and wind action, inundation, irrigation, transportation, and 102 DEIS at 7-1907-196. 103 A revision to the Lead Agencies current definition is particularly necessary given the fact that the Lead Agencies have decided to bifurcate the NHPA Section 106 process from the CRSO EIS. 104 DEIS at 3-1400. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 28 recreation, among others. In addition, there is a concern about losses caused by vandalism and looting.105 The Yakama Nation certainly wishes to avoid these adverse impacts to archeological sites and other cultural resources. The Lead Agencies have an obligation to protect any such sites that become exposed as a result of their actions from looting or vandalism. However, the Lead Agencies decision to frame cultural resources concerns in this fashion ignores the larger context of the CRSs impacts: entire lifeways, villages, economies, ancestral burials and customs were lost	The co-lead agencies respectfully disagree that there was a failure to consider the "significant disruption" of Native American lifeways that has taken place since the start of Euroamerican exploration and settlement of the Northwest. Please see Section 3.16.2.4 for a discussion of how U.S. government policies and settlement affected Tribes in the region. The scope of this EIS is limited to comparison of the No Action Alternative (which reflects operations as of September 30, 2016) to the Action Alternatives. As recognized in the comment, the co-lead agencies continue to consult under Section 106 of the National Historic Preservation Act under the Systemwide Programmatic Agreement for the Management of Historic Properties Affected by the Multipurpose Operations of the Fourteen Projects of the Federal Columbia River Power System (FCRPS) and through the FCRPS Cultural Resource Program. Additionally, the EIS acknowledges there may be the need for additional mitigation implemented through the Cultural Resource Program depending on which alternative is selected by the co-lead agencies.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				through the federal manipulation of the Columbia River. Similarly, the Lead Agencies Affected Environment sections pertaining to cultural resources generally recount the history of Euro-American industrial development on the Columbia River (from the Euro-American perspective). However, these sections fail to describe the significant disruption to the Native culture that resulted from such development and demonstrate a general lack of knowledge regarding the historic context of Tribal and Euro-American population interactions. Without this context, the Lead Agencies cannot give an adequate hard look at the impacts of the CRS on the human environment. The failure to acknowledge the larger historical context of the CRSs impacts on the Yakama Nations cultural resources permeates into the Lead Agencies analyses throughout the DEIS. For example, the Lead Agencies Preferred Alternative largely considers adverse effects such as exposure, erosion, and loss of archeological sites;106 it does not, however, appear to consider whether any of the alternatives would result in beneficial effects to cultural practices. The Lead Agencies crabbed approach prevents proper analysis of cultural resource impacts. Rather than simply noting concerns associated with vandalism and looting (presumably resulting from increased exposure), the Lead Agencies must meaningfully consider these potential adverse effects on Yakama Nation cultural practices, such as gathering food and medicinal resources, consistent with agency Treaty and trust obligations against potential beneficial effects of measures which enable or facilitate cultural practices, such as gathering food and medicinal resources. The Lead Agencies may find these beneficial effects significant enough to warrant re-evaluation of the alternatives and component measures will enable identification of mitigation actions that enable or facilitate cultural practices.	
6299	15	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	C. The Lead Agencies do not explain why the Preferred Alternative will not cause additional impacts to Traditional Cultural Properties (TCP). The Lead Agencies note that, based on available information, and with reference to the assumptions and constraints previously described for TCPs, the Preferred Alternative is unlikely to result in an appreciable increase in effects to TCPs. This type of conclusory statement is simply insufficient under NEPA. In the FEIS, the Lead Agencies must describe the chosen methodology used to reach their conclusion regarding effects to TCPs, along with the reasons [they] considered the underlying evidence to be reliable.	In Section 7.7.18 the co-lead agencies state that Traditional Cultural Properties would continue to experience major effects under the Preferred Alternative. The co-lead agencies discuss in detail the methodology employed to assess impacts to Traditional Cultural Properties in Section 3.16.3.1. The methods used to assess the impacts of the Preferred Alternative are the same as were used in the assessment of the other action alternatives.
6299	16	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	D. The Lead Agencies rely on the Federal Columbia River Power System Cultural Resource Program for mitigation without describing specific measures. The Lead Agencies offer a broad overview of the Federal Columbia River Power System Cultural Resource Program (FCRPS Program) and describe it as a mechanism for compliance with Section 106 of the NHPA.107 For each alternative, the Lead Agencies would use FCRPS Program funding for: activities such as archeological site and traditional cultural property monitoring (pedestrian and drone use), reservoir and river bank stabilization, data recovery, public education awareness, protective signage, and other alternative mitigation to address impacts to [traditional cultural properties].108 These activities, in conjunction with the existing FCRPS Program, would work to continue minimizing any adverse effects to negligible.109 Likewise, the Preferred Alternative relies entirely on the FCRPS Program for mitigation measures.110 Without more, however, the Yakama Nation is unclear how, for purposes of NEPA, the Lead Agencies can effectively mitigate impacts to cultural resources under any of the alternatives. Mitigation must be discussed in sufficient detail to ensure that environmental consequences have been fairly evaluated.111 The Lead Agencies cannot simply list possible mitigation measures.112 Accordingly, the Lead Agencies must explain the mitigation measures proposed for each MO alternative with sufficient detail. The explanations should be clear, specific, and tailored to each alternative. Similarly, the Lead Agencies must describe how the FCRPS will mitigate impacts under the Preferred Alternative. It is also worth noting that the FCRPS Programs Systemwide Programmatic Agreement (SWPA) (which the Yakama Nation is not a signatory to) is inadequate to ensure mitigation.113 The SWPA, which was not intended to act as a mitigation tool, does not fully consider impacts to the loss of ancestral use (e.g. fishing and gathering) sites, legendary sites, village sites, monumental sites, ceremonial sites, petroglyph/pictograph sites and archaeological site, all which the Yakama Nation considers sacred. The SWPA lacks of accountability, specific funding obligations, and requirements concerning site treatment and identification. Federal agencies operating under the SWPA attempt to prioritize sites with known impacts and develop strategies to mitigate those impacts on a case-by-case impacts. The federal agencies have not actually implemented any mitigation measures at 107 DEIS at 5-1112 108 DEIS at 5.4. 109 DEIS at 5-21. 110 DEIS at 7-45 (For new effects to archaeological resources, traditional cultural properties, and the built environment at storage projects caused by implementation of the Preferred Alternative relative to the No Action Alternative, the co-lead agencies would use the existing FCRPS Cultural Resources Program and the SystemWide Programmatic Agreement to implement mitigation actions, as warranted and appropriate.). 111 City of Carmel-by-the-Sea 123 F.3d at 1154 (quoting Methow Valley, 490 U.S. at 351-52. 112 Neighbors of Cuddy Mt. v. United States Forest Serv., 137 F.3d 1372, 1380 (9th Cir 1998) (modified on other grounds, 1998 U.S. App. LEXIS 3923 (9th Cir. 1998) (citing Northwest Indian Cemetery Protective Assn v. Peterson, 795 F.2d 688, 697 (9th Cir. 1986), revd on other grounds, 485 U.S. 439 (1988). 113 The Yakama Nation has already objected to the Lead Agencies reliance on the FRCPS Programmatic Agreement with respect to NHPA compliance through letters dated May 22, 2019 and December 20, 2019. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 30 many of these sites. Moreover, there are a significant number of sites along the Columbia River that the federal agencies have yet to formally analyze. As such, the Yakama Nation cannot be confident that the Lead Agencies will sufficiently mitigate harm to cultural resources by relying on the FCRPS Program alone.	Given the broad, multi-faceted nature of the proposed action, which will occur across a wide geographic area and timescale, the co-lead agencies have proposed to address impacts to cultural resources programmatically; hence, the use of the Systemwide Programmatic Agreement. The advantage of this approach is it allows the agencies to implement a tailored approach to both cultural resource property identification and impact analysis, including the specific type of impact occurring at a specific property location in the future, across the system and at different points in time versus attempting to identify every potential impact that may, or may not, occur at either known cultural resource properties, or those that are currently unknown. The co-lead agencies agree the Systemwide Programmatic Agreement is the correct approach to ensure mitigation of impacts to cultural resources and due to the flexibility built into the document, also believe it is capable of considering impacts to all cultural resource property types, including archaeological sites, the historic built environment, and traditional cultural properties.
6299	17	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	E. The Yakama Nation objects to the Lead Agencies refusal to consider all federal lands in the cultural resources study area as a sacred site. The Establishment Clause of the 1st Amendment to the U.S. Constitution, dictates that Federal agencies will not prohibit the free exercise of Native American religions. The American Indian Religious Freedom Act of 1978 (AIRFA) directs federal agencies to respect and protect Tribal religions and the practice thereof.114 AIRFA is not strictly place based but is also inclusive of the act of religion itself. Consistent with AIFRA, Executive Order 13007 deals directly with sacred sites, their definition and management. Sacred sites are defined as: any specific, discrete, narrowly delineated location on Federal land that is identified by an Indian tribe or Indian individual determined to be an appropriately authoritative representative of an Indian religion; provided that the tribe or appropriately authoritative representative of an Indian religion has informed the agency of the existence of a site. This definition is frequently misinterpreted to put a bulk of the responsibility of sacred site identification on the shoulders of Tribes. However, federal agencies must make a reasonable and good faith to identify sacred sites pursuant to the NHPA.115 A mere request for information by a federal agency to a Native Nation is not sufficient to constitute a reasonable effort.116 Where the federal agency has any indication from a Native Nation that a sacred site exists, it must conduct further investigation.117 The good faith requirement prohibits the federal agency from withholding information on sacred sites from pertinent parties, such as State Historic Preservation Officers that that federal agency seeks concurrence from under the NHPA.118 The problem with the Lead Agencies existing quantification of only two sacred sites within the Area of Potential Effect (APE) of the CRSO EIS is two-fold. First, there is a question about the qualifications of the individuals who made determinations regarding sacred sites for the DEIS. Appendix II of National Register Bulletin 38, Professional Qualifications: Ethnography, outlines in detail the qualifications of individuals who agencies should obtain 114 42 U.S.C. 1996. 115 See Pueblo of Sandia v. United States, 50 F.3d 856, 863 (10th Cir. 1995). In that case, the Pueblo of Sandia (Pueblo) notified the United States Forest Service (USFS) about TCPs that they asserted were eligible for inclusion in the National Register of Historic Places (NRHP) located in a proposed USFS project area in Las Huertas Canyon, New Mexico. The Pueblo was bound by custom to not divulge additional information to the USFS. Consequently, the USFS was unable to get any more information regarding the TCPs from the Pueblo and recommended that there were no NRHP-eligible TCPs in the proposed project area. 116 Id. at 860. 117 Id. at 860-62. 118 Id. at 862. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 31 to gather TCP data.119 These qualifications include an experts ability to speak Native languages, experience with ethnographic methodologies and oral history interviews, and possession of graduate and post-graduate training in ethnography.120 To the Yakama Nations knowledge, none of the archeologists representing the Lead Agencies or the project managers for the FCRPS cooperating groups meet these qualifications or are practitioners in any of the religions significant to the Yakama Nation. Neither the Lead Agencies or the project managers for the FCRPS cooperating groups have employed or contracted an ethnographer to gather necessary information to make a determination that the entirety of the Columbia River is not a sacred site. Therefore, the Lead Agencies must explain substance and reliability of the methodology and evidence that they used regarding sacred sites. Second, the Lead Agencies have not put forth a reasonable and good faith effort to identify sacred sites. Through the FCRPS Program Cooperating Group meetings, the Yakama Nation has repeatedly requested the Lead Agencies to cohesively investigate the entire Columbia River as a sacred site. Nevertheless, the Lead Agencies have made no effort to do so or to even manage cultural resources as a collective unit. This is not indicative of a reasonable effort. Moreover, the Lead Agencies decision to omit these requests from the DEIS (while only referencing information from one tribal representative regarding the entire Columbia River as a sacred site)121 could be construed as a lack of good faith effort. The Columbia River and all associated properties relevant to the protection, preservation and perpetuation of the Native way of life are sacred sites. The Yakama Nations cultural resources specialists define sacred sites areas to include ancestral use, monumental, burial, petroglyph/pictograph, archaeological, and ceremonial sites. Each of these site types are associated with life along the river as provided by the Creator and formed by Speelyi. Speelyi created the fishing sites, the riffles, whirlpools, eddies, swift currents, slow currents, landforms, and gave the people the resources necessary to make a life along the Nchi wana (the Columbia River) and its many tributaries. Each of these things have a name in the Yakama Nations Tribal language,	The co-lead agencies respectfully disagree with the comments regarding the efforts to consider the impacts of the various alternatives on sacred sites and traditional cultural properties (TCPs). The co-lead agencies use the definition of sacred sites provided in Executive Order (EO) 13007, which highlights that the sacred sites must be identified by an Indian tribe, or Indian individual determined to be an appropriately authoritative representative of an Indian religion and be specific, discrete, narrowly delineated. The two sacred sites the comment identifies–the Columbia River and all federal lands in the cultural resources study area are not specific, discrete, or narrowly delineated. As a result, they are not sacred sites within the meaning of EO 13007. Two Tribes identified sacred sites that followed the Executive Order (i.e., Kettle Falls and Bear Paw Rock), and thus those sacred sites were included in the EIS. Respectfully, the co-lead agencies disagree with this summary of their actions regarding compliance with Section 106 of the National Historic Preservation Act. The co-lead agencies have not asserted that consultation with the Yakama Nation is only necessary for impacts to trust lands. The Systemwide Programmatic Agreement provides a framework for consultation with the Yakama Nation and other concerned tribes about cultural resources in the Federal Columbia River Power System (FCRPS) Area of Potential Effects, whether the tribes are signatory to the agreement or not, and whether the cultural resources are on trust lands or not. The co-lead agencies consulted actively with the Yakama Nation during the process leading up to the finalization of the Systemwide Programmatic Agreement, which was sent to the Yakama Nation for their signature in April 2009. While the Yakama Nation has chosen not to sign the Systemwide Programmatic Agreement, the co-lead agencies have continued Section 106 consultation under the Systemwide Programmatic Agreement and actively engage and work with the Yakama Nation in both the Wana Pa Koot Koot (Corps Portland District) and Payos Kuus Cuukwe (Corps Walla Walla District) cooperating groups. Through both this consultation and these cooperating groups, the Yakama Nation have an active voice in the development of annual and long-term work priorities for the resolution of adverse effects to historic properties related from the operation and maintenance of the Columbia River System Projects. The co-lead agencies continue to rely on the Yakama Nations special expertise in cultural resources within the Area of Potential Effect established during consultation for both Portland and Walla Walla U.S. Army Corps of Engineers Districts. As described in Section 3.16.2.7, in the Draft EIS, the co-lead agencies sent a letter to the Yakama Nation and 18 other Tribes in the Northwest in June 2018 requesting them to identify sites that they considered sacred per the definition in EO 13007. There was no response from the Yakama Nation as to this query until now. The comments touch on TCPs, which are conflated with sacred sites. The co-lead agencies used the definition of TCPs as provided in National Register Bulletin No. 38, and the co-lead agencies have followed the guidance in this document regarding the role of Tribes in providing primary information. As described in the Draft EIS, in Section 3.16.3.1, page 3-1362, the co-lead agencies utilized existing geospatial data provided by the Yakama Nation and other Tribes regarding the location and character of TCPs throughout the study area to assess effects. This information was provided by the Tribes as a part of the ongoing Federal Columbia River Power System (FCRPS) Cultural Resources Program and its inclusion in the Draft EIS impact analysis recognizes the special expertise of the Tribes. The method of analysis used to assess effects to TCPs from the alternatives was developed during facilitated meetings of the CRSO EIS Cultural Resources Team. The Yakama Nation, along with other Tribes, state and Federal agencies, actively participated in these meetings as cooperating agencies. Input from the Yakama Nation staff was key in determining the classification scheme used to summarize the frequency of TCP types throughout the study area.

				Ichi Skin Sinwit, known to anthropologists as Sahaptin. Those names speak to the historical events that took place and led up to their existence. The Yakama Nation has written down the history of this creation and shared it with the Lead Agencies through twenty years of cooperative work and contractual relationships. As such, the Lead Agencies have access to reports compiled by the Yakama Nation that are directly at odds with its assertion concerning sacred sites. The Lead Agencies cannot in good faith state that the Columbia River is not a sacred site, arbitrarily ignoring information that evinces otherwise. The Advisory Council of Historic Preservations guidance, Meeting the Reasonable and Good Faith Identification Standard in Section 106 Review, states that a good faith investigation by a federal agency requires certain elements: 119 DEPT. OF INTERIOR, GUIDELINES FOR EVALUATING AND DOCUMENTING TRADITIONAL CULTURAL PROPERTIES (1998). 120 Id. at 28. 121 DEIS at 1355. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 32 The investigation is carried out in consultation with, as appropriate, the SHPO, Tribal Historic Preservation Officer, and any Indian tribe or Native Hawaiian organization that might attach religious and cultural significance to historic properties within the APE;122 The investigation is initiated in a timely manner that allows for appropriate analysis and reporting, with adequate time for review by the consulting parties;123 The investigation is carried out by a qualified individual or individuals who meet the Secretary of the Interiors qualification standards and have a demonstrated familiarity with the range of potentially historic properties that may be encountered, and their characteristics;124 The investigation acknowledges the special expertise possessed by Indian tribes and Native Hawaiian organizations in assessing the eligibility of historic properties that may possess religious and cultural significance to them (regardless of whether or not such tribes and organizations meet the Secretarys qualification standards);125 The investigation is fully supported by adequate funding and other necessary resources;126 and The investigation is not compromised by lack of integrity or omission, such as manipulating or ignoring evidence.127 The Lead Agencies have not complied with these guidelines in analyzing sacred sites or TCPs. First, the Lead Agencies have excluded the Yakama Nation from consultation regarding cultural resources in the APE, asserting that the consultation with the Yakama Nation is only necessary for impacts to trust lands because the Yakama Nation is not a signatory to the SWPA. Second, the time provided for analysis and review (due to the condensed schedule) has been completely unacceptable and inadequate. Third, the Lead Agencies archeologists are not qualified to identify or evaluate TCPs. Fourth, by completing dismissing the Yakama Nations comments regarding sacred sites and TCPs, the Lead Agencies fail to acknowledge the Yakama Nations special expertise and knowledge. Fifth, the Lead Agencies budgetary restraints under the SWPA are inadequate to properly support analysis of sacred sites and TCPs. Lastly, the Yakama Nations experience has been that federal agencies have omitted, manipulated, and ignored available evidence since the inception of the FCRPS Program, including resource reports and monthly meeting minutes.	
6299	18	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	F. The Lead Agencies environmental justice analyses of impacts to cultural resources fail to consider all available information.128 The DEIS states that the population of the Yakama Nation Reservation is over 30,000 people. It also states that there are only 9,000 Native Americans living in Yakima County. Even if those individuals all lived on reservation, which they do not, that leaves 21,000 nonTribal members living on the Yakama Reservation. According to a 2004 study about populations on-reservation and off-reservation trust lands, approximately 33.4% of the population is White, 36.7% is marked as Other, and 23.3% are Native Americans.129 Taking census data alone from the Yakama Reservation does not provide an adequate snapshot of Tribal people, but merely reflects non-native encroachment resulting from allotment acts.130 The DEIS notes that the median household income for low-income, minority, and Tribal communities in the study area is $39,000.131 This is a very high estimate. From 2012 to 2016, Yakama Nation members had an average income of $5,700, with a poverty rate of 42%.132 These statistics likely do not account for the fact that many Yakama households consist of extended family, where one persons income is spread across multiple generations. That income is often seasonal and dependent upon fish runs between the spring and fall months. The Columbia River Indians are a distinct and identifiable population is population where single-person and seasonal income is especially prevalent. Most of the Columbia River Indians are enrolled in one of the Treaty Tribes but maintain an identity as a River Indian. They make their living on the Columbia River and reside in one or more of the Treaty Fishing Access sites throughout the fishing months. The Lead Agencies do not even reference the Columbia River Indians, much less account for impacts that fall disproportionately on this population. The lack of critical data regarding the Yakama Reservation, Yakama members, and the Columbia River Indians means that the Lead Agencies have not adequately considered communities in the affected area. This compromises the Lead Agencies ability to conduct a proper analysis of disproportionate effects on the Yakama Nation. It is also unclear how the Lead Agencies gathered information on and from Tribal communities regarding impacts and then how these impacts were prioritized. The Lead Agencies data in the Appendices for the Cultural Resources, Environmental Justice and Socio-economic sections reveals very little about the impacts Tribal communities would experience as a result of any alternative. A simple statement that salmon are a significant resource to Tribal communities does not explain how Tribal people would be affected by the continued reduction of salmon populations and habitats; adverse impacts to water quality; loss of cultural resources, sacred sites, burial sites, and TCPs; or the mental and 128 See pg. 57-60, infra, concerning environmental justice considerations. 129 4.4% is marked as two or more races. 130 This also extends to income data: even on the Yakama Reservation, there is a disproportionate distribution of wealth and Tribal people are the population with the lowest income levels. 131 DEIS at 3-1430. 132 See pg. 58-59, infra. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 34 psychological impacts felt as a result of continued human burial loss, ancestral village loss, and vandalism to sacred sites.133 The Lead Agencies must address these effects in order to sufficiently evaluate each alternative and the associated disproportionate impacts on the Yakama Nation. One reason for the Lead Agencies failure to assess impacts may be the lack of oral histories and informant interviews with Tribal communities, which have culturally perpetuated through oral tradition for millennia. This is part of a larger failure by the Lead Agencies to collect and consider pertinent information. For example, the Lead Agencies note that sitespecific information is not available with respect to where plant and medicine gathering occurs.134 However, the Yakama Nation has shared this type of information with the Lead Agencies for two decades. Therefore, the Lead Agencies should possess the information in meeting minutes, TCP reports, Traditional Use Reports, Cultural Resource Management Plans, and Determinations of Eligibility forms. These are highly relevant forms of documentation important to determining and assessing significant impacts in the socioeconomic and environmental justice sections of the EIS. By choosing not to utilize them in the DEIS, the Lead Agencies have effectively ignored available evidence that is clearly relevant to their analyses.	The commenter is correct that the census information presented in Appendix O does not represent tribal population residing on the Yakama Nation Reservation. Further, the commenter is correct that a limitation of the median household income data is that it does not account for the likelihood that tribal households contain extended families, and one person's income may be supporting multiple generations. This factor, as well as discussion of other economic aspects specific to circumstances on tribal reservations, and cultural resources is included in the EIS, Section 3.18.2.3 Identification of Indian Tribes. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The purpose of the Environmental Justice analysis included in Section 3.18 of the Draft EIS is to determine "whether there may be disproportionately high and adverse human health or environmental effects on minority populations, low-income populations, or Indian tribes (CEQ 1997). The environmental justice analysis considers the extent to which the alternatives have the potential to affect the availability of fish for commercial, ceremonial and subsistence fishing for Indian tribes, relying on analysis presented in the Section 3.15.4 of the fisheries analysis as well, in making this determination. In addition, Section 3.17 of the Draft EIS discusses how the analysis evaluated impacts to tribal interests, including treaty rights. Where applicable or pertinent for specific EIS resources, the EIS described how tribal interests would be impacted by the different action alternatives in Chapters 3 and 7. Further, impacts to cultural resources are considered in Section 3.16, impacts to tribal health and economic needs are evaluated in Section 3.18 Environmental Justice, and impacts to fisheries are addressed in Section 3.15.
6299	19	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	The Lead Agencies biological analyses contain structural problems that frustrate meaningful review. The Lead Agencies adopted an evaluation and reporting framework for the biological analysis that was redundant, overly complicated, and created a false sense of precision. The Lead Agencies developed a life stage specific analysis for each species of salmon and steelhead affected by the CRS. They repeat this analysis thoroughly in Chapter 3, 7, and the BA. However, after all this analysis, the Lead Agencies draw their conclusions based entirely on modelling results for chinook and steelhead. While they describe in detail each stage of the salmon life cycle for each species, they do not incorporate that analysis into development of mitigation measures or proposed actions (e.g., proposed habitat measures are not linked to expected biological benefits). This flawed approach did not result in an 133 The Lead Agencies note that mitigation for these impacts will be addressed through the SWPA (see pg. 28-30, supra). However, as described above, this document is insufficient to mitigate the entirety of the socio-economic and environmental justice impacts to the Yakama Nations cultural resources. 134 DEIS at 4-76. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 35 accurate depiction of the impacts associated with various measures contained in each alternative. Moreover, the analyses in Appendix E (Fish Technical Appendix), do not always match the results presented in Chapter 3, which in turn do not always match the results presented in the Preferred Alternative and the BA. For example, in Chapter 3, Table 3-68, Table 3-83, and Table 3-97 all illustrate predicted SARs following installation of new surface passage structures under the assumption that these structures would increase passage efficiency by 30%. However, in an April 29, 2019 memorandum, the Fish Passage Center (Center) considered 0%, 10%, 20% and 30% increases in passage efficiencies. The Center concluded that increasing surface passage structures would not have a significant effect on avoiding powerhouse passage. Subsequently, the Lead Agencies removed new passage structures measures in the alternatives. Thus, the Lead Agencies reported SARs in Chapter 7 that were based on an assumption that the Center concluded to be false and measures that the Lead Agencies themselves omitted. Indeed, the Preferred Alternative does not even include new surface passage structures.135 The Lead Agencies have not described the evidence relied on to reach predicted SARs conclusion is valid without the any surface passage structures or, alternatively, how surface passage structures will result in the predicted SARs. As a second example, the Lead Agencies present National Oceanic and Atmospheric Administration (NOAA) LCM results in the Preferred Alternative for Snake River spring and summer Chinook salmon.136 However, in the BA, the Lead Agencies only present the results for MO1 and MO4 relative to the No Action Alternative.137 The Lead Agencies do not provide a reference to the Preferred Alternative analysis, which is the basis of the BA. The Lead Agencies must correct this in the FEIS to facilitate meaningful review of the BA. In a final example, the Lead Agencies do not consistently include confidence intervals throughout the DEIS and appendices. Confidence intervals (standard deviation) are provided in Appendix E but not in Chapter 3, the Preferred Alternative, or the BA. This omission means that it is impossible to evaluate the statistical significance of the data and, by extension, and the benefit asserted by the Lead Agencies.	Mitigation program measures are described in the EIS in Chapter 5. Modeling of alternatives for the Draft EIS did not consider additional mitigation programs such as hatchery production or habitat restoration projects, but impacts were discussed qualitatively. It would not be feasible to rerun scenarios of MO3 using NMFS' COMPASS model and the CSS model with Snake River hatchery production not included or with expanded carrying capacity during the spawning or rearing stages, due to habitat restoration work. The COMPASS model relies on the record of hydrosystem survival data estimated with both hatchery and wild-tagged Chinook and steelhead. NMFS' Life Cycle model reports only wild spawner abundance. Likewise, the CSS Chinook lifecycle model in the Grande Ronde/Imnaha also only included wild spawners. For both models, plus the CSS cohort model, density related effects in downstream locations such as the mainstem, estuary and ocean could only be estimated with hatchery fish present. With regards to powerhouse surface passage efficiencies, the survival results produced by the CSS model at 0-30% efficiency showed that there was a very small predicted level of effect on SARs. Because of the small effect, the co-lead agencies determined that including this functioned as a sensitivity analysis for the surface passage measure. Given the significant cost and minimal biological benefit associated with those structures, removing the measure from the Preferred Alternative was logical. Given the minimal biological effect associated with these structures, we did not include an extended discussion of the powerhouse surface passage measure results beyond the initial description of the Multiple Object Alternative. Consistent with recommendations from the modeling teams as well as independent review (ISAB 2020-1), the co-lead agencies suggest that point estimates may be more informative when used to compare relative differences rather than evaluating statistical significance between metrics and models. That said, confidence intervals for in-river survival are included in the Appendix, although the comment is correct that confidence intervals were not published along with mean estimates in the main tables of the EIS. NMFS' Lifecycle model presents adult abundance with quantiles of 2.5, 25, 50, 75 and 97.5. In contrast with reporting measurements from a study, with a mean and standard error, in a model it can be challenging to define the source of variance that is creating the confidence interval in a life cycle model. Variance is created by the changing river conditions within each season, and additional variance is created by using the 80 year water record. Metrics spanning multiple life stages such as SAR and adult abundance reflect variance in the different stages, both from the 80-year water record and data uncertainty from historical fish survival estimates.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6299	20	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	The Lead Agencies biological analyses include conclusions that run counter to the evidence. The Lead Agencies provide data on upper Columbia steelhead survival for the No Action Alternative in Appendix E (Mean survival 0.6575 (MCN to BON), SD 0.03473).138 In Chapter 7, the COMPASS model results for the Preferred Alternative for mean survival is 0.657 (MCN to BON), showing a -0.1% change in juvenile survival from the NAA. Consistent with the analysis, in the BA the Lead Agencies state that [t]he COMPASS 135 The Preferred Alternative does not even include new surface passage structures. If the Preferred Alternative did include such structures, a 30% increase in spill passage efficiency is extremely optimistic based on available data. 136 DEIS at 7-102. 137 BA at 3-204. 138 App. E, Table 3-5. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 36 model estimates that survival could increase juvenile survival from McNary Dam to Bonneville Dam by less than one percent higher than the 2016 operation. However, Table 3-34 in the BA represents a positive change from current condition for Juvenile Steelhead Downstream Migration from natal stream through the CRS (Bonneville Dam). The Lead Agencies assertion that a positive change will result is counter to data included elsewhere in the DEIS. In other instances, the relative change may be positive but falls within the standard deviation of the model estimates, yet the Lead Agencies determine that there is a positive improvement juvenile survival (despite a lack of statistical significance).	The powerhouse surface passage measure was removed from the Preferred Alternative, after analysis of the MO alternatives showed that these would not significantly improve SAR or in-river survival. The commenter is correct that the NMFS COMPASS model produced a very similar in-river survival estimate under the No Action Alternative and the Preferred Alternative for upper Columbia steelhead. Results for upper Columbia River stocks are beneficial based on Life Cycle model estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. Modeling of alternatives for the Draft EIS did not consider effects of elements of the mitigation programs such as hatchery production or habitat restoration projects. Mitigation program measures are described in the EIS in Chapter 5. The Preferred Alternative includes a modification of the John Day Reservoir operations for predator disruption. Reservoir levels would be increased before Caspian tern nesting season to dissuade terns from nesting on islands in the John Day Reservoir, where they are currently nesting and foraging on ESA-listed salmon and steelhead. In early June, after most of the spring juvenile salmon and steelhead have migrated through the reservoir, the John Day Reservoir will be reduced to the minimum irrigation pool range, which is the previous operational level of the reservoir in order to benefit juvenile fish migration season.
6299	21	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	The Preferred Alternative will not adequately protect upper Columbia salmon and steelhead populations. Under the No Action Alternative, projections for threatened upper Columbia steelhead and endangered spring Chinook salmon survival rates are grim. Both of these species have triggered the AMIP Early Warning Abundance/Trend Indicator.139 This indicator is triggered when the four-year average abundance of naturally produced adult fish falls into the lowest twentieth percentile of returns during the base period. The need for action to protect these fish is urgent. However, the Preferred Alternative does not significantly improve juvenile fish rearing, passage, or survival for Upper Columbia salmon and steel head relative to the No Action Alternative. The Preferred Alternative provides less habitat, predation, and spring flow augmentation than the No Action Alternative. There is no change for adult salmon migration from the No Action Alternative. All NOAA life cycle modeling for the Preferred Alternative in the upper Columbia is based on results for the Wenatchee population of spring Chinook salmon.140 The Wenatchee watershed is the only watershed where both the Chinook salmon and steelhead populations are not at a high risk.141 These results are then extrapolated to all upper Columbia species and stocks.142 The risk to these fisheries in every other upper Columbia watershed is high. Accordingly, the use of data specific to each watershed is more reliable, rather than arbitrarily applying the data from the Wenatchee population wholesale. Furthermore, the NOAA COMPASS model demonstrates no significant juvenile benefits under the Preferred Alternative.143 This is exacerbated by the fact that the NOAA COMPASS model is not sensitive to flow, so it would not detect the negative consequences of reduced spring flow augmentation in the Preferred Alternative.144 139 National Marine Fisheries Service (NMFS), AMIP ABUNDANCE AND TREND INDICATORS (Presentation to the Regional Implementation and Oversight Group (RIOG)) (Feb. 4, 2020). 140 DEIS at 7-94. 141 NOAA, 5-YEAR REVIEW: SUMMARY & EVALUATION OF UPPER COLUMBIA RIVER STEELHEAD UPPER COLUMBIA RIVER SPRING-RUN CHINOOK SALMON (2016). 142 DEIS at 7-95, 7-96, 7-98. 143 DEIS at 7-94. 144 There is a considerable list of winter storage reservoir operation measures that may impact spring flow augmentation (see DEIS at 7-24. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 37 The 2019 CSS Annual Report estimates juvenile survival rates for upper Columbia spring Chinook to be less than 50%.145 However, the DEIS and BA have artificially partitioned survival for upper Columbia stocks and limited their analysis to between McNary Dam and Bonneville Dam.146 This partition fails to recognize the impact of upriver storage project management as a factor in downstream migration. The Lead Agencies cite flow augmentation as a major action to improve juvenile survival, but several measures proposed in the Preferred Alternative would reduce flow during the spring migration.147 The Preferred Alternative relies on Flex Spill to provide any benefits for upper Columbia fish. In order to ensure that BPA financial requirements are met, the Lead Agencies would not implement the Preferred Alternative Flex Spill operation (125% gas cap spill) in the lower Columbia except at McNary dam. Spill would be limited to 120% or less and 40% performance levels at the John Day and Dalles dams respectively.148 Spill would be limited to 150 kcfs at the Bonneville Dam due to erosion concerns.149 Flex spill only benefits upper Columbia stocks at Bonneville dam, yet that measure is expected to provide the only improvements for those stocks. Consequently, benefits resulting from Flex Spill for upper Columbia stocks will be minimal. However, the Lead Agencies do not propose any additional mitigation measures to address declining abundance trends. Finally, as described above, the Preferred Alternative Flex Spill operation is only planned for one year.150 An undefined adaptive management process will direct spill operations for the remaining fourteen years of the BA.151 The FEIS will need to address how near and long term operations that involve Flex Spill will provide sufficient and stable assurance of continuing fish benefits and the appropriate role of adaptive management in that context.	Analysis specific to upper Columbia River salmon and steelhead used current high quality data and the best available scientific information. Data from the Wenatchee River populations of Chinook salmon and steelhead were used as that was the most robust data source available to the co-lead and cooperating agencies. The benefits associated with the Preferred Alternative, including spill levels, flow augmentation targets, and other actions were higher under the Preferred Alternative than under any of the multiple objective alternatives. As this comment indicates, the Preferred Alternative has dam specific spill objectives that were developed as part of the 2019-2021 Spill Operation Agreement. These spill levels, combined with a continuation of flow levels from upstream, resulted in higher in-river survival and SARs compared to either MO3 or MO4, which spilled to 120% and 125% TDG levels, respectively. The statement that the Preferred Alternative only mandates flex spill for one year is not an accurate interpretations of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the consultation. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the CRSO EIS. The co-lead agencies intend to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the goals of the flexible spill operation: additional improvements for salmon and steelhead, additional opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence latent mortality effects.
6299	22	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	The Preferred Alternative will not adequately protect Snake River salmon and steelhead populations. The situation for Snake River salmon and steelhead populations is comparably dire to those in the upper Columbia. Based on the 2016 status review, NMFS concluded that most of the threatened natural Snake River spring and summer Chinook populations remain at high overall risk of extinction.152 The current status of threatened wild Snake River steelhead is that the abundance trend has achieved the AMIP Significant Decline Trigger.153 This 145 McCann, J. et al., Comparative Survival Study of PIT-tagged Spring/Summer/Fall Chinook, Summer Steelhead, and Sockeye 2019 Annual Report (BPA Project #19960200) (2019), Figure 3.7 at 3-41. 146 DEIS at 7-94. 147 In the BA at 3-274, the Lead Agencies state that the actions that have benefitted UCR spring-run Chinook salmon include the following: Minimize winter drafts of the large upper basin storage reservoirs (for flood risk management and power generation) to save water for augmenting spring flows during the peak juvenile passage period (water quantity). However, several of the measures in the Preferred Alternative reverse this strategy (see DEIS, 7-30). 148 DEIS at 7-34. 149 Id. 150 DEIS at 7-33. 151 Id. 152 NMFS, AMIP ABUNDANCE AND TREND INDICATORS (Presentation to the Regional Implementation and Oversight Group (RIOG)) (Feb. 4, 2020). 153 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 38 trigger is reached if the four-year average abundance of naturally produced adult fish falls into the lowest tenth percentile of returns during the Base Period.154 The draft Preferred Alternative does not significantly improve juvenile fish rearing, passage, and survival for Snake River salmon and steelhead.155 COMPASS modeling predicts that, under the Preferred Alternative, juvenile Chinook survival will increase from 50.4% to 51%; CSS predicts juvenile survival will increase from 57.6% to 58.3%.156 This is not a significant improvement.157 Likewise, COMPASS modeling alarmingly predicts a lower juvenile survival for Snake River steelhead for the Preferred Alternative than the No Action Alternative.158 Finally, the Lead Agencies assert in the BA that the Preferred Alternative is expected to maintain or slightly improve survival of endangered Snake River sockeye and threatened Snake River fall Chinook salmon migrating through the hydropower system (depending on the latent mortality hypothesis).159 NMFS lifecycle models from 2016 predicted a decrease in Chinook SARs and abundance if latent mortality remained the same as the 2016 operation.160 Therefore, according to NOAA modeling, all the Preferred Alternatives benefits are based on an assumption that fewer powerhouse encounters due to increased spill will reduce latent mortality. If the latent mortality hypothesis does not provide the benefit anticipated by the models, the Lead Agencies propose no other mitigation to protect these stocks. The Lead Agencies Preferred Alternative relies entirely on the potential improvements from decreased latent mortality. The Lead Agencies provide a discussion about latent mortality and conclude that [g]iven the overall weight of evidence, it is uncertain to what extent CRS operations, as opposed to baseline or cumulative conditions, cause delayed mortality.161 They also include a NOAA study that states that results suggest that after fish leave the hydropower system, bypass passage history has little effect on mortality.162 Accordingly, the Yakama Nation is very concerned that the Lead Agencies do not provide additional mitigation measures to insure against their own assumptions about latent mortality. E. The Preferred Alternative will not adequately protect middle Columbia salmon and steelhead populations. 154 Id. 155 If the later mortality hypothesis proves to be true, then the Preferred Alternative may improve SARs and increase adult returns. However, the Lead Agencies have put no protections in place if the benefits of spill operation arent as significant as expected. 156 DEIS at 7-100, Table 7-24. 157 It is important to note that COMPASS and CSS model results in the Preferred Alternative are exaggerated due to modeling limitations regarding flow and spill inputs. With respect to CSS model outputs, the Lead Agencies note that [t]his dataset for the Preferred Alternative scenario contains only daily average values for spill percent. The Preferred Alternative scenario contains a measure for sub-daily flex spill variations in spill percent; however, since those sub-daily spill operations are not contained in the dataset, the results of our modeling will not predict the potential effects of sub-daily variations in spill. CSS memorandum, (January 24, 2020) CRSO-78. 158 DEIS at 1-104, Table 7-26. 159 BA at 3-68, 3-95. However, the Lead Agencies note that [i]t is also possible that increased spill levels, and associated adverse effects, will be offset by an increase in adult returns due to less powerhouse encounters as hypothesized by the CSS. Id. at 3-67. 160 DEIS at 7-102. 161 BA at 3-13. 162 DEIS at 3-13. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 39 The Preferred Alternatives does not anticipate any changes for middle Columbia salmon and steelhead stocks relative to the No Action Alternative.163 The analyses rely entirely on upper Columbia spring Chinook results.164 In addition, the Lead Agencies have effectively ignored middle Columbia salmon and steelhead in their Tributary Habitat Program.	This comment accurately captures the potential changes to in-river survival associated with CRS model output, but does not account for the multiple other metrics such as Smolt-to-Adult return rates associated with the expected effects on fish based on analysis of the Multiple Objective alternatives and Preferred Alternative in the CRS . The different metrics are more or less sensitive to actions depending on whether the metric is focus on juvenile survival or subsequent adult returns. This is the reason the co-lead agencies did not focus on a single metric to inform their Preferred Alternative. If the lower end of predicted outcomes are observed and are not able to be moderated through adaptive management, the co-lead agencies will reevaluate and assess alternate actions that may be appropriate.
6299	23	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the	The Preferred Alternative will not adequately protect middle Columbia salmon and steelhead populations. 154 Id. 155 If the later mortality hypothesis proves to be true, then the Preferred Alternative may improve SARs and increase adult returns. However, the Lead Agencies have put no protections in place if the benefits of spill operation arent as significant as expected. 156 DEIS at 7-100, Table 7-24. 157 It is important to note that COMPASS and CSS	As noted above, the co-lead agencies used current high quality data for each species analyzed. The co-lead agencies worked closely with cooperating agencies to assess and develop the data sources for each species. The co-lead agencies have included an adaptive management plan in Appendix R of the CRSO EIS that will engage regional state, tribal, and federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation. However, if the lower end

The co-lead agencies ongoing commitment to habitat restoration actions in the Columbia Basin are described in more detail in the agencies' Proposed Action (Appendix V), which the co-lead agencies' submitted to NMFS and the USFWS for consultation under the ESA. The resulting Biological Opinions can be found in Appendix V of the FEIS.
6299	24	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	The Preferred Alternative will not adequately protect lower Columbia salmon and steelhead populations. The Lead Agencies Preferred Alternatives does not anticipate any changes for lower Columbia salmon and steelhead stocks relative to the No Action Alternative.166 As with middle Columbia populations, the Lead Agencies have effectively ignored lower Columbia salmon and steelhead in their Tributary Habitat Program.	See response to Comment 6299-23.
6299	25	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	G. The Lead Agencies have not demonstrated that the Preferred Alternative will ensure improvement in the status of listed stocks relative to the No Action Alternative. The Preferred Alternative relies on unproven spill levels that may not provide benefits beyond the No Action Alternative, and spill levels that may not be achieved at three of the four dams in the lower river due to power considerations and implementation limitations. The NOAA COMPASS and LCM analyses do not demonstrate a benefit under the Preferred Action relative to the No Action Alternative unless the latent mortality hypothesis proves to be correct.168 The Lead Agencies do not propose any new or additional mitigation actions to address uncertainty associated with latent mortality. The mitigation package, in addition to the new spill regime, is based on existing programs that have funding levels that are currently below levels assumed in the No Action Alternative.	See response to Comment 6299-23.
6299	26	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	H. The Lead Agencies failure to adequately protect fish populations under the Preferred Alternative is inconsistent with their Treaty, trust, and statutory obligations. The Treaty of 1855 requires the Lead Agencies to ensure that the operation and management of the CRS under the Preferred Alternative will not result in adverse impacts to fish populations. Specifically, the Preferred Alternative cannot impair the Yakama Nations time, place, method, species and extent of taking fish. The Treaty of 1855s guarantee to a portion of the harvest means that the Columbia River must contain viable fish stocks and sustainable habitat. Moreover, The Lead Agencies have a duty to protect and give full effect to the rights reserved under the Treaty of 1855 pursuant to the federal trust responsibility. 163 DEIS at 7-98, 7-99. 164 DEIS at 7-98, 7-99. 165 This means that the Lead Agencies have effectively ignored an important aspect of the problem. BA at D13, Table D.2. 166 DEIS at 7-108. 167 Again, this means that the Lead Agencies have effectively ignored an important aspect of the problem. BA at D-13, Table D.2. 168 DEIS at7-94, 7-95, 7-100, 7-102. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 40 The Northwest Power Act requires the Lead Agencies to provide fish and wildlife with equitable treatment relative to the other authorized purposes of the CRS.169 Furthermore, the Northwest Power Act demands that the Lead Agencies take into account at every stage of decision-making processes to the fullest extent practicable, the program adopted by the Council.170 The ESA likewise provides rigid and specific protections to many of the stocks discussed above.171 The Lead Agencies biological analyses indicate that the Preferred Alternative will result in negative, neutral, or negligibly positive effects on salmon and steelhead stocks in the Columbia and Snake Rivers. As described above, these species are already imperiled across the Columbia River Basin. Consequently, the Lead Agencies failure to provide for significant positive benefits may result in irreparable harm to these populations. The draft Preferred Alternative will not benefit (and could potentially harm) most ESA-listed salmon and steelhead populations relative to the No Action Alternative. The NOAA COMPASS modeling for the Preferred Alternative did not show significant improvement, which the Yakama Nation considers to be greater than 10%, for any population. The NOAA LCM modeling only detected a significant improvement in abundance and smolt-to-adult return ratio (SAR) for Snake River populations when an arbitrary adjustment is made for assumed improvements in latent mortality. The Lead Agencies intent seems to be that the proposed Flex Spill operation will provide significant improvements in latent mortality that will compensate for deficiencies in fish survival. However, the additional hydro system flexibility and water management measures included in the Preferred Alternative negate the potential benefits of the Flex spill operation and potentially result in conditions for fish that are worse than the status quo. In the BA, the Lead Agencies provide an extensive description of the latent mortality theory. That description concludes that [g]iven the overall weight of evidence, it is uncertain to what extent CRS operations, as opposed to baseline or cumulative conditions, cause delayed morality.172 The Lead Agencies therefore recognize that any significant improvements to salmon and steelhead populations under the Preferred Alternative are fraught with uncertainty. Nevertheless, the Lead Agencies do not propose any significant additional actions or mitigation measures in the Preferred Alternative or BA to compensate for the identified risk of the proposed Flex Spill operation. The Preferred Alternative lacks clear benefits to fish populations, cultural resources protections, or an accurate picture of the Yakama Nations perspective. Consequently, the Yakama Nation is not confident that such an alternative will eliminate or reduce any of the adverse impacts of the CRS described in Section 2.3 of these comments. 169 See 16 U.S.C. 839b(h)(11)(A)(i). Moreover, the array of measures proposed under the Preferred Alternative indicate that power operations, flexibility, and water supply measures far outweigh fish operations (see n. 84, supra). 170 See 16 U.S.C. 839b. 171 See 16 U.S.C. 1531, et seq. 172 BA at 3-16. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 41 This outcome would be unacceptable under the Treaty of 1855, the federal trust obligation, and applicable statutes. If any of salmon and steelhead populations are wiped out or reduced to numbers that inhibit sustainable fishing practices, then the Lead Agencies have impaired the Yakama Nations time, place, method, species and extent of taking fish and violated the Treaty of 1855s harvest guarantee. This would be wholly inconsistent with the Lead Agencies fiduciary obligation the Yakama Nation. Furthermore, the data described above does not represent equitable treatment of fish and wildlife under the Northwest Power Act. A further decline in fish populations is the antithesis of the Councils goals for five million fish and 2% to 6% SARs. The Yakama Nation is also concerned that, in light of the biological analyses results, the Lead Agencies will be unable to meet their ESA obligations. The Lead Agencies must correct these issues in the FEIS. Any alternative that does not lead to significant and measurable positive benefits for salmon and steelhead populations in the Columbia and Snake Rivers is inconsistent with the Lead Agencies obligations under the Treaty of 1855, the federal trust responsibility, the Northwest Power Act, and the ESA.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis in the Fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6299	27	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	A. The Lead Agencies process for developing the power analyses relies on incomplete information to the extent it did not involve all interested parties. In 1999, the Corps convened the Drawdown Regional Economic Workgroup (DREW) as part of its EIS evaluating of the potential impacts from removing the Snake River Dams. The DREW comprised representatives from multiple federal agencies (including the Fish and Wildlife Service, National Marne Fisheries Service, and Environmental Protection Agency), Native Nations, states, and conservation groups. This collective worked cooperatively and transparently to design and review the power studies that would go into the Corps evaluation. The process resulted in studies that reflected a multitude of interests, thereby allowing for a more effective and balanced evaluation of Snake River dam removal. A similarly collaborative model for identifying measures related to power analysis would have, in this instance, produced a more robust information base to inform alternative development and impact assessment. The cooperating agency process did not achieve results similar to the DREW process. The Yakama Nations staff and consultants were only able to participate in a handful of cooperative agency conference calls with regard to power issues. These calls were structured as presentations rather than collaborative discussions. As discussed above, the truncated timeline resulted in inadequate opportunity to provide the Lead Agencies with comments on power issues. As result, information relevant to power analysis was limited or foregone.	Because Bonneville routinely performs hydropower modeling, including for the Columbia River Treaty Review (2011-2014, with the Columbia River Inter-Tribal Fish Commission representing the Yakama Nation), Bonneville developed a proposal for how to structure the hydropower analysis, then discussed this plan with the CRSO EIS hydropower technical team including the cooperating agencies that had expressed an interest in hydropower. The phone call workshops asked for input from the participants; the majority of the responses were clarifying questions rather than suggestions for changing the approach. In addition, Bonneville's CRSO EIS lead for power met, by phone, with the Yakama Nations staff on Oct 18, 2018 and March 11, 2019. Power measures for the Single Objective alternatives, later combined into the Multiple Objective alternatives, were developed through workshops with cooperating agencies, input from co-lead agency staff, and public input during the scoping phase of the EIS (see Chapter 2 of the draft EIS for additional information).
6299	28	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	B. The Lead Agencies fail to clarify that concerns of competitive pressures on BPA are unfounded. In Section 3.7 of the DEIS, the Lead Agencies describe the concerns of BPAs public utility customers that BPAs rates are above the spot market prices. The Lead Agencies note that: [t]he spot market price is not directly comparable to [BPAs] rates because [BPA] provides a high-quality power product that is backed by Federal Base System resources, which includes the federal dams and the Columbia Generating Station. [BPAs] firm power customers, thus, receive a power product that provides a reliable and stable supply of power at predictable prices set by Bonnevilles statutory process. Spot market purchases, in contrast, are volatile, with supply not assured and pricing subject to market spikes.173 This language seems to push back against perceived concerns from customers. However, the Lead Agencies analysis in Section 3.7.3.1, which focuses extensively on the rate impacts of the alternatives, appears to ignore the important distinctions between the value of BPA firm power and the spot market: [t]he MOs long-term cost impacts on [BPA]s wholesale power rates is an important qualitative consideration because of the competitive nature of the industry [BPA] operates in[r]etaining [BPAs] preference customer base will be critical	The commenter contends that the discussion in the EIS regarding the competitive pressures facing Bonneville and its wholesale power rates are unsubstantiated. The commenter outlines several broad areas which, in the commenters view, should be included in the EIS to demonstrate that customers of Bonneville are unlikely to find other suppliers as a result of additional rate pressure or that would warrant additional cuts to Bonneville's programs, such as its Fish and Wildlife Program. To support its view, commenter identifies five general areas that demonstrate that Bonneville's rates are, in the long-run, competitive. These include (1) the stability provided by Bonneville's rates and long-term contracts; (2) spot market prices are not comparable to the high-quality products provided by Bonneville; (3) relying on market products is unstable and unpredictable when compared to sales from Bonneville; (4) purchasing alternative new generation would likely exceed costs of Bonneville's power; and (5) Bonneville's sales to its customers have been increasing. The commenters description of the value of the products sold by Bonneville are in accord with the findings in the EIS. The EIS found that Bonneville products are more valuable and of a higher quality than the power products available on the short-term spot market. See Section 3.7.2.5, at pages 3-801-802 of the draft EIS. As the commenter notes, the products are inherently different in that the majority of Bonneville's power products follow load, which is not an attribute included in a standardized market purchase of power. In addition, the carbon content differences must also be considered, particularly as higher value is assigned to carbon-free generation over power with carbon emissions. Most market purchases, unless procured from a specific renewable resource, will be assessed a carbon-based attribute. Also, roughly $9/MWh of Bonneville's average wholesale rate includes benefits to the region that would have to be added to the cost of market power to
